1 ABSTRACT

The CARBOTRAF system combines real-time monitoring of traffic and air pollution with simulation models for the the prediction of CO_2 and black carbon emissions in order to provide on-line recommendations for alternative traffic management options. The system will be implemented within the framework of a FP7 (ICT for Transport) project funded by the European Union and will be tested in the cities Graz and Glasgow (http://carbotraf.eu/).

2 INTRODUCTION

Traffic congestion with frequent "stop & go" situations causes substantial CO_2 and black carbon (BC) emissions. Both CO_2 and BC emissions are known to contribute significantly to global warming [AEGPL2012]. Exposure to BC may furthermore have important health effects [EHP2012]. The traffic control measures available today (e.g. re-routing, traffic light control, dynamic speed limits, variable message signs) when driven by information collected in real-time from the road network, are able to support the reduction of emissions of CO_2, BC, as well as urban air pollutants. However, supporting the decision making in the traffic control centers to derive the necessary control actions from the information collected, in order to minimise emission requires the understanding of complex interactions between traffic, emissions and pollution density. This area is still subject of investigations.

3 OBJECTIVES

CARBOTRAF combines real-time monitoring of traffic and air pollution with simulation models for emission prediction in order to deliver on-line recommendations for alternative adaptive traffic management. The project work will focus on two main investigations.

(1) CARBOTRAF will provide combined real-time CO_2 and BC emission analysis for traffic situations and subsequent simulation of local air quality. The first phase of the project will evaluate the effects of different intelligent traffic management technologies (ITS) measures on total greenhouse relevant emissions as well as on ambient air quality of BC, by modelling and simulation of selected traffic scenarios for the test cities. The results will provide valuable information on efficient ITS strategies and will be used to define the optimal implementation in the test cities.

(2) Test implementation and test operation of real-time traffic management with online decision support will be the second phase of the project. Using AIT's smart eye TDS traffic monitoring [AIT1] and openUWEDAT [AIT2] data collection technologies a collection of emission-relevant traffic parameters will be developed. Such parameters can be (in addition to vehicle volume, fleet composition and speed), for example the portion of accelerating vehicles to improve emission estimation. These data, supported by data from existing roadside sensors such as induction loops, will be the input to the online decision support system. The decision support system will be based on IBM's Travel and Transportation Software Solutions [IBM1] and ILOG Optimization [IBM2] solution. It will provide recommendations to the traffic control centers, computed from the acutal and predicted traffic situations and emission scenarios. Test operations will evaluate the performance of the online decision support system and the actual effect of the ITS-aided traffic management on the emissions. It will provide guidelines and recommendations for adaptive traffic management regarding both, technical and operational issues. The CARBOTRAF project has started in Sep. 2011 an will run for three years.

4 CONCEPTS

4.1 Emission and traffic scenario look-up-table database

After the selection of the test area which is based on the avaiablility and feasibility of implementing ITS measures that are able to reduce overall emissions, microscopic and macroscopic traffic simulations for different scenarios (e.g. weekday morning, weekend, etc.) and selected ITS actions (e.g. incentive for modal change to public transport, traffic light coordination, re-routing, etc.) will be performed. The results will be used to further refine the test area and select the most efficient ITS actions with respect to overall emissions. These traffic scenarios together with the emissions calculated by emission models will be stored in a look-up-table (LUT) database that links the traffic scenarios with the specific overall emission value for that scenario. Together with emission values the impact of the selected ITS measures on air quality, with a special focus on BC concentration, will be also computed and stored in the LUT. These operations are performed prior to the pilot installations and are sketched on the left side of Figure 1.

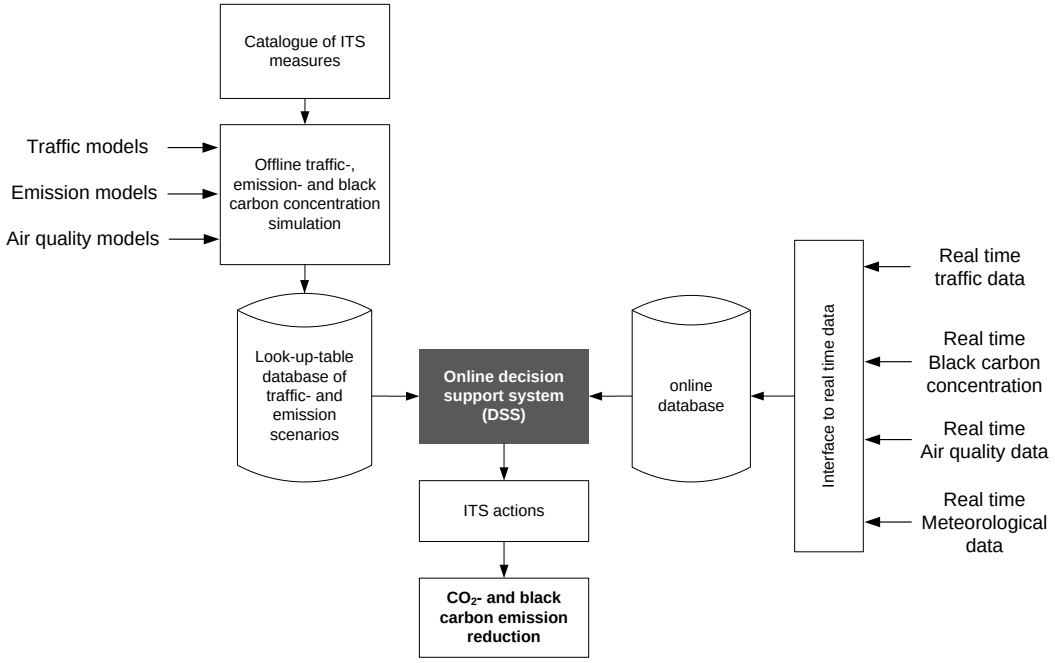

Fig. 1: General architecture of the CARBOTRAF system.

4.2 "Emission-specific" traffic monitoring

Traffic congestion with frequent "stop & go" situations causes substantial increase in emissions (CO_2, black carbon as well as air pollutants) in contrast to free flowing traffic. To derive the necessary control actions from the information collected requires modelling and computing the traffic state depended emission of vehicles. The output of vehicle emission models strongly depend on the acceleration state of the vehicles. Today's traffic monitoring devices typically collect information on traffic volume, fleet composition and average speed. However, there is currently no commercially available traffic monitoring device that is able to collect information in real-time on the composition of the traffic in terms of vehicle acceleration states (accelerating/constant speed/decelerating).

The smart eye TDS traffic data sensor is a fully embedded traffic monitor based on dynamic vision sensor (DVS) technology. The DVS is a CMOS imager chip with very high temporal resolution (better than 1 millisecond) as well as on-chip motion detection and background suppression [LICHT2008]. The pixels of the imager encode motion as time stamped x,y-coordinates in an asynchronous data stream. Thus the DVS efficiently encode the trajectories of the vehicles motion. The current smart eye TDS system monitors traffic on up to four lanes simultaneously and records speed and class individually for each detected vehicle [BAUER2007, GRITSCH2008].

Figure 2 shows data recorded for the concept evaluation of cars entering a roundabout. The still image of the roundabout and the two detection zones defined are depicted on the left of fig.2. Each detection zone extends

about 10 m (equivalent to approximately 40 pixels of the sensor) in the direction of vehicle movement. Example trajectory data are plotted in imager coordinates (x) as a function of time (t). Figure 1 (right) shows examples of about 15 seconds of data of four vehicles trajectories in space-time x,t representation. The high time resolution of the sensor allows extracting the vehicles trajectories with high precision. The trajectories for zone 1 show two vehicles with constant speed (marked "C"), and one vehicle decelerating ("D") and stopping at the entry.

Exploiting this information the individual vehicle data sets provided by the traffic data sensor in real-time are additionally tagged with acceleration information (accelerating/constant speed/decelerating states) to allow inferring the quantity of accelerating vehicles in the vehicle collective. This information will be used in the CARBOTRAF project to support the online calculation of traffic emissions for a test area.

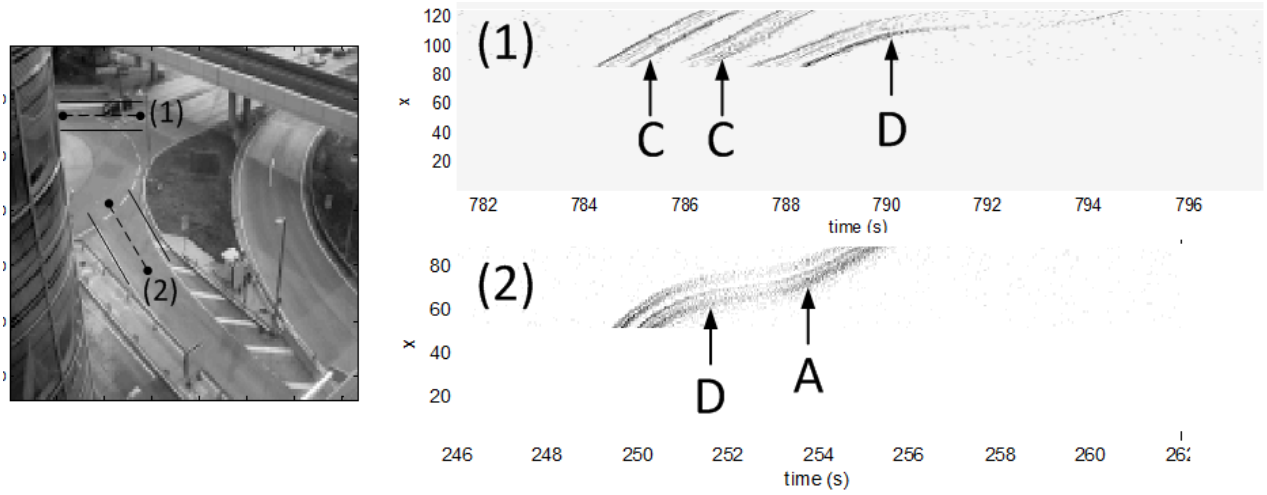

Fig. 2: Acceleration detection by vehicel trajectory analysis with a smart eye TDS traffic sensor. Test data recorded with the sensor at the two entries of a roundabout are shown. Uppercase letters indicate the vehicle acceleration state: "C" constant speed, "D" deleration, "A" acceleration.

4.3 Real time decision support

The decision support system (DSS) based on IBM's Travel and Transportation Software Solutions and ILOG Optimization solution is the heart of the CARBOTRAF system. It will receive real-time data from the sensors deployed in the test area and derives scenario-correlated emission values from the LUT (see fig.1, right). The major steps in the operation of the system are:

Step 1: Real time monitoring of the traffic situation

Traffic monitors (existing devices and additional smart eye TDS with acceleration detection capability installed by the project) measure speed, volume and composition of vehicles and detect emission relevant traffic states (e.g. number of accelerating vehicles). Air quality is also monitored.

Step 2: The traffic situation is predicted by the macroscopic traffic models of the DSS 30-60 minutes into the future.

Step 3: For the current and prediction traffic situations the CO2 and BC emissions are derived from searching the LUT for the scenarios.

Step 4: An improved traffic scenario is selected that is able to satisfy the traffic demand at a reduced total CO_2 & BC emission. Further defined key performance indicators will also be taken into account.

Step 5: ITS action options are displayed to the traffic centre operator who finally deceides on their implemetation („human in the loop").

5 SUMMARY AND OUTLOOK

CARBOTRAF targets to reduce CO_2 and back carbon (BC) emissions by smart traffic management. Pilot operations of the system are planned in Graz and Glasgow. The systems innovative approache links CO_2 /BC- aspects and ITS measures with a focus on a "emission-reduced" traffic rather than a "pure" travel-time optimization.

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

The first result that will be available in the project is the handbook of ITS actions for each of the test cities, resulting from traffic models and simulation of emissions for different scenarios for the selected test area. The handbook will be valuable information on optimal ITS strategies. The test operation of the CARBOTRAF system will evaluate the performance of the online Decision Support System and the actual effect of the ITS recommendations on the total CO_2 and BC emissions. The result will be compiled in a handbook for cities regarding diminution of CO_2 and BC. It will provide guidelines, recommendations and "best practice" solutions for emission reduction by adaptive traffic management regarding both, technical and operational issues.

The goals of CARBOTRAF will be reached by a complementary and coherent consortium of 8 European partners including research institutes and universities (AIT, VITO, IMPERIAL COLLEGE LONDON, Österreichisches Forschungs- und Prüfzentrum Arsenal) and companies (IBM, Air Monitors, European Tech. Serv., EBE Solutions) from 4 European Members States. The expertise of these organisations is sorted from the intersecting areas of smart sensors, traffic telematics, air quality, numerical analysis and computational intelligence.

1 ABSTRACT

The Centrope region is situated at the mutual borders of Austria, the Czech Republic, Hungary, and Slovakia. CentropeMAP is an online geoportal for spatial planning data from this region. It went online in 2005 and was extended by the cross-border statistics database CentropeSTATISTICS in 2010. CentropeSTATISTICS allows its users to create thematic maps and various types of charts on the fly. There is a basic mode with pre-defined maps as well as an expert mode where a lot of layout and classification settings can be defined by the user. The statistics database is continuously expanded in close co-operation with the statistical offices of Hungary, Slovakia, the Czech Republic, Vienna, Lower Austria and Burgenland.

2 INTRODUCTION

2.1 About Centrope

The Central European region Centrope is a cross-border region situated along the mutual boundaries of Austria, the Czech Republic, Hungary, and Slovakia. The Centrope region is not naturally grown – a quarter of a century ago it was still divided by the Iron Curtain –, it is a political and economical construction to help all parts of the region to overcome the unfavourable development during the period of the Cold War when these regions were practically cut off at their edges. So it might not be a surprise that the term "Centrope" is still unknown in common everyday life although a lot of projects and initiatives is running under the patronage of Centrope follwing the motto "An image of tomorrow as a task for today".[1] To enhance the popularity of Centrope an initiative called "MyCentrope" was installed. It collects news and events from the region on its website mycentrope.com and also places advertisements in regional magazines to intensify cultural exchange between the parts of the Centrope region.

2.2 About CentropeMAP

CentropeMAP is a geoportal collecting web map services (WMS) from all parts of the Centrope Region. Its thematic emphasis is on datasets that are of interest for spatial planning and similar professions, comprising multiple data layers from the fields of biota, boundaries, elevation, imagery/base maps, inland waters, planning/cadastre, structure, and transportation. All data is displayed in a cross-border map viewer in a unified map projection although the single datasets are retrieved from distributed servers located all across Centrope.

2.3 About CentropeSTATISTICS

Planners do not need only maps for their work, they also need statistic data to analyse a region. Therefore, the goal of CentropeSTATISTICS is to directly add statistic data to the CentropeMAP geoportal by means of thematic maps. The statistics extension was launched in the year 2010 and features a basic mode with ready-made thematic maps as well as an expert mode: The CentropeSTATISTICS Basic Mode allows to create a couple of thematic maps which have been predefined by the CentropeMAP team. It is mainly for quick queries or for people who do not have much experience in creating thematic maps or charts from statistic tables. The CentropeSTATISTICS Expert Mode gives full access to the whole Centrope cross-border statistics database, you can download these data and set several options while creating your thematic map or chart. The expert mode is meant for planners, statisticians and other professionals who know how to create meaningful thematic maps and charts.

Planungsgemeinschaft Ost (PGO), the initiator of CentropeMAP and CentropeSTATISTICS, is closely working together with the statistical offices of Hungary, Slovakia, the Czech Republic, Vienna, Lower Austria and Burgenland to keep the high quality datasets at municipality level up to date. International

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

statistics workshops twice a year help to guide the further development of the cross-border statistics database containing mainly population, migration, and land use data.

2.4 The CentropeMAP Web

CentropeMAP is accessible via internet: http://www.centropemap.org. The CentropeMAP geoportal can be directly accessed at http://map.centropemap.org, and CentropeSTATISTICS can be started from CentropeMAP. All map layers and statistic tables are available without any limitation.

3 A CROSS-BORDER STATISTICS DATABASE WITH AN INTERACTIVE USER INTERFACE

3.1 Getting started

CentropeSTATISTICS starts with an overview of available data. All tables are hierarchically organised in a menu tree on the left side of the screen, details are shown on the right side (see fig. 1).

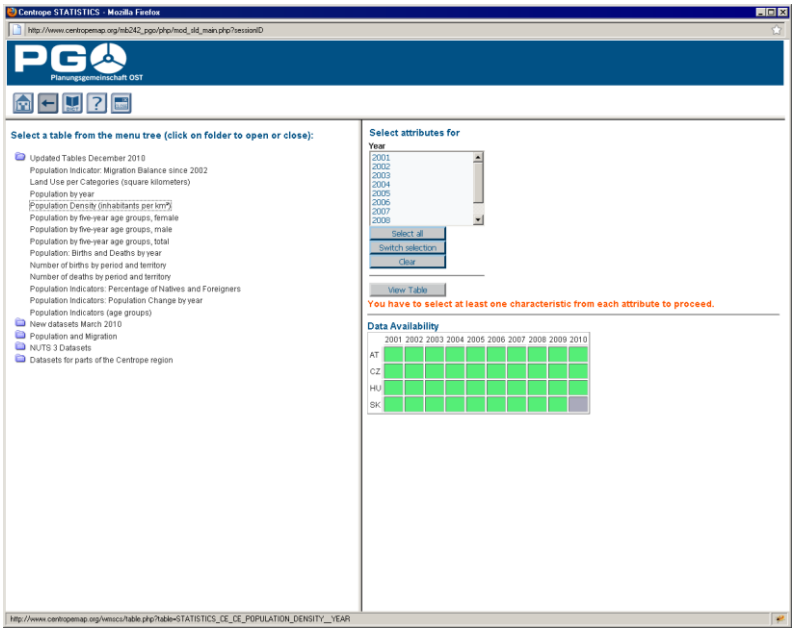

Fig. 1: Table overview.

In the next step, the table is shown (first 30 datasets only so that the download does not take too long). Here the viewer can download the data in CSV or Excel format to use the table locally. When downloading, metadata are automatically included in the download. Apart from simple data download, there are several other possibilities to interactively work with the statistic data provided by CentropeSTATISTICS.

3.2 Creating thematic maps

All table columns suitable for map creation have a “Create map” button on top. Hitting this button allows the user to select various options to design a cloroplethic map which can then be used as overlay in CentropeMAP.

There are several statistical methodes for class definition:

- equal interval: The numeric range of all classes has the same size;
- quantiles: The elements are evenly distributed so that each class contains the same number of elements;
- standard deviation: The class ranges are defined according to the standard deviation of the elements;
- equal area: The elements are distributed in a way that each class covers (approximately) the same area (sum of municipality areas in each class is equal);
- natural breaks (ArcView): The natural breaks algorithm minimises the variance within classes and maximises the variance between classes. This option produces an output similar to the algorithm used in ESRI’s ArcView GIS;

- natural breaks (Jenks): same as above but using the Jenks algorithm which produces slightly different results than the ArcView method;

If there is data with positive and negative values (e. g. population density increase/decrease) and a dichromatic colour ramp is used, special zero handling can be defined:

- no special zero handling: leave everything as it is;
- treat white as zero only: The class including zero is split into two classes, and a separate class having zero as only value is added. Note: The effective number of classes is higher by 2 than the preselected number of classes;
- use white for class incl. 0: preserve class definition, but shift the colour ramp so that white is used for the class including the zero value;
- no white in legend: preserve class definition, but build a colour ramp with no white class.

Of course all class values and all colours can be set manually if something different than the given options is required.

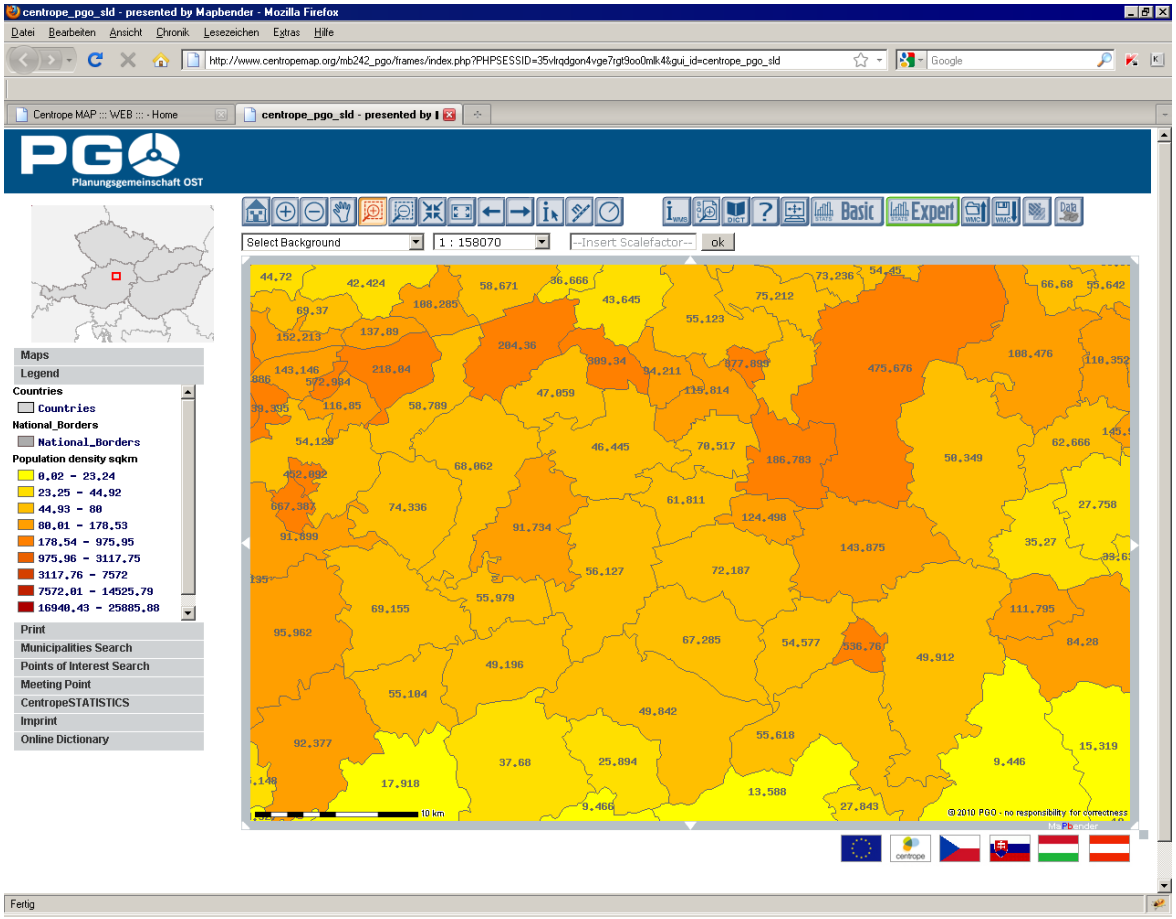

Fig. 2: Thematic map overlay with labels. To see the background layers, transparency can be applied to each theme.

3.3 Creating charts

Like maps, also charts can be created from the table view. In a similar manner also the “Create chart” and/or “Create pie chart” buttons are placed only on top of columns where this option is meaningful. Like with thematic maps, also with charts nearly all design options are configurable and can instantly be applied to the chart which is realised as graphic output (image file).

Depending on the contents, charts can be bar charts (see fig. 3) or pie charts. Bar charts can also be converted into point and/or line charts. Bar, line, and point charts always show a time series of the selected attribute – it is one of the main goals of CentropeSTATISTICS to collect data not only by theme, but also by year to make developments over time visible. The most important datasets are updated every year, others will be made available in decade steps (2011, 2001, 1991, ... – the years of the main census).

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

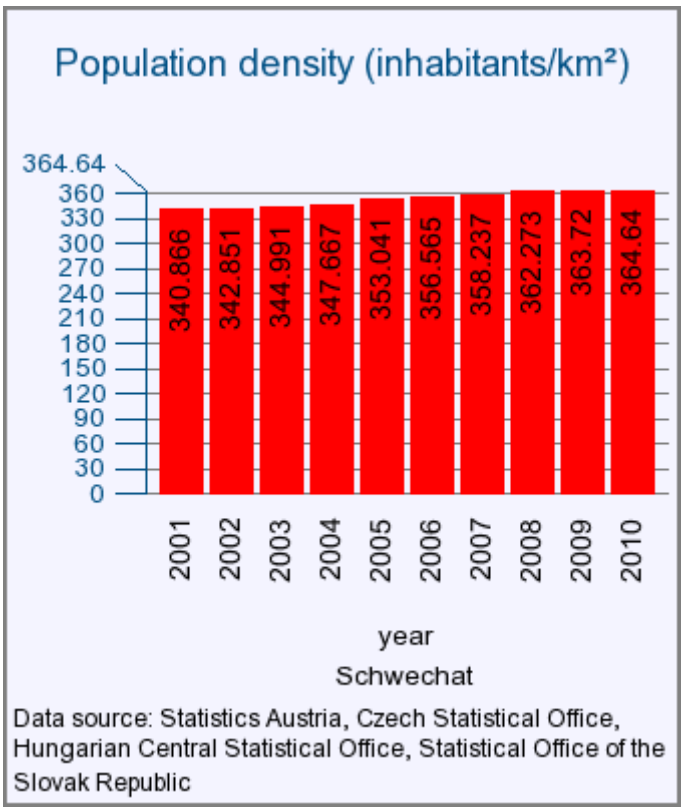

Fig 3: Example bar chart: Population density of Schwechat, Lower Austria, 2001-2010.

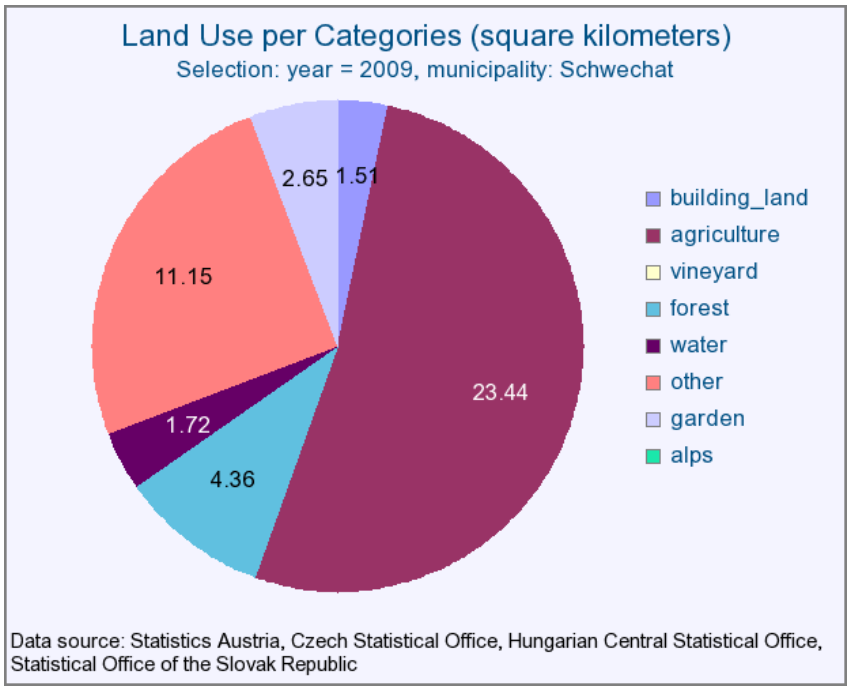

Fig 4: Example pie chart: Land use per categories, Schwechat, 2009.

3.4 Creating custom tables

Since 2011 it is also possible to create custom tables. The user can collect values from different tables and calculate new values on their own. All data in a custom table is treated in terms of geographic intersection so that calculations are done for any area where sufficient data is available. For example, from population time series and area values.

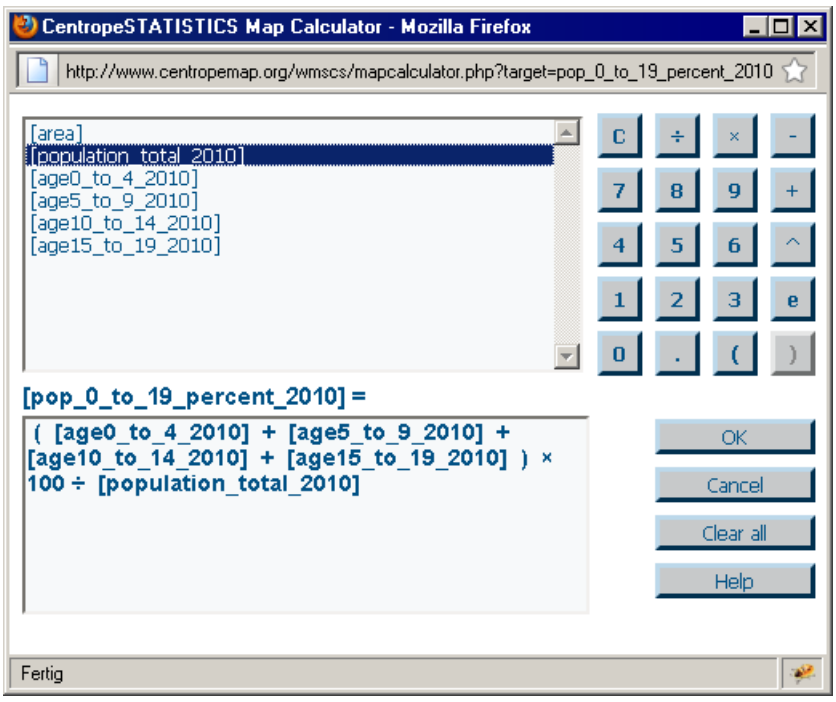

Fig 4: CentropeSTATISTICS map calculator.

The map calculator allows to combine all available attributes with basic arithmetic operations (addition, substraction, multiplication, division, exponentiation. The results are put into a separate column which can also serve as input for thematic map or chart creation.

4 FUTURE PERSPECTIVES AND OUTLOOK

CentropeMAP and CentropeSTATISTICS are growing – slowly, but steadily. Discussions on the extension of the theme range of the CentropeSTATISTICS cross-border statistics database are an issue at each statistics workshop. All incoming datasets have to be checked on their compatibility and comparability with existing data. This is extremely important for statistical data because it has to be verified that datasets from different countries were generated in the same way before they are put together in one table. This is no big deal with population data, but, for example, when dealing with employment or tourism data, some problems arise: Such data are often collected differently – by different institutions, for different dates, following different goals – in each country of the Centrope region, so there has hardly been any possibility to compare data for the whole region. This situation may improve in the future as the statistic offices are more and more following guidelines of the European statistical office (Eurostat). Data delivery from each EU country to Eurostat has already been running for many years; however, these datasets are not on municipality level but on NUTS 3 or NUTS 2 level[2] which limits their use for data interpretation within the range of the Centrope region.

[2] NUTS: Nomenclature of Units for Territorial Statistics. NUTS 3 is district or county level, NUTS 2 is province level. NUTS units need not have an equivalent in existing administrative boundaries of a country.

City on the Edge of Moscow Agglomeration: a Chance for Sustainable Development

Alexander Antonov, Anna Shagova

(Alexander Antonov, Moscow region Institute for Townplanning, 47, ul. Gilarovskogo, Moscow, Russia, alexfusion@rambler.ru)
(Anna Shagova, Land Development Institute, LLC 19/1, B. Sukharevsky per., Moscow, Russia, steps-anna@mail.ru)

1 ABSTRACT

Moscow is the largest city in Europe, economical, financial, research, educational and transit center of Russia. It attracts a lot of newcomers from the whole country and the neighboring states. While the total population of Russia is slowly decreasing, Moscow has shown 10% growth during 2002-2010 inter-census period.

This hyper-centralized position of Moscow affects the development of rural areas of thousands square kilometers and a hundred of cities and small towns in central Russia. Discussions about so called Moscow agglomeration – metropolitan area are popular in the planning community. However, it is still a problem to determine exactly its size, shape and internal structure.

Obviously, all cities adjacent to Moscow Ring Road may be included in the agglomeration. Almost all of them have been focused on low cost multi-stored housing during last 20 years. Now they look like distant "sleeping districts" of Moscow. Probably cities within a distance of 20-50 km from Moscow boarder may be embraced into the agglomeration too. Most of these cities that are situated on radial rail directions are also seeking a doubtful reputation of extremely distant "sleeping districts" by their housing policy.

Cities situated 70+ kilometers away from Moscow are not so uniform in their development. Some of them show economic stagnation and 1-2% population decrease according to census 2002-2010 data comparing to 6% average growth for the Moscow region. Some others are looking for alternative strategies to find specific place on the edge of agglomeration or going further trying to get rid of the "peripheral" complex and become resilient livable urban centers.

The paper explores three cities situated within the distance up to 110 kilometers away from Moscow looking for planning and strategic opportunities and researching threats for their sustainable development.

City of Egorievsk is 225 years old. In the middle of the XIX century city became a center of textile industry. In the beginning of the XX century it was the third city in the Moscow region. During soviet period Egorievsk was developing engineering industry. Both textile and engineering industries failed after Perestroyka came. During the last 20 years Egorievsk completely transformed its economic base, more than 10 new factories were opened: food and construction materials production are the main industries now. As a result the city demonstrates 5% population growth in 2002-2010 period – amazing result for a the city so far from Moscow. Now it has a good position for sustainable development and smart growth.

Town of Veryia is more than 500 years old. In the XVII century during a short period of time it was the largest city in Moscow region. Now it is the smallest one with almost the same population (5000). It seems that the city is still in the XIX century. Nothing had changed through years. What are the prospects for such an "Island of Quite"? Should it look for changes in the XXI century?

City of Kurovskoe is a typical so called "Mono-industrial town". It was founded near a small textile factory with railway station and became a city due to the soviet industrialization in the late 1930-s. In the 1990-s textile factory was closed as in Egorievsk, but the railroad junction formed one of the main cargo stations in the Moscow region. Should Kurovskoe just exploit its strengths or look for more valuable place on the edge of agglomeration?

2 MOSCOW AGGLOMERATION

2.1 Size and Shape: Different Points of View

Moscow is the largest city in Europe, economical, financial, research, educational and transit center of Russia. While the total population of Russia is slowly decreasing, Moscow has shown 10% growth during 2002-2010 inter-census period. This hyper-centralized position of Moscow affects the development of rural areas of thousands square kilometers and a hundred of cities and small towns in central Russia. Discussions about so called Moscow agglomeration – metropolitan area are popular in the planning community. However, it is still a problem to determine exactly its size, shape and internal structure.

Moscow agglomeration has not any political or administrative legislative base – it just a virtual spatial phenomenon. Some experts deny its existence at all. Other planners and geographers consider that agglomeration concentrates along the main transportation routes not further than 20-30 km from Moscow ring road (MKAD). According to another point of view the agglomeration includes not only Moscow region (40000 sq km) but parts of neighboring Tverskaya, Jaroslavskaya, Kaluzhskaya regions. Extreme theory defines "The Great Moscow from Volga to Oka rivers" as a territory of approximately 300x400 km.

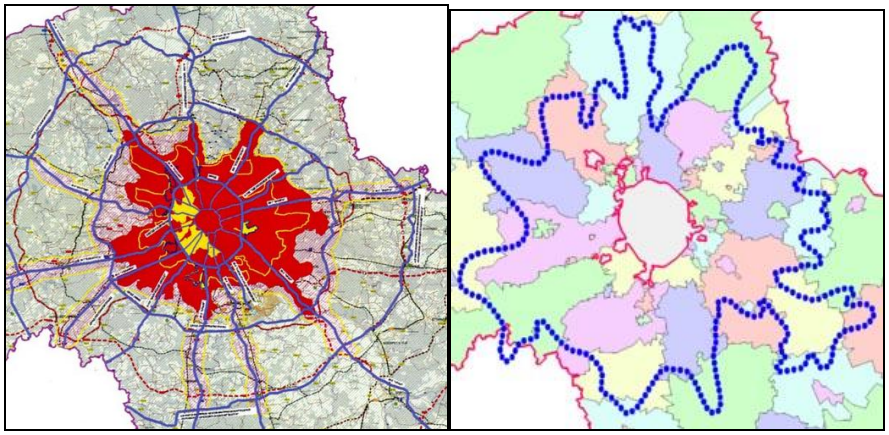

Fig. 1: Different views on Moscow agglomeration.

Regardless different theoretical approaches, all cities in central European Russia more or less are under the influence of Moscow's proximity. They should pay attention to this while thinking over strategic plans and competing for human resources.

2.2 Special Features

Traditionally Moscow agglomeration is compared to London or Paris metropolitan regions. Moscow with Moscow region is similar to Great London and Ille-de France in population size (15-20 million people according to different estimations) and ways of growth – mainly by migration processes from former USSR countries.

Today population quantity in Moscow counts from officially 11,5 million (census 2010) to 13-15 million by various estimations. Moscow region population is 7,5 million. At first glance the metropolitan area seems to be a typical mono-centric agglomeration. However somebody can find special features characteristic only for the Moscow metropolitan area.

Moscow agglomeration ignores sub-urbanization processes unlike Paris or London metropolitan areas. Both psychological and economic reasons have an influence on it. Once become a muscovite the person never would refuse this status. On the other hand Muscovites have considerable discounts for utilities payment; elder people get higher pensions than all over Russia. The retirees prefer to live in Moscow despite low environmental quality.

Sub-urbanization in Moscow agglomeration is substituted by seasonal migration out of the city. Almost all Moscow citizens have the second dwelling somewhere around the city. It may be a small hut or 3-stored estate – in any case it's a place for weekend or vacation living during the summer time.

Moscow and Moscow region both are separate subjects of administrative subdivision in Russia. There is no organizational framework or agreement between two the city and the region aimed for joint development.

2.3 Prospects and trends

Genesis of the Moscow region is an excellent illustration for the urban sprawl processes. Urbanized spaces were widening during the soviet period. The process of sprawl accelerated dramatically during the last 10-15 years. It is very difficult to precisely forecast now the processes of acceleration or stabilization in agglomeration's further development due to the resent president's decision concerning expansion of Moscow itself. Nevertheless somebody may refer to the general centrifugal and centripetal tendencies.

Migration pressure will continues: 15-20 millions ofr young people from Russia and the former soviet republics, still have a dream (or delusion) about career and sweet life in Moscow. Newcomers need housing.

Due to the limited spatial resources inside the city new housing - distant “sleeping districts” - will continue emerging all around Moscow.

Heavy industry, logistics, transit cargo traffic will seek to escape out of Moscow. Probably sub-urbanization processes will go faster due to predictable repeal of privileges for the Moscow citizens. Already now a lot of middle-aged people like to talk about living outside Moscow on pensions.

Obviously the future of the Moscow agglomeration is dynamic and unpredictable.

3 CITIES ON THE EDGE OF AGGLOMERATION

The paper focuses on planning processes and possible strategies in three cities situated on the edge of Moscow metropolitan area: Egorievsk, Kurovskoye and Veryia. These are very different cities in size, population rate, history and economic base. One equal trait for all three – they don’t experience population decrease like most distant cities in the Moscow region.

City	Year founded	Population 1989 census	Population 2002 census	Population 2010 census	Distance from Moscow, km
Egorievsk	1778	72500	68200	70130	108
Kurovskoye	1952	20200	19500	21820	100
Veryia	1371	5900	4900	5370	112

Table 1: General information about cities under consideration.

The pressure of megapolis is not so strong far from Moscow as in the core of agglomeration. The location allow peripherial cities to look for independent strategies, compare alternate visions based on re-mixing or stability and pay more attention to the planning process.

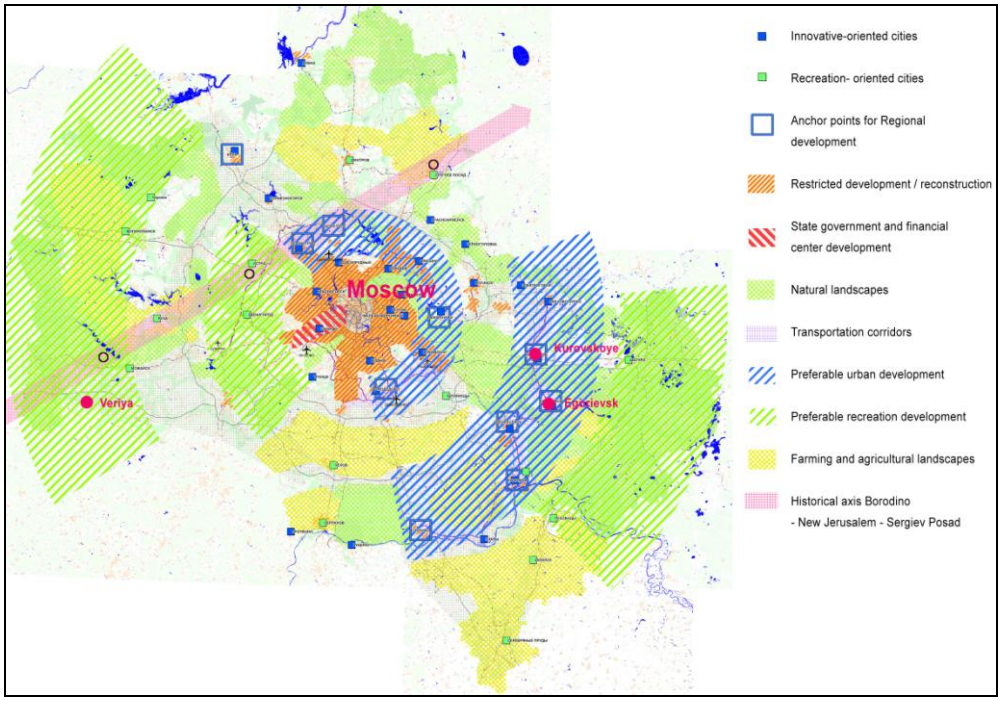

Fig. 2: Principal scheme of Moscow region spatial development.

3.1 Egorievsk

3.1.1 History and Post Soviet Transformation

City of Egorievsk is not so old: it was founded in 1778. Historically it was refuge of Old believers people – a branch of the Orthodox Church that was prosecuted for hundred years. In the middle of the XIX century Egorievsk was a small merchant town surrounded by thick forest with less than 5000 inhabitants.

Textile industry causes the first period of “remixing”: During 50 years population has grown 6 times up to 33000 people, more then 20 factories emerged, but the city community remained small business oriented. In

the beginning of the XX century it was one of the largest cities in the Moscow region formally being a part of the neighboring Ryazan gubernia.

During soviet period engineering industry was developing in Egorievsk. By the late 1980-s the population of the city increased up to 72000 inhabitants. Both textile and engineering industries collapsed after Perestroyka came. 18000 workplaces were lost. Population decreased to 67 000 people.

Egorievsk probably is the only large industrial city in Moscow region which is not situated on transit railways or highways. That is why it is attractive neither for migrants nor for developers of typical multi-stored housing. In the early 1990-s the Egorievsk started to look for new industrial development projects. Careful work with investors allowed the complete transformation of the city's economic base. More than 10 new enterprises were opened. Food and construction materials production became the main branches of industry.

All these years of transition the city was governed by one mayor and the same team of managers. As a result Egorievsk demonstrates 5% population growth in 2002-2010 period – amazing result for the city so far from Moscow. (70000 people – 2010 census).

Economic transformation has no effect on planning processes. The city adopts a policy of reasonable development following the master plan, designed in 1985.

Egorievsk has succeeded in preservation of compact 2-3 storey historical center and in expanding street network. Several housing and industrial development projects were completed. At the same time some planning problems occurred: asymmetry in new housing in the western part of the city and further industrial development in the eastern part, lack of transportation links, critical traffic situation in the historical center, etc.

Abandoned buildings of former textile factories constructed in attractive style of late 1800-s red-brick architecture are bordering the east side of historical center. This brownfield partly includes the valley of the only rive in the city. Industrial buildings are the property of dozens companies. Very few of them have just started slow reconstruction.

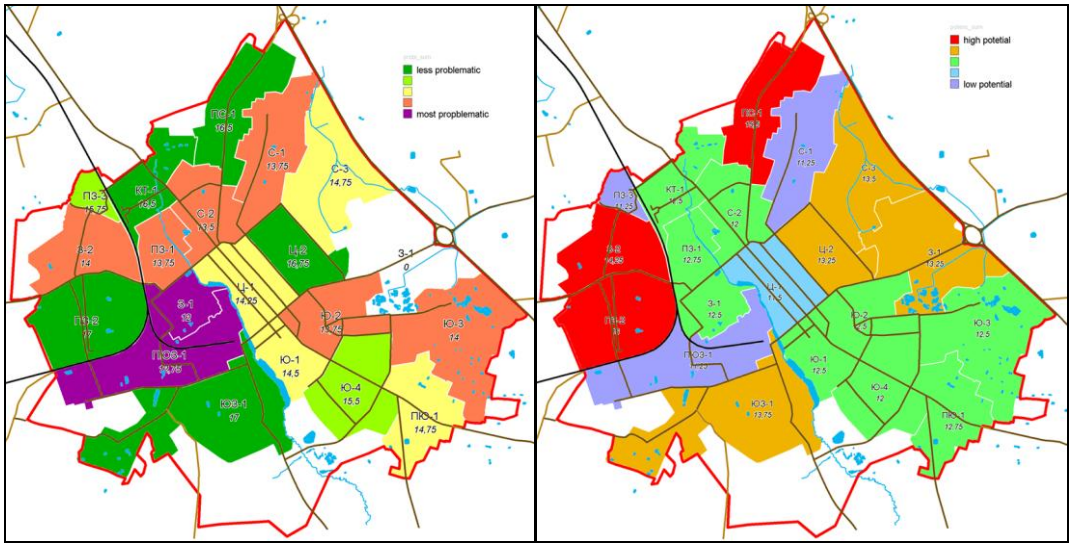

Fig. 3: Egorievsk: the city problems (left) and potential (right); evaluation by planning zones

Generally speaking Egorievsk is one of the most sustainable cities in the Moscow region. There is no need to put efforts on creating city's vision or strategy, as "everything goes well" anyway without a strategy. On the over hand the city has a good starting position for further development and smart growth. But this way needs to be planned and widely discussed in the local community.

3.1.2 Alternative City Strategies

The city may consider some traditional strategies aimed at sustainable growth. Further industrial development or tourism-oriented strategies are the main of them. In both cases the city will face competition with neighbor cities: industrial Voskresensk, Orechovo-Zuevo and historical Kolomna. All of them are larger

then 100 thousand people and have strong advantages in significant positions like energy supply, transit networks or reputation.

Post-industrial innovative strategy that is very popular in today's Russia requests for a new reform of city's economics and society. Innovative competitors are a few so-called "scientific cities" founded all over Moscow region 50-60 years ago for space, nuclear or biology researches. They are not as large as Egorievsk but still keep their intellectual potential and democratically-oriented communities.

3.1.3 Future Vision

All main city strategies in Russia are focused on investors. Cities do all their best to attract large-scale business in goods production or retail. Nobody pays attention to the citizens. Megapolices like Moscow, Perm, Ekaterinburg etc. just have started thinking about public spaces, comfort and livability for their inhabitants, but faces soviet industrial (and post-soviet free-market) inheritance in planning, street networking, "microrayon" housing and traffic.

There is a belief in Russia that small or middle sized cities are limited in their resources for development of modern public spaces and not attractive for creative young people. Is it so? Nobody has verified this statement in practice yet.

Creating a community-oriented city may be a good challenge for Egorievsk to attract creative, intelligent well-off middle class. Here in Russia we have a demand for comfortable urban environment for people who wish to escape from megapolices. Under the circumstances the city should invest more in social services, physical planning and place marketing.

This year Egorievsk is starting to work on its new master plan. According to the current planning legislation in Russia this document officially named "General Plan" is rather an obligation to build a list of social objects and streets than a city development framework.

Probably some kind of planning concept should be accomplished prior to the General Plan adoption. It is necessary to set a strategic vision of city's development for 20-25 years, evaluate planning alternatives. Planning concept should be discussed widely in the local community in order to avoid spatial "west-east" imbalance and keep the preferences of compact shape of the city.

3.2 Kurovskoye

3.2.1 The History

Town of Kurovskoye integrates the history of three completely different settlements. First – the most "historical" settlement was the Guslitsky Transfiguration Monastery – the youngest cloister in the Moscow region built in 1869. It is situated in the western part of the town. Second was a village where a textile factory started its work in the second part of the XIX century. And the third was a small town near the rail station, founded in the beginning of the XX century. These three settlements were united in one town due to the soviet industrialization in the late 1930-s but still are separated by lakes, swamps, railways and streets.

In the 1990-s textile factory in Kurovskoye was closed as the one in Egorievsk, but the railroad junction formed one of the main cargo stations in the Moscow region with locomotive depot. In spite of small industries in the field of construction materials production, woodwork and food production Kurovskoe may be considered as typical so called "mono-industrial town". Railroad infrastructure occupies 1/3 of the town territory. At the same time a new industrial park partly developed by foreign companies (e.g. Michelin, Tegola) is situated 5 kilometers far from Kurovskoe in the village of Davidovo.

Now the population of Kurovskoe is about 22000 people and is notable for a high level of social care. Due to direct railway connection with Moscow (2 hours) up to a half of able-bodied population prefer to work in the center of agglomeration.

3.2.2 Challenges and Prospects

Kurovskoe doesn't look like a city yet. It's rather a pattern of multi-stored housing blocks, private housing and industrial sites with a cascade of ponds and swamps in the very center of the settlement. The General Plan of the town was completed last year. It is focused on traditional priority of housing just mentioning the

significance of developing the central part of the city and need for special projects combining public, business and recreation activities.

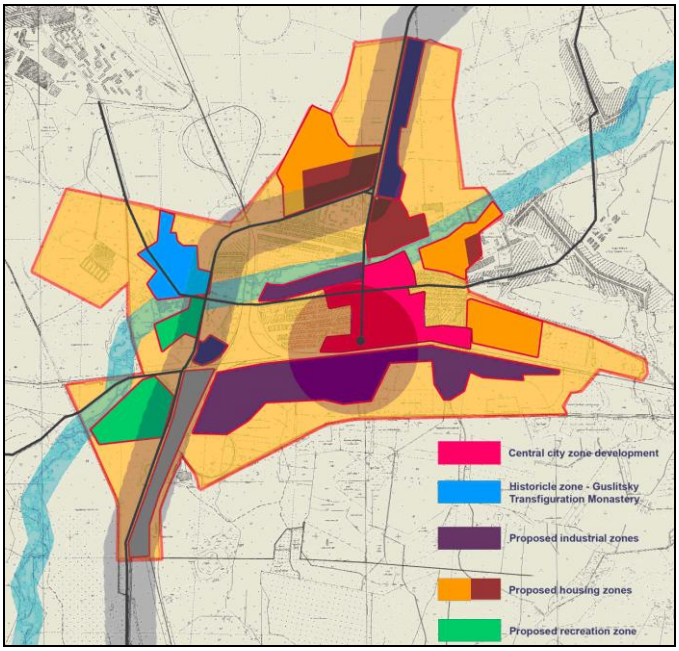

Fig. 5: Kurovskoe: Proposed Structural Scheme

Kurovskoe and Davidovo with its industrial park are different municipalities. They were working on their own plans on the lowest level of coordination. The current General Plan of Kurovskoe pays no attention to the possibility of joint development with neighboring settlements.

Today Kurovskoe faces the necessity of strategic choice – should the town just exploit its strengths as a transportation nodal point or look for a more valuable place on the edge of agglomeration. The potential of logistics development in Kurovskoe is very high. In a few years Moscow will start reconstruction of it's spacious rail cargo fields: all cargo processing will be transferred 50-70 km out of the capital towards the Great Rail Ring. Kurovskoe is a candidate to host this activity. It may offer greenfield sites for warehouse, logistics and industrial development.

Besides that, prioritizing economic aspects may cause a danger of marginalizing the social, cultural and ecological needs of the city. In order to become more livable Kurovskoe should invest much more not only in workplaces and housing but in the urban environment, public spaces and service sector. The city needs any kind of creative measures to push further its development.

3.3 Veryia

3.3.1 The History

Town of Veryia is one of the oldest settlements in the Moscow region. Now it is a typical small town with glorious history in the past. It is situated about 110 kilometers to the west from Moscow far from transit highways and railroads in a less economically developed part of the region.

It hasn't always been like that. Three centuries ago Veryia due to its position on Protva river was in the junction or the trade routes from Russia to Europe and from the north of the country to its new lands in the south. In the XVII century during a short period of prosperity it was the largest city in the Moscow region with population 5941 people (1787). During this period the majority of the churches and public buildings were made of bricks and the town acquired its regular planning form, that remains the same until nowadays.

Fig. 6: Veryia. The bird eye view.

After the Belorussian railway had been constructed in the middle of the 1900-s 27 km to the north from the town, Veryia lost its importance for transportation. No new stimulus for development came with Revolution in 1917. Now it is the smallest town in the Moscow region with population less then 200 years ago – about 5300 people.

3.3.2 The Quiet Town

It seems that the city is still in the XIX century. Nothing has changed through years. According to the statistics there are few small engineering and construction enterprises in Veryia. But they don't seem to be drivers of the town's economics.

The main potential for the city's development lies in its "historicity" and "soulfulness" – features which are so intimate for most Russians. People talk about Veryia with such epithets as "sincere", "quiet", "hospitable" or town "that I want to live in". Together with town's surroundings that are rewarded for the best environmental situation in the whole Moscow region all this attracts a lot of artists, creative people, freelancers, etc. They are not residents but many of them may live in the town (or near it in temporary dwellings - so called "dachas") for months, acquire real estate for living and play a remarkable role in the town's politics, governance and strategy.

Probably Veryia shows more "livability" then most of economically successful cities, which seek for investors, not for community's welfare. From the beginning of the XXI century Veryia is paying attention to its historical image investing in restoration of the churches and public buildings.

Like in Kurovskoe the General Plan of Veryia was completed last year. It pays attention to environmental protection measures, developing transportation, engineering and service facilities, providing recreation-oriented public spaces. At the same time it offers new sites for industrial development and multi-stored housing. Probably the town may try more restricted approach for new civil and industrial construction based not on functional separation but mixing different functions in one quarter or even one building.

3.3.3 Future Vision

What are the prospects for such an "Island of Quite"? Should it look for changes in the XXI century? Unchangeable city in case of Veryia is the same as sustainable, isn't it?

At every epoch somebody can find out two or three hundred wealthy people got tired of megapolis way of life and who appreciate silence and natural landscapes. A few cities in the western part of the Moscow region may offer a good state of historical heritage and environment, combined with better connection to Moscow, better services and more activity in public life then Veryia.

Veryia should define particular thrusts for development in this concurrent environment keeping in mind that „Changes spoil the image". The town can't fully rely on artistic-minded newcomers but should bring up its own creative community based on small services, handicraft industry and artisan production. Typical backwoods – is a good idea for place-marketing. The technologically equipped backwoods with active public life is better!

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

4 CONCLUSION

People need different cities. In order to attract citizens some of them should dynamically change, another should ensure stability and quiet. Thanks to location on the edge of Moscow agglomeration the cities discussed above independently can weigh up different opportunities of and visions on their own development.

Currently general priorities on the state level are housing and industrial sites development. Under the circumstances long term local strategies adoption, careful planning of public spaces and transportation nets, paying attention to environmental quality issues and participation processes can do more for urban community rather than construction of new houses and new factories/

1 ABSTRACT

Several major changes in political and economic organization of the country happened during the formation of the sovereignty of the Republic of Kazakhstan. State administrative and territorial units were integrated, while the capital city was moved from Almaty to Astana. The Head of the state has proclaimed long-term development Strategy of the country - Kazakhstan 2030 for realization of which there is a need to modernize a town-planning basis and generate new long-term town-planning policy.

According to the Government program on forced industrial-innovative development of the Republic of Kazakhstan the Agency for construction, housing and utilities of the Republic of Kazakhstan (hereinafter – Agency) has been charged to develop the General Scheme of the organisation of the territory of the Republic of Kazakhstan (hereinafter – the General Scheme). For independent Kazakhstan this kind of planning document at the level of national scale is being developed for the first time. Within the limits of the development of the General Scheme how the country is organised and should be developed will be considered, while taking into account major sustainability goals. The Agency has founded special town-planning institute responsible for the development of the General Scheme - Astana branch of "KazREIECA" RSE (hereinafter – the Institute).

2 INTRODUCTION

2.1 Description

The General Scheme of the organization of the territory of the Republic of Kazakhstan is a planning project containing long-term vision of territorial development and rational organization of the territory of the Republic of Kazakhstan. It takes into account regional and world processes, the role of the regions in social and economic development of the country.

2.2 The purpose and tasks of the development of the General Scheme

The purpose of the development of the General Scheme is an improvement of quality of people's life, sustainable development of Kazakhstan.

The tasks of the development of the General Scheme (according to the Law of the Republic of Kazakhstan "About architectural, town-planning and construction activity in the Republic of Kazakhstan", article 42):

Maintenance of state regulation of the system of population settling down and distribution of industrial forces;

Establishment of the status, appointment and character of the use of territories taking into account the administrative and territorial division of the Republic of Kazakhstan;

Coordination of inter-regional and interbranch state interests under the programs of social and economic development.

2.3 The structure of the General Scheme

Key points covered within the limits of the development of the General Scheme includes the following questions:

Major principles of population settling down and distribution of industrial forces in accordance with positions of strategic and economic planning;

Substantive provisions of rational management of environmental and economic activities, development of industrial, transport, engineering, social and recreational infrastructure of republican level;

Basic measures on improvement of ecological conditions in regions, preservation of territories with minerals, valuable landscape and objects of historical and cultural heritage, etc.

2.4 Expected results from the development of the General Scheme:

The complex planning analysis of the territory of the Republic of Kazakhstan;

Formation of principles of comfortable residing of the population on territories of the country;

Creation of conditions for increased interaction of central and local executive bodies in terms of rational organization of the territory of the Republic of Kazakhstan;

Development of offers on rational use of resources, overcoming of both economic and social disproportions and increase of social and economic interrelations between regions of Kazakhstan;

Formation of a long-term town-planning policy on the basis of the balanced placing of productive forces and population settlement in the Republic of Kazakhstan territory.

3 INITIAL VARIANTS OF THE DEVELOPMENT VECTORS

3.1 Brief description of the internal features of the organisation of the territory of Kazakhstan

Massive work on collection, analysis and evaluation of the territory of the state has been undertaken within the limits of the development of the General Scheme.

The analysis of world experience of strategic spatial organization and internal features of the organization of the territory of Kazakhstan, influencing the choice of further development direction have been studied to define possible development vectors of the territory of the Republic of Kazakhstan.

The territory of the Republic of Kazakhstan is more than 2,7 million square kilometers with population of 16 million people. Low density of population at 6,2 people per square kilometer, as well as non-uniformity of settlements across the regions should be marked.

The considerable part of territories of South, South-East and East Kazakhstan with the area of 450 thousand square kilometers is covered by the zone with high seismic activity of magnitude 7 or larger where about 7 million people live. Thus, 19 cities, including Almaty, where almost 1,6 million people live, is within the most dangerous area with seismicity magnitude 9 or larger.

Climate biological efficiency is 4-5 times lower than in developed countries due to the adverse environmental conditions. It is possible to name all Kazakhstan as risk agriculture zone (the amount of precipitation varies from 200 to 500 mm a year which is considerably lower than the norm), except for southeast region. Mid-annual amount of precipitations in the basic agricultural areas of USA and Great Britain varies from 600 to 2000 mm, in France – from 600 to 1000 mm. Moreover, desertification processes and uncontrolled migration from countryside to the cities are observed.

A number of experts asserts that Kazakhstan is threatened by total power deficiency, especially in the Southern region. Necessity of power saving demands new, more effective studies of general layouts of the cities and settlement systems as a whole. One of ways of power saving is to increase the general compactness and intensify use of the territory, optimize its functional zoning, etc.

3.2 Brief description of the best international planning practices suitable for Kazakhstan

Spontaneous migratory processes the state should take under control. In USA and Italy, for example, organized migratory processes (tax privileges, favorable investment climate etc.) became a push for economic development of territories.

Similar countries to some signs with Kazakhstan, such as Canada and Australia have concentrated their efforts on narrow environmentally favorable territories. “Urbanization axis of Canada” is the strip, across the border of the USA, occupying the space of 170 thousand sq km where more than a half of population of the country concentrated at the distance of 1200 km. As a result Canada as huge as Russia with the considerably less population thanks to the reasonable organization of the territory gives repeatedly bigger gross product per capita in comparison with Russia or Kazakhstan.

It is necessary to bring territorial structure of the economy in accordance with market structure, to concentrate efforts to the economic complexes which have high enough potential for quality manufacture.

3.3 Preliminary brief analysis of possible development concepts of the territory Kazakhstan

Analyzing the territory of Kazakhstan, the central part, is basically presented by focal settlement systems influenced by extracting character of manufacture. The general decline of manufacture, outflow of the population and discomfortable climate are observed. The central zone with little use for high-grade life, but having high resource potential, is mostly suitable for rotational development method.

Top “northern belt” stretches from East Kazakhstan to Uralsk city where industrially-developed centers of the country are located. Lower so-called «southern belt» has favorable environmental conditions.

Proceeding from the aforementioned preconditions, examples of world planning practice and, taking into account that in the basis of the spatial organization the Forecast scheme of territorial-spatial development of the country until 2020 (hereinafter – the Forecast scheme) is placed, which is comparable to an offered vector of the development of Kazakhstan, the following conceptual model of the organization of the territory the of Republic of Kazakhstan is produced.

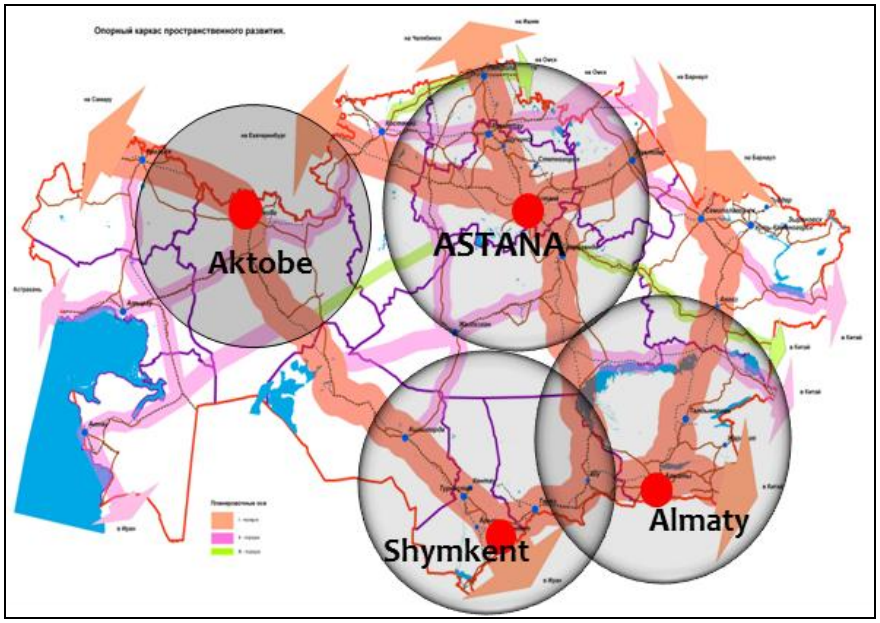

Fig. 1: Development vector according to the Forecast Scheme.

Key "base points" in the Forecast scheme, are offered to be the cities of Almaty, Astana, Shymkent and Aktobe which organically correspond to the considered structure: cities of Almaty and Shymkent are located in so-called “southern belt”, and the cities of Astanas and Aktobe – in “industrial belt” (Fig.1).

Taking into account specialization of the belts, it is necessary to develop intensively corresponding spheres of the national economy in these zones.

In a “southern belt” there is a need to develop agriculture with a full cycle of manufacture from cultivation and storage before processing and release of finished goods. For the given region there is a need to develop such spheres as tourism, public health services, sport, study, science and certain industries.

In “northern belt” development accents should be transferred on intensive industrial development of territories. Planned manufactures should be located as close as possible to “development points” and consider specialization of the territory. Taking into account the neighbourhood of the given region with the adjacent states – Russia in the north and China in the east, it is necessary for the Kazakhstan to develop those manufactures and technologies which allows participation in planned rapid development of Siberia, Far East and Xinjiang Uyghur Autonomous Region.

Agriculture specialization should be guided by environmental conditions of the region, costs reduction and increase of the productivity of manufacture. It is necessary organize the development of engineering-transport infrastructure of the belts to optimize communications and logistics with subcentres which can become regional centers.

Existing urban settlements are subject to radical reconstruction and optimization to the sizes optimal for accommodation settlement and reductions of municipal costs.There is a need in the given process to differentiate each large industrial center, taking into account industrial, social and economic situation.

Strengthening of the border territories can become another development vector for the Republic of Kazakhstan since over 80% of all population of Kazakhstan lives there. During the analysis of the border territories, it is necessary to allocate 4 groups (Fig.2) of resources influencing the organization and preconditions of their development:

At the level of natural resources these are:

Transboundary water, conditions and desertification.

At level of demographic resources these are:

Transboundary migration and the innovative environment.

At level of infrastructural resources these are:

Transport and border object infrastructure.

At level of economic resources these are:

Transboundary economic integration and trade.

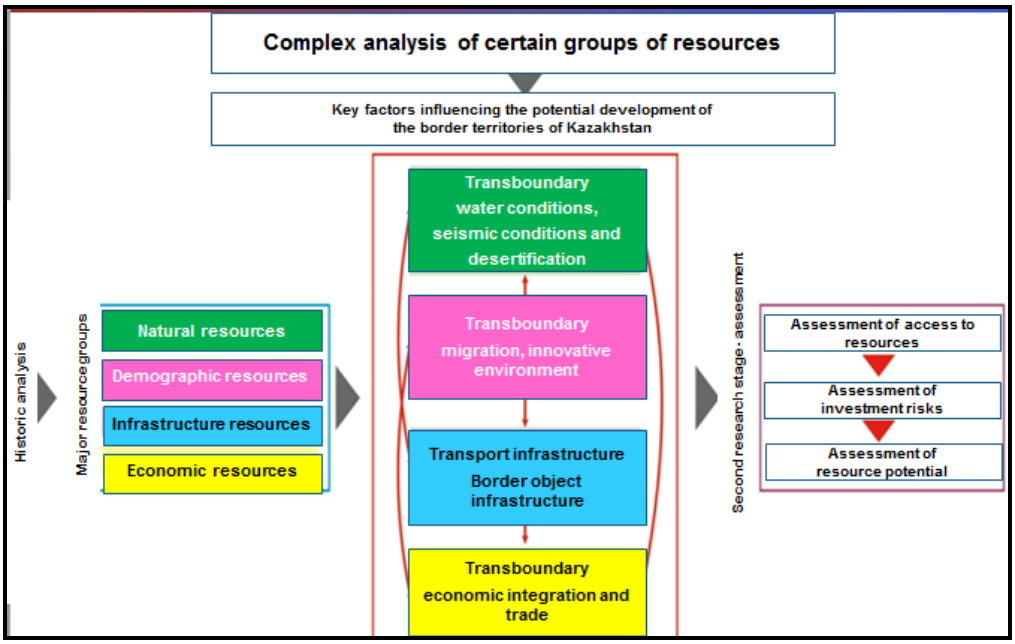

Fig. 2: Complex analysis of certain groups of resources influencing the development choice of the border territories of Kazakhstan.

4 CONCLUSION

Offered development variants of strengthening of the border territories and also active development of "southern" and "northern" belts can become one of the vectors of the organization of the territory of Kazakhstan. After fuller analysis of the initial data, development of different planning variants there can be specifications in the offered concept, and, probably, new conceptual approaches to the organization and development of the territory of the country will be developed. Sustainable and rational organization and development of the territory should become basic principles at the definition of development vector of the country.

Planning development stage of the General Scheme on formation of variants of the organization of territory of Kazakhstan will be undertaken in 2012, including:

Improvements of a demographic situation and regulation of migratory processes, an urbanization and a suburbanization;

Perfection and development of the settlement systems;

Perspective development of productive forces;

Transport-communication and engineering infrastructure;

Improvement of ecological condition of the territory of Kazakhstan and another.

Massive work needs to be undertaken on a way to achievement of effective organization of territory of the country, sustainable development of the entire Kazakhstan. Town-planning science in the world has already developed enormous experience and our task is to shift this positive world practice adapted for the conditions of our country, on the Kazakhstan soil.

1 ABSTRACT

The demographic changes in the developed countries, especially the growing number of elderly citizens, are causing opportunities and big challenges to societies. The need of care and support of seniors is growing fast, also the changes within our ICT based information society increase the gap between the younger generation ("digital natives") and the older generation ("digital immigrants"). Ambient Assisted Living (AAL) offers an approach to meet these challenges. AAL covers different areas, especially ICT based solutions for improving care for elderly persons and also improves access to ICT based services for the large number of "digital immigrants" in terms of e-inclusion.

For research in the field of AAL it is very important to involve actively members of the target groups, which are seniors as primary users, care givers, nurses and relatives as secondary user group and private and public stakeholders as tertiary target group. In the urban area of Schwechat / Austria a collaboration between research teams and all groups of end users was established as a base for performing applied research and development of AAL-products, services and solutions.

Starting with the initial situation and local, national and international basic conditions this contribution describes objectives, methods, outcomes and lessons learned of this cooparative approach.

2 THE SITUATION OF ELDERLY PEOPLE LIVING IN SCHWECHAT

Elderly persons being serviced by mobile care taking organisations have been interviewd about their living situations [Meissl et al. 2007]. The result of these interviews as well as outcomes of consultance conversations with seniors and their family members shows that more than 90% of concerned persons have the whish to stay at their own home even at an old age and they believe that there dwelling situations is suitable; they have problems facing barriers outside their home like stairs at doctor's offices, in shops, etc.

A large group of elderly persons living at their own whome are supported for doing the household and for shopping by their loved ones.73% of the interviewed persons stated to have personel contact to their children or grandchildren on a daily base. Single living seniors and their affiliates are mainly concerned by the following possible disresses:

Fall downs followed by a situation which does not allow to use a telephone or an alarming device

Danger of fire due to not switching of an oven, etc.

Becoming isolated due to building's conditions, eg. a missing elevator leads to dependency on other persons and to loose own autonomy.

3 THE AAL LIVING LAB SCHWECHAT – COOPERATION BETWEEN CARE AND RESEARCH

3.1 History

The municipality of Schwechat, Austria, has initiated several programmes, subsumed under an umbrella called eSchwechat.at to bring forward ICT research and development as well as the concrete usage of ICT in daily life in order to allow people of the community to participate in the e-society, to gain benefits provided by novleous ICT-solutions and to close the digital gap between the younger and the elder generation

One element and outcome of this initiative is the CEIT RALTEC research institute dedicated to ICT-based research and development of ICT-solutions to support and improve the life of older people according to the ideas of AAL. In order to follow the basic principle of user-centred design by active involvmement of

potential end users the AAL Living Lab Schwechat (LL) was was establishd and became a member of the European Network of Living Labs [ENoLL] in 2008.

Since 1996 the municipality of Schwechat operates the Senior Center ("Seniorenzetrum") as a sheltered housing considering elderly peoples pursuit of an autonomous living. The residents can arrange their life to their personal needs in an environment responding to the special cirumstances and needs of getting older. A number of different assisistive technological solutions are in use and are well accepted by the elderly residents. In the field of support services and care for the elderly it is important to think and plan oriented towards the future in order to fulfill the requierments of the next generation by applying technology based approaches. This is seen by the management if the Senior Center Schwechat as a challenge to be actively involved iton the development of new services, solutions and products, to bring own practical experiences and to test and evaluate prototypes of assistive solutions. [Panek P. 2011],[Senior Centre].

3.2 Key Actors and Stakeholders in the LL Schwechat

Besides CEIT RALTEC and the Senior Center Schwechat the following entities play a significant role in the AAL Living Lab Schwechat:

- Advisory board of senior citizens ("Seniorenbeirat"): Its mission is to collect and forward requests from senior citizens in Schwechat, to discuss important topics in the context of senior care in Schwechat, and to organize and coordinate leisure activities for senior citizens.. The members of the advisory board often contribute significantly in their role as multipliers to identify further persons interested in joining workshops and field trial activities in the LL
- Cooperation Platform: Regular meetings between representatives of the Senior Center, mobile care providing institutions and CEIT Raltec to share information, to discuss topics of care provision in the local context and to plan and implement joint projects
- Municipality of Schwechat (SW): Tthe local government authorities are very interested in new technologies supporting the autonomous living of the older population [Hlauschek, et al. 2009].
- SME and industry: involved via local association "Wirtschaftsplattform Schwechat" and through the research consortia, carrying out user-centric work in the LL

3.3 Methods applied

User centric methods often applied are focus groups with older adults [Oberzaucher, et al. 2010], [Panek, et al. 2008], interviews with users and carers [Werner, et al. 2011], [Panek, et al. 2007], workshop meetings with users and care experts for requirement gathering via low fidelity prototypes and for presentation of results, different types of evaluation activities (from lab tests to field trials) [Zagler, et al. 2009], [Schumacher, et al. 2007], [Bergvall-Kåreborn, et al. 2010], [Wilson, et al. 2008]. An iterative approach is used in nearly all cases

4 PROJECTS CARRIED OUT

The projects carried out are focused on the research and development of new systems for empowering older adults to live a life as independently as possible.

IAP-Video phone for elederly people: within this industry funded project a touch screen based video phone for older persons was developped and evaluated together with a group of eldely people [Oberzaucher, et al. 2009].

eHome: CEIT RALTEC and 3 Austrian partner developped an assistive smart home solutiuon for safe and comfortable living of single living seniors. The solution was field tested in more than 10 private appartemts in the area around Schwechat [Diermaier, et al. 2008], [Werner, et al. 2011], [Mayer, et al. 2011]

LLM (Long Lasting Memories): CEIT RALTEC, the municipality of Schwechat and 10 European partners enhanced eHome by adding components for physical and cognitive training for seniors. The solution was tested at the senior's centre and at private premises of elderly citizens in Schwechat. Additionaly the LLM-system was validated in 4 different European counries [Konstantidis et alt.2010].

vitaliSHOE: CEIT RALTEC, acting as project leader, developped in cooperation with Austrian industry and rsearch institutions a mobile gait analysis and fall prevention solution. Senior's and care givers of Schwechat have been evolved as active partners [Oberzaucher, et al. 2010].

MyTablet: a usability study of state of the art tablet PCs has been performed by active inclusion of seniors living in Schwechat [MyTablet]

KSERA: this assistive robotic solution developped by 4 European research and indsutry partners is currently validated at the premises of the Senior Center Schwechat by elderly citizens supported by reaerch staff of CEIT RALTEC.

AAL Demo Appartment

In 2009 "AAL demo-apartment" in the Senior Center [Demo-Apartment] was set-up. This project was initiated and organised by the team of the Senior Center supported by the municipality, CEIT RALTEC, mobile care providers and enterprises. A dedicated flat was equipped with already available assistive technology and offers the possibility to test technical aids and provide hands-on experience in real life settings for seniors as well as family and staff. Many companies have followed the invitation to support the project and have provided products for free. The demo-apartment can be visited by anyone interested and explanations are given by professional technical engineers and experienced nursing staff. The flat is also used to provide some insight in upcoming future systems by exhibiting some selected research prototypes [Werner, et al. 2011] and to gather feedback on those prototypes from the visitors of the demo flat [Panek, et al. 2011]. This project is good example of cooperation of a public body (municipality of Schwechat), care giving and a research institute getting a useful result for every day's life

5 INITIAL RESULTS AND LESSONS LEARNED

Issues which came up during the above listed projects are discussed below and provide some concrete examples of the research context in which they became known:

- **Speaking the same language:** ICT researchers and users not necessarily speak "the same language" which can cause non trivial communication problems [Panek 2007]. Some expressions might either not be understood by people who are not familiar with modern ICT or even scare them off.
- **Person of trust:** For sorting out problems it was found to be of high value to have social worker / care persons on board who are well familiar with the test persons and can communicate with them on a meta level (with regard to the project level). The eHome project [Werner, et al. 2011] [Mayer, et al. 2011] for example is a very sensitive project as the researchers get a very detailed insight into the living situation of the person and his/her daily activities.
- **Recruiting users:** First users were recruited with the help Senior Center and advisory board. After initial successful projects, it also turned out that involved users helped us by recruiting other persons they knew as additional new users for upcoming research activities. This is obviously a very positive indicator. On the other hand, being successful in establishing an active group of older adults participating in research activities brings up a new issue: persons who are closely connected to these activities might be biased e.g. when giving their comments and opinions about prototypes to be evaluated.
- **Time and efforts needed:** Ambient Assisted Living (AAL) and assistive technology supporting older adults are very relevant topics for European society. User-oriented research and technical development in these areas do need a significantly high amount of time and resources in order to come up with innovations which are mature enough to enable sustainable improvements regarding quality of life of older persons and carers (cf. our "demo apartment" project).
- **Other issues:** lack of time with the mobile care providers, positive feedback from involved users asking us and our LL partners for status updates, progress and next steps to which they can contribute. In some specific cases, it is difficult or may not even be possible to evaluate research prototypes with the real target user group (e.g. persons with mild dementia and/or persons prone to fall frequently cannot test pure research prototypes with not yet guaranteed performance levels due to ethical, practical and legal reasons).

6 CONCLUSION AND OUTLOOK

After nearly six years of cooperation of the municipality of Schwechat and CEIT RALTEC, the results are very promising for research as well as for the care giver's and the municipalitie's activities. A user club of older adults engaged in researcj activities could be established, an informal structure of regular meetings between core partners and regular meetings of other partners (mobile care providers, senior's advisory board, senior's centre) proved to meet the needs. Several projects could be completed successfully; involved partners are satisfied and very active in continuing with this endeavour. This cooperation is a good base for establishing national and international contacts and working cooperation for future R&D projects.

After the successful set-up of the AAL demo apartment the fruitful cooperation of municipality and research is continuously going on. Outcomes of user-centred research projects are going to be applied in the field within new approaches of Schwechat to support the life of their older citizens. Just before publication of this article the detailed planning for a multigenerational residential settlement ("Siedlung Frauenfeld") within the municipalitie's area started. CEIT RALTEC is currently bringing in practical experiences gained within research projects accounting for barrierfree design issues, intermediate inputs for planning high-tech assistive solutions, etc.

To arrive at a conclusion it can be stated that the concrete pragmatic approach of cooperation between local care giving and research chosen in Schwechat has proven to be a good choice.

7 ACKNOWLEDGEMENTS

The research institute CEIT RALTEC is owned by the municipality of Schwechat and is carrying out RTD projects funded by various sources, in particular EU, FFG and private companies. We are grateful for the support given by the city administration. Our special thanks goes to all the volunteers participating in research activities, to the team of the Senior Center and the representatives from mobile care organisations for their valuable contributions and support

1 ABSTRACT

New types of large mixed-use developments of properties run by specialist operating companies prove in many western European countries their potential to attract purchasing power, create jobs and income for the local population beside other desired positive external effects. These new types of mixed-use developments are a response to the continuous rapid social, economic, environmental and cultural changes which today´s modern cities are facing. The case-study research of twenty-five successful developments of managed real estate with new types of mixed-use, also defined as managed facilities, between Barcelona and Berlin clearly highlights the principles, processes and success factors involved as well as the risks which need to be considered–representing a first step towards understanding and managing real estate development as an open dynamic system and hopefully towards more and new types of these desired developments. The project was funded by Deutsches Seminar für Städtebau und Wirtschaft (DSSW) in Berlin.

2 INTRODUCTION

Real estate development with respect to the social, economic and ecological effects is definitely a complex task and from a research point of view still unexplored in many ways - especially regarding special purpose and managed real estate development the theoretical background is lacking. Managed real estate (see fig. 1), will also be defined as "managed Facilities" and will be called accordingly in the following. From an investor's point of view managed facilities fall into category of "high risk" [1] (Bienert, 2005, p.8-9). The need to explore these risks and to establish methods for an appropriate risk management is also evident from a practical point of view. Finally, these types of developments are socially relevant and contribute to the development of organized synergies between different types of uses which make cities or parts of cities more sustainable. Looking at existent mixed-use developments in the outer skirts of the city of Vienna, where different types of mixed-use have been placed randomly and in an unplanned manner, the necessity for organized, managed real estate becomes obvious.

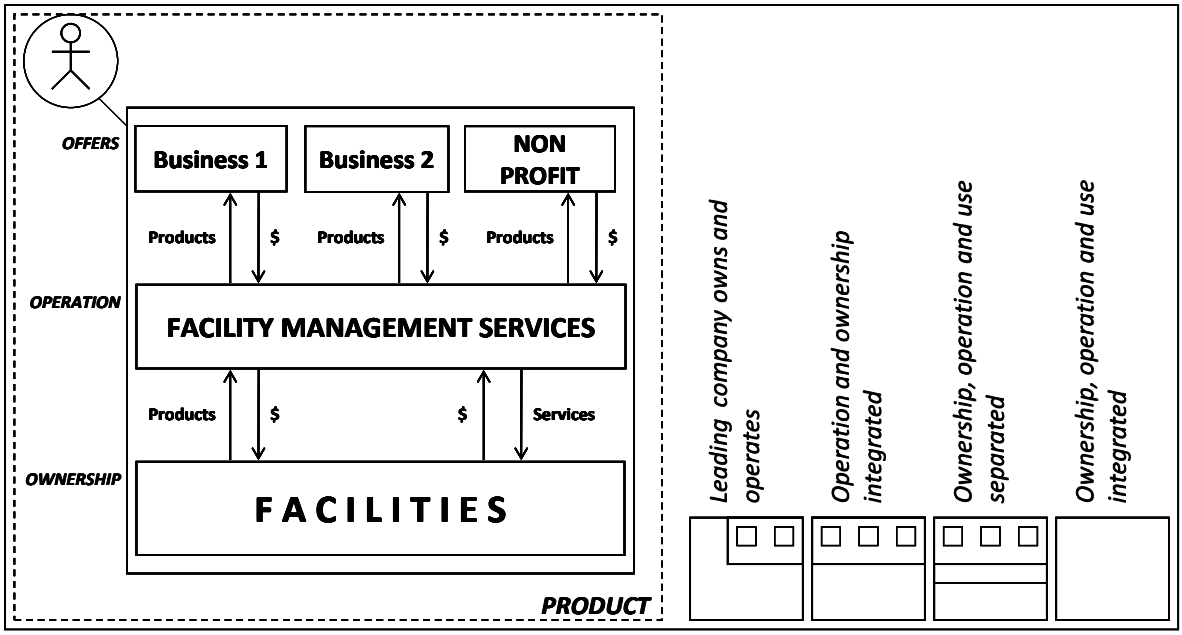

Figure 1: Model of Managed Facilities

Experience, especially in eastern Germany, show: large real estate developments run by operating companies–e.g. shopping centres–are highly accepted by the customers. On the other hand in city centres,

[1] Bienert, S. (2005). Bewertung von Spezialimmobilien : Risiken, Benchmarks und Methoden. Wiesbaden, Gabler.

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

where landlords only desire to maximise rents and the establishment of appropriate "city management" structures fails, customers find an unsatisfying mix of offers and uses, landlords end up with a bad performance of their properties and purchase power migrates to other regions - a typical prisoner's dilemma [2]. Besides this well know phenomenon new types of managed facilities with new types of mixed-uses emerge especially in Western Europe. They initiate or support e.g. business clusters of creative industries and create positive effects on the local and regional development. A private company, for example, revitalizes with a network of tenants around the topic "arts" the Baumwollspinnerei in Leipzig - a huge former industrial site. The Klassikstadt in Frankfurt offers everything for the lifestyle of fans of vintage cars–and thus initiates the transition of a problematic part of the city. In Berlin an intermediate organisation founded by women provides a business incubator: the "Weiberwirtschaft". The objective of the organisation is to support enterprises managed by women and to enable them to profit from the synergies between these enterprises. The municipality in Barcelona revitalises its traditional market halls with a new mix of shops and improved infrastructure especially regarding the logistics infrastructure–and thus preserving an important aspect of urban culture. These new types of managed mixed-use developments with their positive effects on the regional development still occur far too seldom. Theoretical knowledge and expert knowledge are missing. Especially the problem regarding the assessment and management of risks leads to difficulties in financing and attracting institutional investors required for this kind of development.

3 TARGET AND FRAMEWORK OF THE RESEARCH

Within a time frame two years, the Chair for Real Estate Development at Vienna University of Technology has conducted explorative research on more than 25 cases of managed facilities in order to explore the generic principles and processes of these developments. The analysis focused on different types of mixed-use, with different types of developers (private, public and intermediate) in towns with different numbers of inhabitants. The main targets of our research were to enable more developers to work in this domain, to boost investments in managed mix-use facilities and to enhance the financing, through more knowledge on the risks involved and through making the risks manageable.

Most of the analysed cases could be defined as corporate real estate, neglecting the fact, that they also represent public infrastructure. They could also be seen as special-purpose real estate [3] focussing on the functions of the building, e.g. Entertainment Centre. The authors propose the term "Managed Facilities" with special regard to the managing entity ensuring the business success of the mixed-uses, e.g. cinema operation and catering, by providing much more than a coherent plan for the uses. All Developments could accordingly be called "Facilities Developments".

The research focussed mainly on "successful" cases. The developments reach their primary goals–even though the goals might be different in every case - and create positive external effects, e.g.:

- they are economically sustainable
- they revitalize problematic parts of the cities
- they create positive desired or external effects on the local development, like income and employment
- they maintain purchase power in the region
- they contribute to the profile of the region
- they use and strengthen the potential of the region and reduce deficits

4 RESEARCH QUESTIONS AND METHODOLOGY

The explorative studies concerning the real estate development principles, processes, actors and success-factors of the cases analysed were developed by an interdisciplinary team at the Chair for Real Estate Development. Within the analysis, the focus was mainly on the following research questions:

- Do the developments need certain preconditions, concerning the site, municipality e.g.?

[2] Poundstone, W. (1993). Prisoner's dilemma : John von Neumann, game theory and the puzzle of the bomb, Oxford University Press.
[3] Bienert, S. (2005). Bewertung von Spezialimmobilien : Risiken, Benchmarks und Methoden. Wiesbaden, Gabler.

- Do certain players regarding their organisational or individual capabilities ensure successful developments?
- Do certain constellations of players lead to successful developments?
- Do certain processes lead to successful developments?
- Which are the success factors and the critical factors for the development of managed facilities?
- What do architects contribute to the successful outcome of a project?
- What is the role of the state and how importance is financial or other support of the government?

Due to the fact that to the author's knowledge theoretical background on managed mixed-use facilities is missing the research was designed as explorative case study. "A case study is an empirical inquiry that investigates a contemporary phenomenon within its real-life context, especially when the boundaries between object of study and context are not clearly evident. It copes with the technically distinctive situation in which there will be many more variables of interest than data points.[4]" (Yin, 2003, p.13-14)

The research team decided to analyse a variety of cases in order to come to generic conclusions and to explore if a common ground connecting all different cases can be found. The selection process for the cases ensured the variety of the cases concerning the following factors:

- inhabitants of the municipality
- public, private and intermediate initiators
- concept of use, respectively mixed-use
- support of small- and middle-sized businesses (SMEs)
- inclusion and development of historic substance of building structure
- single type of project vs. repeatable type of development

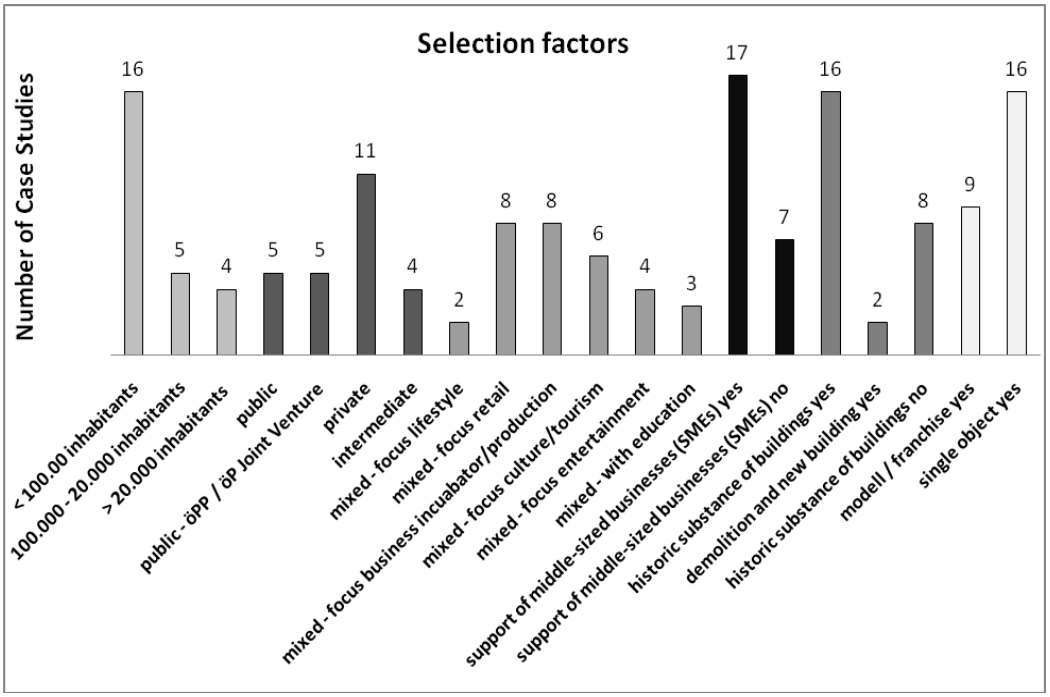

Figure 2: variety of the selected cases

For this analysis the authors designed a special investigation scheme based on theories concerning case study methodology [5], but also regarding aspects of systems theory, predominantly referring to the science of systems that resulted from Bertalanffy's [6] General System Theory (GST) and Ulrich and Probst [7], who

[4] Yin, R. K. (2003). Case study research : design and methods. Thousand Oaks, California, Sage Publications.
[5] Dul, J. and T. Hak (2008). Case study methodology in business research. Oxford ; Boston, MA, Butterworth-Heinemann.
[6] Bertalanffy, L. v. (1984). General system theory: foundations, development, applications ; . New York, NY, Braziller.

further explored systems theory in the area. The main assumption is that we are not able to understand techno-social systems–like projects–by analyzing the single entities in an isolated way; we have to understand the relationship between the entities and the context of the techno-social system to be able to understand its behavior–its contribution to the outcome of a project.

The case studies were carried out in five parts:

Part 1–characteristics of the project

The first part considered the "real-life" context of the project, the different constraints, especially:

- type of city
- number of inhabitants
- unemployment rate
- demographic dynamic
- economic data like purchase power

In addition the project itself was also characterised e.g. by:

- type of development
- type of use / mixed-use
- target group
- USP
- initial situation
- trigger of the project
- positive/negative effects

These data were collected through publications concerning the project and by narrative interviews with the developers involved or other key players.

Part 2 - players and their relationships

The players were distinguished in private, public and intermediate and characterised by:

- role within the project
- resources relevant to the project
- activities and outcome of the activities within the project
- time of involvement within the project
- targets and interests

Lastly the relationships between the players within the projects were analysed and represented graphically. Due to the fact, that the relationships of the entities within a project are heterogeneous they were named respecting their qualitative aspects: owners, awarding permission, providing service etc.

These analyses were carried out via narrative interviews with the developers involved or other key players.

Part 3–processes

In Part 3 of the research project the development processes were analysed–again by narrative interviews.

The processes were characterised by:

- constellation of players
- course of action
- time dimension

[7] Ulrich, H. and G. J. B. Probst (1995). Anleitung zum ganzheitlichen Denken und Handeln Ulrich, H. and G. J. B. Probst (1995). Anleitung zum ganzheitlichen Denken und Handeln ein Brevier für Führungskräfte. Bern ; Wien [u.a.], Haupt.

- instruments
- results

If possible the interrelation with other processes was named.

Part 4–special aspects of the development due to its purpose

This part of the evaluation respected the fact that the development of buildings with a special purposes may cause the need for:

- individual or organisational competences for this type of development
- necessary milestone for success
- deal structures
- miscellaneous

Part 5–success factors / critical factors

This part of the research considered the risks of the development–risks understood as chance and danger and distinguished in that way–again carried out by narrative interviews with the developers involved or other key players.

The results of the evaluations lead to conclusions i.e. answers to the research questions and assignment regarding the behaviour of the management of future managed facility projects - outlined briefly in the following. The conclusions were verified by analyses of cases of unsuccessful developments and with experts.

5 RESULTS

The approx. 25 case studies analysed have shown the following results:

5.1 General framework

- *Successful development of managed facilities is possible almost everywhere.*

Success–defined as the sustainable achievement of planned private, public or intermediate sector goals–is not per se linked to aspects such as the purchasing power or the existing image of a location, but: projects need to be customized for each and every location and situation from recognizing the potential of that specific location to knowing the constellations of the stakeholders (players) involved, and thus need to be tailor-made. Projects are required to purposefully include the conditions already available and present at the location. Small scale projects have to utilize the chances; large projects might even be able to reduce deficits of a site or area.

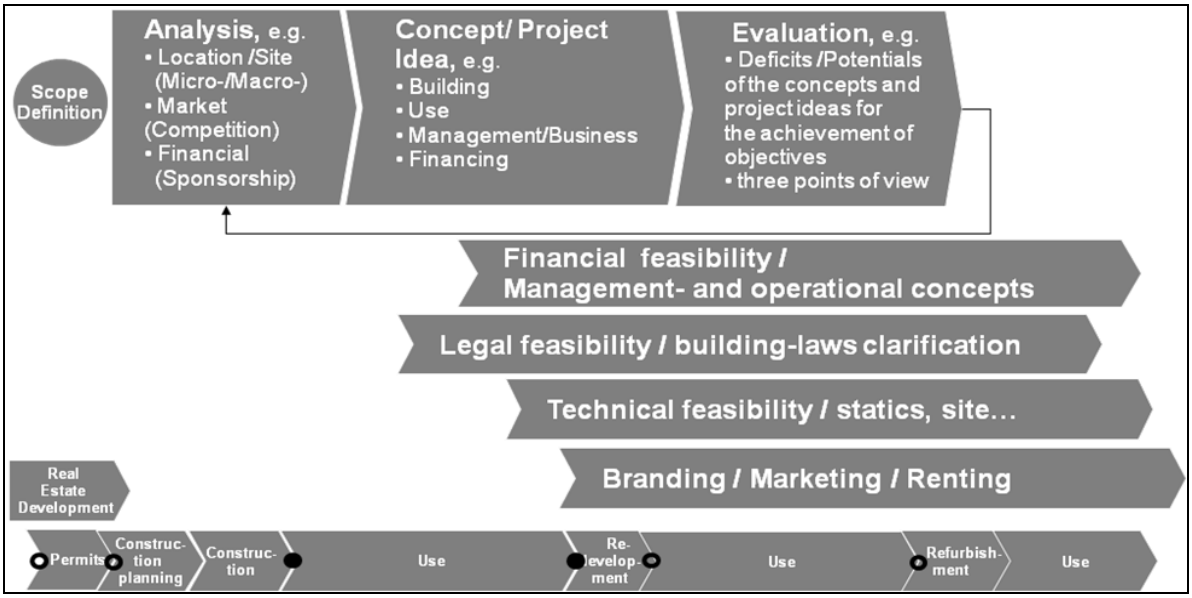

Figure 3: Process-model

5.2 Processes of Real Estate Development

- *The development of managed facilities in a narrow sense is not a chronological process, but a repetitive (iterative) process characterized by the steps analysed, concept (design) and assessment/evaluation, with the possibility of exit or entry into the next phase after every iterative cycle.*[8]

Consequently, successful facility development in the narrow sense can be seen as a cyclic process of optimization - in this case of public or business infrastructure.

The case studies have clearly shown two things: The grounds for a successful project are laid within the frames of the facility development in the narrow sense. A project failure though, is also possible at every other point in time.

5.3 Success factors, respectively critical factors

- *In numerous developments of managed facilities one person delivers business know-how–normally concerning the business the infrastructure is developed for - that leads to a competitive advantage of the facility and good business conditions for the tenants or in the case of public infrastructure to positive social effects.*

Success in corporate real estate development is linked to the business success of the tenant(s) or operator. Know-how and also innovation concerning the business of the tenant(s), concerning the infrastructure a certain business needs and concerning possible synergetic effects with other businesses seems to be a scarce resource concerning the development of managed mixed-use real facilities. In most of the cases it leaded to a competitive advantage of the development and of the tenants, e.g. within the project Cinecitta in Nürnberg (cinema and catering) business know-how and innovation concern different aspects:

- procurement of the projectors
- procurement of the film rights
- film projection
- ticket control
- ground floor plan
- catering concept

Business know-how is an asset and a critical factor, due to the fact that it is rarely explicit or freely available. The early inclusion of necessary management know-how concerning the business processes the facility is built for, should not be confused with an early and exclusive contracting of a company for the operational management.

- *The "completeness of competencies" concerning the development of managed facilities is a main success factor.*

All of the cases have confirmed that the completeness of necessary competences or knowledge is essential. Project developed through networks without compentencies in the real estate or construction domain, show with significant frequency a lack of legal or constructional know-how that endangers the achievement of the project goals–e.g. within the building of "Weiberwirtschaft" in Berlin, contaminations were found after the tenants had moved in and there was no liability of the former owner agreed in the contracts etc. Projects are jeopardized if even one "capability" is absent.

- *A sufficient equity position (capital base) of developers of managed facilities is essential for the project´s success.*

The explored cases have revealed, that in sixty percent of the cases, developers of managed facilities had problems with finding capital i.e. they didn't have a sufficient equity base and had difficulties in attracting investors, especially institutional investors. This greatly jeopardizes the initiation or the development of their project. In cases where the developers had a sufficient equity base i.e. they were able to invest the necessary

[8] Real Estate Development Model, by Univ. Prof. Dietmar Wiegand, TU Wien und Karl Giger, Red KG

capital without being required to rely on institutional investors, the developers had a competitive advantage and factor that highly contributes to their project´s success.

Managed facilities are often categorized as "high risk" by financiers e.g. due to difficult third-party uses. Therefore a first successful letting i.e. accommodating part of a business or comparable measures are important to yield trust. In the numerous explored case studies, private parties have confidence in project success much earlier than institutional investors.

5.4 Stakeholders

- *Managed facilities are not per se developed more successfully by a specific group of stakeholders– here a distinction needs to be made between the types of managed infrastructure.*

Basically, stakeholders (players), who have little or no knowledge about the business (or the activities) for which the infrastructure is being developed, should consult and include competent parties. Stakeholders (players) on the other hand have quite different qualities: e.g. networks need time to learn to work together; in this case a small scale project at the beginning is recommended.

- *Public stakeholders and public sponsorship are no guarantee for positive socio-economic or spatial effects, but valuable "incentives" and "helpers".*

Most of the Explored Case Studies have some kind of a public sponsorship, which differs in its variety and amount. The amount of the sponsorship is less relevant though, than its point of use (catalyst function) and the benefit it creates - among other things also due to the fact that the sponsorship is connected to co-ordinated project goals, which are in accordance with public interest.

5.5 Architecture

- *The architecture itself delivers an important contribution to a successful development of managed facilities, although very project-specific and in different forms.*

A business incubator for women, such as the "Weiberwirtschaft" in Berlin, needs small and flexible spatial structures, in order to support and enable the growth and shrinking of businesses. Entertainment centres can be developed as brands, but even without branding they always need a good and functional logistics concept. In the case of "Klassikstadt Frankfurt", where customers and fans of vintage cars, who are in love with design, history and technology also expect an ambient reflecting history and design.

6 CONCLUSION AND OUTLOOK

In conclusion, the explored cases have shown that development of managed facilities is

- possible even in economically weaker regions, but need to be tailor-made
- in an early phase a cyclic process of optimization and not a step by step process is required

In managed facility developments:

- the know-how concerning the business the facility is built for is essential and leads to competitive advantages [9]
- the equity base is essential
- the involvement of the public sector doesn´t necessarily lead to success, but it helps
- architecture is essential but in completely different forms

The explorative case studies have also clearly revealed, that the existent theories, methods and processes-models of real estate development, established primarily from a point of view of investment-bankers, concerning properties which combine build substance and services as so-called "facilities" of public or private infrastructure, have to be "re-thought" and newly written.

In conclusion it can be said that the development of managed mixed-use real estate uses regional potential or in the case of large developments with public funding reduces existing regional deficits.

[9] Probst, G. J. B. (2000). Kompetenz-Management : wie Individuen und Organisationen Kompetenz entwickeln. Wiesbaden, Gabler.

We propose that mixed-use within the managed facilities can also be defined as a kind of cluster [10] (see also Maskell), where the single businesses existing "under one roof" are concentrated as a vertical, diagonal or horizontal cluster, depending on the kind of organizational and legal structure (see also figure 1).

Three types of clustering are defined in today´s literature [11]:

(1) Horizontal: co-location of competitors, same level of value creation, e.g. same types of businesses are co-operating with each other;

(2) Vertical: co-location of companies of different and successive value chains, e.g. as in the case of Klassikstadt, different businesses, but belonging to one value chain–cars;

(3) Diagonal: businesses are working together, but creating different products and services, which are seen by the consumer as one product.

The conclusions of the case studies can be read like a check-list:

- my project uses the regional potential or changes deficits with the support of public funding
- mix of uses / cluster is the best possibility in the given context
- business know-how is in the project guaranteeing competitive advantages [12]
- capabilities are compete

The explorative studies are a starting point for future research. We need to further develop theories and models concerning the network or business clusters creating benefits for the operator and the customer. Methods for risk management and methods to measure and control the external effects of managed mixed-use development need to be established. State support needs to be made transparent and linked to positive effects. Finally the measurement of external effects of real estate developments on the region could be redesigned and become extended to other properties part of urban policies.

Conclusively it can also be stated, that planned managed mixed-use real estate contributes to a "smart" urban development, by organizing and exploring synergies between different types of uses which are necessary, needed, suitable or attractive on specific locations or certain parts of the city, which leads to the assumption that planned managed mixed-use developments are more sustainable and resilient in today´s rapid urbanisation.

1 ABSTRACT

Internet access has become such an important requirement for our daily lives that the United Nations proposed to give it a status of a human right in 2011. Still Internet usage in Europe varies strongly depending on regional aspects, age and qualification. Elderly people are among the user group that is affected most by the digital divide because of technical, social and economical barriers. This paper covers the question whether the current generation of tablets has the potential to reduce these barriers, especially for older users. Two main studies were undertaken to evaluate usability and acceptance of a chosen tablet and to investigate longer-term effects of tablet usage. The results of the studies show high satisfaction and acceptance rates among the target group and suggest a stronger focus on senior specific applications for tablets as well as initiatives to target the higher information demand regarding tablets in special and technological solutions in general of the older user group.

2 INTRODUCTION

Internet access and usage has become a very important part of our daily lives. Although nearly 100% of Europe's population between 14 and 30 make use of Internet based services regularly, access for the older generation above 65 is still limited to a comparatively small group of only 30% according to studies of GFK Austria [1] and the Initiative D21 in Germany [2]. The resulting digital divide excludes especially older people from parts of social life. The most prominent reasons for the digital divide are high technological, economical and social barriers that hit especially people with a low affinity to technical solutions. Among these barriers are according to [3,4]:

- High acquisition and maintenance cost especially in rural areas where Internet availability is low,
- Strong Respect for new technical solutions because of low personal experience and fear of dependence on technical support of technically versed people such as younger relatives,
- High complexity and hence low learnability of technical user interfaces, especially when it comes to personal computers

2.1 myTablet–the project

MyTablet is a research project that was undertaken in 2011 by the Austrian non-profit research institute CEIT RALTEC and got nationally funded by the "Internet Privatstiftung Austria (IPA)". The project's goal was a scientific evaluation of a current tablet computer concerning the suitability as a device to support older people to access the Internet. This idea is based on the hypothesis that tablets are easy to use for seniors since they contain a touch based user interface, which offers less functionality and hence less complexity in comparison to user interfaces of commonly used operating systems. Furthermore tablets lower the acquisition costs since they eliminate the need for a wired infrastructure at home.

2.2 Regional aspects of the mytablet project

Access to the World Wide Web is rare among older people living in cities and the problem aggreviates in rural areas when physical access to network structure is limited. Tablets could be a solution to lower the digital divide since they could tackle several aspects at once:

- providing physical access by using wireless broadband, which is, in comparison to access via the local land line, largely available also in rural areas. (see also [5])
- reducing the technology entry thresholds by providing an appropriate user interface also for unexperienced users such as older adults and people of neal-illiterate social classes.

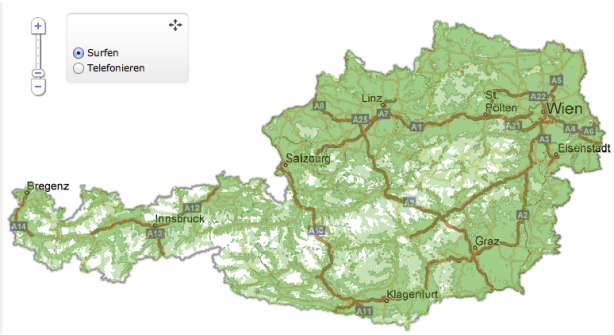

Fig. 1: 3G coverage of the leading Austrian 3G provider (green = up to 40mbit)

Tablets provide a wide range of applications that target to enhance the mobility of users, Apple's "Appstore" for example holds two categories called "navigation" and "travelling" that together provide the users with functionalities such as car navigation, ticketing for public transport, car parking aids and ticketing, city travel guides, etc. The easy availability of those functionalities can lead to a better information distribution also among older users.

3 EVALUATION OF A TABLET

Two main usability trials were conducted. Within a first short-term trial, where eleven older people took part, the usability and acceptance of a chosen tablet was evaluated. To evaluate whether or not the so gathered results can be maintained over a longer period of time, field trials were carried out with four of the eleven test subjects. In these trials the test participants received a tablet for the duration of one month each with the condition to document the usage.

3.1 Usability Study–short-term trial

The main goal of the short-term usability study was to rate the usability together with seniors and evaluate, which functionalities can be used intuitively or after only a short introduction on the device.

Central research questions were:

- How do the trial participants experience the usability of the tablet's user interface in particular and the usability of the device in general?
- Are basic and common functionalities such as web browsing and e-mailing easily learnable; how much explanation and introduction on the tablet is necessary?
- What are general pros and cons on this technology (in comparison to usual PCs or Laptops) in the eyes of the older target group?

3.1.1 Description of trial participants

Eleven seniors (four male, seven female) with an average age of 71 years took part in this first trial. Younger people (age < 60) and technically experienced ones (by means of a questionnaire on technical affinity) have been excluded from the study.

The final group of trial participants included six people without knowledge about PCs or web services at all and five people with basic experience in working with a PC.

3.1.2 Test setting

As test setting a preconfigured and, as far as possible, especially to the needs of the target group customized iPad v1 from Apple was chosen because of the high availability on the market.

The tablet featured a reduced set of nine very common and basic applications offering functionalities such as:

- web browsing
- email client
- Google maps application
- YouTube–video portal

- Access to the online store of a big Austrian food store chain
- Picture viewer
- Bookmarks to websites for weather information, news and Google search

The following figure shows an image of the test setting during the usability study.

Fig. 2: Trial participant and test setting during the usability study

3.1.3 Test flow

Single user interviews were used during the usability trial with each user in sessions taking up to two hours. The trial was split into three parts:

(1) Introduction with explanation about the project and hands-on tutorial on the tablet for approximately 30 minutes

(2) Main part including tasks that were executed by the test user while using the „thinking-aloud“ method [6,7] and obtrusive observation [10] by the research team.

(3) Final qualitative questionnaires regarding the subjective usability, acceptance and satisfaction of the user as well as general feedback about the used tablet.

During the main part the trial participant had to fulfil certain tasks embedded in the framework of possible real-life scenarios. Each task was composed of several consecutive steps that needed to be completed correctly in order to fulfil the task. The execution of these test tasks was observed and evaluated by the researcher team and generated the main results of the first trials. Among the tasks were typical strategies used to obtain information such as „undertaking a web research using Google“ or „reading of a received mail“ or „gaining information about the weather forecast“ using a specific weather application.

3.2 Field Trial–long-term trial

Validation of the gathered results of the short-term trial and gaining information about the long-term use and satisfaction regarding the tablet device were the main reasons of the field trial.

3.2.1 Description of trial participants

Four users of the usability study where randomly chosen for the user group of the long-term trial. Users with even only basic experience where excluded from the list, since the focus was laid on inexperienced users. Finally four women living in Schwechat and Vienna and aged in average 69 years took part.

3.2.2 Test setting

In order to allow the users to experiment with the functionalities of the tablet, the test setting was altered after the usability trials. In addition to the applications installed for the usability trials, around 30 applications were evaluated and chosen that matched the interest of the test participants.

Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

Fig. 3: main screens of the user interface during the field trial

The field trials were conducted either in Vienna or in Schwechat, Austria.

3.2.3 Test flow

After an additional lesson on the usage of the device for a duration of two hours, each test user received an Apple iPad v2 for the total duration of 1 month. During this time the users did document their tablet usage in a diary and had the possibility to contact a project team member in case of problems with the device or questions regarding the project.

4 RESULTS

The results shown in the following chapters are a summary of information and experiences gained during the short-term usability and the long-term field trial and can be split up into results gained during the tests by interpretation of the users' behaviour and results gathered by retrospective analysis of questionnaires.

4.1 Evaluation of the general usability

If asked about the general usability, all users of during the short-term tests and the long-term trials concluded that they find the tablet would be „easy to use". Problems were found in the fact that applications are provided by various developers resulting in a heterogeneous user experience across the applications. This issue was also raised earlier by Raluca Budiu and Jakob Nielsen in [11]. Nevertheless, during the final interviews all users declined the statement „it was too time consuming to learn the different functionalities".

Some users showed an initial fear in using the tablet caused likely by a general high respect regarding the usage of new technology, but that feeling vanished during the first hours of usage, which helped them to explore new functionality on their own. Most users stressed out that the tablet is not intimidating to them since it does not look like a complex machine and particularly liked that it is possible to return to the (well known) main screen by simply pressing the only button on the device at any given time.

English language is not commonly understood by older people and can not be completely avoided during the use of tablets even if the local language of the device is set to the native language, since many terms used in the World Wide Web and IT in general are Anglicisms not well known among German speaking seniors.

All trials were conducted using the UMTS capability of the device, which provided a satisfying connection to the test participants; all of the users declined the question that the device seems to react too slow. One participant particularly remarked the positive point that the tablet also works at her secondary residence in lower Austria and liked to travel with the tablet.

4.2 Evaluation on the ease of learning

It took around 40 minutes of training prior to the first trial until the research team felt confident that the participant is able to understand and fulfil simple tasks on the device such as looking up the weather using an provided „app" or checking the emails on its own. Another hour of training was given to the four test users selected for the field trials until the test participant felt confident to use the device without help alone. During the field trial all together nine meetings of roughly one hours duration were conducted to provide additional help. Four of these meetings (one per test participant) were pre-planned and conducted after the first two weeks of usage; the other five meetings were needed to answer specific questions that arose during the usage.

During the final interviews novice users mentioned that the usage needs some experience, but they were confident that they are able to learn how to use the tablet if given enough time. To learn new functionality (apps) of the tablet in self-study was rated as easy by two of the four participants of the field-trial, one was unsure, one found it rather difficult. One of the most central found problems was the difference in usability between applications that results in the need to learn and understand each new application again.

4.3 Evaluation of usage patterns

To evaluate the usage of single applications the test participants were asked to fill out a diary on a daily basis regarding their usage behaviour. Most prominently used during the trials were games and riddles for brain fitness followed by information services such as Google search and weather forecasts.

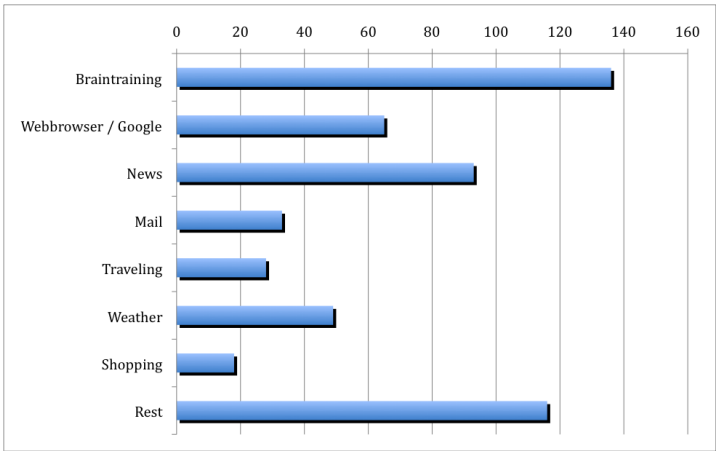

Fig. 4: usage statistics of the applications used

83 test days were included in the evaluation; by using several applications a day, values higher than 83 could be reached. The assumption that the level of usage will decline over the test periods because of losing initial interest based solely on the novelty of the device could not be validated. In contrary, the users tended to use the tablet slightly more often and for a longer time duration since during the field trials they experienced new functionalities they can use.

5 CONCLUSIONS & OUTLOOK

The results of the undertaken usability studies showed that tablets really can lower some of the barriers of accessing the Internet and hence make it easier to use online services independently for people who are inexperienced in using the Internet. The most essential advantage of tablets over common PCs seems to be the non-technical look and feel accompanied by the simple touch based navigation of the devices, which lowers the barrier to adopt the new technology.

During and after the trials all participants stated that they had a positive impression of the tablet used; during the final interviews some said that they now feel more confident in using technical solutions in general.

Barriers were found that can not be overcome by using a tablet. For this study the device had to be preconfigured and technical support was given during the field-trials. This initial set up and occasional support during the usage is needed and needs to be given by a friend, a relative, a carer or an institution.

5.1 Acknowledgements

Special thanks go to our test users for their active participation. The work done in the project “myTablet” has been funded partly by the „Internet Foundation Austria (IPA)“. CEIT RALTEC is a non profit research institute partially funded by the municipality of the city of Schwechat.

Evaluation Performance Comparison of Surveying and Mapping Systems for Updating the City Geospatial Progress

Mahmoud Al-Hader

(Dr. Mahmoud Al-Hader, AADC, ADWEA; Al Ain, UAE, mahmoud.alhader@aadc.ae)

1 ABSTRACT

The update of current geospatial data progress at the city scale is utilizing the normal data collection techniques such as GPS, Total Station and level equipments. Due to limitation and complexity of using these techniques on the city scale, where it needs a proper geodetic network to establish a mesh of control points prior to precisely conduct any physical data collection. On the other hand, the needed resources are also huge to run these techniques on the city scale and in daily bases; where the accuracy of the data will be affected and not consistent due to large number of involved resources performing different quality.

The development of new methodologies and using new techniques are needed to facilitate the daily update of the city geospatial development progress to precisely allocate the location of services to significantly enhance the overall maintenance and operation performance.

The technical comparison between the most common surveying technologies provides a more obvious performance understanding for each technology. Each technology has been evaluated based on several efficiency factors; each efficiency factor measure's the technology performance in that particular factor.

2 BACKGROUND

Bernardini et al., (2002) mentioned that in most situations, a single scan will not produce a complete model of the subject. Multiple scans, even hundreds, from many different directions are usually required to obtain information about all sides of the subject. Curless (2000) argues the variety of technologies for smartly acquiring the shape of a 3D object. Schmidt et al., (2007) mentioned that the GNSS-receivers are becoming more and more efficient, smaller in size, weight and price which results in the fact that GNSS-receivers are nowadays a mass product. Wanyun (2010) says as of 2010, the United States NAVSTAR Global Positioning System (GPS) is the only fully operational GNSS.

The Russian GLONASS is a GNSS in the process of being restored to full operation (21 of 24 satellites are operational). Schwarz et al., (2007) discuss a process which was mainly driven by the need of highway infrastructure mapping and transportation corridor inventories. Cameras, along with navigation and positioning sensors, e.g., GPS, and inertial devices such as IMU, were integrated and mounted on a mobile vehicle for mapping purposes. Objects can be directly measured and mapped from images that have been georeferenced using navigation and positioning sensors. Zhang et al., (2003) discuss the latest development and evolution of surveying and mobile mapping technologies that opens new avenues for the acquisition, update, fast and online processing of data. Jeong et al., (2006) provide an effective base for the management of information on construction and repair of highway and its auxiliary facilities. Cracknell et al., (2007) emphasis that the non-metallic objects, such as rain and rocks produce weaker reflections and some materials may produce no detectable reflection at all, meaning some objects or features are effectively invisible at radar frequencies. Ying Cao et al., (2009) investigate an interoperable framework to disseminate earth Science data to different application domains. The proposed framework can manage different Earth science data products and raster snapshots over time through the use of relevant metadata information. Liu Yong et al., (2007) evaluate the effectiveness of radar data processing, it is necessary to have an evaluation System of Radar Emulation. According to the requirement of the real-time, accurate and vivid display of the radar data processing efficiency in modern battle field emulation also discussed. Omar Munyaneza et al., (2009) discussed the required time of satellite radar altimetry in order to measure the time required for a pulse to travel from the satellite antenna to the earth's surface and back to the satellite receiver.

3 INTRODUCTION

The conducted research is oriented to implement one of the smart Geospatial updating for some of the smart city components. The implementation of the research focus on updating of polyethylene city infrastructure networks using laser scanning technologies from the surveying and data collection perspective. The research has investigated a new perspective of the laser scanners which is the mobile (mounted on top of vehicle)

scanner integrated with complete navigation and orientation platforms. This chapter is discussing an evaluation of geospatial technical comparison between RTK GPS, Total Station, GNSS reference station, static laser scanning, mobile laser scanning and aerial photographs in terms of collecting the spatial data. The geospatial technology achieved the best evaluation performance is subject to more deep analysis and investigation for developing a mathematical model to detect the daily progress of the polyethylene city infrastructure networks.

The conducted research is oriented to implement one of the smart Geospatial updating for some of the smart city components. The implementation of the research focus on updating of polyethylene city infrastructure networks using laser scanning technologies from the surveying and data collection perspective. The research has investigated a new perspective of the laser scanners which is the mobile (mounted on top of vehicle) scanner integrated with complete navigation and orientation platforms. This chapter is discussing an evaluation of geospatial technical comparison between RTK GPS, Total Station, GNSS reference station, static laser scanning, mobile laser scanning and aerial photographs in terms of collecting the spatial data. The geospatial technology achieved the best evaluation performance is subject to more deep analysis and investigation for developing a mathematical model to detect the daily progress of the polyethylene city infrastructure networks.

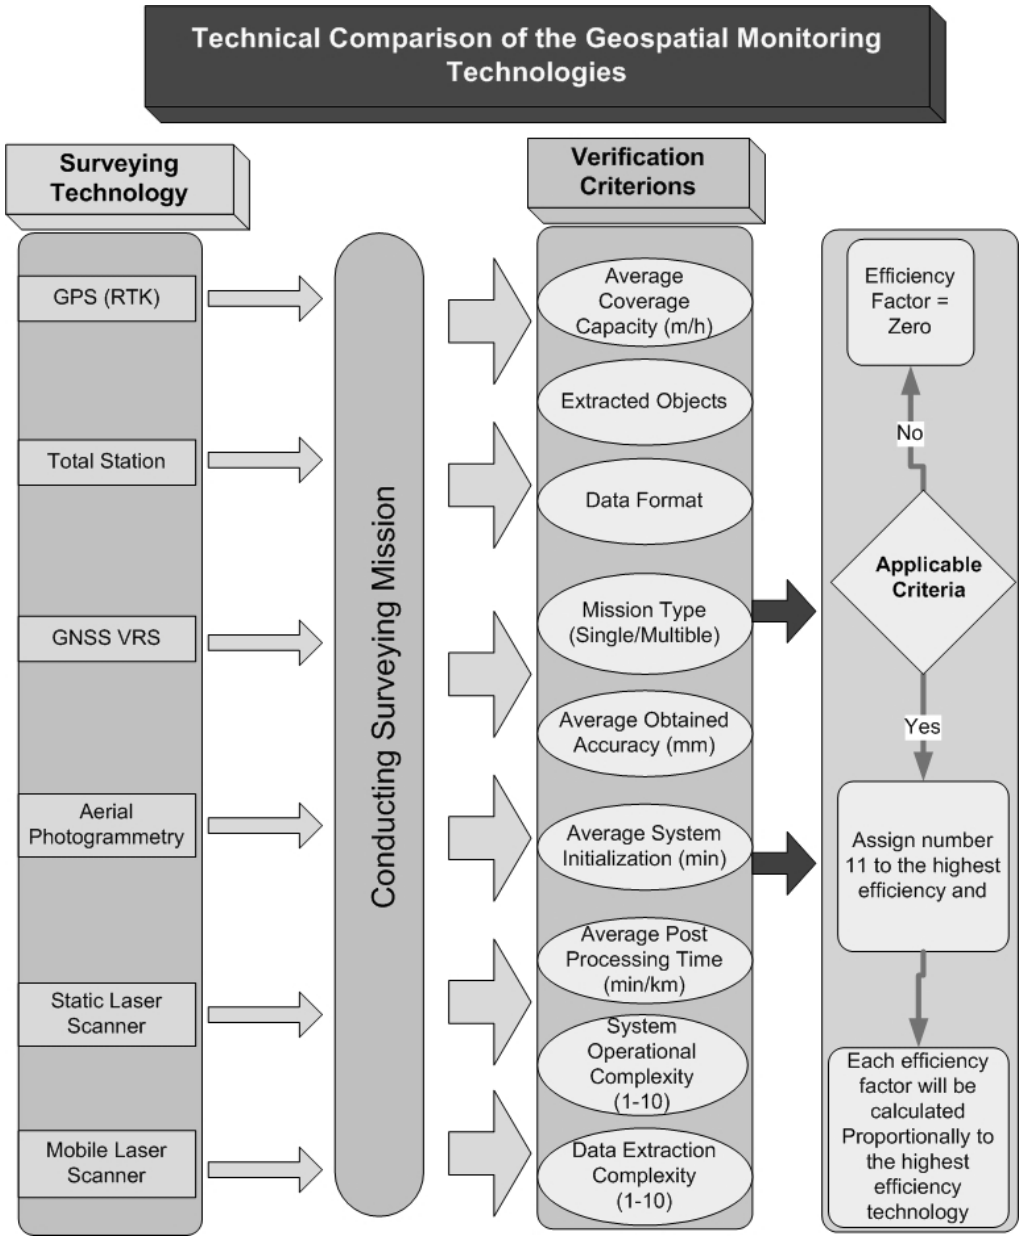

Fig 1: Technical comparison of the geospatial updating technologies.

In the sense of GIS and geospatial applications, the research has conducted two surveyed sites in UAE, Dubai in order to reflect/monitor two kind of utility infrastructure networks. The validation area is about 300 m width and 2 km length, where it is currently in the infrastructure development. Currently the deep utility networks such water transmission, electrical transmission, district cooling; sewer and storm water are still ongoing. The research is to utilize the mobile laser scanning in several missions to survey the several pipe diameters for both distribution and transmission networks in order to check the practicality of implementing the new smart geospatial updating technique.

4 TECHNICAL COMPARISON BETWEEN THE GEOSPATIAL UPDATING TECHNOLOGIES

The research conducted a technical comparison between the common geospatial updating technologies in order to evaluate efficiency factor for each geospatial updating technology. The technical comparison methodology has been designed based on identifying most of functionalities and capabilities adopted in each technology. The average coverage capacity, extracted objects, data format, mission type, average obtained accuracy, average system initialization, average post processing time, system operational complexity, data extraction complexity are the investigated functionalities, where each function has an efficiency factor. Each surveying technology will be subject to mission data collection and data extraction, where some of surveying technologies are not applicable with all efficiency factors. Taking into consideration that some of criterions cannot be precisely measured like measuring the system complexity, accordingly these criterions will be estimated.

5 EVALUATION OF RTK GPS AND MOBILE LASER SCANNING NAVIGATIONAL GPS

A geospatial technical comparison has been conducted between RTK GPS observations and mobile laser scanning navigational GPS observations. The RTK rover antenna has been mounted on top of the car besides the mobile laser scanning GPS unite. The RTK GPS observations have been conciliated with the RTK GPS base station during the post processing. The mobile laser scanning navigational GPS observations have been conciliated with the observations collected from the GNSS reference station. The combination of the navigational GPS and the GNSS reference station observations is generating more enhanced accuracy. In order to compare the obtained accuracy for each technique, the matching in easting and northing is needed, where there is an acceptable tolerance (10 cm) in the horizontal location. The matching in horizontal location is the base for comparing the vertical accuracy, where each technique is measuring the same Z value with respect to technique level of accuracy. Fig 2 shows the matched and directions not matched horizontal locations for both RTK GPS and mobile laser scanning GPS observations. The matched observations (points having the same XY coordinates) used to compare the obtained Z values. Each not matched point has a shift in certain direction, the reference point of the shift directions are the RTK GPS points.

The collected XYZ points from RTK GPS system and mobile laser GPS system having slightly different accuracy level. The RTK GPS points have been adjusted based on the base station, where the mobile laser scanning GPS points have been adjusted based on the combination of GNSS corrections while conducting the post processing. The adjustment of the RTK GPS points implemented on the fly using the radio link. The GNSS reference station is having more observations in less epochs for more satellites (GPS & GLONASS) than collected in the GPS base station. The difference in number of observations between GNSS reference station and GPS base station generates difference in observations accuracy.

The vertical positioning (Z values) is the base of building up an accurate 3D models for the modeling the collected city infrastructure polyethylene pipelines and other features. The research investigates the Z differences and considers it as a base for evaluating the positional accuracy between the RTK GPS observations and the mobile laser scanning GPS observations. Prior conducting the vertical positioning comparison, the horizontal positioning for the two points (RTK GPS point and mobile laser GPS point) must be matched. The points matching cannot be obtained without resolving the accuracy discrepancies; the accuracy discrepancies could be generated in X direction or in Y direction. The elimination of the discrepancies is difficult to be modeled for each direction separately; where it can be combined in one complex number and conduct the linear matching accordingly. The generation of complex number is must be rounded with respect to the accuracy for RTK GPS observations accuracy and mobile laser scanning GPS observations accuracy in order to avoid the improper miss matching. The observations rounding for X direction and Y direction for RTK GPS and mobile laser scanning GPS is 10 cm. The rounding is calculated

based on the average horizontal positioning RMS generated in the RTK GPS; where the GNSS has 3 cm average RMS accuracy. Due to the tolerance in the horizontal location and the need of conducting a high accuracy assessment; the collected observations needs some filtrations before conducting the matching and rounding activities.

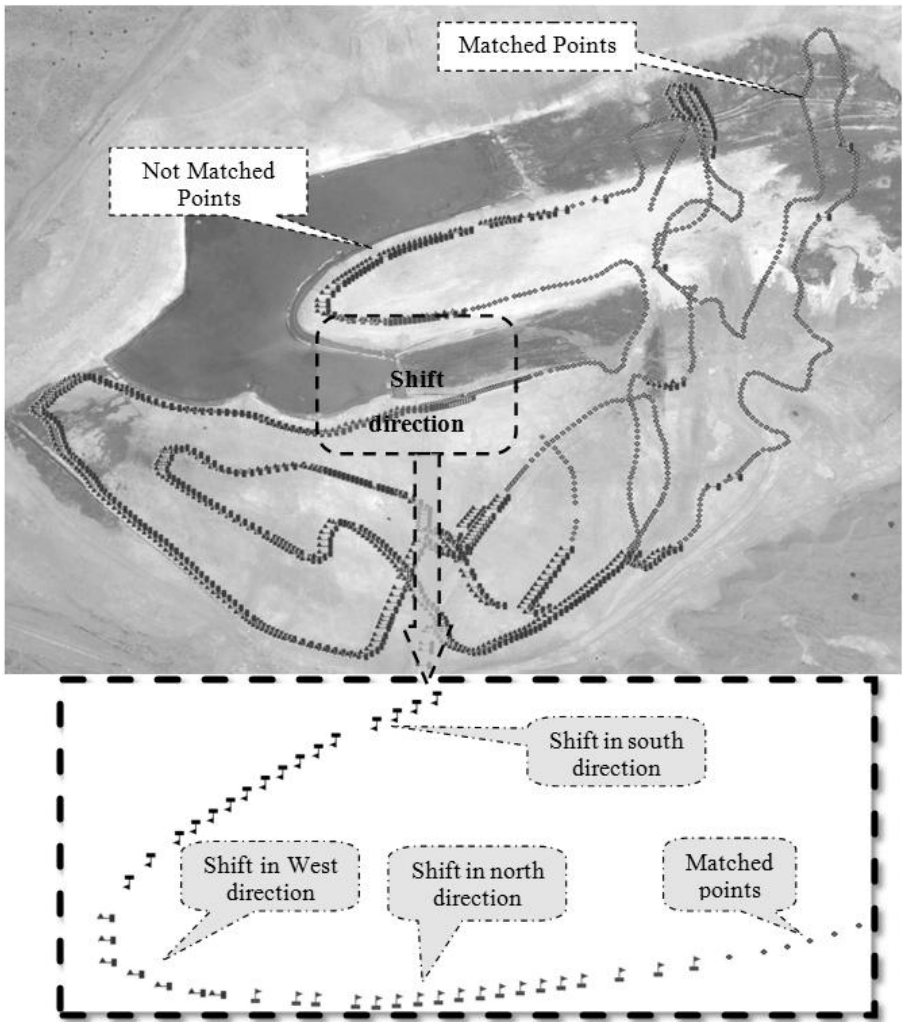

Fig 2: Matched and directions of not matched RTK GPS points with mobile laser scanning GPS.

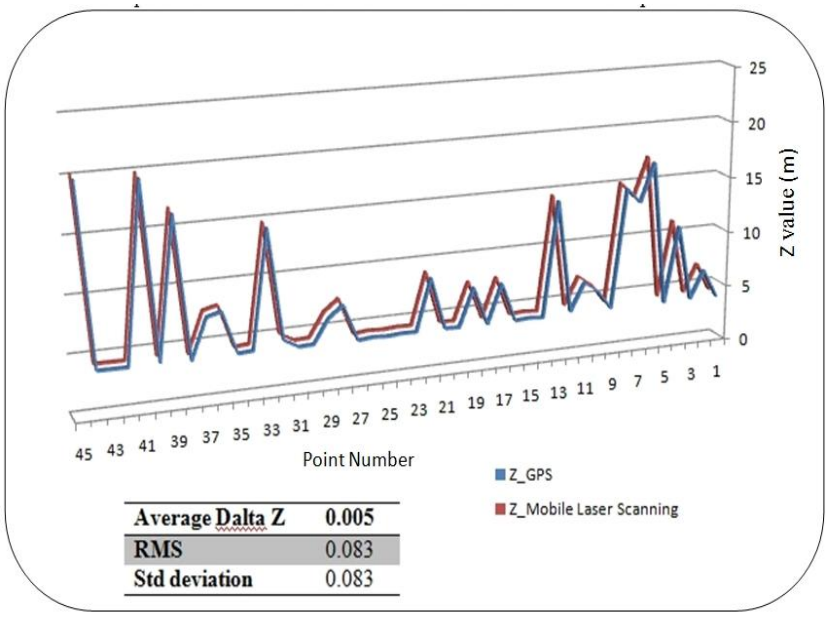

Fig 3: RTK GPS and mobile laser scanning accuracy assessment.

The relation between each two points, since each point has approximate matching in XY and Z; then the linear filtering will produce better accuracy assessment. The linear filtering can be achieved by producing complex numbers by concatenating X and Y in one complex number for both RTK GPS points and the mobile laser (GPS points). The complex number is generated based on the rounded XY coordinates (10 cm) for the RTK GPS and mobile laser scanning GPS. The matched horizontal coordinates are subject to compare the Z values; where the horizontal positioning is known and accordingly the variation in vertical positioning for the RTK GPS and mobile laser scanning GPS can be investigated and modeled. After utilizing complex numbers matching, the matched filed observations for both RTK GPS and mobile laser GPS are about 528 matched points where 604 not matched. Fig 3 shows the accuracy assessment of the first 45 points, where the root mean square has been calculated for the all Z values for the matched points.

6 EVALUATION OF STATIC LASER SCANNING

The evaluation of static laser scanning specially in the terms of obtained accuracy, coverage capacity, system initialization, objects extraction, data format and mission type has been concluded based on conduction of two static laser scanning missions. The two static laser scanning missions conducted different type of scanners; one mission using Lieca scan station 2 and the other using Trimble GX standard scanner. The reason of using different types of scanners is to evaluate the capacity of static laser scanning independently. The area of interest is about 0.126586 Sq km, where the best RMS value is 4.8 cm and the lowest operation time is 4 hours; Table 1 presenting the summary of results for each scanner type.

Trimble Scanner (GX Standard)	
Area	0.126586 Sq km
RMS	20 cm
Stations	6
Points Collected	576,069
Time (hr)	6
Leica SCAN STATION2	
Area	0.126586 Sq km
RMS	4.8 cm
Stations	4
Points Collected	4,265,519
Time (hr)	4

Table 1: Results summary for each type of scanner.

The static laser scanning needs known control point prior conducting the mission in order to georeference the collected point cloud data. The accuracy validation process implemented using known locations inside the scanned areas, while these known locations (sharp angles of some features like stones) are observed using precise GPS surveying technique (2 to 5 cm). After conducting the scanning and post process the observed point cloud data prior generating the 3D surface model, the coordinates of the known points (XYZ) compared with the coordinates extracted from the generated 3D surface. The difference in horizontal and vertical coordinates considered to evaluate the positional accuracy of the static laser scanning. The collected point cloud data using static laser scanning utilized to build up the 3D surface model. In order to have the same area for comparative purposes; the boundary of the area has been identified by set of surrounding known control points.

7 EVALUATION OF AERIAL PHOTOGRAPHS

The evaluation of aerial photogrammetry in the terms of obtained accuracy, coverage capacity, system initialization, objects extraction, data format and mission type has been concluded based on conduction an aerial photogrammetry mission. The mission is conducted in the same area of interest where the static laser scanning missions conducted in order to precisely compare the system initialization, coverage capacity and obtained accuracy among other technologies. Three aerial photogrammetry missions conducted in the same area but in different areas overages in order to conclude better evaluation especially in the sense of coverage capacity, operation time and obtained accuracy. The research conducted short, medium and long term missions for better validation. The area of short term mission is about 12.44 Sq km, where the RMS value is 30 cm; the area of medium term mission is about 43.9 Sq km, where the RMS value is 18 cm. The area of the

long term mission is about 27.32 Sq km, where the RMS value is about 28 cm. the average obtained RMS is about 25 cm, where the average area coverage per kilometer is about 10 km/hr, refer to Table 2.

Mission	*Area coverage (km^2)*	*time (hrs)*		*Area (km^2/hr)*	*RMS (cm)*
1	12.44	1.3	10	30	
2	43.9	5	9	18	
3	27.32	2.5	11	28	
		Average	10	25	

Table 2: Summary of aerial photogrammetry missions.

The coverage capacity, obtained accuracy, system initialization, objects extraction, data format, post processing time and mission type technical comparisons are based on physical verification and observations. Due to the importance effect of the system operational complexity and data extraction complexity; the evaluation emerged based on qualified surveyors and engineers experience.

8 RESULTS OF THE GEOSPATAIL TECHNICAL COMAPRISON AND OVERALL EVALUATION

The final rating is shows the performance of using the mobile laser scanning technology in general field survey activities especially on the city scale data collection and progress updating. The positive rating of the mobile laser scanning technology is strongly supporting the utilization of this technology in city infrastructure updating; where new methodology and mission planning is required to utilize the best capabilities in the sense of geospatial updating. The research considers the laser scanning technology as a main platform for reflecting the physical geospatial city activities conducted on the city infrastructure networks. The aim of using the city infrastructure as a base of the overall geospatial city updating and surveying is the high interaction between the city infrastructure networks and the overall city operations including the utility services.

The average operational coverage capacity efficiency factor is measuring the technology site data capturing productivity. The coverage capacity is also indicating practicality and usability of the technology from the users. The best average operational coverage capacity efficiency factor was achieved by using aerial photogrammetry; where the efficiency factor is 11 (most efficient utilization). The worst average operational coverage capacity efficiency factor was achieved using total station technique; where the efficiency factor is 0.6 (lowest efficient utilization, only 5.5%). However, dynamic laser scanning efficiency factor was the second best average operational coverage capacity efficiency factor.

The object extraction efficiency factor is also measuring performance of the overall data production. The object extraction is related to the data format and the data completeness within the same mission. The good coverage efficiency drives better data completeness within the same mission and accordingly better data extraction. The best objects extraction efficiency factor was achieved by using dynamic laser scanning and static laser scanning; where the efficiency factor for both techniques are 10 (91% utilization). The aerial photogrammetry is also provides very good efficiency factor. The worst objects extraction efficiency factor was achieved also using total station technique; where the efficiency factor is 1 (9% utilization). However, GNSS VRS and GS RTK techniques are also provide bad objects extraction efficiency factors.

The data formatting efficiency factor is measuring the level of integration between the systems. The vector data format can be easily and more performed in the sense of data integration, import and export functionalities. Raster data format needs more editing and extraction efforts to enhance the data extraction/production activities. The best data formatting efficiency factor was achieved by using all surveying techniques (dynamic laser scanning, static laser scanning, GNSS VRS, total station and GPS RTK) except aerial photogrammetry; where the efficiency factor is 11 (100% utilization). The reason of bad data formatting efficiency factor for aerial photogrammetry is the resulted raster data format; where the efficiency factor is 4 (36.4% utilization).

The mission type (single/multiple) is measuring the capability of the surveying technique in conducting more data capturing planes for different purposes in the same mission. The best mission type efficiency factor was

achieved by using dynamic laser scanning and static laser scanning; where the efficiency factor is 11 (100% utilization). Aerial photogrammetry provides very good mission type efficiency factor; where the factor is 7 (36.6% utilization). The worst mission type efficiency factor was achieved using GNSS VRS, total station and GPS RTK techniques; where the efficiency factor is 2 (18% utilization). However, aerial photogrammetry efficiency factor was the second best average operational coverage capacity efficiency factor.

The obtained accuracy efficiency factor is key performance indicator for the overall surveying operations. The accuracy is highly dependent on the surveying application, technique and the expected resulted production. With respect to data capturing and data production for city infrastructure networks; the accuracy level shall be in centimeter level; where the majority of distribution networks are less than 15 cm diameter. The best average operational obtained accuracy efficiency factor was achieved by using dynamic laser scanning, static laser scanning and total station; where the efficiency factor is 11. The worst average operational obtained accuracy efficiency factor was achieved using aerial photogrammetry; where the efficiency factor is 3.3 (30% utilization). However, GNSS VRS and GPS RTK factors were provided an acceptable efficiency.

The system initialization is measuring the time consuming for making the system up and running and ready to surveying. The initialization efficiency factor is affecting the overall system performance. The best average operational system initialization efficiency factor was achieved by using GNSS VRS; where the efficiency factor is 11. The worst average operational system initialization efficiency factor was achieved using aerial photogrammetry, static laser scanning, dynamic laser scanning and GPS RTK techniques; where the efficiency factor is 1.2 (10.9% utilization), 1.8 (16.4% utilization), 2.4 (21.8% utilization) and 2.4 (21.8% utilization) respectively. However, total station efficiency factor provided an acceptable efficiency factor.

The post processing efficiency factor is mainly measuring the geometrical corrections, color balancing (for image production) and overall data production. The post processing can be exempted if the real time correction functionality is available. The research is debating the utilization of post processing correction using the GNSS VRS data. The best average post processing time consumption efficiency factor was achieved by using GNSS VRS and GPS RTK technologies; where the efficiency factor is 11. The worst average post processing efficiency factor was achieved using aerial photogrammetry technique; where the efficiency factor is 1.2 (10.9% utilization). However, total station, dynamic laser scanning and static laser scanning efficiency factors provided very good post processing efficiency factors. The system operational complexity efficiency factor is measuring the usability of the system from the end user and it needs high level of resources qualifications. The high complex system requires more qualified resources; where it needs more operational support, training and cost. The best system operational complexity efficiency factor achieved using dynamic laser scanning and GNSS VRS technologies; where the efficiency factor is 11. The worst system operational complexity efficiency factor was achieved using aerial photogrammetry technique; where the efficiency factor is 6.1 (55.5% utilization). However, GPS RTK, static laser scanning and total station efficiency factors provided high efficiency factors.

The data extraction complexity is very important factor; where it measures the performance of the data production. The data extraction complexity can be recognized for only the multiple mission type; where the single mission type having only single data production which in most cases having automatic or semi-automatic extraction tools. The multiple mission type having varies types of features and each feature is subject to be extracted. The data extraction complexity is mainly related to data format in the sense of vector or raster data format. The best data extraction complexity efficiency factor was achieved by using dynamic laser scanning; where the efficiency factor is 11. The lowest data extraction complexity efficiency factor achieved using aerial photogrammetry technique; where the efficiency factor is 6.1 (55.5% utilization). However, static laser scanning efficiency factor was the second best data extraction complexity efficiency factor. The overall efficiency factors evaluation concluded by gathering and averaging all efficiency factors for each surveying technology. The overall efficiency factors are measuring the each surveying technology from general perspective considering the nine technical factors. The highest efficiency factor achieved using dynamic laser scanning; where the efficiency factor is 7.6 (69.1% utilization). The lowest overall efficiency factor achieved using total station technique; where the efficiency factor is 4.8 (43.6% utilization). However, GNSS VRS, static laser scanning, aerial photogrammetry efficiency factors provide good overall efficiency factors.

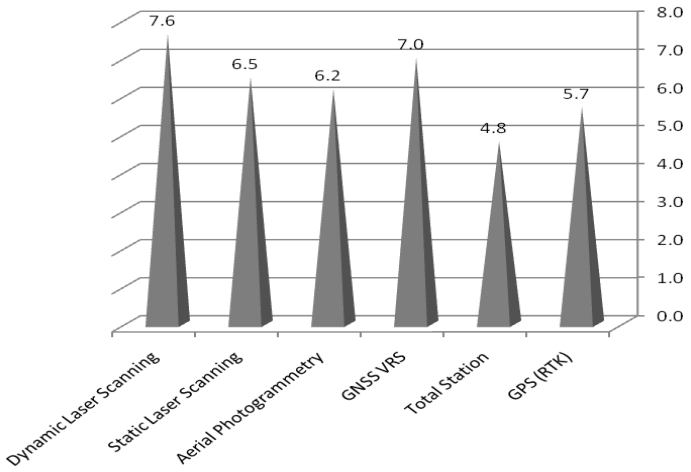

Fig 4: Overall efficiency factors evaluation.

1 ABSTRACT

As the objects of urban planning have the inhabitants or visitors as a target groups, it is often sought to get some input into the planning process by the target group.

This paper discusses the possibilities of using psychometric, internet based, assessment tool to evaluate the attitudes of people towards different aspects of the urban planning and solutions and the people's preferences toward them in urban environment as an alternative to the most often used questionnaires. These used to be costly in the "paper" times. Today, there are other issues, like the ICT barrier (be it age, connectivity or other resource).

The paper is based on a pilot study which has been run in 2008 at one of the many housing estates in Czech republic, that have grown through the ages of the communist rule and are in general a good example, where the urban planning can go to extremes, when searching for a price/m2 solution.

The pilot study proved, that it is possible to get relevant feedback, further more, opened more issues that are addressable in such projects and are not so easy to be solved by conventional questionnaires.

2 INTRODUCTION TO THE PROJECT

In 2008 the Ministry of regional development opened a call for architectural solution to further development of the housing estate – Karviná, Hranice. A project had been started by Ing. Arch Eva Špačková (Špaček projekt s.r.o., www.spacekprojekt.cz).

As the requirements of the project were to include the sociological study before starting to design, it has been decided to run a questionnaire, and in parallel, to use an internet based psychometrical methodology to gather basic information on the attitudes of the inhabitants of the housing estate towards its present status quo and also towards general requirements to living environment.

The main tasks of the survey at that time were to find out, what are the needs of the inhabitants related to their living environment, and the survey was oriented in two directions:

- to find out the key benefits of the present urban solution and their possible improvements;
- to find out the key risks that the inhabitants are perceiving within their neighbourhood.

At the same time, the survey should validate the possibility using the internet based psychometrical diagnostics, that is of:

- receiving feedback from large amounts of people in short time;
- minimising "role playing" when answering questions from the questionnaires which means receiving a better value of the results.

It was decided to use a internet based survey methodology because it binds both requirements together.

(a) the results are available instantly either at the time of the survey (as a preliminary results) or right after the end of the survey.

(b) survey respondents are presented with words (one after another) each surrounded by the same eight colour balls, out of which they select three. This process eliminates the "role playing" within the responses, as the respondents do not have any clue of what the "correct" answer (reaction) is and so they "just select colours".

The other reasons were (1) the ratio of resources needed to the richness of the results, for the questionnaire has always to be printed out, handed out in large numbers and have the process of gathering it back for evaluation (2) the individual psychometric values that are provided as the results of the survey, which can easily be used to match project main targets.

Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

3 INTRODUCTION TO THE METHODOLOGY

This chapter discusses the internet based psychometric diagnostics methodology, which was used for the survey. The methodology is based upon words and colours.

In general, when composing a questionnaire for a survey such as in the discussed project, there are many questions being alike.

Do you agree, that the most important problem to solve in your neighbourhood is ….

Do you agree, that the mos important inprovement to your neighbourhood could be …

Are you satisfied with living in …

Do you plan to move to a different address …

The used methodology, instead of requiring the user to think about the replies to all of the questions, records instead „only“ selections of three colours (out of eight) chosen by the participant of the survey when being presented a single word.

The selection then repeats for 60 basic words, which include words such as Me, I want, I must, Reward, Weather, Partner, Energy, People, Nature, … These „basic“ words, which are used also in other application fields of the internet based psychometric diagnostics are then accompanied by next „topic“ words, up to a total of 120.

The topic words always represent the focus of the survey. Words used in this survey are discussed in greater detail in chapter 3.2.1.

3.1 Colours

Have been used in history in large scale and are still being used for diagnostic purposes.

In modern times, Max Lüscher and his studies proved, that human perception of colors is affected by human emotions.

Current usage of colours in diagnostics:

- Lüscher institute (http://en.wikipedia.org/wiki/Max_L%C3%BCscher);
- Colour Association, o.p.s. (www.camethod.com);
- Balance management (www.balancemanagement.com);
- DAP Services (www.dap-services.com).

3.2 The usage of colours in the diagnostics

The coloured circles (since 2007 shaded to provide a full spectrum of the different shades of each colour) are now a protected (Alicante) result of the 25 years of research, which was targeted to have an input from the respondent that would be maximally independent on the differences in displaying colours on different types of displays and also to match human individual colour preferences.

Also, for the accuracy of the diagnostics process, the colour circle rotates during the diagnostics process, as for the respondent not to get used to “clicking always in the same positions”.

Instead of word, pictures, photographs or even animations can be placed in the middle of the circle. The ability of the diagnostic test to record and then evaluate associations in the human brain expressed by selecting colour circles remains unchanged in all cases. DAP Services is running marketing surveys for companies, that want to know, how will their target groups perceive certain types of packaging or even the design of the goods.

3.3 Words, associations

Associations were studied and used

http://en.wikipedia.org/wiki/Association_(psychology)

http://en.wikipedia.org/wiki/Free_association_(psychology)

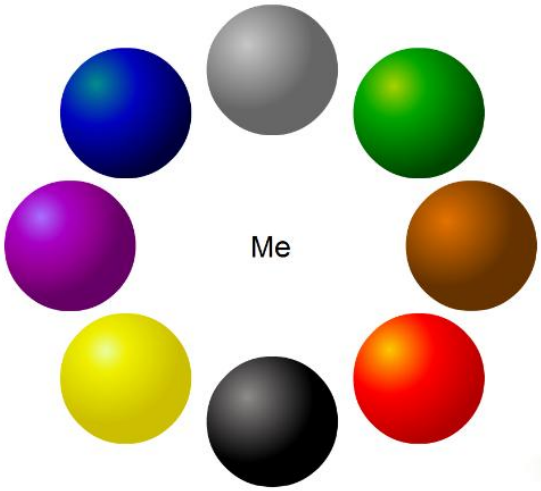

Fig. 1: Colors used within the survey.

3.4 Words used within the survey

This chapter presents the individual words that we have used within the survey and discusses the reasons for including the words in the survey.

Mostly the "topic" words are listed here. The standard words are in bold and underlined.

Words	***Factor***	***Notes***
Me, Anonymity, Guests, Neighbourhood, **Society**, Dog, Youth, **Loneliness**, Privacy, Mothers with children, **People**, Strangers	Communities	We wanted to find out, what are the relations of the individuals towards communities.
Street, Walkway, Internet, Pedestrian zone, Road, Roadway, City centre, Paveway, Path, Orientation,	Communications	These are communication words
Park, Town square, Parking possibilities, Garden, School, Playground, Services, Kindergarten, **Nature**, Market place, Coffee shop, Library, City/Town, Spa park, Mothers' club, Youngsters' club, Seniors' club, Car, Music club,	Facilities	
Sport, Dance, Games, Walking, Cycling, Barbecue, Picknick, Playing, Party, Resting, Cleaning services, Activity, **Movement**,	Activities	
Accident, Noise, **Risk**, Criminality, Litter,	Unwanted	
Art, Statues, Safety, Parking fees, Beauty, **Change**, **Information**, Ownership, Peace, **Health**, Freedom, Country	Other	

Table 1: Words used within the survey.

From the table there is to be seen a clear concept of selecting words, that at best match attitudes to the daily life of the housing estate inhabitants.

Some of the words might seem a bit awkward in the context of such survey, but the table includes only a simple translation of the words, not the transformation of the associations, which would be needed to conduct a similar study in different languages.

For example, the associations to the czech version of the word "Movement" (pohyb) have nothing to do with social movements, it associates only the movement in the physical sense of the word.

3.5 Respondent´s processes at the time of survey

To give the reader a closer understanding of how such a survey is being run from the point of the respondent, we have described shortly in this chapter some details about how-to (participate as a respondent):

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

At the time of survey, the user is directed to a web page. The link usually reflects the actual project (as with the current REAL CORP evaluation: www.dap-services.com/projects/real-corp2012). This leads to a page that collects the age and gender of the respondent.

After entering the age (selecting year of birth), and gender, the respondent is asked to provide his own colour preferences by clicking on all eight provided coloured balls. After the initial color selection, the respondents then choose three colors for each displayed word (see Fig.1). At the end of the survey, sociological data are entered and before that, once again the respondent selects all eight colors.

The duration of the survey for the respondent is about 20 minutes.

3.6 Motivation of the respondents

Internet questionnaires usually have a 2%-3% return rate. This drawback can be adressed by our methodology in the following way: as the psychometric survey includes the „standard“ words among the „topic“ words, it is possible to use the existing database (of over 350.000 respondents) to provide a personal feedback to the respondent, regarding to his own psychometrical measurements.

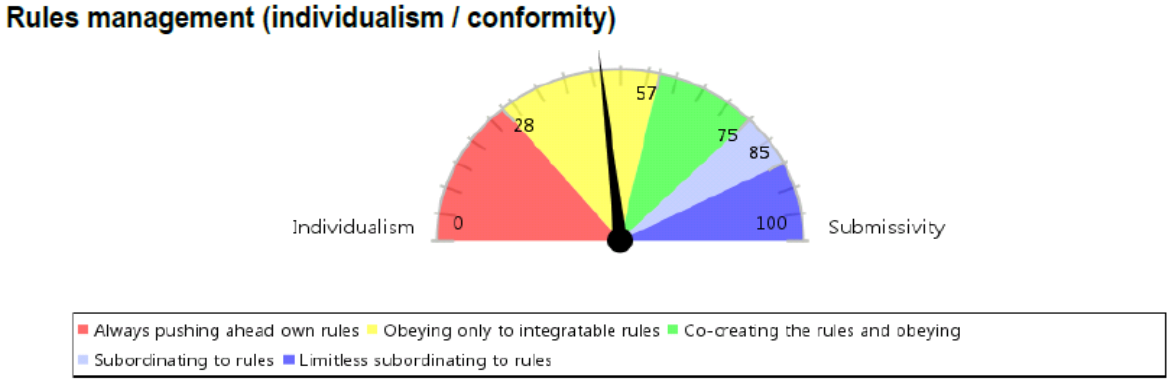

Fig. 2: Example of result: Rules management.

For example the following values can be returned to the respondents:

It is also a benefit for the survey, when the motivation of the respondents is addressed by providing by this personal results, because the organizer of the survey can then receive a validated array of e-mail addresses of the respondents.

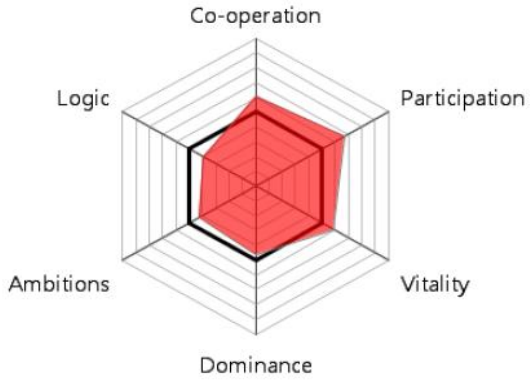

Fig. 3: Example of result: Constructive behavioural types.

3.7 Evaluation

The color reactions of the respondents to the words are then evaluated based on two factors. (a) correlations, (b) colors. The evaluation process is currently beíng patented and is part of the company internal know-how.

As a result

- the words can be identified and related to attitudal groups;
- there can be correlation networks identified among the words.

In this project, high correlations were measured for the following words, which we have grouped to form factors within positive and negative attitudes.

4 INTERPRETATION OF THE RESULTS

Each measured result can be interpreted in the context of the current project.

In this project we have interpreted the results in the main identified factors as follows.

4.1 Positive attitudes

Positive attitudes were identified as those scoring high in correlations to the following association chain:

I want + I may + I can + Reality + I reward myself

which can be interpreted as respondents „real wish that will bring self-reward“. This correlation chain was identified in a statistically relevant amount of responds.

Summary of positive attitudes interpretation

The respondents value possibilities for safe and various movement activities, accessibility to information and neighbourhood that will be pleasant and will not allow for harmful agressivity.

Detailed positive attitudes interpretation

For positive attitudes the following words/association chains scored high in their colour selections correlations:

(A) Movement + Walking + Health + Fun + Rest + Peace

This can be interpreted as the needs of the respondents concerning their surroundings. They require a restful pacefull zone with no limits on movements, where health „improvement“ can take place, and at the same time the place should allow to host social events (an opposite to Loneliness).

(B) Internet + Children mothers' club + Library + School + Mothers' leave

This can be interpreted as the needs of the respondents concerning further education and of the mothers who are at home with their kids concerning the available infrastructure services.

(C) Orientation + Ease of finding one's way out

This can be interpreted as the need of the respondents to have a good knowledge within the housing estate in relatio mainly to safety (pavements, roads, parking places), getting information, local activities, as well as from the risk point of view (places with potential agressivity).

4.2 Negative attitudes

Negative attitudes were identified as those scoring high in correlations to the following association chain:

I do not want + Risk

For negative attitudes the following words/association chains have scored high in their colour selections correlations:

(A) Criminality + Risk

The respondents want to live in a safe place and perceive their neighbourhood as not being safe and free from criminality.

(B) Noise + I do not want (+ kindergarten, playground, park, guests)

This can be interpreted that noise should not be in associated places (see brackets above), and where the guests are.

(C) Litter + I do not want (+ park, playground, walkway)

This adresses the negative attitudes of respondents to litter in the associated places (see brackets above).

(D) I do not want + I see + town + street + accident + car

The respondents do not wish to be endangered by the traffic in the streets.

(E) Garden + Country + Services + Town square

The respondents wish to have better access to own gardening possibilities, better access to services associated to country (fresh food, food markets).

5 CONCLUSION

Using internet based psychometrical diagnostics has been proven as being functional in providing feedback for urban planning and solutions.

In general it can be used wherever the infrastructure allows for an internet connection (even though there are tablets, which are able to save the results of the diagnostics locally and send it for procession as soon as they connect).

The key factor of internet based survey – the motivation to undertake the survey can be in this case supported by providing a personal feedback for the respondent at the same time (as a reward for completing the diagnostics). If the respondent agrees to receive such a personalised psychometrical result (see chapter 3.6) there is also his e-mail address recorded for future reference.

For the cases, where information technology gap should be the core of the problem, there still are to be used questionnaires.

Positives

- in developed countries with accessible internet infrastructure and narrow (or none) human/ICT barrier, quite a large amounts of data can be gathered, mostly using today's social networking tools to run some form of a contest with an ipad2/3 as the main prize;
- the results can be computed and generated throughout the survey and the process of input can be easily monitored; are available instantly on demand, as they are generated from the database based on the actual status of the data;
- the respondents have very little (next to none) possibilities to see what results are there to be produced which makes it for them even easier to run the diagnostics (having the freedom “not to think” while letting the associations appear in their minds and letting literarely their hands to choose the colours.

Negatives

- there still is some work on the interpretations, they are not yet fully end-user readable;
- ICT gap/barrier does not allow for use in some cases.

5.1 Future possibilities

We are in active search for a strategic partner (for each major world language) that would like to use the methodology to form a language specific product, that would have at least two forms, one more open to perform more research-oriented surveys, and one, configurable, but more closed, that could be used widely to support the urban planning and development.

To see how our reports can look like, check out our partners site at www.balancemanagement.com.

Most probably, within a year or two, there will be a feedback solution based on the discussed methodology, that can be easily used and is such a low cost that it gradually becomes a usual way of gathering feedback in this case.

From 5 to 10 %. The Challenge to Double Vienna's Modal Share of Cycling

Andrea Weninger

(MSc. Andrea Weninger, Rosinak & Partner ZT GmbH, Schlossgasse 11, 1050 Vienna, weninger@rosinak.at)

1 ABSTRACT

Cycling plays a crucial role in the mobility strategy of the City of Vienna. On the basis of the executive agreement of the city government of 11 November 2010, the ambitious objective lies in doubling the share of cycling in the city by 2015 (from 5.5% to 10%, 2011 already 6%). Therefore cycling is given high political priority today and in the future and enjoys strong structural and organisational backing by the City Administration.

The dynamic development of cycling in Vienna is noticeable at all levels. On the streets but also in newspapers and magazines, it is obvious that a bicycle culture has evolved in Vienna.

Vienna needs highly developed cycling routes that permit comfortable travelling through the city and into the city. The more cyclists are on the streets the more pressure lies on infrastructure with a high quality. The city has to upgrade its infrastructure on an ongoing basis. A parallel step has to be the promotion of cycling to convince Vienna's population of the many positive arguments that advocate cycling. One highlight of this extended campaign is a special concentration of measures during the "Bicycle Year 2013". Above all, the Velo-city, the premier international conference on cycling, will be held in Vienna on 11th-14th June 2013. This conference is to endow Vienna's cycling activities with additional dynamism and should act as a driver for the implementation of planned measures.

This paper is a compendium of Vienna's bid to the Velo-city conference in 2013 supplemented by further information and data on cycling development and cycling cultures in the city.

2 DEVELOPLEMT OF CYCLING IN VIENNA

2.1 Dates and figures

Vienna looks back on a very long tradition of leisure cycling. Over the past 15 to 20 years, bicycles have become increasingly popular as an everyday means of transport; however, for a long time the share of cycling in the modal split of Vienna was constant at around 3%. A marked upswing in cycling was recorded since 2006. The share of cycling rose to 5.0% in 2010 and now 6.0% in 2011, which corresponds to a relative share increase by about 50%. There are notable seasonal fluctuations: during the "cycling season" from April to October, the share of cycling in the city's modal split is approximately 6.6% and even over 9% in the inner districts. Conversely, the average counts for January usually are only about 15% to 20% of those for June. The counts for 2011 presented another notable increase in bicycle use.

In the 1960s and 1970s, the rise in prosperity and the rapid growth of car ownership led to a strong focus on car-friendly urban planning in Vienna; bicycles were exiled from the streetscape. While the footpath network and public transport system were substantially upgraded, cycling was not promoted: the cycle way network was reduced from 23 kilometres in 1970 to eleven kilometres in 1977. Most cycle ways had to cede their space to ever-growing car traffic. Starting in the 1980s, this trend was reversed. The future cycle way network was to ensure that streets would be recovered for pedestrians and cyclists, rendering them more vibrant and appealing. As a consequence, the cycle way network was extended to 168 kilometres by 1986. As a first phase, "sub-networks in recreational and suburban zones as well as along the Danube and Danube Canal, including main connecting cycle ways" were built.

In 1993, the Vienna City Council adopted new guidelines for the Vienna Transport Concept, aiming at an increase of bicycles in Vienna's overall modal split to 6% of all trips. A key prerequisite for this was the creation of a main cycle way network in 1994. For the first time, the use of bicycles for shopping or trips from and to school and work was promoted. A campaign for cycle parking facilities in public space ("Vienna Rack", "Wiener Bügel") launched in 1985 was systematically continued. Vienna Underground passengers were allowed to take their bicycles along. Due to the dynamic development of cycling, the main cycle way network was revised in 2000, with a special focus on closing gaps in the network and fine-tuning organisational measures. This concept laid the basis for the measures planned for the next years. In the early

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

1990s, Vienna's cycle way network was only 190 kilometres long – yet by 2012, it had been expanded to more than 1,200 kilometres.

2.2 A change in transport policies

On the basis of the executive agreement of the city government of 11 November 2010, the ambitious objective lies in doubling the share of cycling in the city by 2015 (from 5.5% to 10%). In the meantime Vienna has reached 6.0% of all trips. Cycling is given a high political priority today and in the future and has a new strong structural and organisational backing in the City Administration.

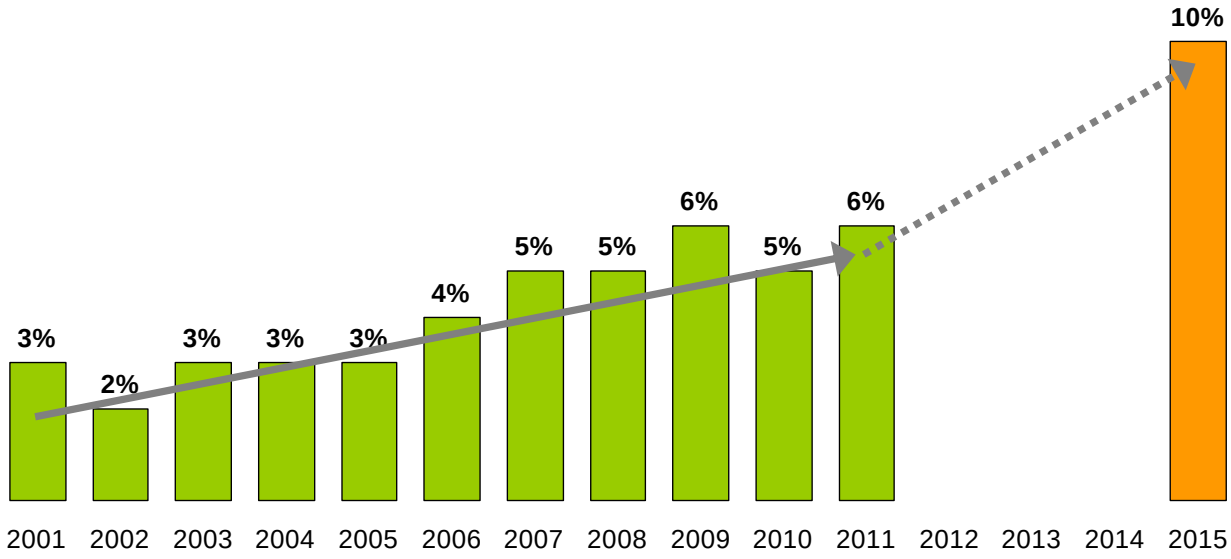

Fig. 2: Development of the share of cycling in Vienna's Modal Split

2.3 A changing bicycle culture

A look at Vienna's streets shows clearly that a bicycle culture has evolved. There are more and more cyclists – men and women of any age – in everyday traffic. Even lifestyle magazines and dailies feature cycling as an interesting topic on their covers; many shop displays use bicycles as decoration elements. Riding a bicycle is not only an alternative to a car, it has become a civil society movement within urban development, urban cultures and urban lifestyles – even in Vienna. Cyclists are reclaiming public space and changing urban images – faster than expected. From the creation of freaky bikes, bike kitchen and critical mass movements, cargo bikes, cycle chique and messenger culture the whole range of urban bike culture and bicycle enthusiasm is becoming a part of urban development and neighbourhood activism.

Fig. 1: Cycling in Vienna, photos by Martin Friedl, Michael Szeiler

Fig. 1: Shoe shop display and an optician using the bicycle as advertising theme, photos by Andrea Weninger, Matthias Schmidt

2.4 Challenges for cycling in Vienna

Vienna is characterised by a number of specific traits that entail specific challenges for bicycle traffic:

- Traditionally, Vienna boasts a very high (by international standards) modal split share of public transport, which currently has attained 36% (2011). The Vienna Underground network was and still will be expanded, accompanied by ongoing improvements of the tram and bus service. As a result, public transport is prioritised in public space design and at traffic lights.
- The historic core and the districts inside the Gürtel boulevard are highly condensed. This entails narrow streets and a great number of buildings from the Gründerzeit era – these residential buildings offer very little space for storing bicycles.
- Cars are mostly parked on the street. Due to relatively narrow streets, many of them are one-way. Opening one-way streets to bicycles (contraflow cycling) was established in Vienna quite some time ago and constitutes a key measure to render cycling more attractive.

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

- Because of the often narrow streets and manifold forms of use of the streetscape (public transport on its own lanes, public transport stops, sidewalks, car parking), the space available for cycle ways is limited. Plans therefore need to ponder the interests of all road users very carefully.
- Not all parts of Vienna are flat. Elevations must be overcome as well; this may discourage people to take up cycling on a daily basis.

These traits of the city have led to the formulation of numerous special and individual solutions to encourage cycling (e.g. contraflow cycling, ambitious programme to step up parking facilities, etc.) under complex frame conditions.

3 GETTING MORE PEOPLE ON THEIR BIKES

The improvement of the cycling infrastructure must be stepped up. Vienna needs highly developed cycling routes that permit comfortable travelling through the city and into the city. The more cyclists pedal on the streets the more pressure lies on infrastructure with high quality. The city has to upgrade its infrastructure on an ongoing basis; this will be complemented by projects as the housing estates Bike City and Car-free Development but also by the opening of more and more one-way streets to contraflow cycling. Other important projects include "bicycle-friendly streets", the upgrading of main routes like the Ring-Rund-Radweg with peak user volumes of more than 7,000 cyclists/day and of course further enlargement of cycle parking facilities in public space (over 30,000 slots at the moment) and new solutions for the combination of cycling and public transport. Cyclists need more cycle parking facilities and garages, especially at railway stations.

A parallel step has to be the promotion of cycling to convince Vienna's population of the many positive arguments that advocate cycling. Bicycle culture has to be fostered, so that bicycles will become an everyday means of transport of a lot more Viennese.

Many infrastructure measures and PR activities will be implemented in 2012 and 2013 to generate a positive spin for this issue. One highlight of this extended campaign is a special concentration of measures during the "Bicycle Year 2013", which is to create internal and external dynamism to motivate and mobilise all relevant stakeholders. The cycling season starts with the Bike Festival and the RadpaRADe in spring, a lot of cultural and cycling events will be presented during the year 2013. Starting in April 2012, the new FahrRADhaus (bicycle house) will address all questions related to urban cycling: a one-stop shop provides information, cycle training, flea markets, services and deals with suggestions to cycling in Vienna.

The Bike to Work campaign "Radelt zur Arbeit" [1] generates an initiative for specific target groups: information, incentives, testimonials, etc. demonstrate the potential advantages of integrating cycling into corporate mobility. In addition, a number of leading companies were to be motivated to become more bicycle-friendly. In 2011 the campaign sucessfully involved 4,000 workers from 700 participating Viennese companies to highlight the potential of bicycle use for enterprises.

Above all the Velo-city, the major international conference on cycling, will be held in Vienna on 11th-14th June 2013. This conference is to endow Vienna's cycling activities with additional dynamism and should act as a driver for the implementation of planned measures.

4 VELO-CITY VIENNA 2013: THE SOUND OF CYCLING – URBAN BICYCLE CULTURES

The Velo-city is the European Cyclists' Federation's (ECF) series of conferences is the premier international planning conference on cycling. [2] The Velo-city is to encourage cycling as part of daily transport. The conference series started in 1980 in Bremen followed by Barcelona, Munich, Brussels, Copenhagen, Seville etc. and Vancouver in 2012. Velo-city conferences have more than 1,000 delegates from all over the world.

The conference attracts delegates involved in transport planning and consulting, policy and promotion of cycling programs. Planners, engineers, architects, non-governmental organisations, academic researchers, physicians, environmentalists, business and industry representatives will share their knowlede on the cycling issue.

[2] http://www.ecf.com/projects/velo-city-2/

Fig. 3: The Velo-city Conference will take place in Vienna from June 11 to 14, 2013

The motto of the Velo-city conference in Vienna is "The Sound of Cycling – Urban Cycling Cultures". As in other European metropolises, different bicycle cultures have emerged in Vienna: urban chic, retro, neo-eco, minimal, new racing sports, family cycling, ... All these styles of spatial utilisation have their own rhythm and contribute towards the variety of ecofriendly traffic. In this way, they change and enrich the sound of the city.

With respect to culture and bicycle culture, the thematic focuses of the conference will reflect international trends and developments in the field of cycling. More information will be online in July 2012 on the website www.velo-city2013.com.

1 ABSTRACT

A key objective of this contribution is to evaluate the suitability to geosimulate housing market conditions. Systems for geosimulation, such as multi agent systems (MAS) or cellular automata (CA) exhibit various lacks when it comes to usability, data handling, data availability, visualization of simulation results and, not least important, GIS-MAS/CA coupling. This contribution evaluates different systems for geosimulation to identify lacks and to define an appropriate system for the geosimulation of urban housing market conditions. Systems considered include UrbanSim, REGISTA (Reality Emulating Geographical Information System for Territorial Analysis), MAGI (Multi Agent Geosimulation Infrastructure), Agent analyst and OBEUS (Object Based Environment for Urban Simulation). Prior to the evaluation a generic conceptional process framework for a housing rent appraisal simulation as an organizational geosimulation framework for housing market analysis is set up. This framework contains process components such as visual interpretation and descriptive statistics of housing market data, generation of spatially interpolated surfaces and intersection with (socioeconomic) ancillary data. The preliminary study serves as groundwork for the creation of a prototype simulation in the test area of the German city of Potsdam.

2 INTRODUCTION

The focus of this paper is the design of a conceptional framework for a housing rent appraisal simulation. A further focus lies on the the evaluation of different modeling toolsets for the purpose of modeling conditions in housing rental markets. In recent years the term geosimulation was used as a fuzzy phrase under which a whole range of new spatial simulation approaches has been subsumed. Torrens and Benenson (Torrens & Benenson 2004), the developers of the Geographic Automata System concept, consider geosimulation as "urban geosimulation". Spatially-related automata are the basis for their concept of geosimulation. The difference to conventional urban simulations are the constitutional "elements"of geosimulation, e.g. human individuals and infrastructure entities. The interactions between complex and dynamic phenomena in urban systems are modeled.

Urban simulation models in a traditional sense represent urban units in different scales of aggregation (e.g. census tracts, administrative boundaries etc.); geosimulation models are based on spatially non modifiable objects e.g. homes or households. This view of geosimulation already adresses one of the problems of geosimulation approaches, the acquisition of spatial data at the highest possible scale. Most popular tools in geosimulation are automata, mostly cellular automata (CA), and agent-based modeling approaches as multiagent systems (MAS). In the first volumeof their book series "Geosimulation" Koch & Mandl (Koch & Mandl, 2011) give some recent applications of geosimulation in the field of urban development, land-use change, gentrification etc.

3 CONCEPTIONAL PROCESS FRAMEWORK FOR A HOUSING RENT APPRAISAL SIMULATION

In general, existing housing market models are real estate appraisal models and concentrate on modeling effects on the housing price but not on housing rent. In this presentation an adaption of existing models to simulate effects on housing market rents in "core cities" of urban areas, following the nomenclature of the German Federal Institute of Urban- Construction and Regional Science, is suggested (BBSR 2011). Common approaches of real estate appraisal models are hedonic approaches where the bundle of the overall housing price is broken down in different prices, often using ordinary least square estimation methods (OLS) (Liu, 2011). Further methods are the application of moving window regression analysis, GWR (Geographically weighted regression analysis) and moving window kriging (Montero et al., 2011).

The goal is to adapt a model to the aim of housing rental appraisal and to integrate the adaption into a geosimulation process framework. The hereby suggested conceptional simulation process framework (figure

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

1) consist of six modular components. The process starts with a data acquisition and preprocessing component following and extending a process chain for a GIS-based housing market analysis suggested by Schernthanner & Asche (Schernthanner & Asche, 2010). This analysis includes the visual data interpretation, descriptive statistics and the rent appraisal of the current market situation via methods coming from geostatistics (Kriging, GWR). Next comes submarket creation by means of polynomial declustering, followed by the core component, a multiagent based geosimulation of rental market conditions and a final forecasting/prognosis component based on the result of different simulation scenarios concludes the framework. While the process components from data acquisition to the rent appraisal of the current market situation have been evaluated (highlighted green in figure 1), prototype development for the simulation components is on the way. Core component is a multi agent simulation (MAS). The MAS component incorporates agents representing virtual tenants interacting in urban real estate submarkets. The agent's interactions allow conclusions to dynamics in rental trends based on their interactions. The process framework serves as simplified assumption of the complex dynamics in rental markets and their influence on the formation of apartment rents in core cities (see figure 2).

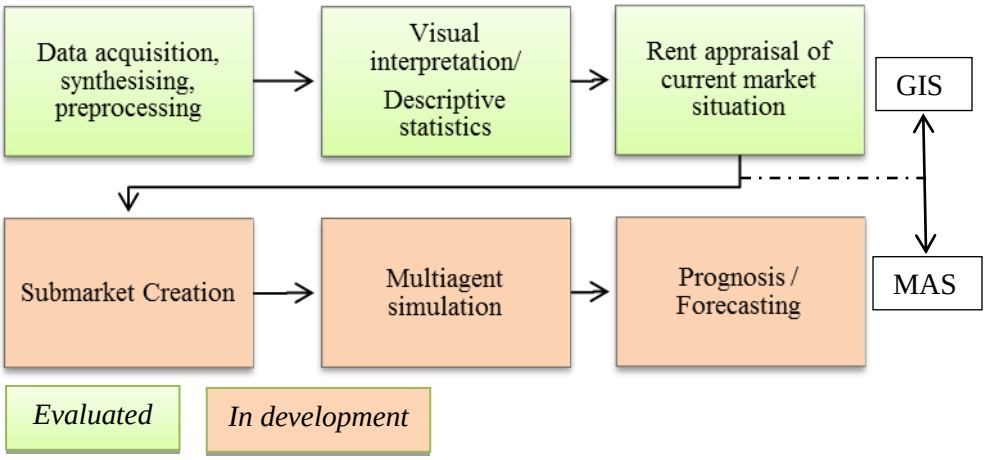

Fig. 1: Conceptional process framework for a housing rent appraisal simulation.

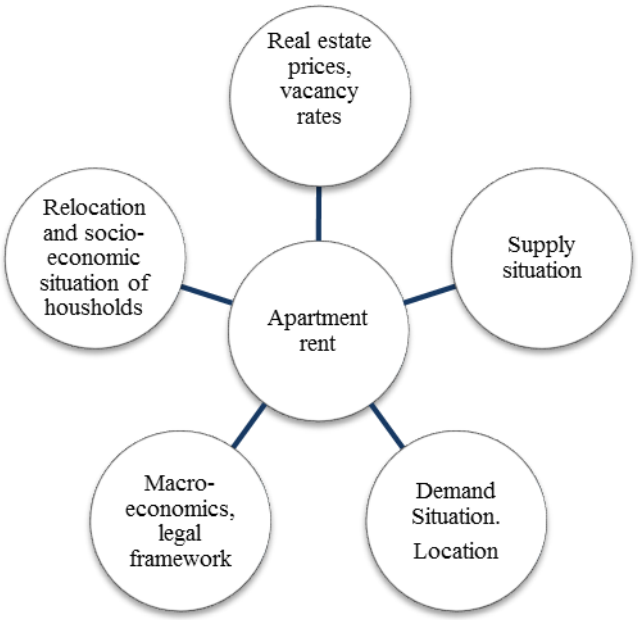

Fig. 2: Influence factors on the formation of apartment rents (own representation based on Waddell, 2011).

4 METHODOLOGY OF A TWO STEP EVALUATION PROCESS

Choosing an appropriate modeling system is a comprehensive task. The intended audience to use geosimulation modeling systems are expert groups made of specialists in the field of spatial planning, urban planning, GIS etc. Ideally a modeler possesses perfect knowledge about the geosimulation system to use, in

practice the complexity of geosimulation systems show that this assumption does not fit to real world conditions. Therefore different researchers suggested different criteria to evaluate simulation systems previously to the actual geosimulation process (Smith et al., 2007). The evaluation of simulation systems is important groundwork for setting up a prototype simulation following the designed framework. The evaluation process consists of two steps. First a criteria-based search process is done searching for geosimulation software. Criteria have been taken from guidelines suggested by Smith et al. (Smith et al., 2007) and have been adopted and extended to suit to the suggested geosimulation framework. Second step is a simplified form of a cost benefit analysis as performed by e.g. Krüger (Krüger, 2006), Schernthanner & Tyrallova (Schernthanner & Tyrallová, 2010), based on the principles of cost-benefit analysis introduced by Zangemeister (Zangemeister, 1973). Criteria simulation software has to possess to fulfill a certain function were scored in a 5 point scale according to their relevance to achieve a certain target, by summing the overall scores a cost benefit is calculated for each geosimultion system. Scoring is a subjective process based on the performer's knowledge. Nevertheless general recommendations for the use of geosimulation software can be derived aligned to the goal of the simulation of housing markets. Nine criteria have been scored in the evaluation process, 45 points is the highest possible score, meaning that a simulation system is perfectly suitable for the suggested simulation framework.

4.1 Evaluated Criteria

The criteria have been divided in three general criteria simulation software systems had to possess; these criteria have been used for the search process. Geosimulation systems had to be of the CA and/or MAS type and had to have any kind of GIS coupling. Further divisions have been the criteria that have been evaluated by a cost benefit analysis:

- License: Open Source, Closed source, Shareware, Freeware or Unknown.
- Import Export functions.
- Help system: Documentation, "How-to", and Community.
- Degree of maintenance: is the system actual, out date.
- Programming: Scripting / Objectbased, necessary programming knowledge.
- User interface: GUI and/or command line.
- Results: Visualization.
- Complexity of data requirements: Minimum to maximum data requirements.
- Availability of real estate models (model templates).

Scores range from 0 points (criteria not suitable for) to 5 (perfectly suitable). In addition, the software system training time was examined based on experience found in literature and own tries resulting in training time assumptions.

4.2 Simulation software systems

The following software systems have been identified for further evaluation: UrbanSim, REGISTA (Reality Emulating Geographical Information System for Territorial Analysis), MAGI (Multi Agent Geosimulation Infrastructure), Agent analyst and OBEUS (Object Based Environment for Urban Simulation). Beside the evaluated systems several other systems exist, e.g. MASON or Netlogo. Castle et al. (Castle et. al., 2007) give a good overview over existing software for geosimulation.

UrbanSim/OPUS (Open platform for urban simulation) is a modular open source simulation software system for the analysis of urban development in the context of urban planning. Software development was initiated in the 1990s by Paul Waddell (Waddell, 2010) at the University of Berkley. Real estate demand and supply models exist but so far only indirect effects of infrastructure changes on the attractiveness of residential areas can be measured by the simulation software (Liu, 2011). REGISTA (Reality Emulating Geographical Information System for Territorial Analysis) is a CA-GIS concept presented by Blecic et al. (Blecic et al., 2009) . Blecic et al. developed a CA-modeling toolbox with tight GIS coupling to uDIG an open source desktop GIS. Blecic et al. (Blecic & Cecchini, 2008) also developed MAGI (Multi-Agent Geosimulation Infrastructure), an agent-based simulation software with tight GIS coupling. Agent Analyst is an extension of

ESRI ArcGIS developed by the U.S. Argonne National Laboratory's Center for Complex Adaptive Agent Systems Simulation in collaboration with ESRI (Environmental Research Institute). The software is a middleware coupling ArcGIS capabilities with Repast, an open source multi agent system, allowing users to run Repast models within ArcGIS . Repast itself is a free open source simulation toolkit, implementations of the Repast framework for housing applications already exist e.g. done by Jordan (Jordan, 2011). OBEUS (Object based environment for urban simulation) has a special status as it aims to implement the Geographic Automata System (GAS) paradigm described by Torrens and Benenson (Torrens & Benenson 2004) combining MAS with CA. OBEUS was developed as part of a unfinished PhD project by Vlad Kharbash (Benenson & Kharbash, 2005).

5 RESULTS AND CONCLUSION

A cursory examination might find that several promising modeling systems exist for the implementation of the suggested modeling framework. Lacks not recognized at the first glance could be identified in the evaluation process. Most projects seem to be in a permanent experimental status within an academic domain, few operational models exist. The learning curve for all the systems is steep and all the evaluated systems lack a satisfying visualization of simulation results. UrbanSim receives the highest score (33) but the training time that has to be calculated to set up a basic model and the enormous amounts of high scale geodata (e.g. socioeconomic data at household level) that has to be acquired to set up a basic model disqualifies UrbanSim for prototype development for one single person. Patterson and Bierlaire (Patterson & Bierlaire 2008) give an detailed description in the time that has to be spent to set up an UrbanSim model, they categorize the learning phases to understand UrbanSim into a familiarization phase during 0,5 person-months, an implementation phase lasting 1,5-2 person-months and an evaluation phase lasting 0,5-1 person-months, Nguyen-Luang (Nguyen-Luang, 2008) even claims that an interdisciplinary team of 4 people and a period of 4 years for a successful operational implementation of UrbanSim is necessary (Nguyen-Luang, 2008). REGISTA, although a promising approach, is not available; evaluation has been done only based on literature review, due to this fact the reached score of 23 can´t be compared with the other tested systems as the system can´t be accessed for prototype creation. MAGI (28) developed by the same research group as REGISTA (Blecic & Cecchini, 2008) unites MAS and GIS under one graphical user interface, biggest problem of MAGI is, that the software seems to be without maintenance since the first version published in 2007. Agent Analyst (18) also is without maintenance, Mathur (Mathur, 2007) even states: "I feel that the Agent Analyst was developed as an experimental product and has since then been without patronage or support". OBEUS has not been evaluated by scores, because the simulation system is not accessible.

In assumption that a big research team consisting of about 4 persons can set up a prototype, UrbanSim would be the software of choice for prototype creation. Repast (without Agent Analyst) and Magi are the authors' first choices for prototype development.

1 ABSTRACT

The latest generation of 3D Urban Information Models (UIM), created from accurate urban-scale geospatial information, can be used to create smart web services based on geometric, semantic, morphological and structural information at urban scale level. UIM can be used by local governments to:

- Improve decision-making on issues related to urban planning, city management, environmental protection and energy consumption based on urban pattern and its morphology.
- Promote inclusion among various users groups (e.g. elder or diversely able citizens) through services that account for barriers at city level.
- Involve citizens at wider scale by collecting geo-referenced information based on location-based services at urban scale.

Based on interoperable 3D UIMs, i-SCOPE delivers an open platform on top of which it develops, within different domains, three 'smart city' services. These will be piloted and validated, within a number of EU cities that will be actively engaged throughout the project lifecycle. The services will address:

- Improved inclusion and personal mobility of aging and diversely able citizens through an accurate city-level disable-friendly personal routing service that accounts for detailed urban layout, features and barriers.
- Optimization of energy consumption through a service for accurate assessment of solar energy potential at building level.
- Environmental monitoring through a real-time environmental noise mapping service, by leveraging citizen's involvement will who act as distributed sensors city-wide measuring noise levels through their mobile phones.

All smart services will be based on already available technologies which will be integrated, deployed and made publicly available from a "3D smart EU cities" portal. Potential trust, privacy and data security risks and vulnerabilities, i.e. due to localisation of people, are integral part of the project and will be explicitly addressed.

2 INTRODUCTION

The term "smart city" has been introduced as a liveableness qualifier for urban environments, where advanced technology, tipically based on web-services and web-applications, are made available to the community through latest communication infrastructures (integrating both wired and wireless technologies) delivering "smart" functionalities that can simplify citizens' life or facilitate take-up of new business models by companies, in the context of houses, offices and public places. The scope of smart cities has been further extended through the introduction of advanced mobility management solutions, dealing with both transport infrastructures and information/monitoring systems. Last, but certainly not least, smart city services are being developed to address environmental monitoring and energy efficiency issues. This is affecting not only the energy retail market, where utilities can benefit from smart grid technologies, but also the building construction sector, where the design of low-environmental impact buildings can significantly benefit from more efficient services optimising heating, air-conditioning or power consumption.

The European Commission, within the so-called Digital Agenda, is paying significant attention to smart cities, as technologies associated to smart cities can bring to an improved knowledge-based economy, to better social inclusion and, in more general term, to a more livable environment. The technological and societal evolution required by the concept itself of smart city can act a flywheel that can help Europe

maintain a leading position at the global stage. Several research programmes, initiatives, projects and pilots, are being promoted within Europe and beyond.

The overall ambition is not only new technological but, most notably, societal in that smart cities will have to change the way people interact with others and with the urban environment itself. This is why i-SCOPE (Interoperable Smart City services through an Open Platform for urban Ecosystems), the project presented within this paper, has -among its founding principles- the integration betweemn the "real" city with its "virtual" counterpart, made of ubiquitous and pervasive services for improved mobility, inclusion, energy efficiency. Such a co-existence of real and virtual cities is hyielding a new articulated ecosystem, where citizens' life are closely integrated with urban-level IT services, giving birth to what is often referred to as the "hybrid city".

Moreover, in i-SCOPE different issues, transcending the mere technological domain, are being tackled, including apsects dealing with social and environmental issues. Indeed in i-SCOPE each technological solution is not considered as an achievement "per se", but it engineered following an open-innovation, user-driven approach, with the ultimate goal of promoting a so-called "humane city".

The rapid technological evolution, which is characterizing all the disciplines involved within the wide concept of smart cities, becomes a key factor to trigger true user-driven innovation. For this reason, i-SCOPE is making a substantial effort to maximise user-driven innovation by involving, from the earliest stages of the project, citizens, public officers, high-tech entrepreneurs, administrators, decision-makers. This way an bottom-up research process based on open the innovation system, is being promoted within three key research domains: 1) inclusive routing, to facilitate personal mobility of diversely-abled citizens; 2) solar impact analysis, to promote energy savvy planning policies; 3) crowdsourced environmental monitoring, to be able to use citizens and mobile IT technologies (i.e. smartphones) as distributed sensors of environmental information.

3 OBJECTIVES

The objectives of i-SCOPE are manifold. First of all i-SCOPE will eliver an open-source toolkit based on 3D Urban Information Models (UIMs), developed according to the principles of service-oriented architecture, and based on use of open standards from the Open Geospatial Consortium (OGC). The toolkit will be released as open source solution ready to be deployed by city administrations. The toolkit will include services capable to create 3D urban models from raw data such as surface models (e.g. LIDAR), terrain models and building floor plans according to the OGC standard CityGML.

The toolkit will include smart services that will be used to:

- Improve decision-making in planning processes and policy design at city-regions management levels, with regard to issues related to energy efficiency and noise levels, based on urban pattern and its morphology.
- Promote inclusion and mobility of differently-abled people and elderly users through guiding technologies, based on use of mobile IT devices (e.g. smartphones) that can help them overcome barriers at city level and that support them during their daily urban trips.
- Involve citizens at wider scale in the collection of real-time location-based information at urban scale with particular attention being paid to mapping of noise. It should be noted that the third domains has clear policy implications in that creating technology capable to deliver real-time noise mapping can help city achieve the requirements of the Environmental Noise Directive (END) (2002/49/EC). The Directive, which clearly expresses the importance of the participation of all involved citizens, among other obligations, enforces Member States to provide strategic noise maps on a regular basis (5 years) as of 2012, for major roads, railways, airports and agglomerations (>250k inhabitants), using harmonised noise indicators. These maps can be used to assess the number of people annoyed and sleep-disturbed respectively throughout Europe, to address issues emerged during each assessment period, and to create action plans for said target areas. The approach pursued by i-SCOPE is in line with Article 9 of the Directive which states that citizens must be provided with clear and accessible noise maps, disclosing areas exceeding value limits.

The aforementioned smart city services will be tested within a variety of real network ecosystems available in the cities involved in the project, ranging from city-wide sensor networks (as in the case of the city of Velletri, Italy), to large scale regional optic fibre networks (in the case of Trento and Lazio Region, Italy), to mobile location based services.

Due to the nature of the technology being developed, which heavily relies on location based services and tracking of the users' position, i-SCOPE will pay significant attention to the development of trustable, secure privacy schemes to ensure the highest level of protection of users' information. This is necessary since such a set of real-time, location-based mobility services poses significant security and privacy issues (due to traceability of people's location, actions, travel plans etc). The i-SCOPE project shall ensure that the privacy of users is respected whilst providing protection of the data at the core of the system and the interaction of users with that data in line with the data protection laws.

Furthermore i-SCOPE aims at providing a significant contribution to standards in the domain of smart city services, through contribution to extension and wider adoption of the OGC standard CityGML as key enabling open standard for 3D smart city services. With specific regard to this, i-SCOPE has the following goals:

- Promoting establishment of a common "Urban Information Model" (UIM) based on CityGML within a network of cities in Europe of relevant critical mass, and to create specific applications on top of these UIMs. It is worth noting that the outcomes of the project will neither be isolated nor stand-alone. In contrast, the adoption of a common standard (i.e. CityGML) ensures that applications realized in City A can be transferred and utilized in City B. This represents an important asset of the project and an essential factor to facilitate cooperation within the cities.
- Accelerate the uptake of CityGML as the reference standard to support simulation at urban and regional level, by integrating or extending existing open platforms in several EU cities. In practice this will done by making combined use of existing mobile technologies, location based services, sensor networks, high performance networks and 3D technologies and by integrating them into a comprehensive software suite that can deliver novel services to tourists, local residents, businesses and and public administrations.
- Extend the core CityGML open standard, through a formal submission to the OGC consortium, to define specific CityGML Application Domain Extensions (ADE) relevant to the pilots selected, specifically in the domain of inclusive routing, solar energy assessment and noise mapping.
- Promotion of a number of targeted awareness activities to accelerate the uptake of CityGML as the reference standard to support urban-scale smart services, sustainable planning and simulations.

4 THE PROJECT DESCRIPTION

4.1 Issue proposed and target users

i-SCOPE delivers an open source toolkit for 3D smart city services based on 3D Urban Information Models (UIM), created from accurate urban-scale geospatial information.

The smart services proposed address the following three scenarios:

(1) Improved inclusion and personal mobility of aging people and diversely able citizens.

(2) Energy dispersion & solar energy potential assessment.

(3) Noise mapping & simulation.

The targeted users of i-SCOPE are:

- Diversely-abled citizens needing customised routing instructions. Specifically, mobility impaired users or people with limited ambulation requiring barrier-free routing functionalities or visually impaired users who cannot read maps and need voice-based semantically rich routing instructions.
- City administrations that need to define policies in terms of heat dispersion and solar potential at urban level as well as experts/professionals/companies that need to have high precision solar potential assessment.

- City administrations needing to assess noise through simulation as well as existing mapping data in order to create noise maps according to EU Directive 2002/49/EC on noise. Citizens, who can access real-time data as well as accumulated maps on areas and time-scales of interest.

4.2 Usage

The typical use case of i-SCOPE starts with a differently-abled user, for instance with mobility constraints (e.g. a wheelchair user), who starts an App in their smartphone looking for a route that can guide them through the city along barrier-free routes. Directions are provided by the smartphone through an easy-to-use Augmented Reality interface.

Another differenty-abled users, with serious visual impairement, asks for a customised route that can guide them through the city. The smartphone in this case starts providing spoken, semantically-rich instructions describing the surrounding context in detailed manner. Additional feedback is also provided through a portable Braille displays connected to the smartphone via Bluetooth.

In a different scenario a city planner starts a 3D web application to create very high-resolution solar potential maps of the city. This is required to define new policies or incentive schemas at the city level. The solar potential map is created, through a specific web services, from an interoperable 3D model of the city. Professionals can also use the 3D web-client to access the 3D city and provide for a specific building information on a refurbishing project, for instance uploading relevant data, such as thermo images, regarding energy performance of a building. This is part of a compulsory procedure to obtain an certification on energy rating of the building.

In the last scenario a city administrator starts a 3D web application to access noise data being retrieved by citizens through their mobile phones. Users are used as remote sensors and the data generated by their smartphone through an ad-hoc App, can be used to generate 3D real-time noise mapping data. The system also allows accessing historical data regarding noise maps. Citizens can use the App to provide real-time measurements of noise levels in specific parts of the cities to file an official complaint for excessive noise exposure (e.g. due to vicinity of roadwork or entertainment venues).

4.3 Innovative features

From the aforementioned use cases it is clear that i-SCOPE features a number of innovative aspects. With regard to the first use case Most routing and navigation systems have been developed for vehicles. i-SCOPE smart routing service returns orientation and navigation information, customised to cater for diversely able users, providing:

- Automatic map-descriptions in words (e.g. for visually impaired users or in contexts where visual information cannot be accessed).
- Maps with larger fonts and/or mouse over acoustic descriptions.
- Navigation descriptions in easy to hear versions.
- Navigation directions provided in a format suitable for Braille displays.
- Information about the surrounding, i.e. streets (name of the street, lengths, type, crossings), landmarks (points of interest, orientation points) and areas (parks, squares).
- Navigation functionalities without distances (in meters) but based on landmark descriptions.
- Context awareness, through a “visual map in words” (automatically read aloud by the client) providing all the required spatial information.
- A visual map whose graphical appearance is adapted to the specific user requirements of visually impaired users.
- A simple button to invoke the “where am I?” function providing additional descriptions of the surrounding targeted to people with reduced orientation skills (e.g. elderly users).

When observing the second use case, dealing with solar potential mapping, i-SCOPE provides an improved solution, if compared to current solar assessment GIS (e.g. ESRI Solar Analysis), since it ensures a calculation based on real 3D layouts of buildings. Traditional applications instead calculate solar potential based on raster data that need to be created separately from existing terrain and, if available, merging

building information. Other online services (e.g. Photovoltaic Geographical Information System by JRC) is simply based on the position (lat/lon) and through manual specification of the roof layout (orientation, slope etc.). i-SCOPE solar assessment is based on accurate 3D georeferenced models of urban environment and therefore accounts for:

- Real layout of roofs and other structures (e.g. walls, slabs etc.).
- Correct positioning.
- Shadowing effects induced by adjoining buildings as well as vegetation, infrastructures (e.g. power line posts).

Unlike other solution all the aforementioned information is automatically calculated from a high precision UIM available in the interoperable standard CityGML. In turn as output the services delivers:

- Interoperable provision of solar maps through Web Coverage Service (WCS) or Web Map Service Time (WMS-T).
- Solar simulations can be calculated through a remote service, based on interoperable standard WPS. This way any client (including commercial or open source GIS software) can perform simulations by invoking a smart service based on an interoperable protocol.
- Finally i-SCOPE promotes an innovative scenario to support the update of data on heat dispersion from community of citizens and professionals. This information can be later accessed by city administration for planning or taxation purposes. City administrations can easily create maps to show how policies have contributed to improving energy efficiency in areas of the city.

Last but not least, the third scenario, dealing with noise mapping, has a distinct innovation flavour in that:

- Noise simulations can be calculated through a remote "smart" web service, based on interoperable standard Web Processing Service (WPS). This way any client (including commercial or open source GIS software) can perform noise simulations by invoking a smart service based on an interoperable protocol.
- The EU Directive 2002/49/EC on the assessment and management of environmental noise requires large cities in Member States to produce noise maps and action plans to curb noise pollution. Current efforts to comply with the directive are based on simulations rather than field measurements, based on statistical data for transport (air, train and large roads) and industry. By using measurement data collected by citizens as well as by traditional sensors, possibly in combination with statistical data (e.g. on urban traffic flows), these existing efforts can likely be improved upon and will certainly throw a different light on the actual situation.
- Simulated maps are by construction dated (typically 3 years back), and they are in terms of averages over day, evening and night periods over a whole year. Real-time maps provide finer granularity in terms of time as well as space.
- Simulated approaches map the situation at 4m above the ground at each house's most exposed facade, while real-time noise mapping through mobile sensor networks provides a people-centric view on urban

4.4 Technology

i-SCOPE integrates open source technologies and previously developed partner projects within a comprehensive toolkit promoting interoperability through the use of OGC and other open standards for data exchange and services. This allows for independent development and functionality deployment provided by different web-services. In i-SCOPE pre-existing technologies, wherever not available as services, will be wrapped by a service layer in order to ensure compliancy with the overall schema The following diagram provides an overview of the project architecture.

i-SCOPE will significantly rely on CityGML. This is the open standard for interoperable encoding of 3D Urban Information Models. Since i-SCOPE refers to Smart Cities CityGML and its extension according to the requirements of the project is the most prominent solution. The standard is being developed by the Open Source community under coordination of OGC. As previously mentioned, i-SCOPE requires extension of the core standard as well as the creation of two Application Domain Extension (ADEs) and the extension of a

third one (on noise) of the current CityGML. This will extend modelling capabilities making CityGML compliant to the requirements of the three scenarios tackled by the project:

- Sun Potential Mapping
- Noise Mapping
- Differently-abled-friendly routing

i-SCOPE services will integrate the BRISEIDE (www.briseide.eu) platform along with the processing services required. The toolkit is currently undergoing extensive testing in several pilots across Europe and provides services to access spatio-temporal data both in terms of data access and data processing. i-SCOPE will also extend the routing algorithm developed by BRISEIDE. This is based on OpenStreetMap available dataset, and it can exposed as an OpenLS service. Additionally in i-SCOPE the new service will provide a routing algorithm that will be friendly to people with disabilities. For example; the dataset will provide information on ramps to get on the pavement after crossing a street. The routing algorithm will use this dataset to provide the person using the i-SCOPE service with routes that:

- Require the lesser effort to get from point A to point B;
- are the quickest in terms of time,
- are the shortest in terms of overall length,
- always accounting for the requirements of disabled people.

i-SCOPE will also rely on integration of existing technologies. Specifically i-SCOPE will integrate a tool to generate 3D city models based on existing geodata developed by MOSS (a German company partner of the project), that can provide combine different data such as terrain models and floor plans to produce a realistic 3D city as CityGML. The technology will be customized and adapted to i-SCOPE's requirements in order to operate as a web service through a software layer that can provide interoperable access to simulation functionalities via a WPS (Web Processing Service). i-SCOPE will also integrate existing noise simulation technology, currently developed on top of Oracle and ESRI technology. To do so an WPS component will be developed to ensure interoperable communication with noise simulation software as interoperable web service. Similarly i-SCOPE will also deliver a service for sun potential calculation and production of solar irradiation maps by extending the "r_SUN" function – module of GRASS by creating a WPS interface.

i-SCOPE will also use services developed by partner CEIT that can create semantic spatial descriptions from GIS repositories. The spatial description derives from vector data so that a largescale mapping is possible. This method makes it possible to describe the shape of crossings, blocks, etc. in words and in a standardised way.

The project will also integrate noise level mapping technology based on NoiseTube, a technology initially developed within the scope of the FP6 project TAGora by Sony CSL in collaboration with Vrije University Brussels. The NoiseTube application for smartphones allows users to collect geo-located noise level measurements and share them in real-time. The NoiseTube server software, accumulates and stores all shared data and uses it to generate noise maps (as OGC KML files), user tag clouds and basic statistical noise information.

The web client will be based on 3D Geobrowser, developed by Fondazione Graphitech to access and manage geographical information according to OGC standards. This is a mature software, that currently supports exchange of map information in a totally interoperable manner; loading of CityGML models; access to processing features as WPS. The system is based on an enterprise level SOA designed to provide all the access, management and processing functionalities of multi-dimensional GIS and satellite data through OGC – OpenGIS Consortium compliant web services. Within i-SCOPE the 3D Geobrowser will be extended to provide support for CityGML at high level of detail.

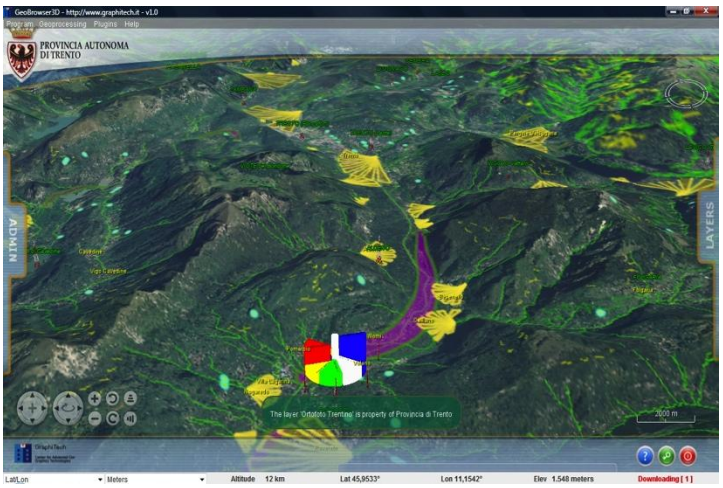

Figure 1: the 3D web-based GeoBrowser by Graphitech

5 CONCLUSIONS

i-SCOPE is facing very critical issues connected to the future quality of life and economic/financial performances of our cities and city-regions. Decision making processes, at local, regional and national scale, are more and more connected to the use of complex tools based on articulated and mult i-SCOPEs informative systems and related digital tools.

The three adjectives (smart, inclusive and sustainable) characterizing the EU2020 strategy request for major change in the way of defining the way of being competitive and at the same time keeping under control the unbalances connected to regional disparities, but even to look for more effective and efficient solutions in the se of digital data. In fact, this way, especially those connected to the definition of smart solutions for the economic growth of European cities, city-regions and major scale territories, is strictly connected to the proper design of an EU Digital Agenda (DA).

The i-SCOPE outcomes are to identify in set of tools, services and policies that will contribute to major horizontal tasks connected the EU digital Agenda (e.g. access of data owning to public sector information, and enhancing the EU innovation capacity), but, at the same time, the project's outcomes will affect and impact on the realms of a) interoperability and standards of spatial data, b) the research and innovation sectors and c) trying to propose effective solutions to major social challenges (e.g. ageing issues).

Moreover, the implementation of smart services in the urban realms could be one of the innovation to consider for town planner in order to understand and better design the new planning challenges determined by ICT inputs, solutions, opportunities. It is to consider that for many cities, and this is valid even for i-SCOPE pilot partners, "going smart" could be currently seen just as a slogan useful to be in a stream of EU investments. It is important to understand, in implementing i-SCOPE, which ICT solutions can really make the difference in terms of a) making planning instruments more effective and efficient (re-thinking the way of designing planning tools), b) moving the decision making process to a wider arena (communities matter), c) opening new opportunities for public and private spaces in the city (technology helps in exploiting hidden, until now, potentialities). i-SCOPE introduces services based on 3D data and technologies in the world of town planning, where decision making is literally and legally centred on 2D tools; this is definitively a frontier to consider, smart technologies based on use of 3D data. Smart services should not just focus on practical application (e.g. this part of cities is suitable or not for solar enegy tools…), but should be capable to contextualize the capabilities of facilitating practical application into a major urban strategic framework, if the smart cities services find the way to pass from the scale of 'solutions providers" to that of strategic organiser of cities potenitalites in terms of energy, noise, use of spaces, mobility, services to citizens and so on at urban and metropolitan scale, at this point we cann see them as vectors of innovation within the many contexts of urban planning.

Concluding, the many i-SCOPE outputs, from the more technological ones to the definition of indicators and frames for policies, will fall on different categories (from meta data modelling, definition of platform to the design of services and urban/territorial policies) that cannot bring to a synthesis if not faced in the context of a pluralistic and multi-faced governance based on the directive and directions given by the EU. The

questions connected to inter-regional/cross border use of data, those connected to the indications for the design of trans-national services (the market is definitively global), the other linked with the indication to provide for the design of policies and strategies (the EU should provide a soft creation of coherence among all national and local policies in order to avoid unbalances in use of funds and in the definition of policy principles) are just few examples that demonstrate how the i-SCOPE purposes cannot be solved at local or at national level, but required to be set up, experimented and implemented at EU scale through the implementation of a partnership including, public administration (cities and regions) SMEs and research centres.

6 ACKNOWLEDGMENTS

The project i-SCOPE has received funding from the EC, and it has been co-funded by the CIP-ICT Programme as part of the Competitiveness and innovation Framework Programme (http://ec.europa.eu/ ict_psp) under the objective identifier 5.1: Open Innovation for Internet-enabled services in 'smart' cities' (GA N. 297284). The author is solely responsible this work which does not represent the opinion of the EC. The EC is not responsible for any use that might be made of information contained in this paper.

Identification of Innovative Solutions to Decarbonise Transportation of People and Goods in Smart Cities

1 ABSTRACT

The two major challenges mankind has to face during the 21st century in the context of transportation are urbanization and CO_2 emissions. These two phenomena cause serious problems and bring along a strong need for the implementation of innovative and "smart" solutions in future cities. The substantial need for these solutions, however, can lead to interesting commercial opportunities for innovative companies.

In the light of this trend development an innovation project, which was based on the lead user approach, was conducted by the Institute for Entrepreneurship and Innovation (E&I Institute) at the Vienna University of Economics and Business (WU Wien) in cooperation with Kapsch TrafficCom AG (Kapsch). The latter is a member of the Kapsch Group, a worldwide renowned Austrian company. Kapsch operates in over 35 countries and is a leading international supplier of intelligent transportation systems (ITS). Its core business is the development and supply of electronic toll collection (ETC) systems, and the technical and commercial operation of the latter.

Finding radically new concepts and solutions is always a challenging task. However, the lead user method is an applicable tool to gain deeper insight into complex problems and to produce highly innovative ideas and solutions.

The main goal of this research project was to find innovative solutions to decarbonise transportation of people and goods in "Smart Cities". Several important constraints have to be considered in connection to the underlying problem. Firstly, solutions must be commercially realizable by the year 2025. Secondly, commercial business models should be marketed on a B2G or B2B basis. Thirdly, the focus lies on cities with more than two million inhabitants. In addition, solutions must be scalable. Finally, any solution ought to lead to a reduction of CO^2 emission.

A major difficulty for the conducted lead user method was the definition of the search field and the term "smart city". In general, there is no singular definition of what makes a city smart and there is also no clearly defined strategy which must be implemented in order to improve a city's smartness (Austrian Institute of Technology, 2011). Smart cities have several dimensions as outlined by the European Commission (2009): smart mobility, smart environment, smart governance, smart people, smart living and smart economy. While the interdependencies of these dimensions were only investigated in phase 1 of the lead user project, it was necessary to narrow down the search field so as to be able to find feasible concepts and solutions.

2 SMART MOBILITY

The current mobility trend can be characterized by the rapid exhaustion of fossil fuels combined with increasing environmental, health and safety problems (Grob, 2009). Especially in Asian cities the rapid urbanization and motorization, which is due to an increased income level, led to poor conditions of urban transportation (Morichi, 2005). Thus, smart mobility solutions would need to primarily solve problems of accessibility and availability of sustainable macro (for longer travel distances, e.g. trains) and micro mobility (for bridging the "last mile", e.g. flexible public individual transport), combined with efficient Intelligent Traffic Control (ITC) systems. Lenz (2011) pointed out that travel behaviour is ever more diversified nowadays, which leads to a shift from mono-modal to multimodal transport. This means that different transport modes in cities (trams, buses, metro, trains, cars etc.) will need to be interlinked and coordinated to ensure short travel times. Additionally, this requires an interconnectivity of all transportation modes and/or users so that shared information can be used to improve the prediction of traffic flows (Kambitsis, 2010).

In addition, transportation modes themselves can be improved in a smart way. By converting fuel-driven cars into electric cars, for instance, this approach has already been put into practice. Several countries have

already built large funds to facilitate this development with regards to their public transportation systems (Coune, 2011). However, the common "last mile" is still not covered–even if the public transport systems are

very advanced (i.e. micro mobility). This is one reason why further solutions in the area of electric vehicles are still required (IET-Transport Forum, 2003).

Shared-vehicle concepts might also intelligently reduce the number of cars in cities (Winterhoff et al., 2009). A reduction of the number of cars used in cities is necessary as space (especially in connection with parking lots) becomes more and more limited. Furthermore, the abandonment of cars in cities would also tackle the problem of CO_2 emissions.

3 DOOMSDAY SCENARIO FOR FUTURE CITIES

To get better insights into the problems inhabitants of megacities face today, Kapsch prepared a "doomsday scenario". In this presentation current trends and developments are projected into the future with the aim to show how cities would look like by the year of 2030 if no further actions were taken (see Figure).

Fig. 1: Excerpt of the doomsday scenario of Kapsch

In order to get to a common understanding of what goals we addressed, we envisioned a future smart city which they presented to all project participants (see Figure 2).

Fig. 2: "Beautyville" Vision of a Smart City by Kapsch

4 OBJECTIVE AND METHODOLOGICAL APPROACH: THE LEAD USER METHOD

The objective of the project was to find innovative solutions for megacities in order to lower their level of CO2 emissions and leverage their citizens' satisfaction by enhancing life quality by application of the lead user method. Involving lead users and experts from all over the world shall help to overcome functional fixedness which often occurs within a company and in turn hinders innovative progress. Involving people from analogous markets should further encourage this out-of-the box approach.

High competition, shorter product life cycles and rapid technological change made it crucial for companies to constantly innovate. Especially radical innovations are needed in order to remain competitive. In this respect traditional marketing research methods often fail to deliver valuable results.

Most marketing research methods work with random samples of customers in order to ensure that they represent the average typical customers (Lüthje & Herstatt, 2004, p. 554). They are often restricted to obtain only information about the users' needs and assign the task of generating ideas for solutions to manufacturers (Gary L. Lilien, 2002, p. 1043).

However, average users are strongly constrained by their real world experience, an effect called "functional fixedness". Studies showed, for example, that those who use an object or see it used in a familiar way are blocked from using it in a novel way (Gary L. Lilien, 2002, p. 1043). In order to forecast their needs in the future or assess a radically new product, the customers have to master the very difficult mental task of imaging a context of use, which does not yet exist. Therefore, average users are unlikely to contribute insights into new product needs and possible solutions (von Hippel, 1986, p. 791).

In contrast, so called "lead users" do not have to imagine themselves in a not yet existing situation because the "new" is already familiar to them. (Lüthje & Herstatt, 2004). According to von Hippel lead users have two distinguishing characteristics: "(1) They are at the leading edge of an important market trend, and so are currently experiencing needs that will later be experienced by many users in that market. (2) They anticipate relatively high benefits from obtaining a solution to their needs, and so may innovate." (von Hippel, 2005, p. 22). The first characteristic is based on the assumption that market needs evolve over time and are driven by important underlying trends. Therefore, solutions developed by lead users today will be attractive to many users tomorrow (see Figure 3). The second was derived from studies showing that the greater the expected benefit from a needed innovation is, the greater the investment in obtaining a solution will be (von Hippel, 2005, p. 22).

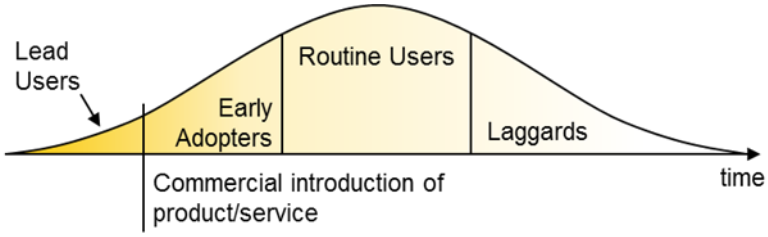

Fig. 3: Lead users' position in the adaption curve (Churchill, von Hippel, & Sonnack, Lead User Project Handbook, 2009)

The lead user research method exploits this fact by integrating lead users directly into the company's concept development process. Consequently, the project team can benefit from both the solutions and the information concerning the underlying need held by lead users (Churchill, von Hippel, & Sonnack, 2009, p. 6).

Products developed by lead users are often commercially attractive, have higher novelty and address newer customer needs (Gary L. Lilien, 2002, p. 1055). Furthermore, the method is not restricted to leading edge users in the target market, but also tries to make use of users from advanced analogous markets, which have similar needs in a more extreme form. This approach increases the likelihood of identifying radically new ideas for new products and services that will be "breakthroughs" for the target market (Gary L. Lilien, 2002, p. 1043).

In many cases lead users do not request financial compensation for their services. This phenomenon is called "free revealing" and means that all intellectual property rights to the information are voluntarily given up (von Hippel, 2005, p. 9). It mainly appears when lead users are part of other fields and industries and would not feel any negative competitive effects from revealing what they have done, or when they developed their

innovation just to solve their own specific need. In these cases lead users are generally happy to share their knowledge (von Hippel, 1999, p. 54).

Freely revealing users may benefit from enhancement of reputation, from positive network effects due to increased diffusion of their innovation, and from other factors like being able to buy a well-produced solution to their need (von Hippel, 2005, p. 9).

As shown in Table 1, lead users can be found in both low and high technology fields (Churchill, von Hippel, & Sonnack, 2009, p. 11). The percentage of users who improve prototypes or develop new solutions is significant. The numbers range from 10% to nearly 40% depending on the industry (Lüthje & Herstatt, 2004, p. 556).

Study	Field of innovation	Users sampled (n)	% of users who developed solution for own use
Lüthje (2004)	Equipment for outdoor sports (Germany)	153	10%
Lüthje (2003)	Medical surgery equipment (Germany)	261	22%
Franke and Shah, (2002)	"Extreme" sporting equipment (Germany)	197	38%
Tietz, Morrison, Lüthje and Herstatt (2002)	Kite surfing equipment (Australia)	157	26%
Lüthje, Herstatt and von Hippel, 2002	Mountainbike equipment (USA)	287	19%
Morrison Roberts and von Hippel, 2000	Library information search system OPAC (Australia)	102	18%
Herstatt and von Hippel, 1992	Pipe hangers hardware (Switzerland)	74	36%
Urban and von Hippel, 1988	PC-CAD for the design of printed circuit boards (USA)	136	24%

Table 1: Fraction of users who build solution for own use (Churchill, von Hippel, & Sonnack, Lead User Project Handbook, 2009)

In recent years there has been an increasing interest in applying the lead user method to the development of products and services (Nikolaus Franke, 2006, p. 302). It was successfully used by numerous world leading companies like 3M, Johnson&Johnson Medical and HILTI (Lüthje & Herstatt, 2004, p. 553).

5 PROJECT DEFINITION AND GOALS

After Kapsch had decided to conduct an innovation project in cooperation with the E&I Institute, which is among the leading departments all around the world regarding the implementation of lead user projects, they nominated a group of people who worked out a more detailed area of focus within the search field of smart cities together with the E&I Institute. Out of two remaining subfields, namely "decarbonising urban transport" and "smart energy solutions", the former was chosen as it seemed to be related to the more urgent need for solutions, especially from a user`s perspective, and in turn to a higher chance of commercial success.

The next task was to find a precise description of the search field and the overriding goals of the project. The following constraints were thus set: The main focus of the project should be to identify innovative solutions, with commercial potential, that decarbonise individual and/or public transportation of people or goods while increasing the users' convenience.

Furthermore, some specifications were made to narrow down the focus and to provide the project team with a better understanding of the expected outcome of the lead user project:

- The underlying concepts to the solutions should be highly innovative, but must be commercially realisable by the year 2025 or 2030 at the latest.
- All existing and future technologies, systems and products may be used to draw concepts. Creativity should only be limited by realistic technology forecasts.
- Development phases of three to five years are expected.
- Commercial business models should be marketed on a B2G or B2B basis.

An expansion to the B2C market will only be considered if there turns out is a major business opportunity that requires this step to be taken.

- The main focus should lie on cities with more than 2 million inhabitants. Solutions have to be scalable.
- Smart cities are defined as to be systemic, human, anticipatory, resource-efficient and technologically innovative.

Concerning the regional focus of the project, it was agreed that both, cities in developed and in developing countries were of interest to the project partner and that a better regional focus could be developed during a later phase of the project.

6 DATA COLLECTION AND ANALYSIS

In a first step, the search field was narrowed down to the most accurate needs and trends. In order to do so, the students involved in the project systematically skimmed through the relevant literature, browsed the World Wide Web and conducted more than 500 interviews with experts and megacities' citizens who were affected of the problems described above.

We thereby identified 18 needs which were then ranked according to their importance. After having presented the outcome of the need and trend analysis to the project partner, the latter agreed to the recommendation of focusing on the four suggested needs, namely:

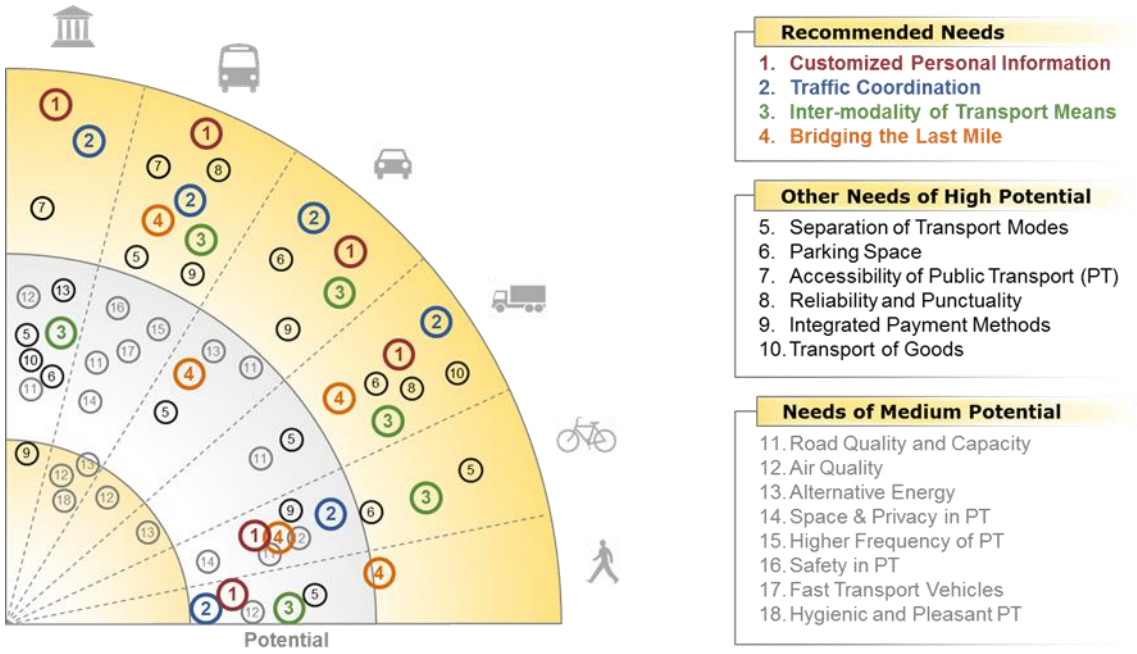

Fig. 4: Trend matrix (own contribution)

6.1 Need for Customized Personal Information

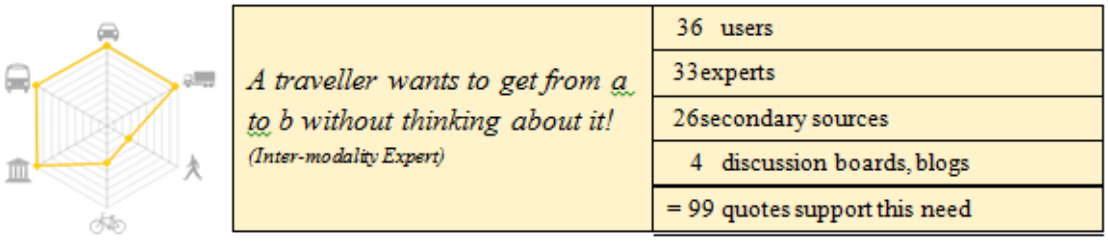

Fig. 5: Need for Customized Personal Information (own contribution)

Both users and system operators strive for information that would be real-time, accurate and relevant and simultaneously presented in a user- friendly fashion. This need turned out to be extremely relevant with a full score of five out of five and is relevant for all participants of public transport. This is not as surprising when considering the fact that information sharing can influence a passenger's comfort, might enhance

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

accessibility to divergent destinations as well as improved itineraries and, last but not least, can lead to time efficiencies.

In the first instance it should be emphasised that users want an easy access to relevant information that would provide details concerning all modes of transport. It should help every traffic participant, from a cyclist to a driver to a metro operator, in a seamless transition from point A to B. It is imperative that information is reliable and 'up-to-minute', because otherwise it would not fulfil its task of assisting travellers in trouble and enabling a stress-free journey. A few examples of the nature of information needed would include schedules for different transport modes, envisaged delays, accessibility information, traffic congestion and availability of cycling paths. Providing such information would definitely solve the general confusion with currently often incomplete, lagged and unreliable information. Furthermore, it would also reinforce the image of stability and security of the transport system.

6.2 Need for Traffic Coordination

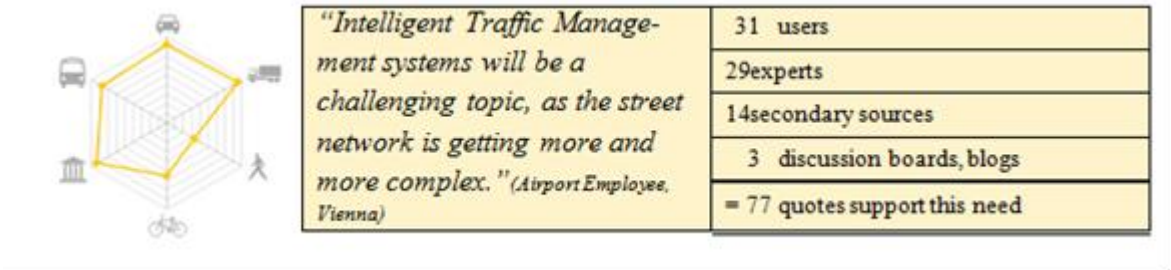

Fig. 6: Need for Traffic Coordination (own contribution)

Due to rapidly changing traffic conditions it is getting important to communicate on-site information as quickly as possible. Improved traffic management is essential for a better coordination of traffic participants. A reason for this is the constantly rising number of cars. Furthermore, the local situation in different cities should be taken into account when thinking about the management of traffic. The importance of this need is reflected by the fact that it affects all inhabitants of cities, such as pedestrians, cyclists, car drivers, logistic companies as well as public transport and the government. Therefore the need for better traffic management received the highest relevance.

Drivers are frustrated by a discontinuous traffic flow since time is getting more and more important in today's world. Also, logistic and service companies providing cities with goods and fulfilling important tasks lose time and money if the traffic management is poor. Especially emergency and breakdown services need to move fast from one place to another. Pedestrians and cyclists are also affected, as red traffic lights and traffic congestions slow them down as well. Thus, all traffic participants ask for coordination mechanisms which immediately adapt to changes. Therefore, also the government is interested in solutions to this need. A good and adoptive infrastructure for everyone is essential in order to assure a high quality of life in big cities.

Besides, parking is another important issue influenced by traffic management. Drivers looking for a parking space reduce speed and block other traffic participants. Therefore, better information on the availability of parking is also required.

6.3 Need for Inter-modality of Transport Means

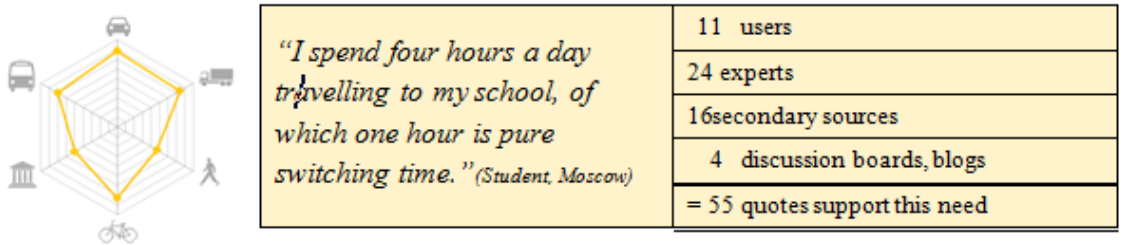

Fig. 7: Need for Inter-modality of Transport Means (own contribution)

Integrating various–public and private–transport modes and in turn minimizing the time spent both on travelling and changing means of transport was the idea behind intermodality. This need received the highest relevance of five out of five points and is relevant to all participants. However, we considered governments, public transport, private drivers and logistics service providers to be most affected.

As road networks become more congested, other various modes of transport will need to take an increasing role. It is important to help people to switch between private and public transport; therefore, a better link between these two is necessary.

Since travel distances are increasing in megacities, it is not possible to get to the destination using only one mode of public transport. However, those different modes are often not synchronized or not well planned - this can prevent people from getting where they want as fast as they could if everything worked smoothly. As several users expressed during the research, people are "... not going to use public transport instead of ... [their] car unless it is as convenient." Hence, an optimal integration of various transport modes should provide a complete door-to-door service for customer, because people do not like changing transport modes. They want to minimize time they spend on that and do not want to lose a single minute waiting for transport.

Intermodality can basically split up into four main demands: Firstly, traffic systems should be comprehensive. In concrete terms, travellers require a complete door-to-door service in form of one integrated system for all modes of transport. Secondly, schedules should be integrated, more flexible and aligned to allow reducing time. Thirdly, simplicity is important: people do not want to spend time thinking about which combination of transport to use, but rather demand a predefined solution. Finally, seamless switching options are important in order to provide barrier-free and time-efficient movement between transport modes.

People want convenient (parking) solutions in case they have to use their cars or bicycles to get to remote public transport stations that are not in walking distance from their homes. All of the above should be managed in order to increase public network attractiveness.

6.4 Need for Bridging the Last Mile

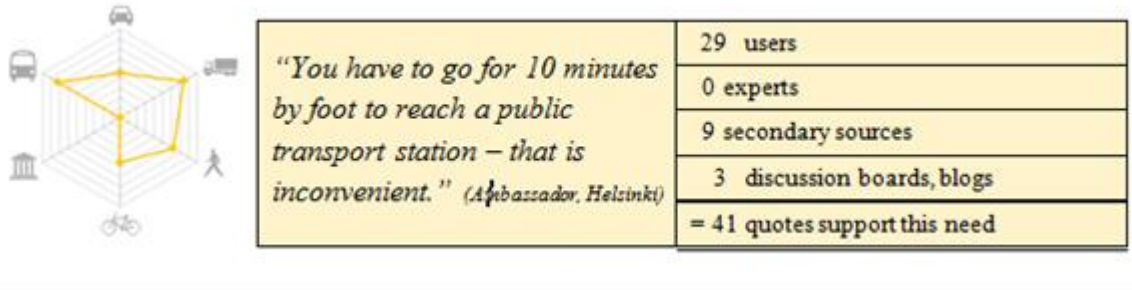

Fig. 8: Need for Bridging the Last Mile (own contribution)

The "last mile" need describes the need for more convenient and more efficient movement of people from a transport hub to their final destination. The need received a relevance of four out of five. Especially inhabitants of suburban areas and people facing physical difficulties are affected.

People are unwilling to walk long distances between transport stations and targeted final destinations, primarily due to personal safety and time issues. These issues are important for people who experience health issues or face the physical difficulty to carry different goods on their own. Also, the question of covering the last mile is especially acute where land-use patterns have moved more jobs and people to suburbs with a lower population density. These regions are often not within walking distance to existing public transportation options. Transit use in these areas is often less practical which in turn promotes either a reliance on cars resulting in more traffic congestion and pollution, or forces people to change their place of residence and move to a convenient, but more expensive area.

Traditional issues connected to the "last mile" need in public transit include the lack of feeder buses, of improved bicycling infrastructure as well as of an urban planning reform:

- Lack of biking infrastructure and bike-sharing solutions

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

Biking is increasingly being looked at as an important mean to connect people to the network of transit systems. Efforts should include improving bike infrastructure such as creating dedicated bike lanes and building bike stations at transit hubs, encouraging employers to provide shower facilities and other bike friendly amenities, as well as effective highly adaptable bike sharing programs.

- Lack of adequate planning-based solutions

"Last-mile-barriers" could be eliminated by locating housing close to transit and providing other transit incentives.

- Lack of shuttles and feeder buses

Shuttle services that connect transit with commercial centres and/or places of employment could help overcome the "last mile" barrier.

During the next phase (=identification of suitable problem solvers within the trend fields) more than 600 people were directly contacted in order to find the most suitable lead users and experts. The communication media ranged from phone and Skype calls (approximately 700) to emails (roughly 300) and forum entries (about 100). Out of a total of 617 people as many as 110 people were interviewed at least twice, 39 lead users and experts were regarded as "perfect fits", and in the end 27 of them were invited for innovation workshops.

7 CONCLUSION

In the course of three workshops with nine lead users and experts participating at a time, nine innovative concepts were finally presented:

7.1 The Hive

The HIVE system (Humans use Information to choose Vehicles to travel in an Environmentally friendly way) allows traffic participants to adapt to special needs of the various traffic situations on the basis of information gathered via car2car communication.

7.2 JA–the Journey Assistant

JA is a software-program which allows its user to personalize his/her journey. Offering various journey opportunities to the latter, it does not only combine the different modes of transport, but also integrates the opportunities of the whole city into one system. Due to its self-learning intelligence it is able to adapt to the user's preferences.

7.3 E-chair

The e-chair, a small electric vehicle, serves its user to cover the last mile and longer walking distances within the city. Due to its shape and an integrated system which communicates with the environment, it allows the user to drive on walkways or crowded areas.

7.4 The HUG

Several interchange points, big hubs, will be implemented in each city. Each passenger will be connected to a traffic system which allows the passenger to opt–depending on the purpose of the journey and other important facts as the weather–for a personalized vehicle which brings him/her to the interchange point closest to his/her final destination. This hub station provides for further individualized vehicles to cover the last mile.

7.5 Why not Number One

"Park Now" or "Why Not Park Number One" is utilizing existing Kapsh ITS technology for optimizing the parking situation in a city. A central system is aware of space available in parking lots as well as the parking costs and will automatically lead the cars to the free parking lot closest to the driver's final destination.

7.6 Star egg vision

Traffic participants can become members of a traffic community. A Smart-phone app allows them to enter their upcoming journey. A dynamic system matches the needs of all members and suggests the most efficient journey and possible collaborations with others for each user.

7.7 S³

The goal of the S³ system is to provide open, reliable real-time traffic information for users and systems. S3 helps to better coordinate traffic in a city and will make transportation more convenient and time-efficient.

7.8 Move your Black Box Information System

Move your Black Box Information System is a system that helps optimizing an individual's route and the traffic flow at the same time by merging information on public and private transportation which can be gathered by implementing sensors on the road. Intermodal transportation solutions, time-efficient locomotion and the reduction of congestion shall form the positive output of the system.

7.9 Free Move–Move Free

This concept addresses the problem of inefficiently used road space resulting from rigid traffic management. Rather than offering an innovation to an existing infrastructure frame and rules, FreeMove innovates the frame itself. Traffic rules should be adapted to the needs of a user.

Implications of Land Use Mix on the Sustainability of African Urban Centres: A Case Study of Stellenbosch, South Africa

Walter Musakwa, Adriaan van Niekerk

(Dr Adriaan van Niekerk, Stellenbosch University, Chamber of Mines Building, Cnr Merriman Avenue and Rynveld Street, Stellenbosch, avn@sun.ac.za)

1 ABSTRACT

Sustainable development has emerged to guide land use management in most cities yet it is an elusive concept to put into practice. Most African urban centres employ the ubiquitous advocacy-based indicators which dominate sustainability programmes and hinder sound decision making. Moreover, there is paucity in research that investigates land use mix and its impact on urban sustainability in African urban settings. Land use mix is of particular importance given Africa's history of fragmented spatial planning. This paper investigates the use of earth observation data to derive a land use mix index (LUM) and to calculate land use frequency (LUF). It proposes the use of decision consequence analysis as a simple way to put sustainable land use planning into practice and to support day-to-day land use decisions. A model that computes the land use mix and LUF was developed using ArcGIS 10. The results demonstrate that the use of decision consequence analysis, earth observation data, LUM and LUF can aid local planning authorities to go beyond descriptive analysis of urban sustainability to a more robust and objective analysis. Local planning authorities can also use the land use mix index and LUF to effect policy change on sustainability and for day-to-day decision making.

2 INTRODUCTION

Sustainable cities are high on the development agendas of many nations, but are of particular importance in African countries that are experiencing alarmingly high rates of urbanisation (UN-HABITAT, 2009; Shen et al., 2010). Rapid urbanization often leads to land use practices that disregard future needs and cause inevitable problems such as; urban sprawl (Breheny and Batey, 1992), brownfields (Burton, 2000), sedimentation of watersheds (Farrow and Winograd, 2001), urban pollution (Brandes et al., 2010), overcrowding (World Commission on Environment and Development (WCED), 1987), increase of natural and man-made risks (World Bank, 1994), collapse of public services (UN-HABITAT, 2002), soil degradation (Sattler et al., 2010) and haphazard development (Hicken, 2009), often leading to the consumption of natural landscapes needed for urban parks and recreation (Barredo and Demicheli, 2003; UN-HABITAT, 2002).

3 SUSTAINABLE DEVELOPMENT AND LAND USE PLANNING

Sustainable development is a fuzzy concept (Winograd and Farrow, 2007) encapsulated in the seminal definition by the Bruntland Commission as "Development that meets the needs of the present without compromising the ability of future growth to meet their own needs" (WCED 1987, p 23). It follows that for urban land use to be sustainable it has to meet the needs of the current as well as future urban citizens (Seghezzo, 2009; Wolf and Meyer, 2010). Accordingly, cities should be able to sustain the call by today's citizens to alter land use without jeopardising the future generation's needs. Sustainable development and urban land use planning are noble concepts (Hall, 2010), but the challenge is to put them into practice. Ideally, they should be incorporated into a comprehensive decision framework to guide daily, personal, business or policy decisions (Hall, 2010; Ness, 2001). These grand intentions are, however, difficult to monitor and implement given their complexity, vagueness and, at times, immeasurable tenets (Zhang et al., 2011). Sustainability often remains a condition that can be used and abused by various stakeholders without clearly defining what it implies in a land use planning context (Hall, 2010). What is required is a model of sustainable development which accurately captures and allocates costs, such as environmental damage, pollution and land consumption. Decision consequence analysis (DCA) can assist in simplifying the complexities associated with sustainable land use management.

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)

4 DECISON CONSEQUENCE ANALYSIS

DCA formalises the decision-making process by making use of decision theory, probability and statistics (Hall, 2010). The process breaks down complicated problems, such as sustainable development and land use, into increasingly smaller units until the particular component can be accurately analysed and understood within the context of the overall problem. The basic elements of DCA are an unacceptable current condition and a desired future condition. To achieve a transition between these two it is necessary to have an understanding of each condition, to identify possible pathways between the two and a way to measure the progression between them.The current action trigger in most African cities and towns is the high rate of urbanisation which leads to unsustainable land use practices (Klosterman, 2001). The challenge is how to measure or diagnose progress between the current state and the desired state (objective) of maintaining sustainable land use practices. A proposed solution is the employment of objective metrics developed using geographical information systems (GIS) and data collected with earth observation methods.

5 EARTH OBSERVATION

Campbell (2006) defines remote sensing of the earth's surface (earth observation) as the practice of deriving information about features on the earth's surface using images acquired from an overhead perspective. Earth observation has the capability to provide a quick synoptic view of a city and is consequently extremely valuable for collecting information in developing countries were municipal records are seldom able to keep pace with the rate of development (Hall, 2010; Repetti, Soutter & Musy, 2005). Earth observation also uncovers aspects of the built environment that are often opaque to urban planners and social scientists (Bar and Ford, 2010) and has been used in sustainability studies as a data source for indicator development (National Academy of Sciences, 2003). These indicators include land use/cover (Barredo and Demicheli, 2003), road networks (Victoria Transport Institute, 2010) and building density (Angel, 2010). It is difficult, time-consuming and prohibitively expensive to collect such data by other means (e.g. field surveying) (National Academy of Sciences, 1998).

6 SUSTAINABILITY INDICATORS

Sustainability indicators are bellwether tests of sustainability and they reflect something basic and fundamental about the long-term economic, social, and environmental health of a community (Maclaren, 2004). Such indicators are pointers toward progress or lack of the overall health of a community, neighbourhood, town, city, region or larger area and must reflect the overall well-being of urban land use, should be integrating, forward-looking (Maclaren, 2004), distributional, and subject to feedback loops (Hall, 2010). Examples include (1) land use change (Wang, Cheng and Chen 2011), (2) land use mix (LUM) (Song and Rodriguez, 2005) and (3) land use frequency (LUF) (Guindon and Zhang, 2005). Employing such indicators replaces the ubiquitous advocacy-based approaches which dominate the sustainability programmes in Africa and hinder sound decision making.

Land use change is an important indicator in urban sustainability as it measures the rate of transformation of mostly agricultural and natural ecosystems to intensive urban uses (Wang, Cheng and Chen, 2011). It has been demonstrated that a high rate of land use change due to urban growth leads to increased motorised transport (Victoria Transport Institute, 2010), energy consumption (Urban Land Institute, 2010), loss of agricultural land (Comber, Brunsdon and Green, 2006), loss of biodiversity (Yang et al.; 2009) and increased water pollution (Zhang et al., 2011). Similary, the impact of LUM on urban sustainability has been demonstrated by Song and Rodriguez (2005). The land use mix index is based on the principle of people moving between different activities or different destinations such as home to workplace or shops, and home to civic institutions such as places of worship and parks (Litman, 2010; Polzin, 2006). The LUM index is consequently a measure of variation (Song and Knaap, 2005), dispersion or diversity of land uses (Neat GIS Protocols, 2010). The equation for the LUM index is:

$$= \{-\Sigma_k[(p_i)(ln\, p_i)]\} / (ln_k)_k$$

Where is the proportion of each land use class per neighbourhood; is the natural logarithm; and is the number of land use classes. Essentially, the LUM measures the extent to which land uses are heterogeneously distributed within a neighbourhood (NEAT GIS Protocols, 2010). The index values range from zero to one where 0 indicates land use homogeneity, which is less sustainable, while a value of 1

represents heterogeneity which is more sustainable (Song and Rodriguez, 2004). The LUM can be global (GLUM) and local (LLUM), where the GLUM is a measure of the overall mix of a city or town while the LLUM shows distributin of the LUM within neighborhods of a city. Ultimately, the land use mix affects sustainability through its impact on environmental, social and economic costs (Figure 1).

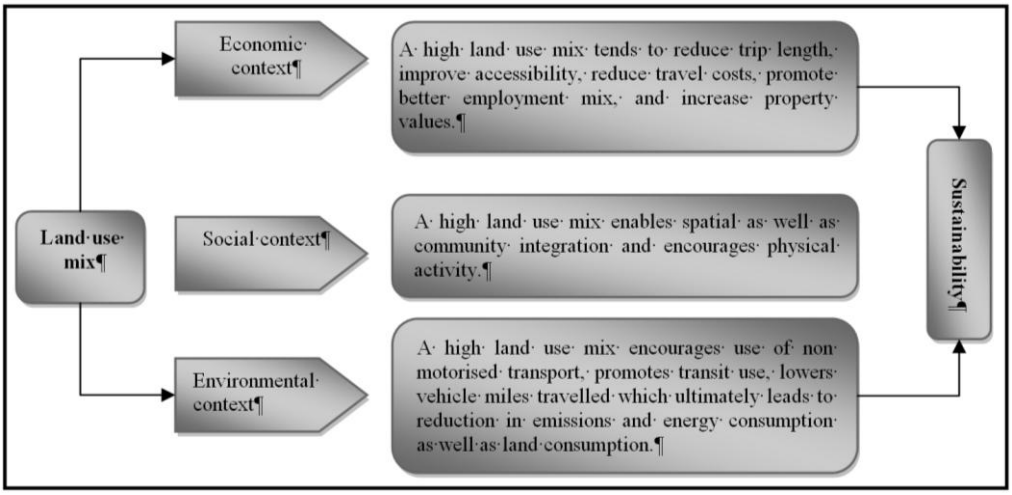

Fig. 1: Impact of land use mix on urban sustainability.

Alternatively, land use frequency refers to the number of land uses found in a neighbourhood or city. It is analogous to having a variety and complimentary of land sues such commercial, residential, education and recreation within a neighbourhood (Song and Rodriguez, 2005). Similar to the land use mix index, land use frequency has perceived social, environmental and economic impacts.

7 METHODS

Study area

Stellenbosch, the second oldest town in South Africa, was chosen as study area. The town is situated in the Western Cape province of South Africa approximately 55 km east of Cape Town's central business district According to Interstudy (2009), Stellenbosch has an estimated population of 60 000 of whom 27 700 are students (Stellenbosch University, 2010). Stellenbosch consists of suburbs of great wealth coexisting with impoverished townships, informal settlements and poor households. Consequently, Stellenbosch faces the challenge of balancing urban and economic growth against expansion into and consumption of valuable agricultural land, and the preservation of natural and cultural heritage while simultaneously attempting to alleviate abject poverty.

Data collection, land use mapping and analysis

Ortho-rectified colour aerial photographs and cadastral data of Stellenbosch where obtained from the Centre for Geographical Analysis (CGA) for 2000 and 2010 respectively. SPOT5 imagery for 2010 was acquired from the South African National Space Agency (SANSA). A land use map of 2000 was obtained from Dennis Moss Partnership. A land cover classification was performed on the 2010 SPOT5 imagery, using a supervised Geographical Object-Based Image Analysis (GEOBIA) approach. The resulting land cover map was visually interpreted along with ancillary data to develop a land use map. Land uses were classified per land parcel in ArcGIS 10 by means of a land use classification rule set which was adapted from Anderson et al.'s (1976) land use classification scheme.The land use maps of 2010 and 2000 were used to calculate GLUM, LLUM and LUF indexes. The latter two indexes were calculated for neighbourhoods 2x2 km in size. This neighbourhood size was selected as they correspond to actual land use development patterns and are sufficiently large for use of none-motorised transport and automobile use (Ewing and Cervero, 2001). All analyses were automated in the model builder tool of ArcGIS 10.

8 RESULTS AND DISCUSION

Land use mix index

The GLUM index for Stellenbosch is relatively high, registering, 0.74 and 0.72 in 2000 and 2010 respectively. The high global land use index value suggests heterogeneity in land use patterns as well a surge

toward spatial integration of land uses in Stellenbosch. The high value denotes a high level of social integration and the index functions as a proxy for the vibrancy of the civic life in the town. Given South Africa's spatial policy which is geared toward integrated development, the GLUM index can be used as a measure of spatial as well as social integration.

Unlike the GLUM index, the LLUM index is a breakdown of the global index. Figure 2 shows that some areas in Stellenbosch have higher LLUM index values and that there is a band of relatively low LLUM (less than 0.6) stretching from the south-western (near Technopark) to the eastern parts (in Uniepark) of Stellenbosch. This band of low LLUM suggests a lack of diversity in land use and spatial dispersion of land uses and these have adverse social, environmental and economic costs which hamper sustainable development. In the north-eastern parts of Stellenbosch, spesifically suburbs Welgevonden, Khayamandi, La Colline and Onder Papegaaiberg, the land use mix index rises above 0.6 suggesting diversity of land uses which minimises economic, social and environmental costs.

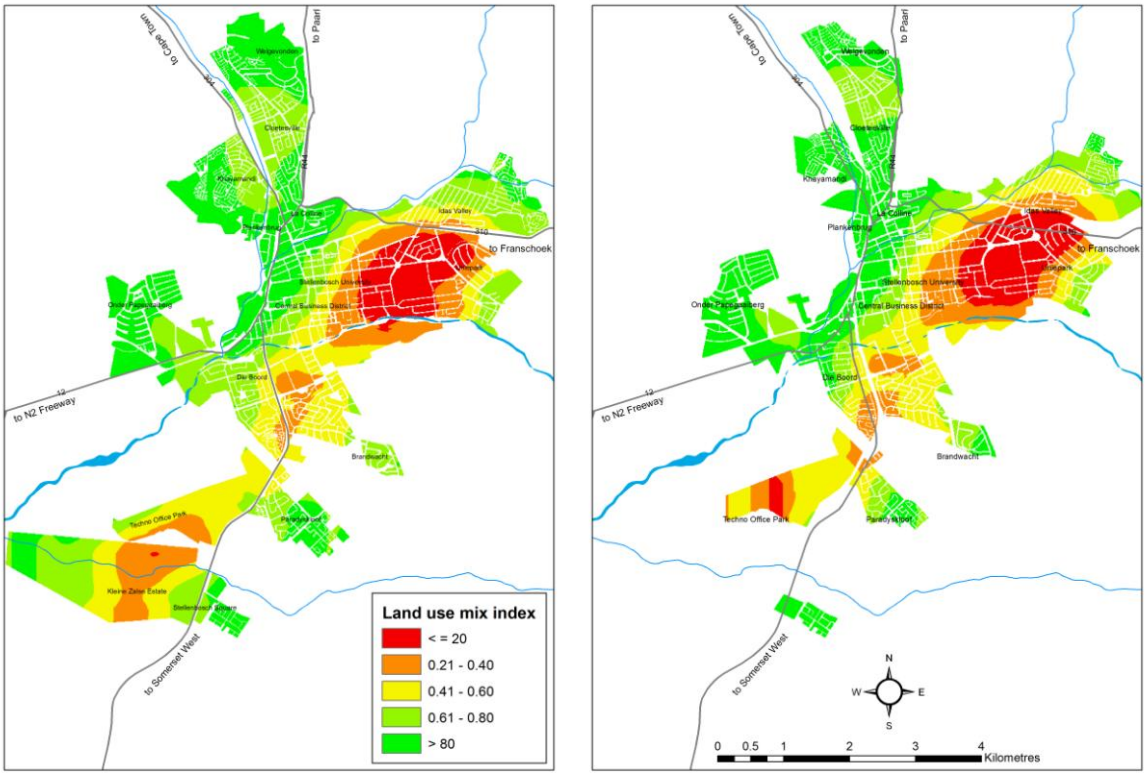

Fig. 2: Distribution of land use mix index values in Stellenbosch, (a) 2000 and (b) 2010.

Over the ten year pereid the change in the LLUM is minimal, however most changes occurs in the urban edges, near Stellenbosch Square in the south and Welgevonden in the North, which could potentialy indicate urban sprawl. Analysis of the change in LLUM can assist planners and decisions makers to implement local planning policies that encourage mixing of activities. Inspection of the LUF per neighbourhood portrays how LUF affects the LLUM.

Land use frequency

The map of LUF for Stellenbosch shows an intensification in the land uses from 2000 to 2010 (Figure 3). There is a band of low LUF per neighbourhood stretching from Technopark, Paradyskloof to the southern parts of Stellenbosch with fewer than nine land use classes per neighbourhood in 2000. This band dimisishes in intensity in 2010 with a general increase in the number of land uses noticable in the southern parts of the town. However, this increase can be partly attributed to the addition of Kleine Zalse Estate and the Stellenbosch Square shopping centre development, which had a positive effect on LLUM in the southern parts of Stellenbosch.

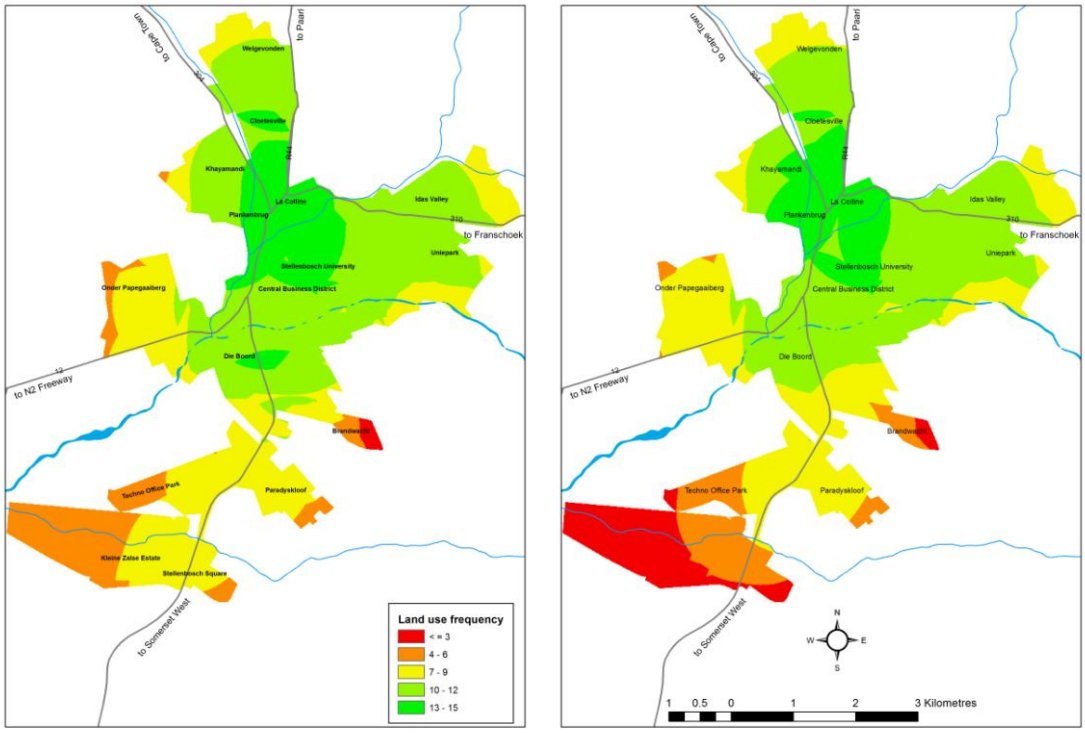

Fig. 3: Land use frequency distribution in Stellenbosch, (a) 2000 and (b) 2010.

Low LUF does not necessarily correspond to a low land use mix. For example, neighbourhoods abutting the Central Business District have a LUF of between 10 - 12 due to land use gentrification as a consequence of the change to greater mixed use comprising commercial and residential uses, yet those central neighbourhoods exhibit LLUM index values of 0.6 or less. In contrast, neighbourhoods abutting Welgevonden in the north experienced an intensification of LUF over ten years accompanied by an increase in the LLUM from 0.3 to 0.8. Similary, the LUM in southern parts of Stellenbosch changed as a result of the new commercial (Stellenbosch Square) and cluster housing (Kleine Zalse Estate) developments where the LUM mostly registers values of 0.6 or less. LUF and the LUM are correlated closely although an increase in the LUF does not necessarily equate to an increase in the LLUM. The LUM and LUF are objective, but they cannot be used in isolation as they cannot indicate areas where urban sprawl is potentially occuring particulary around Stellenbosch square in the south and Welgevonden in the north.

9 CONCLUSION

The study has demonstrated that the LUM and LUF are essential indicators in descring the mix of land uses which is a crucial factor in acheiving urban sustianability. The LUF and LUM allow planners to advance from basic descriptive sustainability reports, which can be subjective and rudimentary, to more robust objective assessments which can be actively applied in decision making. Moreover, these indicators aid in the identification of best practices which can be replicated elsewhere.Though the LUM and LUF are objcetive they fall short in identifying urban sprawl as such they should not be used alone. Both earth observation and DCA make it possible to put the elusive concept of sustainable development into practice to make day-to-day planning decisions or effecting policy changes.

1 KURZFASSUNG

Zu Beginn wird auf die zunehmende Bedeutung der Bürgergesellschaft an partizipativen Beteiligungsverfahren in der nachhaltigen Stadt- und Siedlungsentwicklung verwiesen sowie auf die Probleme der Kommunikation zwischen Experten und Laien im Bereich der planenden Disziplinen kurz eingegangen. Anhand der Darstellung heute verfügbarer Informations- und Kommunikations (IuK)-Technologien wird die potentielle Eignung der Augmented-Reality (AR)-Technologie für Kommunikationsprozesse im Bereich der Baukultur hergeleitet.

Anschließend wird dargelegt, welche Zielestellungen in dem Forschungs- und Entwicklungsprojekt ArchKM-AR formuliert wurden, um einen anwendungsreifen AR-Prototypen zu erstellen, der von Laien und Experten gleichermaßen nutzbar ist. Die dafür notwendigen Arbeitsschritte, mögliche Anwendungsszenarien sowie ein Ausblick beschließen das Papier.

2 HINTERGRUND UND PROBLEMSTELLUNG

Partizipative Beteiligungsverfahren sind eine Bereicherung in Entscheidungs- und Planungsprozessen der Stadtentwicklungsplanung um wichtige Fachkompetenzen, um Meinungen, Ideen und Kreativität. Die Meinungs- und Interessenäußerungen sowie die Bewertungen durch die teilnehmende Bürgerschaft sind dabei Ausdruck politischer Teilhabe als Voraussetzung einer funktionierenden Demokratie. Sie verschaffen Entscheidungs- und Planungsprozessen im Idealfall nicht nur die nötige Akzeptanz, sondern sind ebenso wichtige Grundlage für ihre konsensfähige Durchsetzbarkeit.

Die Bundesstiftung Baukultur erklärt das Planungs- und Bauwesen zum „sichtbaren nationalen Markenzeichen, mit dem die Bürger sich identifizieren, das Lebensqualität steigert und attraktive Städte und Gemeinden sichert." (SCHADE-BÜNSOW, 2009). Wird dieses Ziel erreicht, gelingt eine nachhaltige, langfristig stabile Stadtentwicklung.

In den aktuellen Diskussionen um Baukultur zeigt sich, dass das öffentliche Interesse an ihr steigt–und dass die Meinungen darüber zum Teil recht weit auseinander liegen. Gründe dafür liegen im divergierenden Verständnis sowie in der unterschiedlichen Wahrnehmung von Architektur- und Gestaltqualität bei Laien und Experten. Was aus dem unterschiedlichen Wissen über Architektur und Baukultur, und ebenso aus den Unterschieden von Fachsprache und Alltagssprache resultiert. Dabei zeigen Untersuchungen, dass eine Vereinheitlichung der sprachlichen Kodierung dazu beiträgt, die Barrieren in der Experten-Laien-Kommunikation zu überwinden. Möglich wird sie, wenn die Vermittlung von Wissen und Informationen von der verbalen hin zur visuellen, bildlichen Darstellung verschoben wird. Insbesondere sehr realistische, d.h. perspektivische Darstellungen in Malerei und Fotografie entsprechen weitgehend der Wirklichkeit und rufen damit ein hohes Maß an Verständnis hervor (Pohl, 2003).

Zum anderen ergibt sich ein unterschiedliches Verständnis von Gestaltqualität und Baukultur aus dem sinkenden Vertrauen in die Gültigkeit der Urteile und Ratschläge von Experten (Bromme & Rambow, 1998)–verursacht u.a. durch die stetige Diffusion der Grenzen zwischen wissenschaftlichem Wissen und Alltagserfahrung (Bromme u. a., 2004). Als Katalysator dieses Prozesses entwickelten sich in den vergangenen Jahren die modernen Informations- und Kommunikationstechnologien (IuKT). Sie ermöglichen die stetig erleichterte Aneignung von Wissen, so auch Expertenwissen, und damit eine Expansion von technischem und naturwissenschaftlichem Wissen in Richtung der Laien.

So verhält es sich auch in den planenden Disziplinen. Hier führte die Einführung rechner- und informationsgestützter Werkzeuge zur Erweiterung des zweidimensionalen Zeichnens über die dreidimensionale Konstruktion von Gebäudemodellen hinaus, bis zur Berücksichtigung weiterer planungsrelevanter Dimensionen bzw. ergänzender geometrischer und semantischer Informationen (BIM = Building Information Modeling).

Die Neuen Medien und Technologien leisten daher heute bereits wichtige Beiträge zur Architekturkommunikation und befördern Entscheidungs- und Planungsprozesse. Konkrete Anwendungsfälle aus den Bereichen Virtual Reality (VR) und Web 2.0 haben dies in der Vergangenheit bewiesen (OKUPE, 2007) (BURG, 1999).

Unter der Betrachtung der stetig wachsenden Medienkompetenz der heutigen Informationsgesellschaft (STATISTISCHES BUNDESAMT, 2011) und der zunehmenden Verbreitung intuitiv zu bedienender und weitgehend barrierearmer Endgeräte, wie Smartphones und Tablet-PCs, wird daher die Frage aufgeworfen, welche innovativen Technologien den positiven Trend zur bürgergesellschaftlichen Beteiligung an partizipativen Prozessen zusätzlich unterstützen und damit zur Stärkung von Zivilgesellschaft und nachhaltiger Stadtentwicklung beitragen können.

Andere Branchen, wie die industrielle Fertigung oder die Computerspielindustrie, sind den planenden Disziplinen dabei in technologischer Hinsicht voraus. Sie setzen verstärkt auf Virtual- (VR) und insbesondere Augmented-Reality-Systeme (AR), die nicht nur komplexe räumliche Daten verarbeiten können, sondern zudem multimodale Eingabemöglichkeiten vorhalten. Hierfür wurden bereits Prototypen entwickelt (BEUCHERT, 2010). Insbesondere die AR-Technologie bietet für den Bereich Architektur und Städtebau ein weites Anwendungsspektrum, verfügt sie doch aufgrund technischer Voraussetzungen über die Fähigkeit, auf Basis der Bildverarbeitung Kommunikationsprozesse im Sinne einer nachhaltigen Planungspolitik zu vereinfachen und zu beschleunigen. Dort bleibt sie jedoch bis dato weitgehend ungenutzt.

Im Projekt sollen die fachlichen Grundlagen zur Entwicklung einer AR-Software für diese Zwecke praxisnah erfasst und analysiert werden. Das Vorhaben evaluiert über eine Statusanalyse und Expertenbefragungen aktuelle Methoden und Technologien im Bereich AR. Anhand der Vorarbeiten wird ein Konzept für den vorgesehenen Anwendungskontext eines AR-Systems erstellt. Im weiteren Verlauf erfolgen die Entwicklung neuer Softwarekomponenten, die Modifizierung und die Anbindung bestehender Programmkomponenten, sowie die Zusammenführung der einzelnen Bestandteile in einer praxistauglichen AR-Anwendung unter der Einbindung einer ergonomischen Benutzeroberfläche. Das Hauptziel besteht in der Entwicklung einer funktionsfähigen Augmented-Reality-Anwendung für mobile Endgeräte im Einsatzfeld der Baukultur: Städtebau und Stadtentwicklung fallen ebenso darunter, wie Architektur, Landschaftsarchitektur, Denkmalpflege und Archäologie. Darin soll sie der Exploration, Kommunikation, Kollaboration, Wissensvermittlung, Interaktion und dem Marketing förderlich sein. Als Zielgruppen wurden Laien und Experten im Themenfeld der Baukultur definiert. Weitere Ergebnisse des Forschungsprojektes sollen darüber hinaus Erkenntnisse und Empfehlungen zur Verwendung existierender AR-Autorensysteme hervorbringen. Die AR-Anwendung wird für mobile Endgeräte, wie Smartphones, Ultramobile-PCs, Handhelds etc., konzipiert und hergestellt.

3 ZIELSTELLUNG

Ziel des vorgestellten Forschungsvorhabens ist die Konzeption, Entwicklung und Erprobung eines Augmented-Reality-Prototyps mit vorwettbewerblicher Reife als Werkzeug der Exploration, der Laien-Experten-Kommunikation, der Partizipation sowie des Marketings in der Architektur und fachverwandter Disziplinen unter Nutzung aktueller Virtualisierungstechnologien sowie zur Verfügung stehender Datenschnittstellen und tangibler Benutzerschnittstellen.

Der Prototyp wird in seiner Entwicklung an gängigen mobilen Endgeräten wie Tablet- oder Ultramobile-PCs, also Geräten mit hinreichend großen Displays, ausgerichtet werden, die über alle notwendigen sensorischen Erfassungs- und Eingabesysteme verfügen (GPS, WLAN, UMTS, Kompass/ Beschleunigung, Kamera, Mikrofon etc.). Die Portierung auf PC-basierende Endgeräte birgt eine sehr niedrige Nutzungs- und Kompatibilitätsschwelle infolge der weiten Verbreitung des Standardbetriebssystems. Die zu verwendende feature-based Tracking-Technology ist hochinnovativ und bietet ein markerunabhängiges Erkennen von Raumgeometriedaten. In Verbindung mit den Datenquellen GPS-, Kompass- und Beschleunigungsmessung ist beim featured-based Tracking eine sehr hohe Registrierungspräzision im Außen- und Innenbereich zu erwarten, was der Darstellung zu einer sehr hohen Darstellungsgenauigkeit (Überlagerung synthetischer Raumdaten mit Realbildaufnahme) verhelfen wird. Zur effizienten Abwicklung kollaborativer Arbeitsprozesse wird der zu entwickelnde Augmented-Reality-Prototyp die Möglichkeit des photo-based Tracking vorhalten.

3.1 Erkenntnisziele

Das o.g. Vorhaben soll Aufschluss geben zu den Forschungsfragen:

- Eruierung der Möglichkeiten der Anbindung/Nutzung bestehender (mobiler) AR-Systeme
- Untersuchung des Imports von Planungsdaten aus derzeit genutzter Standardsoftware (CAD/GIS/etc.)
- Erhebung, ggf. Entwicklung von Planungsdaten-Schnittstellen sowie deren Evaluierung
- Ermittlung von Handlungsanweisungen/eines Leitfadens zur Nutzung von ARTechnologien für Experten und Laien; inkl. Ermittlung des Arbeitsprozess (Geschäftsprozessanalyse) und Dokumentation und Aufbereitung als Leitfaden anhand des entwickelten Prototyps
- Möglichkeiten der Entwicklung eines anwenderfreundlichen Prototyps, der hinsichtlich seiner Handhabung (inkl. Aufbereiten von Daten, Workflow) und Visualisierung-Qualität für die Praxis geeignet ist.

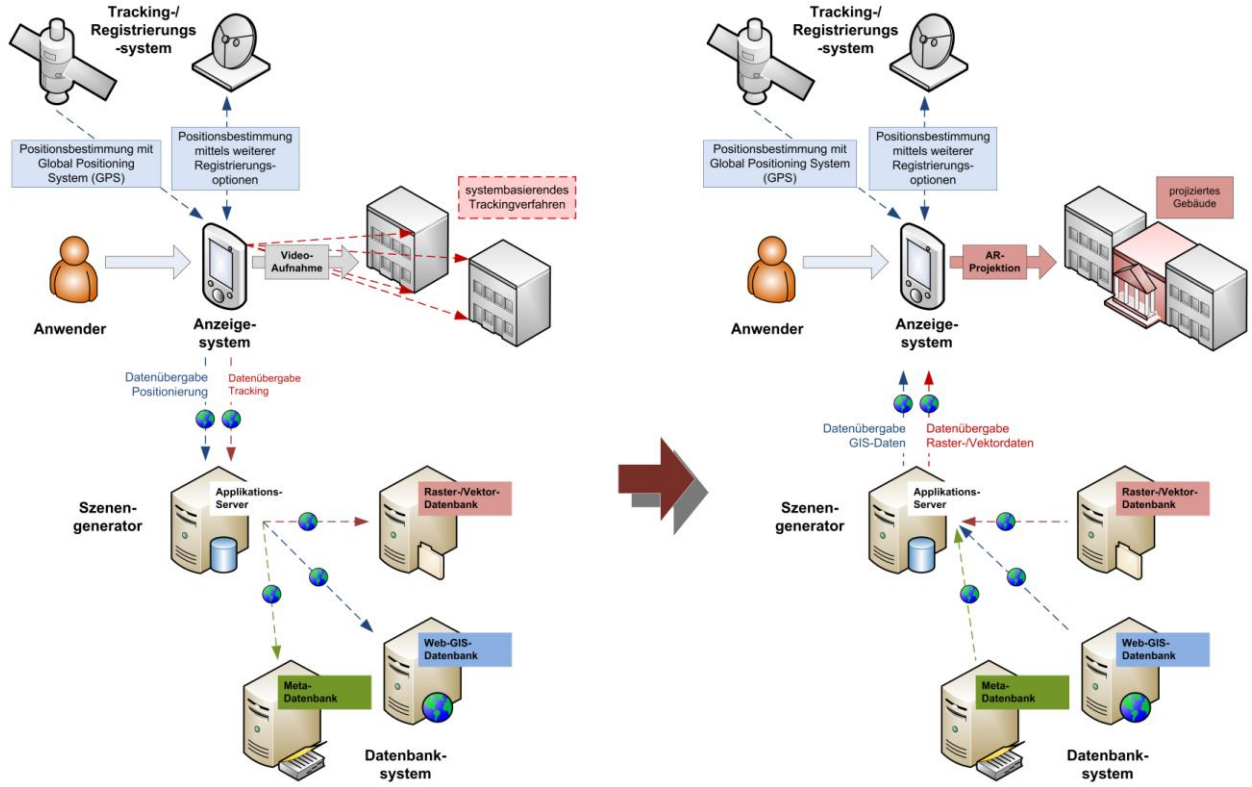

Fig. 1: Aufbau u. Funktionsweise eines AugmentedReality-Systems (Quelle: eigene Darstellung, nach (SCHILLING, 2008), S.9)

3.2 Innovationscharakter und inhaltlicher Nutzen

Der Innovationscharakter des Prototyps liegt in einer anwendungsreifen mobilen Augmented-Reality-Applikation auf Basis eines feature-based Tracking-Verfahrens, die sowohl für Experten als auch für Laien intuitiv benutzbar ist.Ein solches System existiert derzeit am Markt nicht und zahlreiche Forschungsvorhaben belegen den Stellenwert des Themas Augmented Reality als Werkzeug der Architekturvermittlung.

Der inhaltliche Nutzen besteht in der weitgehenden Sicherstellung einer barrierearmen/-freien Kommunikation und Kollaboration auf den Ebenen Laie-Experte, Laie-Laie und Experte-Experte in deren Folge die Verständlichkeit von Baukultur gefördert wird, damit die Motivation zur Partizipation (E-Partizipation als Bestandteil von E-Government und Web 2.0) an Planungsprozessen steigt und letztlich die Akzeptanz von Planungsvorhaben und Entscheidungsprozessen nachhaltig befördert wird.

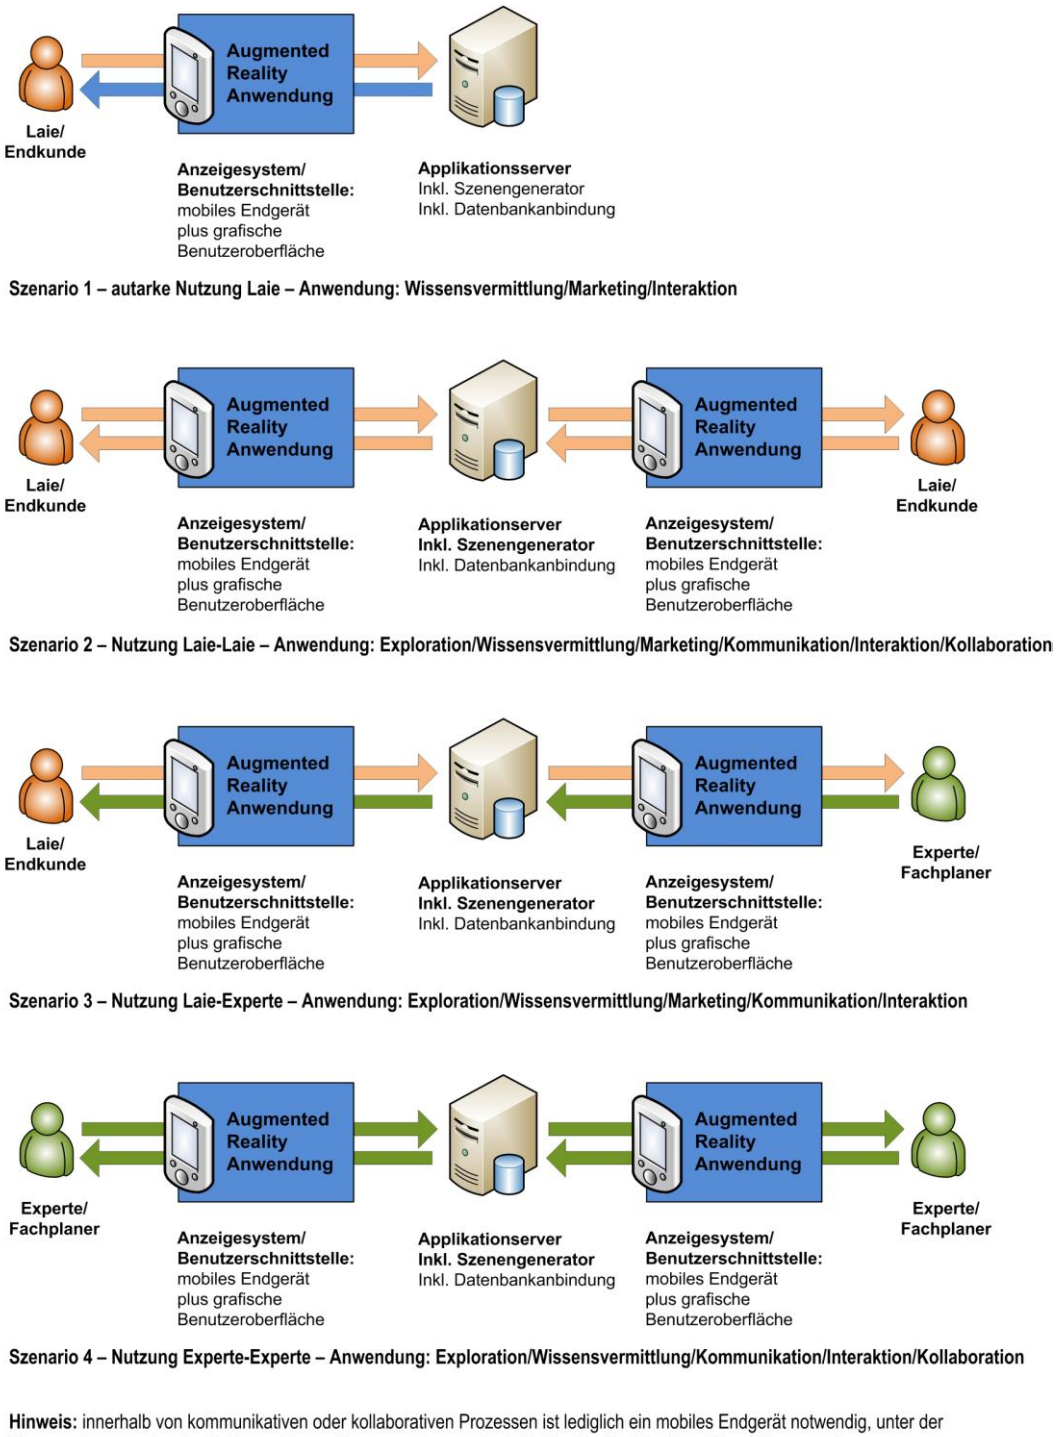

Fig. 2: Szenarien der Nutzung von AR-Systemen im Architekturbereich (eigene Darstellung, 2009)

3.3 Anwendungsszenarien

3.3.1 Architekturkommunikation

Ein Anwendungsfall ist die Bereitstellung von Planungen in Form von AR-Daten für Neubau- und Sanierungsmaßnahmen oder Wettbewerbsverfahren. So erhalten die Zielgruppen, wie Bürgerschaft, öffentliche Auftraggeber, etc., Zugriff auf Inforamtionen zu Planungsvorhaben und kann sich ein dezidiertes Bild vom zukünftigen Zustand des Planungsgebietes/-objektes verschaffen. Werden zusätzliche objektorientierte Modelldaten hinzugefügt, ist der Empfänger der Informationen in der Lage, sich ein eigenes Urteil zu bilden und dies interaktiv oder in angeschlossenen Beteiligungsverfahren kund zu tun. Dem Planer eröffnet sich so die Chance durch eine verständliche Sprache einen wichtigen Beitrag zur Baukultur zu

leisten. In Kommunikationsprozessen mit Planungspartnern kann AR als Werkzeug der Zusammenarbeit über Unternehmens- und geografische Grenzen hinweg zum Einsatz kommen. Augmented Reality hilft so in kollaborativen Arbeitsprozessen bei Planungs- und Bauvorhaben den wichtigen Kommunikationsaspekt hinreichend zu berücksichtigen und zu befördern.

Fig. 3: Anwendungsbeispiel der Nutzung eines AR-Systems im Architekturbereich (HOCHSCHULE ANHALT, 2012)

3.3.2 Denkmalpflege/Archäologie/Tourismus

Mit der Anbindung an Datenbanken internetbasierender Geografischer Informationssysteme (Web-GIS), an Wissens- und Informationsdatenbanken (zwei- und dreidimensionale Rasterbzw. Vektordaten) können mit Augmented Reality auf mobilen Endgeräten Informationen zu historischen, möglicherweise bereits verschwundenen Gebäuden oder Bauwerken zugänglich gemacht werden. Denkbar sind in dem Zusammenhang virtuelle Rekonstruktionen des kulturellen Erbes. So dass Ausgrabungsstätten geschont und tatsächliche Rekonstruktionen mit Rücksicht auf den Verlauf der Geschichte obsolet werden.

4 VORGEHENSWEISE

4.1 Themenkomplexe

Wegen des umfänglichen Themengebietes und der angestrebten Interdisziplinarität wurde das Vorhaben in vier Themenkomplexe gegliedert:

4.1.1 Kommunikation, Marketing

Dabei werden Aspekte der Kommunikationspsychologie in Kommunikationsvorgängen zwischen Experten und Laien bzw. innerhalb von Expertengesprächen untersucht.

4.1.2 Visualisierung, Interfacedesign

Es wird hierbei auf die Potentiale und Grenzen derzeitiger Visualisierungsmöglichkeiten in der Architektur und ihren fachverwandten Planungsbranchen fokussiert. Gemäß der Zielstellung und des geplantes Einsatzes von mobilen Endgeräten für AR-Systeme, werden im Sinne des anwenderzentrierten Projektansatzes Konzepte zur Ausformung ergonomischer, multimodaler Benutzeroberflächen (Interface-Design) entwickelt. Sie gewährleisten eine benutzerfreundliche und intuitive Bedienung, sowie die Möglichkeit interaktiver Eingaben in Echtzeit und des kommunikativen Austausches.

4.1.3 Augmented-Reality-Umgebung

Hierin wird sich der technischen Konzeption und Realisierung der AR-Umgebung zugewandt werden. D.h. alle serverseitigen Komponenten und Funktionalitäten des mobilen Endgerätes sind herzustellen; darunter zählen Tracking, Registrierung und die Sequenzgenerierung für die Interaktion in der erweiterten Realität (AR-Umgebung); Schnittstellen für Datenaustausch zwischen Endgerät und anderen Systemkomponenten, wie dem Applikations-Server, werden programmiert sowie die Benutzeroberfläche mit allen notwendigen Funktionalitäten für das mobile Endgerät hergestellt

4.1.4 WebGIS-Umgebung, Georeferenzierung, Standortinformationen

Ein zentraler Punkt der Anbindung synthetischer Daten an das AR-System besteht in der Herstellung von Georeferenzen über die Verknüpfung mit sogenannten WebGIS-Servern. Damit eröffnet sich die Möglichkeit der geografischen Verortung digitaler Daten und ebenso des Einbezugs weiterer Dimensionen (Zeit) und anderer Metadaten (geografische Informationssysteme und/oder Wissens- und Artikeldatenbanken, ggf. von Drittanbietern).

4.2 Projektphasen

Sämtliche o.g. Themenkomplexe durchlaufen gleiche oder ähnliche Projektphasen bzw. wissenschaftliche Arbeitsschritte, die der nachfolgenden Grafik entnommen werden können. Hervorzuheben ist die Statusanalyse deren Ergebnis ein Pflichtenheft ist, das konkrete Aussagen trifft zu:

- den einzusetzenden Technologien: Auswahl der geeigneten Trackingmethoden, Daten- und Protokollstandards (VRML, EDIFACT, WMS; WFS, GBF, SOAP etc.),
- zu entwickelnde Programmfunktionalitäten zur Administration der Systemkomponenten (Back-Ends) bzw. Anwenderschnittstellen (Front-Ends), zur Gestaltung der entsprechenden Benutzeroberflächen (Screen-Design),
- mzusetzende fachliche Methoden und Möglichkeiten der Interaktion und Kommunikation

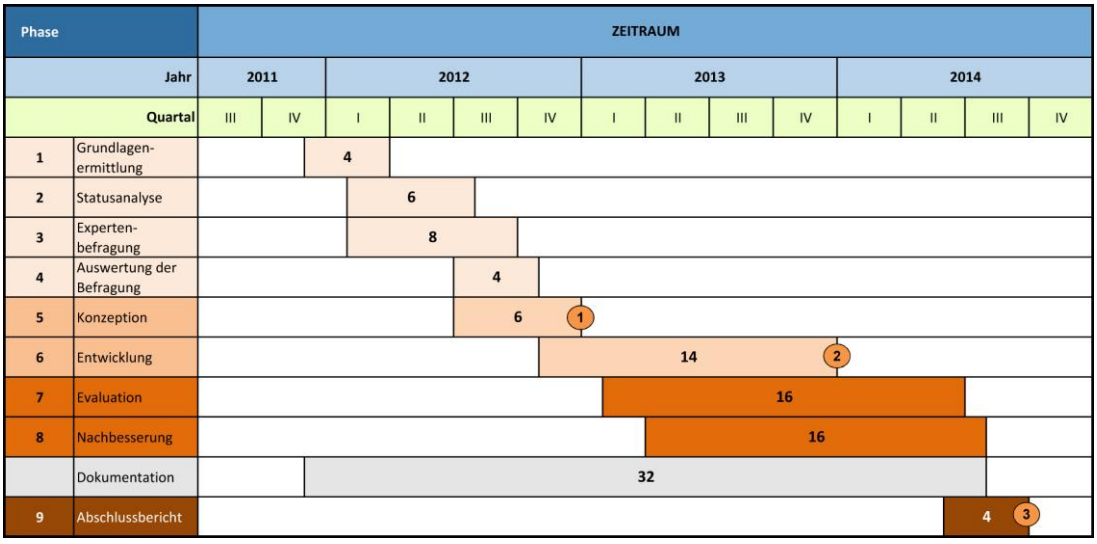

Fig. 4: Meilensteinplan für das Forschungsvorhaben (Quelle: eigene Darstellung, 2009)

5 AUSBLICK

Die wissenschaftlichen Ergebnisse des interdisziplinären Projektes werden zeitnah in die wirtschaftliche Entwicklungspraxis übertragen, so dass auf Grundlage der Vorhabenergebnisse gemeinsam mit den beteiligten Projektpartnern eine zügige Weiterentwicklung des Prototypen bzw. einzelner Komponenten angestrebt wird. Ziel ist die Entwicklung eines marktreifen Produktes. Ferner werden die beteiligten KMU ihr Produkt- bzw. Dienstleistungsportfolio auf Basis der Forschungs- und Entwicklungsergebnisse zum Zwecke der Vermittlung von Baukultur erweitern und anpassen können.

Im Mittelpunkt steht überdies der zukünftige Einsatz der innovativen Technik als Kommunikationswerkzeug innerhalb öffentlicher Beteiligungsverfahren sowie unterstützendes kosten- und ressourcenschonendes Instrument der Planungsvermittlung.

6 ERGÄNZENDE ANGABEN

Dieser Beitrag wurde erstellt im Zusammenhang mit dem Forschungs- und Entwicklungsvorhaben *AugmentedReality (AR) als Werkzeug der Architekturkommunikation und des Architekturmarketings– Konzeption, Entwicklung und Erprobung eines mobilen ARPrototyps für Planung, Beratung und Kommunikation in Architektur, Landschaftsarchitektur und Denkmalpflege (ArchKMAR).*

Das Vorhaben wird im Rahmen des BMBF-Förderprogramms Forschung an Fachhochschulen mit Unternehmen (FHprofUnt)

GEFÖRDERT VOM

Bundesministerium
für Bildung
und Forschung

7 KONTAKT

Das Forschungs- und Entwicklungsvorhaben ArchKM-AR ist ein kooperatives Projekt der

Fachbereiche 1 und 3 an der Hochschule Anhalt. Projektleitung: Prof. Dr. Claus Dießenbacher, Dipl.Ing. M.A. René Krug.

1 ABSTRACT

The project CircUse–Circular Flow Land Use Management is financed from the program CENTRAL EUROPE. Twelve partners are preparing the concept of Circular Flow Land Use Management, which represents an integrative policy and governance approach. This would presuppose a changed land use philosophy with regard to land utilization. Such modified land use philosophy can be expressed with the slogan "avoid–recycle–compensate".

To implement the CircUse philosphy the developing of action plans on a local level with the circular flow land use management concept included can be an appropriate way. Action plans have been initiated by the CircUse partners countries taking part in the project. An element of an action plan can be the development of institutional models or rather management structures–case studies will show ways to devolop such structures. Furthermore an initiated training course to circular flow land use management fosters awareness and implementation of the philosophy. The following text will give an overview of above mentioned activities which support sustainable land management.

2 ACTION PLANS TO CIRCULAR FLOW LAND USE MANAGEMENT

In general action plans represent a package of measures, which can contribute to promote more sustainable land use in our cities and regions. The action plans help to steer brownfield redevelopment and promote land utilization with specific focus on the new European funding period 2014-2020.

The project CircUse developed action plans in six partners countries to influence urbanised land governance, planning, information, organization, stakeholders´ co-operation, marketing of the inner development potential, funding and budgeting arrangements. These action plans have covered various scales of operation, ranging from a site-based plan to a regional plan. Plans were produced in English and in the local language, hence, partners can share on a transnational basis the experiences they have gained while preparing and negotiating their action plan. These plans demonstrate six various approaches to sustainable urbanised land use management with a common aim: more sustainable urbanised land use.

The integrated action plans for circular land use management of urban regions represent a package of measures which can be implemented or initiated locally. These have been prepared for the project pilot areas of the Ústí NUTS III region (CZ), for the Trnava microregion (SK), for the region of Voitsberg (AT) and for Middle Saxony (DE). They promote the increased use of existing urbanised land and contribute to brownfield redevelopment strategies. The packages of measures usually aim at reducing zoning for development of undeveloped land and exploiting the inner development potential of urbanised land. In addition, two other pilot areas have also prepared action plans but with different focuses. In Asti (IT) the focus of the action plan has been put on implementing a new tool, the Spatial Development Support System (SDSS), which will be tested on Asti's pilot case. In Piekary (PL) the focus falls on the selection and site specific planning with investments for the greening of a brownfield. The action plan is prepared for the district of Piekary, where the funding for the plan has been allocated. This plan includes measures for economic and social reactivation of the post-industrial district coping with all negative effects of the past with all the sites's constraints keeping it currently unusable.

The integrated land use management action plans for circular land use management are informal instruments which establish circular flow land use management on a short and mid-term basis. The plans result from discussions among stakeholders on the aims of land use policy and incorporate the outcomes from various analyses of existing local, regional and national governance instruments. Assessments of spatial and organisational shortcomings were also considered. These plans reflect the willingness of participating

stakeholders to work jointly on improving the sustainability of urbanised land use within their jurisdiction or interest area. The plans help to unify the interests of various local stakeholders and help to set up common goals, identify measures, and find funding sources which would lead to the fulfilment of the identified goals. Also the documents allocate responsibility and budgets for realising these measures. Such plans are normally closely linked with established instruments of formal and informal spatial planning. However, the action plans also list stakeholder responsibilities, aspects of organisational and management processes, as well as performance reviews and a time schedule for implementation.

Preparation of an action plan is a process which leads to specific packages of measures necessary for the short and mid-term timeframe to make progress towards accomplishing the policy aims of sustainable urban and regional land use. Integrated action plans are highly implementation-oriented. They cannot and should not replace current planning but instead the measures depicted in the action plans should be combined with spatially relevant formal and informal planning or existing sectoral planning and concept planning. One of the most important benefits of the action plans is that they provide a framework for transparency in decision making processes, a flow of information, and an improved communication structures.

The approach proposed is multidisciplinary, based on economic, social and environmental aspects: so the potential partnerships are high in number and importance. Such partnerships are moving towards a more strategic and collaborative approach, ensuring more intense relationships able to create additional value to the project. This shift represents an opportunity to maximize benefits for partners and citizens. This kind of approach is used for collaborative activities, including the development of interoperability, cross-sectorial participation and new opportunities offered by innovative solutions.

3 INSTITUTIONAL MODELS FOR CIRCULAR FLOW LAND USE MANAGEMENT

The success of circular flow land use initiatives is closely linked to the availability of adequate operators and financial tools to implement these policies. Given the fact that private initiative is limited, the creation of specific agencies is recommended. Even though land management is a main component of regular local government actions, the implementation of the circular flow land use management concept still needs a management structure. The creation of specific agencies could be an important tool to assure the delivery of a better public service in close relation with private stakeholders.

Over the years many different models for these agencies have been tested in Europe, with differing structures (100% public / 100% private / public-private mix); legal forms (private limited / private not-for profit / charitable etc. [1]); geographical boundaries (from site-specific to city / municipality, sub-regional or regional areas); and operational remits (from basic site remediation & recycling, through to responsibility for wider economic and/or social responses).

3.1 Management structures in Europe

Specific models for operators in Europe are the creation of development agencies, such as the legal structures of “Etablissement Public Foncier” in France and the “Land Restoration Trust” in the United Kingdom and the former regional development company North Rhine-Westphalia (Landes-entwicklungs¬gesellschaft Nordrhhein-Westfalen (LEG) (NRW-URBAN) with the “Grundstücksfonds in North Rhine-Westphalia.

The three selected case studies highlight innovative institutional solutions of circular land management on inter-municipal and regional level. They go beyond purely marketing or project-oriented approaches. Common features are:

- The main goal is a sustainable urban and regional development
- They are not based on individual projects or individual portfolios
- They prepare the development of problematic sites
- All institutions are not profit-driven and nor complementary and they are not competing with the private housing sector

[1] There is some debate as to how truly ‘private sector’ these agencies are. It is true to say that they are created by the state and the extent of their true independence is very often dictated by the prevailing structures of governance; however it is accepted that many do operate on a daily basis independently of other government/state agencies.

- They are dependent on the close cooperation of local authorities
- They have access to ongoing public funding programs (eg. from ERDF), which remain unchanged
- They are set-up as "interdisciplinary teams" where, alongside the planning qualifications, qualifications for environmental remediation, legal, administrative and financial sciences are also involved

3.2 Development of management structures in the CircUse project

The development of this management structure could be also part of a regional CircUse action plan (see above). Such a structure should have defined competences, a business agenda and a mission statement that matches the regional development plan. These tasks can be either fulfilled by an already existing or by a newly established organisation. Both approaches have their pros and cons. In the CircUse project both models will be tested–because it developes innovative agency models in the Silesian region in Poland and the region Voitsberg in Austria.

In the City of Piekary in Poland, circular flow land use management objectives will be implemented through the existing Piekary Śląskie Industrial and Technological Park EkoPark Ltd. (short term: Ekopark) organisation. This organization in Piekary will be used to implement a new land management function. The aim of the CircUse activities in Piekary is the start of operations for the management structure to carry out the tasks of investment planning, maintenance of a land management database, and public awareness activities. The main responsibility of this CircUse pilot project will be the establishment of a future concept for a 130 hectar former mining area as well as a new definition of tasks and proposals for new management structures to foster land revitalisation. Above all, a feasibility study will describe the business agenda for land management and the organisational integration.

In the Austrian pilot region of Voitsberg in Styria, a new land management agency will be established. Similarly, the Voitsberg region was also a former mining area. For this region, an operational structure and a business plan for a new land management agency will be developed. In this CircUse pilot project so far, main regional stakeholders were identified, tasks defined, and the work on an management concept has started. The business plan depicts the business agenda of the future agency and a sustainable financing plan. The management agency's main responsibilities will be data monitoring, development of an overall concept, initiation of sustainable projects, transfer of information, and awareness building. The aim of the CircUse activities in the region of Voitsberg is the presentation of a model agreement for setting up a land management agency that is transferable to other PPs.

The evaluation of the activities and experiences of the pilot regions Piekary and Voitsberg and the comparison with other good European practices will result in a model for appropriate management structures in Central Europe. Based on the experience from Piekary and Voitsberg an implementation concept for the other CircUse pilot regions will be developed. All CircUse partner regions will select and discuss proposals on adequate local/regional institutional models based on the European examples and first steps of the pilots in Silesia and Styria.

In general the conjunction with instruments of a circular flow land use management "co-operation" and "organisation/management" and "management" are important fields of activity. Therefore new structures of organisation, management and co-operation were developed and tested in the framework of CircUse project.

4 CIRCUSE TRAINING COURSE

Besides new management structures, it is also important to disseminate the circular flow land use philosophy to those actively engaged in land management activities. To do this, training course material concerning circular flow land use management was developed within the CircUse project and is offered to local authorities and other stakeholders for adaptation and reuse. The development of training materials was based on the realisation and evaluation of a "pilot training course". The pilot training course "Land use of tomorrow in the region of Voitsberg" was held in May 2011 in Baernbach (Austria). This step was important to gain practical experience regarding the functioning of a previously prepared training course method. Based on the experience of the Baernbach pilot training course, a "Guideline for the preparation of a CircUse training course in partner countries" was developed. The guideline for a sustainable land management

training course is aimed at the promotion of the idea of circular flow land use management in EU member states.

The guideline includes training course materials consisting of six modules. These modules include strategic and instrumental aspects of a circular flow land use management in the fields of urban and regional planning, soil and land use information, co-operation (e.g. municipalities, public and private partners), funding programmes and schemes, as well as economic incentives. The course material has a transnational character since it will be able to be transferred and used as a training support in other regions and also in other projects concerning sustainable brownfield and greenfield management. The following table lists the names, aims and contents of the six course modules.

Modules	**Aims**	**Contents**
Land use impact – problem analysis and interactions	• introduction to the issue of circular flow land use management • general awareness raising referring to problems with land take development • identification of interdependency and interdisciplinary nature of the problems associated with uncontrolled land taking	• land consumption in the relevant country (e.g. brownfields: inventory and potentials, settlement development and follow-up costs for infrastructure) • objectives of the national sustainable strategy (if existing) or other relevant political documents of the relevant country • current situation of the state, region or city • outcome and results of land consumption in the last decades (ecological, social and urban development problems)
Principle, aims and strategy	• understanding of the methodical approach of circular flow land use management • clarification of terms referring to the method • show the additional value of CircUse to conventional planning traditions	• principle of circular flow land use management • objectives of circular flow land use management • strategy of circular flow land use • management scopes of action of circular flow land use management
Pilot municipality – land potentials and development scenarios	• development of the future City …(insert city).. with consideration of the CircUse principle • check of inventory potentials for inner development • become acquainted with balancing approaches and scenario development to achieve sustainable land management • become acquainted with practice tools for the implementation of circular flow land use management in the municipality/region	• circular flow land use management in the municipality • land take potentials in the inner area and outskirt area • land balances and prognoses for the land demand • data management • development of planning at municipality level • scenario techniques
Stakeholders	• identification of approaches for all relevant administrative and private actors • identification and analysis of behaviour patterns, motivation, support and opposition • awareness raising for network development and the creation of adequate cooperation and organisational structures	• spectrum of actors • demands for land use • setting up of building, types of cooperation and organisational forms
Instruments	• development of understanding regarding the effects, potentials to achieve objectives, and efficiency of single instruments • development of knowledge concerning an adequate use of instruments • awareness raising for possible new (e.g. economic) steering instruments for sustainable land use management	• mix of instruments: fields of action and strategic objectives • existing instruments for stronger regional circular flow land use management to foster an inner development • additional existing instruments of a circular flow land use management in regions with a growing development dynamics (special issue: protection of free space and regeneration areas) • additional existing instruments of a circular flow land use management in regions with a shrinking development dynamics (special issue: re-and deconstruction, renaturation) • new instruments for a regional circular flow land use management
Action plans	• introduction to requirements, objectives and the development of action plans • knowledge building of a general processing algorithm and adaption approaches on the way to action plans • Implementation of objectives und instrument proposals to measurements and activities in the frame of integrated action plan	• general information on action plans • preconditions for the development of action plans • land policy objectives of action plans • structure of action plans • exemplary measurement packages for a regional action plan

Table 1: Six modules of the CircUse trainings course for local authorities and stakeholders, German Institute of Urban Affairs

The guideline will help to implement a CircUse training course in EU countries; all users, though, have to adapt and optimise it referring to national or regional purposes. Therefore, the curricula has to be adapted by integrating aspects of policy framework, of the countries' and regions' general grade of development and experience in the field of land use management, the specific situation of land consumption and the schedule

of responsibilities for tasks of land use planning and land use decision making between all relevant stakeholders. It is important to remark that all these aspects are dependent on a relevant urban region or municipality and cannot, therefore, be directly transferred from one to another EU member state.

The adaption of the course material should be implemented on the municipal or regional level. For the organisation of a training course it is important to start planning at an early stage. Preparations should be started five months before the fixed date of the training course. Relevant stakeholders on the regional level will vary from region to region, but will be identified among the following groups:

- land use planners and environmental experts in municipalities and regions,
- decision makers on a municipal and regional level (in administration, as land owner and developer),
- other interested expert audience.

It is always important to include the decision makers and other responsible stakeholders for the relevant issues. In general, the training course should be a two days event. It is suggested to seek the involvement of an experienced moderator for the implementation of such CircUse training course on local level.

The "Guideline for preparation of CircUse training course in partner countries" is published on webpage www.circuse.eu.

5 CONCLUSION

The potentials, chances, and preconditions for implementation of a circular flow land use management are ambitious, but sustainable changes of current behavior are needed. Common problems and a diversity of national and regional frameworks could be faced by a common strategy of circular flow land use management. The implementation of circular flow land use management needs an integrated approach which encompasses the wider spectrum of policies and activities providing a package of instruments (policy mix). In this instance, current and potential new instruments should be gathered according to regional differences in framework conditions. Permanent knowledge acquisition and awareness of circular land use management are crucial preconditions for a successful implementation of a strategy for reducing land take and strengthening inner development. The instruments, action plans, and training courses presented above contribute significantly to the improvement of land management by both teaching those causing unsustainable land use and offering a tool for the better management of land.

1 SUMMARY: FILLING "TRANSIT CONVENIENCE GAPS" WILL OPEN POSSIBILITIES FOR ECO-MOBILITY WITH IRRESISTABLE CONVENIENCE

Very high densities characterizemany transforming and new urban centres in Asia and China. Allocating the right mix of uses and finding good economic models for real estate development and property ownership to achieve economic sustainability continues to be challenging in light of competing developments in all larger cities. Creating robust urban morphologies, roadway- and public space typologies that balance multiple modes of transport in the public realm effectively, while managing local preferences requires planning geniuses – or even better: intensive horizontal cooperation and coordination – to achieve compactness and livability. Serving new Asian and Chinese high density centres with transportation often becomes the single-most critical concern of planning and approving authorities. Apparently, relying heavily on individual car-ownership and road-based transportation cannot be a satisfactory solution and already results in gridlock and in an unpleasant fight for public space between buses, cars, pedestrians and others. It is not uncommon in Asia that private vehicles are given high priority, discriminating pedestrians due to an implied difference in social status and to promote a car-based economy. Intelligent solutions for eco-efficient urban mobility need to be based on public transportation and have to match or even have to go beyond the best of what we have in cities around the world today in terms of a wider range of (electric) and innovative vehicles, attractive places of interchange, finer networks of accesibility, real-time mobile mobility information systems as well as consumer-oriented operations and reasonable pricing and convenient payment systems.

China is in the very fortunate situation of having a leadership that understands the importance of good infrastructure and thus funding and implementing networks for various modes of transport, private and public, road-based and rail-based enjoys a high priority in Chinese cities. A system of urban highways, ring roads and arterial roads has been constructed over the past 15 years. Three LRT/MRT lines are in operation and several more are planned. The main mode of public transport at present are buses. One experimental BRT line in the Yuzhong district has been largely regarded as a failure, but this is aguably due to suboptimal routing. The existing and planned LRT/MRT system will greatly improve accessibility within the metropolis. However it seems that there is a systemic service gaps both between the lines as well as between the actual stations particularly in centre locations. In Chongqing the topography of steep valleys and hills up from the Rivers as well as a hard rock geology presents an additional challenge to development and connectivity.

The authors identify systemic „transit convenience gaps" most urban public transportation systems intrinsically have. And, we believe that, if these gapse were to be filled, it would make public-/semi-public-/shared mobility solutions more user-friendly and convenient. Innovative solutions and creative technology for vehicles, places for intermodal exchange and mobility information for mobile devices will make a huge difference. If the focus is on user-friendliness, availability, positive experience, safety and security, there is a substantive potential for much higher acceptance of transit and eco-mobility choices.

Four transit convenience gaps have been identified by the authors for the transit system in Chongqing and in the Jiangbei Centre area:

(1) MRT/LRT lines station distances are too far apart from each other to make it convenient to walk to a station and to walk between stations. This becomes apparent when compared with other world cities.

(2) The mesh of MRT/LRT lines leaves gapse that are too great to be convenient to walk to stations. An intermediate system of rapid transit within a district or between two districts is needed. Ideal would be BRT or a streetcar.

(3) The inconvience that exists between bus-service and taxis or private vehicles could be filled by service through minibuses or vans, public and semi-public models are possible.

(4) The gap bewteen walking and bicycle riding or cars and taxis might be filled with publically available, individual mobility assistants like Segways, e-bikes and other innovative tecnology yet to come.

2 CHONGQING AND "TWO RIVERS" NATIONAL LEVEL SPECIAL DEVELOPMENT ZONE: DEVELOPMENT TREND NORTHWARDS WITH JIANGBEI BEING MOST CENTRAL

Chongqing is on its way of becoming a major urban agglomeration and economic powerhouse on the upper reaches of the Yangtze River in China's western region. Urban and economic development is surging and the city has redeveloped in its centre area and expanded over the past ten years almost beyond recognition. High density places have been rising and continue to develop in the historic centre of the Yuzhong peninsula bounded by the Yangtze and the Jialin Rivers. And several centres outside the historic urban area are under way. The most notable centre development is the new Jiangbei CBD just north of Yuzhong across the Jialin River. This CBD is the most significant centre development of the „Two Rivers" national level special development zone that is north of the Jialin river and west of the Yangtze River and includes the airport and Yangtze Port facilities as well as several large scale industrial clusters. This new development direction northwards will put the Jiangbei CBD in a strategic centre of gravity of the region.

The ongoing urbanization can be described, in a simplified manner, as two primary patterns. 1. Core city redevelopment: high-density mixed-use development and re-development of historic areas on the Yuzhong Peninsula and 2. New city districts and industrial development: development primarily with functional separation and a system of super-blocks and overly wide roads radiating primarily north into the"Two Rivers" zone. In this process a system of high-density commercial and business centres and many high-density residential compounds as well as manufacturing and logistics zones are being allocated and built. This model can be observed in many places throughout urbanizing China and in other countries in Asia.

The city's dramatic topography at the confluence of the Jialin and the Yangtze Rivers with steep slopes at both rivers and hills elsewhere presents major challenges to urban development. The topography also offers many opportunities both for unique place settings and views, natural district ventilation and creative pedestrian connections with public escalators and elevators that are be planned in some new areas, comparable to Hongkong's „Mid-level" area south of „Central". However, „bull-dozing" away hills to ease development is a commonly accepted practice to increase developable land in the city.

Planning and implementing an eco-efficient transportation and mobility system in Chongqing in light of these circumstances faces several challenges:

- The topography is a challenge for development planning as well as for transportation planning;
- Due to the topography, the use of bicycles is not part of Chongqing's mobility vocabulary,
- Codes and transportation engineers tend to prioritize private vehicles with wide roads and many highway-style intersections over transit and non-motorized traffic,
- MRT/LRT are difficult to construct due to the steep topography and a hard-rock geology,
- The development model of separating uses on an urban superblock scale makes walking from residences to work, factories, offices, as well as to restaurants, shopping and parks very inconvenient due to long distances.

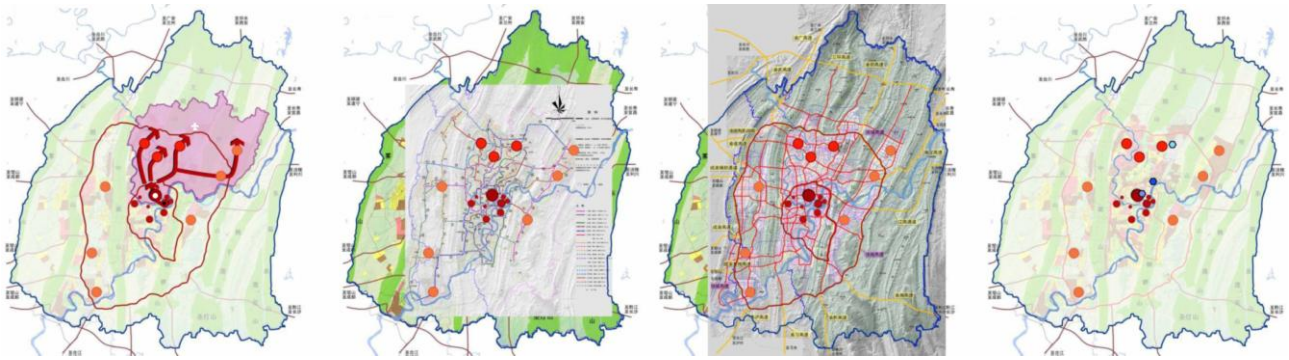

Image 1: Chongqing strategic urban area plan within outer ring road. The purple area in the left image is the "Two River" zone. In blue is shown the future outer ring road and red the ring road and orange the arterial roads system Red dots are centres. Arrows indicate growth trajectory. Second image shows planned MRT/LRT. Third image shows existing and planned trunk roads. Right

image shows locations of international airport (north) container port and high-speed railway station locations. All these initiatives support a shift of gravity from historic Yuzhong Peninsula with the new "Jiefang Bei" CBD (black dot left image) towards the north with Jiangbei CBD (white dot left image)becoming clearly most accessible and central.Significant improvements to public transit are essential filling the transit convenience gaps much needed to avoid gridlock. Source: Stefan Rau over Chongqing's strategic plan.

3 HYPER-DENSITY DEVELOPMENT PROPOSAL AND TRANSPORTATION CHALLENGES

The new Jiangbei CBD is continuing to be refined and developed. Within this high-density environment the authors were asked by a private client to propose a master plan including programming, land use and –intensity definition, building types development, open space configuration and transportation concepts. For the relatively small site of five hectares within a dense urban context that has been developed over the last 15 years, the authors proposed a very high density with a floor area ratio of nine (FAR: 9). Although this is very high, there are many examples of such densities within mixed-use centres and mixed-use developments in Asia and China.

The justification of the density in this particular site is based on several factors such as central location, proximity to a green space and the lack of several urban functions that might be allocated within the site to complement land uses in the context and complete the land use mix creating compactness and "short distances". Accessibility to the centre area at large is excellent with a new subway and arterial roads. However, access to and from the micro-location of the site itself needs to be improved as well as management of circulation in and around the site.

Due to the centrality of the location and the anticipated density, regular in-progress discussions with and informal pre-approvals from the district planning department, district government and the city department of planning were essential. The proposed very high density and the details of the mix of uses were disucssed at length to ensure an optimization of functions that would complement those already existing, planned and under construction in adjacent areas. This exercise results in a conceptual reduction of distances from housing to jobs, commerce, services, education, health care and open space within the new centre. In short: the objective was to create compactness.

What has been the biggest concern of the local officials however, was vehicular accessibility avoiding roadway congestion and the planning of sufficient number of parking spaces as well as access to parking that avoids backlogs onto roads. The authors were very concerned about access via public transportation and in reviewing the transit system - existing and planned - major shortcomings on a systemic level were identified and they had to be overcome through innovative concepts.

Image 2: High density developments in the area of the Jiangbei CBD. Pedestrian environment has some nice elements in some places already but need to be completed and connected to become a cohesive, convenient, pleasant and safe system: Pathways through green spaces. Beautifully landscaped and wide sidewalks with cars at times parked on them. Public stairs and public escalators enhance walkability. Roadways with Taxisand capacity to handle exclusive bus-lanes/BRT. Source: Stefan Rau and Wang Dan.

4 EXISTING AND PLANNED MRT/LRT SYSTEM LEAVES TWO SYSTEMIC GAPS: NETWORK LINES ARE TOO FAR APART AND STATION DISTANCES ARE TOO GREAT

In Chongqing the planned network of MRT and LRT lines is very ambitious and it is very laudable. However there are two kinds of convenience gaps in this system, the first being the lines are too far apart and the second being the sations are too far from each other.

The mesh that is woven with planned and existing MRT and LRT lines leaves holes to great to be conveniently serving all urban areas. This is surely due to the difficulties dealing with the topography and the involved capital investments due to the geology.

To solve this systemic problem, the authors recommend to introduce a bus rapid transit overlay inbetween the rail-based transit network. This BRT system can easily be accomodated within the existing new road carriageways, built in the last several years. This would be easy to install with exclusive bus lanes and effective bus stops and flexible to change routings if adjustments are needed for better service.

The second type of gaps that are created by the MRT and LRT network is that distances between two stations are too far apart from each other to be conveniently serving citizens and not condusive for them to switch from a car to public transit. The concept behind this is to have the trains run quickly from start to end which is a reasonable objective with respect to speed and effectiveness. However, it defeats the purpose of a public transit system which is to offer a convenient mode of transportation, a desirable service for people to use.

If compared with cities around the world it becomes apparent that Chongqing's MRT and LRT network and station distances leave too many convenience gaps. This may be true for other networks in other Chinese cities as well, where station distances are spaced 1 to 2 kilometers apart generally, and not becoming significantly denser in center areas as is the case in other world cities with successful transit systems with a high modal split of public transit ridership.

The authors recommend to review this principle both for Chongqing and as well for other Chinese cities and simply add stations inbetween on existing and planned lines to enhance user-friendliness and make people use transit as their first choice of getting to and around in the cities and their high density centres.

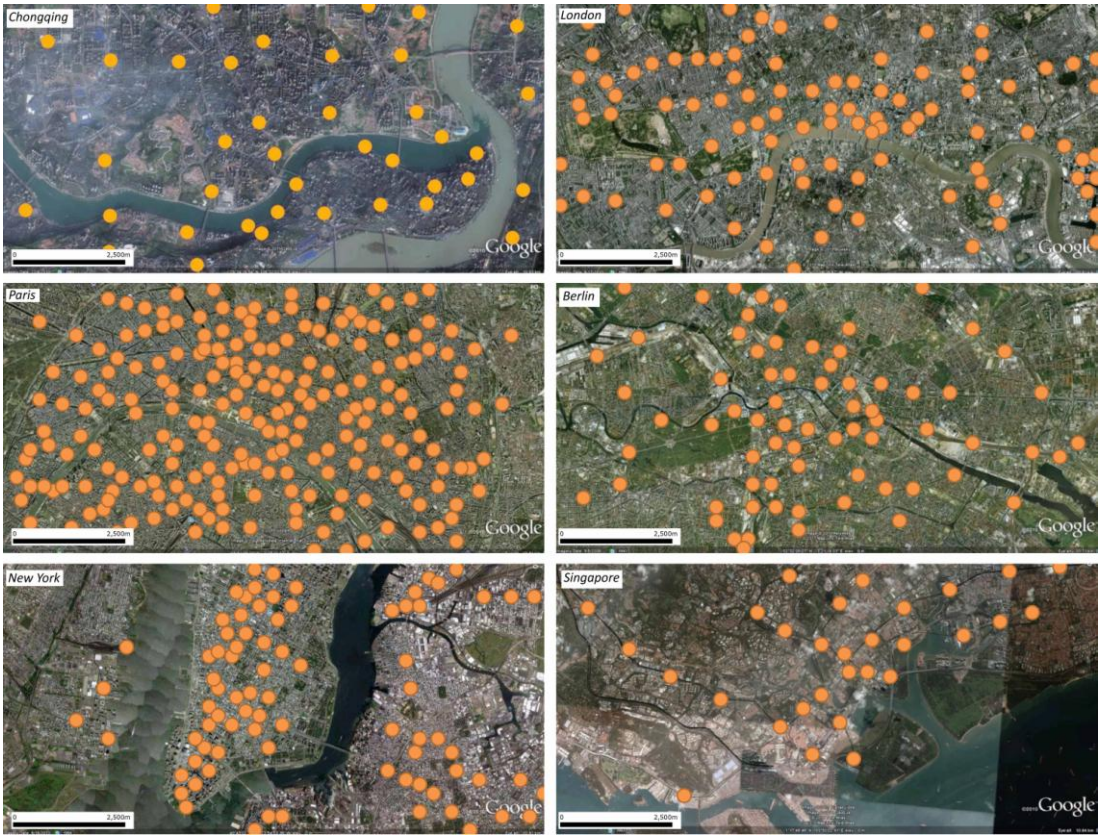

Image 3: Comparing subway station density of six cities. Chongqing's planned subway line stops to be implemented by 2030 (top left) is by far the city with the station distances too great to be convenient for citizens to use.Clear transit convenience gaps. Singapore (bottom right) comes next and here it isapparent that in the central locations station distances become nearer compared with peripheral locations. Source: Stefan Rau over Google Earth and Google Maps.

5 BUS LINES AND BUS STOP DISTANCES TEND TO BE TOO FAR APART AS WELL

In Chongqing and in many Cities in China buses tend to have stops spaced rather far apart compared with buses in western cities. The reason behind this is identical with the reason behind the distance between subway stops: long-distance speed and effectiveness. Also in this case it comes at the cost of convenience for commuters. More stops, even stops on demand on every intersection would make it much more attractive for people to switch to buses and thus many traffic jams due to individual vehicles can be avoided.

Not too seldom it can be observed that bus routes and bus stop locations stay unchanged even with new transit lines opening and at time bus stops are not relocated to be next to transit stations which makes interchange inconvenient.

Bus routes need to be adjusted and revised to respond to transit system changes and to respond to changes in land uses and densities reflecting new magnets of trip generation. Stops need to be nearer to one another in dense places and on-demand in lower dense places.

6 PROPOSAL FOR ECO-MOBILITY CHOICES AND MULTI-MODAL PUBLIC TRANSPORTATON: STRATEGICALLY FILLING THE "TRANSIT CONVENIENCE GAPS"

Solving traffic challenges for cities especially in high-density environments is rather ciritcal in various respects. Accessibility, urban livability, community life, environmental quality, public health, safety and security in public spaces, eco-efficiency and low-carbon economy are all directly related to urban transport and vice versa.

If a commonly accepted goal is achieving low-carbon eco-efficient mobility, we must be serious about the need to get people out of their cars by offering most attractive, convenient mobility choices that cannot be resisted. It is of utmost importance that public transportation service offers convenience to individual mobility needs of all residents, workers, shoppers and visitors both to get to and from the centres as well as to get around inside the centre areas.

To achieve convenience we have to fill „transit convenience gaps" that seem to exist systemically in most places, not only in Asia. These gaps exist due to, among other reasons: physical urban patterns, transport technology used, the scale of vehicles and operations economics.

These convenience gaps may be filled through various means, number one being intermediate sized vehicles and innovative new vehicles. Number two, most importantly – as we don't have to reinvent the wheel – is employing creative models for shared ownership and mobility services, management and operations models are most needed with many encouraging examples already in place in various cities. Number three is information on mobility choices and ordering capabilities ought to be readily available on people's mobile phones real time and anywhere on the go.

Image 4: Proposed multiple modes of transport integrated to become an eco-efficient and convenient mobility system. Filling transit convenience gaps. Source: Stefan Rau and various internet sources for icons.

The authors were originally asked to work on a five hectare site and ended up consulting transportation consultants and the district and city government on improving the transportation system. For the example in the Jiangbei Centre of Chongqing, a place with virtual non-existance of bicycles due to topography and culture and in addition to roadway- and roadway management improvements as well as parking provision,

the authors proposed eight specific strategies to provide an attractive and convenient system of eco-mobility filling the transit convenience gaps:

(1) MRT/LRT more stops:

Additional stops in-between existing and planned stations to serve residences and offices within a five to ten minute walk maximum. China's subway systems tend to have distances between stations too great reasoning speed is of greater importance than convenience. However a balance needs to be found and convenience and other factors of user-friendliness will ultimately decide on the success of system which can be measured by transit ridership and modal split.

(2) BRT added in-between network:

Introducing a City-wide BRT system on the existing and planned new roads which have enough capacity to give one lane exclusively to buses. The BRT lines strategically fill the systemic gap between subway lines that exists also due to the topography and it will provide rapid transit within a district and between two districts. BRT seems to be an obvious choice offering effectiveness at a very reasonable capital upfront investment while also being flexible with routing and adjustments over time.

(3) Improved bus routing and added Minibus service using electric vehicles:

Introducing a district-wide minibus sSystem with convenient stops and personal cargo delivery will serve the need for a strategic level of public or semi-public service needed below that of buses and above that of taxis or private vehicles. On-demand stations and service flexibility will make this effective and convenient to go around within a district and to go to and from MRT/LRT stops.

(4) Renting/Sharing/Pooling a variety of vehicle types:

Introducing a variety of vehicle types and vehicle sizes and ownership models as well as management and operations models with vehicle stations in every residential community and even every residential block and high-rise buildings and with branches in all major office and commercial buildings. Car or vehicle sharing associations and vehicle rentals with membership or preferential treatment and competitive rates will be fun and attractive and combines the best of all: providing individual mobility and great choices of vehicles on demand and tailored to the actual need each time, with the benefit of a hassle-free mobility not needing to worry about vehicle maintenance.

(5) Slow-moving individual mobility assistants:

Electric bicycles, segways and a new generation of assisted electrical slow moving individual mobility devices will fill a gap where one feels walking is just a little too far and takes just a little too long or is inconvenient due to topography. In addition to private ownership and parking options offered in many, convenient and safe locations, shared and rental models of these mobility assistants should be offered to ensure availability of devices and flexibility of useage.

(6) Pedestrian friendly environments, fine-meshed networks, safety and security:

Pedestrian system planning is introduced with completed pathway-network, road crossings, public elevators and escalators to overcome hills, and overall design for pedestrian safety and security. Walking needs to be a most safe and pleasant experience to be the first of all choices to get around in a centre area. To improve pedestrian connectivity sometimes it is needed to create additional infrastructure, beyond sidewalks and pathways. In centre areas that could be a system of elevated walkways directly linking the commercial areas of buildings with one another and connecting to public transportation. And it could be a system of undeerground connections from subways directly to buildings along commercial or cultural pathways. Attractive and safe public spaces, sidewalks, plazas, parks and pathways are essential for a walkable place and a prerequisite for people to chose walking as a first choice of getting around. Detailed planning and urban design is required to ensure seamless, safe and attractive connections between different modes of transportation on foot.

(7) Inter-modal transit stations and eco-mobility centers and -stations:

Changing from one to another mode of transportation is an inconvenience most of the time. One aspect is the proximity, accessibility and attractiveness of stations. Here the authors proposed that in every residential compound and all major residential, office, commercial and service buildings there would be an inside and outside space with a variety of vehicles, storage space and with supplemental services like lounge,

conference room, wifi, concierge, convenience retail and small services. These are offered in two categories as comprehensive eco-mobility centers with many choices of transportation modes and vehicles and as eco-mobility stations sometimes just canopy roofs or niches or rooms with vehicle or devices storage outside or inside a building. Of course inter-modal transfer stations are associated with all subway stops and there will be safe and attractive exchanges with buses, minibuses, rented/shared vehicles and slow-moving individual mobility assistants.

(8) Interactive, real-time mobility choices information and ordering system for mobile phones:

On the level of operations the authors propose creativity on design, prizing, fare integration, real-time mobile information on mobility choices, mobile orders of vehicles and customization of service.This may be realized with GPS tracking of all modes of transportation and en-route vehicles and information on time, route details, energy use and carbon footprint for each specific mobility choice will give every individual all options for an intelligent, custom-tailored mobility choice at each situation.

7 CONCLUSION

For high-density urban centres effective eco-mobility is needed to avoid gridlock, excessive use of energy and to enhance livability and environmental quality. Especially in the hyper-dense Asian and Chinese urban centres, transportation increasingly challenges the centres' livelyhood. While the synergies of the mix of uses and the densities are appreciated, the experience of congestion increasingly becomes a turn-off for business locators and residents chosing their housing.

To solve the accessibility challenge to and within the new hyper-dense Chinese and Asian urban centres we need a variety of creative solutions both for the hardware of lines and vehicles but also for the software of operations and service design to systematically fill the transit convenience gaps. The focus of the action needs to on maximizing the convenience of mobility consumers when conceptualizing eco-efficient mobility solutions.

During their planning effort for a private client and in negotiations with the district- and municipal governments, the authors identify three major „transit convenience gaps" of public transportation service that need to be filled strategically. Filling these „gaps" seem to be of strategic importance as they indeed seem to be systemic and not only in centres in Chongqing, China or Asia. To improve public transportation service aiming for ecologically-efficient mobility the authors recommend three strategies to address these „gaps".

- Rapid transit for intra-district and inter-district transport filling the inconvenience gap in the MRT/LRT network. Electric run BRT is the system of choice with flexibility and low-cost and streetcar a long-term solution.
- The inconvenience gap between in the bus-service and inbetween bus service and taxis or private vehicles might be filled by electric minibuses/vans as well as ubiquitous electric-car sharing and e-car-rentals. PPP is encouraged.
- The convenience gap bewteen walking and bicycle riding or cars and taxis might be filled with readily available, individual mobility assistants like Segways, e-bikes, smart-wheels etc.

Due to the very high densities of residents, jobs and shoppers in the new Asian centres, the market vialbility for these intermediate public and semi-public mobility solutions are, and the authors are quite firm on this: most certain.

It's the Footprint, Stupid! Urban Assessment by Footprinting Public Transit

Markus Ossberger

(DI Dr. Markus Ossberger, Erdbergstrasse 202, 1031 Vienna, markus.ossberger@wienerlinien.at)

1 ABSTRACT

In terms of energy consumption, emissions and the necessary sealing of surfaces, transport systems play an important role in the city. Roughly 37 % of the final energy used (City of Vienna 2009) are required for transport. Transport is also the main source of greenhouse gas emissions, accounting for 42 % of Vienna's total greenhouse gas emissions and recording the greatest increase of such emissions (up 37 % for the period 1990-2005, see ANDERL, GANGL et al. 2009). As regards building materials, civil engineering structures house roughly one fifth of such materials in Vienna .

Hence the solutions chosen for transport are essential for the sustainable development of cities.

Public transit is said to be environmentally friendly and, a more recent development, also sustainable. An interesting approach is to think of ways and means of illustrating its eco-friendliness or sustainability. In fact, the terms "environmentally friendly" and "sustainable" are regional compacts on how much our natural environment (including animals) can tolerate in terms of ultimate sink. This also refers to its absorption capacity. There are no generally recognised standards available as yet for sustainability. Therefore the present paper proposes to use a highly aggregated quantity as a starting point for orientation in (ecological) sustainability considerations. To put it more succinctly, the paper addresses the issue of the ecological footprint (EF) which serves to measure the appropriation of "nature", i.e. of ecosystems, by humans. The EF approach juxtaposes the biologically productive land surfaces appropriated for human use with the biologically productive areas that are available. This is measured in surface units (e.g. hectares). EF accounting is intended to show the relationship between nature's exposure to human demand and the amount of biological capacity available to nature.

2 URBAN ASSESMENT

2.1 Result – the ecological footprint

To identify this footprint, Vienna's public transit provider WIENER LINIEN commissioned the Institute of Water Quality, Resource and Waste Management of the VIENNA UNIVERSITY OF TECHNOLOGY to conduct a study (BRUNNER et al. 2011). Within the given framework of Wiener Linien, it has been calculated that one trip on the metro leaves an ecological footprint (EF) that is three times smaller than the one left by a person travelling by car. Provision of infrastructure and rolling stock accounts for 43 % of the metro's EF, metro service and the upkeep of station services account for 57 %. In terms of urban planning, the surface needed for the extension of the U2 line is six times smaller than the one needed by the MPT reference system. One of the strategic aims of the City of Vienna is to achieve a 40 % share in the modal split for public transport; this would result in a reduction of the EF of one U2 ride by 10-20 % (~0.14 m2/passenger kilometre/year). (BRUNNER et al. 2011). But first the benefits of the ecological footprint versus conventional methods will be shown based on cost benefit analysis, as this is the method which is most widely used in the world, including Austria, where guidelines issued by the Austrian Association for Research on Road, Rail and Transport (FSV) mandate such an analysis for any infrastructure investment.

2.2 Economic assessment and use of resources

As a rule, economic analyses assume an unlimited amount of resources. Such assumptions can only be understood if we take a closer look at the times when these theories were developed. The very idea of finite resources was alien to representatives of both the classical and the neoclassical schools of economic thought. This is why the two theories are based exclusively on the exploitation of existing raw materials, but they ignore the changes in natural deposits and fail to reflect the risks of supply. Even an economy that is supplemented – in ecological terms – by a closed substance cycle does not take material deposits into consideration; furthermore, the raw materials included in this cycle will ultimately enter ecological processes as emissions. Therefore it only considers the input side of materials, while on the output side it focuses exclusively on the benefit components of goods, with the materials as such being ignored. An examination of the economic benefit or of the social welfare gains based on economic considerations or simply the

application of the Kaldor-Hicks criterion (benefit cost quotient of the cost benefit analysis) are ultimately always summaries of current assessments, i.e. unrealised gains. Since at the end of the day the balance of savings and debts will always be zero, i.e. money has no value of its own, it will be the material goods which decide whether the individual and/or the state or humankind as a whole have become richer or poorer in the context of any given measure. Therefore the material or resource base is of key interest for political decision-making. It is surprising that so far the issue of resources has been addressed mainly in philosophical sustainability terms or under the aspect of primary energy sources. In this context one question is essential: how can one capture and account for the available "stock", i.e. the existing natural resources and the raw materials (goods) already processed?

One of the central tenets of neoclassical economic thought is that of the relative scarcity of resources. Lionel Robbins (1935) is one of the authors who established this as a cornerstone of modern economics. His approach went hand-in-hand with the fact that only the scarce resources traded at market prices were taken into account far into the 1960s. Resources having no market price were considered either not at all or only in terms of public goods. To this very day they eke out a rather wretched existence in economic theory as "external effects" and play only a minor role in decision-making processes.

Maybe many economists, politicians, but also engineers, are still under the strong influence of classical economic thought as propounded by Adam Smith, whose assumptions concerning future production methods were very optimistic. They must be understood in the social context of his time, but they were relativised as early as 1800 when Robert Thomas Malthus asked the question of whether the quality of available land would suffice for meeting people's food requirements. In the first half of the 19th century classical economists paid much attention to the issue of natural resources. This implies that they still had an integrated picture of economic and ecological processes. Their thought linked the limits of production with the extent of raw materials that can be taken from nature without having a negative impact on agricultural production. Today we would probably describe this approach as "adjusting to ecological cycles". But what is important is that in those days economic and environmental processes were seen to be inextricably linked.

This changed abruptly in the second half of the 19th century when economists turned their attention to the "market", to "market mechanisms" and, first and foremost, to the "benefit concept" as a basis for the "value concept".

Technical progress relies on the use of "stock goods", i.e. of "non-renewable" resources, which are mostly fossil raw materials and metals. This has two essential effects:

- There is a limit to the extraction of stock goods, i.e. one day they will no longer be available.
- Having been used in production and consumption processes, they enter ecological processes as emissions. This is particularly true of metal alloys, smoke and/or air emissions and plastics. Once emitted, they form part of an environment where normally they are not present in such large quantities. The Industrial Revolution was a period of transition from a more or less closed cycle of production and consumption to an open economic system based on the consumption of these co-called "stock resources".

This had and still has a major impact on the "problem-solving capacity" of our economic system (of neoclassical make).

- Focusing on the "market" as a place where goods are traded at certain prices has resulted in a situation where seemingly unlimited renewable resources such as air, water, etc. are given no or low prices and are therefore considered to be of no relevance to decision-making or to the market as such.
- No-price resources, though scarce, have been ignored by economic theory. This might have been appropriate for classical 18th century economic thought, but it certainly is no longer appropriate today.
- In neoclassical theory the available factors of production - no matter whether prices are attached to them or not - are assessed by individuals. This engenders major ecological and thus economic risks whenever the value of nature is dissociated from human needs. If in the long term the economy is to make appropriate adjustments to the quantity of available resources and the tolerance limits for exposure in the various spheres (especially the biosphere and atmosphere), we need a clear overview

of the flows of the resources concerned (INPUT/OUTPUT) in order to understand the cycles we want to create and control in the end. But this is not enough! A renewed transition to a sustainable economic order is fundamentally different from the one that led away from the closed production and consumption cycles of pre-industrial periods. Nowadays we need to manage and keep flowing not only the "renewables" but also and in particular the "stocks". The latter are not renewable and their quantity remains constant. Therefore they need to be addressed in a manner similar to the one used for fertile soil, which is not available in unlimited supply either.

This signifies that sustainable economies need detailed knowledge of flows and stocks, as otherwise we are unable to identify the availability of resources in future. In terms of materials and substances we also need to know the precise amount of discharges and emissions into the ecosystem referred to above, which would be impossible without detailed knowledge of flows and stocks.

2.3 Consequences for the assessment of urban areas and functions (urban assessment)

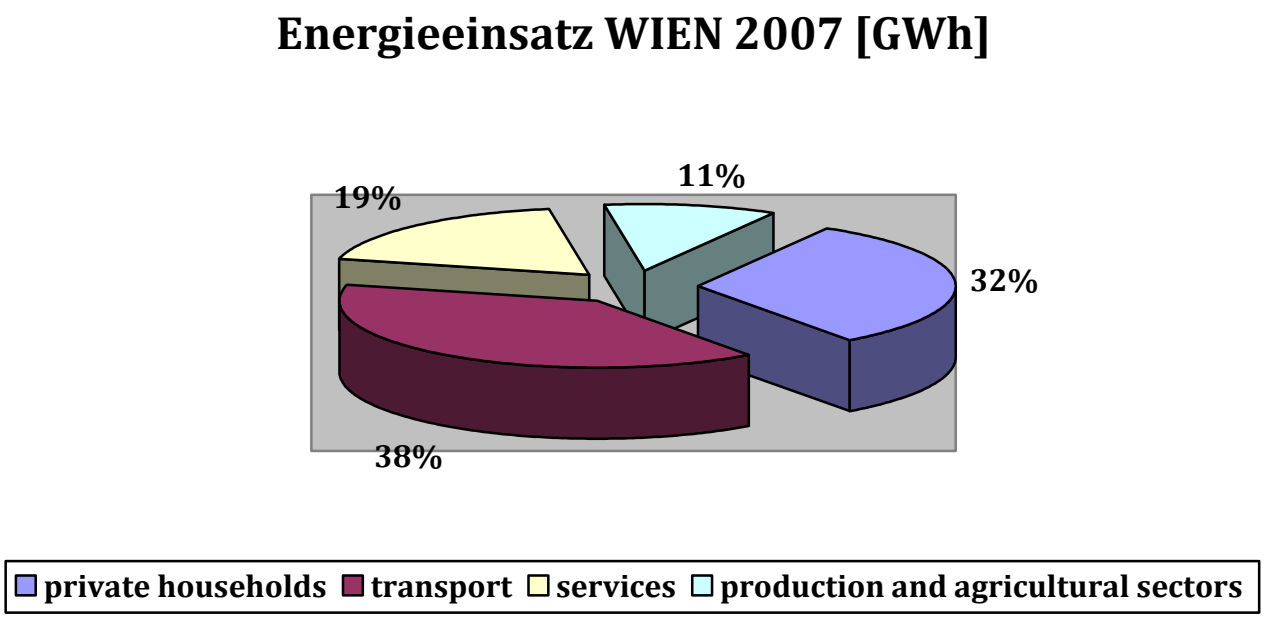
The above brief introduction into neo-classical theory and cost-benefit analysis clearly illustrates that the assessment of any given city's policies and ecological situation cannot be based on economic considerations. Not because economics were one-sided. But because economics simply do not have the relevant information on materials, substances and energy flows. What options are available to us?

In order to assess the situation of a city we need a complete picture of its resources and energy flows.

Vienna offers a number of interesting data sources to give this picture.

Every year Vienna's Municipal Department 20 (MA 20) issues an energy flow diagram for the city.

For instance in 2007 final energy consumption was 131,580 TJ (36,550 GWh) according to the city's energy balance. Fossil fuels and combustibles account for 62 % of this amount. A breakdown of the sources of energy shows that oil accounts for the largest portion (two fifths or 42 %) followed by natural gas and electricity (20 % each). District heating supplies 15 % of final energy. Renewable energy sources account for 3 %, ambient heat for 0.3 % and coal for 0.2 %.



Energy use for Vienna in 2007 [GWh]

Final energy consumption by sectors is as follows:

- Private households account for 30 % or 39,735 TJ (11,852 GWh)
- Transport accounts for 40 % or 52,100 TJ (14,472 GWh)
- Public and private services account for 19 % or 25,226 TJ (7,007 GWh)
- Production and agricultural sectors account for 11 % or 14,520 TJ (4,033 GWh)

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

53 % of the final energy consumed in Vienna was used for power and lighting, 32 % for space heating and 14 % for process heating. Since then these figures have risen continually.

Total consumption was 46,627 GWh in 2010, with transport accounting for only 31 % of the energy used in that year (14,414 GWh). This goes hand-in-hand with a changed modal split: public transport (PT) up from 35 % to 37 % and motorised private transport (MPT) down by the same percentage.

This clearly illustrates that the targets to be attained by the transport master plan of the City of Vienna are major steps towards a sustainable transport system featuring a modal split of 25 % for MPT and 40 % for PT.

Various renewable energy sources are used to generate electricity and heat in Vienna. The identified installations for the use of renewable energy account for over 16 % of all power plants in Vienna with a total installed capacity of 210 MW of electricity generation. The most important renewable energy installations in Vienna use hydropower, wind power and – since completion of the biomass power plant in the district of Simmering – also solid biomass.

If we include the small-scale hydropower plants of Wildalpen, Hirschwang, Hinternaßwald and Gaming, total installed capacity will rise to 270 MW of power generated by renewable energy sources, i.e. more than 20 % of Vienna’s portfolio of power plants.

A closer look at the energy flow diagram shows the superiority of Vienna's PT in energy terms.

Meanwhile, only some 625 GWh (traction power, diesel and liquefied petroleum gas; figures for 2010; source: Wiener Linien) are used for 37 % of trips (PT), whereas motorised private transport (including fuel tourism from the eastern region) and goods transport consume 13,246 GWh. This corresponds to a ratio of energy consumption of roughly 1:20 in favour of PT. If this ratio is reduced by fuel tourism and goods transport, it still amounts to more than 1:5.

Energy sources as contributors to substance flows only account for 3 metric tonnes per inhabitant and year compared with a total of 200t per inhabitant and year. True, this is a small quantity, but it has major system implications, in particular for transport.

An analysis of material and substance flows should start with water, as for the most part it is nothing but a throughput quantity.

Brunner shows for Vienna that roughly 147,000 litres of water per inhabitant and year enter the city (system boundary = city boundary) to enable Vienna to meet all functional requirements, 143.000 of which 143,000 litres exit the system in the form of waste water. Wiener Linien, by contrast, need a mere 96 litres per inhabitant, more than half of which is used for metro construction.

A closer look reveals that building materials and consumer goods are essential for monitoring the city’s flows. These two form so-called anthropogenic stocks, i.e. man-made deposits of resources which are currently explored in great detail concerning their recyclability under “urban mining” approaches.

The size of these deposits is enormous. Already now every inhabitant of Vienna "carries a backpack” of such deposits of resources weighing roughly 350 metric tonnes. Each year it grows by another 8-12 metric tonnes, primarily due to brisk construction activity.

This clearly illustrates that urban assessment must be based on closed-system accounts of energy and resources in order to identify the relative proportions of energy consumption (PT:MPT) and be able to provide appropriate estimates of air emissions, fine dust particles and so-called fugitive emissions based on the use of energy and the increase of anthropogenic deposits. This paves the way for any kind of impact assessment supported by an objective quantity structure that can be used as a basis for such assessments.

The importance of micro-simulation, in turn, loses in importance as the macro-level can show where the actual potential resides.

Example: If we reduce the energy used in Vienna on the basis of fossil fuels (according to the energy flow diagram of 2010) by one percentage point, 130 GWh will no longer be needed. This amount corresponds to almost 20 % of the energy use of Wiener Linien. In emission terms this signifies that the current 3.3 million metric tonnes of CO2 are reduced by 33,000 t or by 24 % of what Wiener Linien emit.

A consistent analysis of the targets defined in the transport master plan reveals: motorised private transport (MPT) must lose one quarter of its market share, i.e. reduce CO2 emissions by 825,000t, while public transport (PT) emits an additional 15,000t at most due to this shift in the modal split. In actual terms, the

increase for PT is less as the limiting energy and thus also the limit emissions are almost zero owing to the more favourable dynamics of vehicle movements.

I will not go into more details. The above explanation was meant to show that closed-system accounting for materials and substances, as well as linking them up with the energy flows, will greatly facilitate urban assessment and lift the veil of mysticism that currently shrouds such assessment.

Urban metabolism today primarily works like a linear throughput reactor: water and air flow from the supplying hinterland to the city and on to the disposal hinterland mostly in linear form. With current urban growth we see that the closed substance cycle can meet the rising demand for long-lived goods (e.g. building materials) only to a very limited extent. Demand of the growing city greatly exceeds the supply of secondary substances. The materials and substances accumulated in the city, i.e. the "urban stock", constitute a future source of raw materials (recycling) on the one hand. But on the other hand this stock is a long-term hazard to the quality of water, soil and air if it is not managed with due consideration of its environmental impact. Substance flows entering the environment of the local, regional (or global) hinterland can be more significant than those within the city itself.

Therefore it is essential to restrict oneself to the appropriate quantity structure and adhere to a clear distinction within the impact assessment itself where actions form part of subjective and value-linked decisions. This will not be addressed in the present paper. What is much more important is that the sum total of material and energy in the ecological footprint provides a highly aggregated indicator for assessment at the highest level, i.e. in the thin atmosphere of policy-making.

2.4 On the eagle's wings - the ecological footprint

The Canadian William Rees and the Swiss Mathis Wackernagel developed the model of the ecological footprint: it indicates in hectares how much surface area is needed by any given individual based on the consumption patterns this individual chooses to satisfy his or her needs.

If the entire productive surface of the earth were evenly distributed among all people, this would result in an average of 1.7 hectares or 17,000 square metres. This is equivalent to the size of 3.5 football fields. Currently the average ecological footprint worldwide amounts to 2.2 hectares per person. In other words: we use up more area than is available. Our planet earth is not big enough to satisfy our needs the way we are satisfying them today. We not only live off the interest payments but we are already living off the "ecological capital". The ecological footprint shows that our current consumption pattern is not sustainable.

In future our needs will have to be satisfied in a way which ensures that we make ends meet with the surface area available. For this reason we try, for example, to reduce CO2 emissions and to promote organic farming and local supply chains .

The City of Vienna could, for instance, set itself the target of reducing the ecological footprint from currently 3.9 ha/inhabitant/year to the globally compatible amount of 1.8 ha/inhabitant/year. The use of energy and material would have to drop to the same extent along the entire cycle of production and use, i.e. the life cycle. What would this signify in practice?

For this purpose let us take a closer look at the urban footprint itself.

In 2001 the Municipal Department for Environmental Protection – the MA 22 – had the ecological footprint measured for the City of Vienna. Each Viennese needs an average of 3.9 hectares of surface area. This is far beyond the target value of 1.8 hectares per capita. But in comparison with other large cities in the world Vienna fares very well.

Nevertheless the ecological footprint shows that we consume too many goods and agricultural products, too much energy and water, i.e. too much of what is termed "resources".

"Resources" include natural resources such as soil, water and air. They also include the material and substance flows triggered by human activities and the accumulated "stocks", such as building materials, consumer goods, waste, carbon dioxide, nitrogen and heavy metals.

Resource management means analysing the metabolism of the city and evaluating it based on viable criteria and indicators. This is how urban metabolism can be controlled by efficient measures. Resource management is a central component of sustainable development. Sustainable exploitation of our environment means that the consumption of renewable raw material, water and energy resources must not exceed their rate of

renewal. We must not consume non-renewable resources at rates which exceed their replacement by durable renewable resources. Sustainable use of the environment also means that the emission of pollutants must not be greater than the capacity of air, water and soil to absorb and decompose such pollutants.

2.5 The ecological footprint left by transport in the City of Vienna

The ecological footprint of the City of Vienna is comparable to that of other major cities and at 3.9 hectares per inhabitant of sub-average proportions. In order to come close to the environmentally sustainable limit value of 1.7 ha per capita, other measures for reducing this footprint are necessary.

In this context the policy area of mobility plays a major role. In the whole of Austria mobility accounts for 22 % of the national footprint, with 90 % of it being caused by motorised private transport and air travel. Although 34 % (meanwhile 37 %) of all trips in Vienna are made by public transport (PT), i.e. twice as many as nationwide, the city continues to pursue the policy goal of further shifting the modal split towards soft forms of mobility (PT, bicycle, walking). These plans are a significant contribution to reducing the ecological footprint of Vienna.

The objective of a joint project of the VIENNA UNIVERSITY OF TECHNOLOGY and of WIENER LINIEN was to compare two advanced modes of transport, i.e. "metro" and "motorised private transport" (MPT), with the help of the "ecological footprint" assessment indicator. The unit of reference chosen for this purpose was the ecological footprint expressed in one passenger kilometre units for the two means of transport. The study involved the newly built extension of the Vienna metro line U2 from stations Schottentor to Seestadt and a MPT reference system with the same transport capacity. To reduce the ecological footprint of Vienna's transport sector, greenhouse gas emissions must decrease. Energy efficiency measures in public transport will not produce the kind of economic and environmental outcomes as those achievable by the reduction of greenhouse gas emissions caused by MPT. Moreover, it may prove to be expedient for Wiener Linien to slightly expand the scope of public transport by widening its range of services and lines in order to achieve a shift from MPT to PT. However, such measures might reduce the coefficient of utilisation of metro capacity, which in turn would increase the ecological footprint of Wiener Linien. Within the given framework of Wiener Linien, it has been calculated that one trip on the metro leaves an ecological footprint that is three times smaller than the one left by a person travelling by car. The annual share of the U2 extension in Vienna's ecological footprint (EF) amounts to roughly 0.05 %, while choosing to travel by private car equals a share of 0.16 %. Provision of infrastructure and rolling stock accounts for 43 % of the metro's EF, metro service and the upkeep of station services account for 57 %.

With a share of 99.9 % in the entire EF of the U2 extension, energy surfaces are the dominating factor for absorbing CO2 emissions. Footprint analysis is very sensitive to the chosen electricity mix and energy requirements (which may range from 0.16 to 0.25 m2/passenger kilometre/year). Land required by soil sealing has no appreciable influence on total EF. But in terms of urban planning it is significant. The surface needed directly for the extension of the U2 line is six times smaller than the one needed by the MPT reference system. One of the strategic aims of the City of Vienna is to achieve a 40 % share in the modal split for public transport; this would result in a reduction of the EF of one U2 ride by 10-20 % (~0.14 m2/passenger kilometre/year).

2.6 Outlook: moving towards resource management

The ecological footprint is well and widely known since it is easy to understand and offers a great variety of applications. Such features make it an ideal candidate for media communication. However, the results of individual EF studies are of only limited comparability due to greatly varying system boundaries, allocation rules, conversion factors and functional units. The move from EF to resource and environmental management requires a broader set of methods. Owing to its methodological restrictions and its function as a highly aggregated indicator the ecological footprint is not ideally suited for supporting operational management in taking decisions. Both aspects imply the need to develop an information pyramid of graded levels depending on the target group concerned. The pyramid's apex would be formed by indicators that can be easily communicated by the media to the general public, while the base would be formed by fundamental analysis to inform operational management. The material and energy balances of an enterprise would be part of this knowledge base. Alongside the quantification of direct effects they serve as a point of departure for taking stock of the indirect effects (hinterland). If only the ecological footprint of Wiener Linien were to be

reduced, the future focus would have to be on: a) using those types of concrete and steel for construction which have caused fewer CO2 emissions in upstream processes; b) prioritising an electricity mix for operation which involves fewer CO2 emissions; c) reducing the energy consumption of rolling stock and stations; d) increasing occupancy rates; and e) finding the optimum mix of trams, buses and metros with due regard to the function of each of these modes of transport. Individual measures resulting from the EF concept may conflict with the targets set by transport politics and economics. Example: one method of increasing occupancy rates could be to restrict the service times of public transport. This illustrates that, in the total assessment process, an ecological footprint analysis is only one indicator which needs to be supplemented by other instruments better suited to map the objectives of passenger services offered.

Land Uses: Anything Anywhere & Anytime? Yes, but How Thematically and Where Areally?

Ioannis Tsouderos, Despina Dimelli

(Professor Ioannis Tsouderos, National Technical University of Athens, ioatsou@otenet.gr)
(Dr. Dimelli Despina, National Technical University of Crete, dimelli@arch.tuc.gr)

1 ABSTRACT

The development of Athens from the beginning of the 19th century and particularly after the arrival of 400.000 refugees from the Asia Minor, was realized without a regulatory plan, with complete absence of cadastre and any kind of street plan, on huge properties of few owners that were divided in small plots, were sold in low income class and were arbitrarily constructed. The basic priority of that period was the coverage of the urgent housing needs while the city's planning seemed a luxury.

The economic and social improvement that followed, after the second world and the civil war, dictated by the worldwide standards, had gradually led in a quantitative and qualitative development of urban land uses. These land uses were continuously mixed without regulatory plans to restrict or allow their allocation, until the 80' decade, so under the exclusive influence of market forces, anything was allocated anywhere, anytime. The plans that were legislated in the late 80's didn't result the desired land uses allocation as they didn't provide a strict frame for which land uses would be allowed and where they would be alllocated. The aim of the current paper is to investigate these land uses self regulation during the period where planning did not exist and later during the period where plannung existed, but it provided to land uses the freedom to be allocated almost anywhere.

The procedure that has been followed is the use of records from three successive censuses of employment and population in 1978, 1991 and 2001 for the Athens basin the center of Greece. The study of the diachronic thematic and areal redistribution of land uses in this area shows that although it was realized without any regulatory restriction and complete absence of principles until 1989 and under the influence of an indefinite plan since 1989 it is characterized by a deterministic land uses auto-regulation based on its citizen's everyday life needs. These continuous changes are defined and guided by markets forces, employment, land values in the context of the Total Urban Functional Demand (TUFD). It is remarkable that the formed groupings explain the 64% of the observed diversity of the recorded cases.

This auto-regulation refers to

(a) The reveal of Land Uses groupings which present continuous ameliorations, regarding their Urban Functional Relevance (UFR). This UFR refers to land uses that must co-function in certain city's areas aiming to their own Optimum Function (LUOF) as well as the City's Total Function (CTF).

(b) The way these groupings are allocated in the urban tissue, realizing gradually functional improvements of their distribution, aim a) to the Traffic Minimization (TM) but also in b) the formation of Autonomously Functioning Urban Sectors (AFUS). This deterministically, without regulatory principles, re-allocation and mixture of land uses is not being realized with random mixtures. As it is proved by the functional structures that result from the analyses in the three censuses records, the functions groupings that are revealed are composed by functions that aim to and are guided by the optimum city's function. It is also realized that these groupings through time are composed by different functions, fact that can be considered as improvement of city's functional behaviour.

It is obvious that those two urban dimensions interact in a perpetual completion to the urban sustainability and resilience and secure the better respond to city's change.

2 INTRODUCTION

Each city defines its general function in its urban planning wider area. Land uses are the substance of urban planning that defines city's form and function. In urban planning in Greece,land uses planning since 1833, defined only the kind and position of public uses. It was 1979, when for the first time not specific functions but groups of functions were allowed to be allocated .The ambiguity of this kind of planning gave the city's functions the freedom to be allocated with their own criteria dictated by market forces.

The gigantism of Athens capital, which constantly attracted new citizens, with intensity that differed according to political, economic e.tc. conditions led to plans which tried to manage land uses in the urban tissue. In 1985 a regional plan that was legislated tried to relieve thecenters population congestion and lead

to multi-centric development. In time new urban plans for each of the Athenians basin municipalities were legislated in order to achieve the better management of land uses allocation. Unfortunately the legislated plans of "laisser faire" without a strict frame of allocation gave in first regard the chance to anything to be allocated anywhere, anytime without any areal and thematical discipline.

The current research will reveal the thematic areal and diachronic redistribution of land uses in Athenians basin, an area that by the way concentrated the majority of the country's population and employment. Although the centre of Greece was developed without any regulatory restriction and complete absence of principles until 1985 and under the influence of indefinite plans since 1985. So, the final result of land uses allocation is characterized by their auto-regulation based on its citizen's everyday life needs. We will focus on land uses groupings that have been realised through time, with or without restrictions, which result gradually to functional changes of their distribution

3 METHODOLOGY

Our main aim is to examine the form and the composition of land uses groupings. We examine three dates 1978, 1991 and 2001 in order to obtain a more general and continuous in the time picture of them. The land uses groupings will be revealed with the use of Principal Components Analysis. This statistical technique reveals the structures of the variables that are inserted in the Analysis, which in our case are land uses, measured by their recorded employment. These Analyses reveal the functional structure of the Athenians basin expressed by the extracted Components. These Components are structured by the best linear relationship of the land uses. That is to say which land uses are areally related. Finally the Components are rotated in varimax rotation which allows the best thematic and areal correlation of land uses. In order to achieve the best comparability of the three extracted structures we force the Analysis to extract five components for every available assessment.

4 LAND USES GROUPINGS IN THE THREE DATES

In 1978 the Athens basin was a pole of new residents attraction, with industrial zones developing in its around while the tertiary activities were developing in its central core. The employment that was recorded was 619.664 people. The majority of employees were concentrated in the tertiary sector (57%) while the industrial and manufacture activities gathered the 43% of the recorded employment. This time as told, in the Athens basin existed nor regional neither urban planning, in order to define the detailed allocation of the 37-differnent kinds of land uses. So, the main parameter that influenced land uses allocation was the coverage of the basin's citizen's everyday life needs that ensured the best activity's function, hence it's maximum profit.

The extracted functional structure, from the Principal Component Analysis, in 1978 is composed by five components (groupings of land uses) that explain the 24,5% of the total variance of the existing employment situation (Table 1). This percentage seems to be very low in order to explain adequately and

persuasively the existing shaped structures, but it must be pointed out that the Analysis is forced to reduce the number of Components in order to be comparable with the structures of 1991 and 2001. It must also be pointed out that the above results from an Analysis of 38.322 areal units in which we examine totally 1.417.914 observations (37X38.322).

The first group of land uses (composed by 12 of the 14 tertiary activities) defines Central daily needs land uses while the rest four groupings are formed exclusively by the remaining 23 industrial uses. It has revealed that although restrictions regarding land uses did not exist, the activities themselves seeking to take advantage of the profits that can be ensured by certain areas position have shaped cores where activities are concentrated. It has also revealed that industrial uses have shaped groups as they need areas with common characteristics that means low land prices and adjacency with main axes and in some cases they function on an assembly line.

In the period since 1978 until 1991, have intervended the legislation of the Regulatory basin's plan and the Urban plans for each of the 56 basin's municipalities. Those plans aim, was to create sustainable areas, develop sub-centers and isolate the industrial uses in certain areas while they encouraged the mixture of all uses in order to achieve multifunctional areas.

The employment that has been recorded in 1991 in the 51 activites have increased to 898.307 (from 619.664 in 1978), with 71% distributed in the tertiary sector while the employment in manufacture industries has

decreased from 266.455 to 258.305 employees. The extracted functional structure, in 1991 is composed by five components (groupings of land uses) that explain the 35% of the total variance of the existing employment situation (Table 2). The fact that although the absolute number of employment has increased and the total explained variance of the existing employment situation has also increased shows the tendency for a certain land uses regulation. Central activities remain the main grouping of land uses with increased variance. The second grouping is composed by Public central activities and the rest three groupings are composed by relevant and in some cases functionally connected activities.

THE LAND USES GROUPINGS IN 1978

Component	Economic activity	Employees	Loading	Variance
CENTRAL DAILY NEEDS LAND USES	Retail Trade	101.711	,638	6,673
	Wholesale Trade	49.353	,625	
	Transactions of Affairs	15.921	,604	
	Brokers and representatives	5.454	,590	
	Insurances	6.605	,544	
	Clothing and footwear Industries	38.815	,440	
	Restaurants and Hotels	31.703	,423	
	Rest Industries	7.199	,408

Tables 1-3.

The decade from 1991 to 2001 was characterized by the constant review of the existing plans that faced difficulties in their application as they did not face the obvious demands of the city's function. The census of 2001 employment shows that it has increased in a 38% percentage (from 898.307 in 1991 to 1.245.542 in 2001). This increase is recorded in manufacture and industrial activities (22,4%) and in the tertiary sector (38%) The P.C.Analysis has revealed that, the five groupings that are extracted explain 49% of the total

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

variance of the existing employment situation (Table 3).. The first grouping presents a high mixture of central, industrial and manufacturing land uses as it contains 22 of the total 51 urban functions, explaining at the same time 22,09% of the total variance. The second grouping contains 9 central activities and only one manufacture activity. It is obvious that the land uses are creating groups in a bigger degree in relation with 1991 and also that land uses are still mixed without a strict functional criterion.

5 THE ALLOCATION OF THE LAND USES GROUPINGS

For the examination of the land uses groupings allocation, the revealed components are grouped in three categories: the central, the industrial and the mixed groupings. The distribution of the components of the three dates in each of the above three categories is shown in table 4.

SHAPED GROUPINGS			
DATES	**CENTRAL FUNCTIONS**	**INDUSTRIAL FUNCTIONS**	**MIXTURE OF CENTRAL AND INDUSTRIAL USES**
1978	Central daily needs land uses, (1st)	2nd , 3rd, 4th, 5th Industrial land uses	
1991	Private central uses(1st) , Public central uses (2nd)	3rd, 4th, 5th	
2001	Central land uses (2nd)	3rd, 4th, 5th	1st

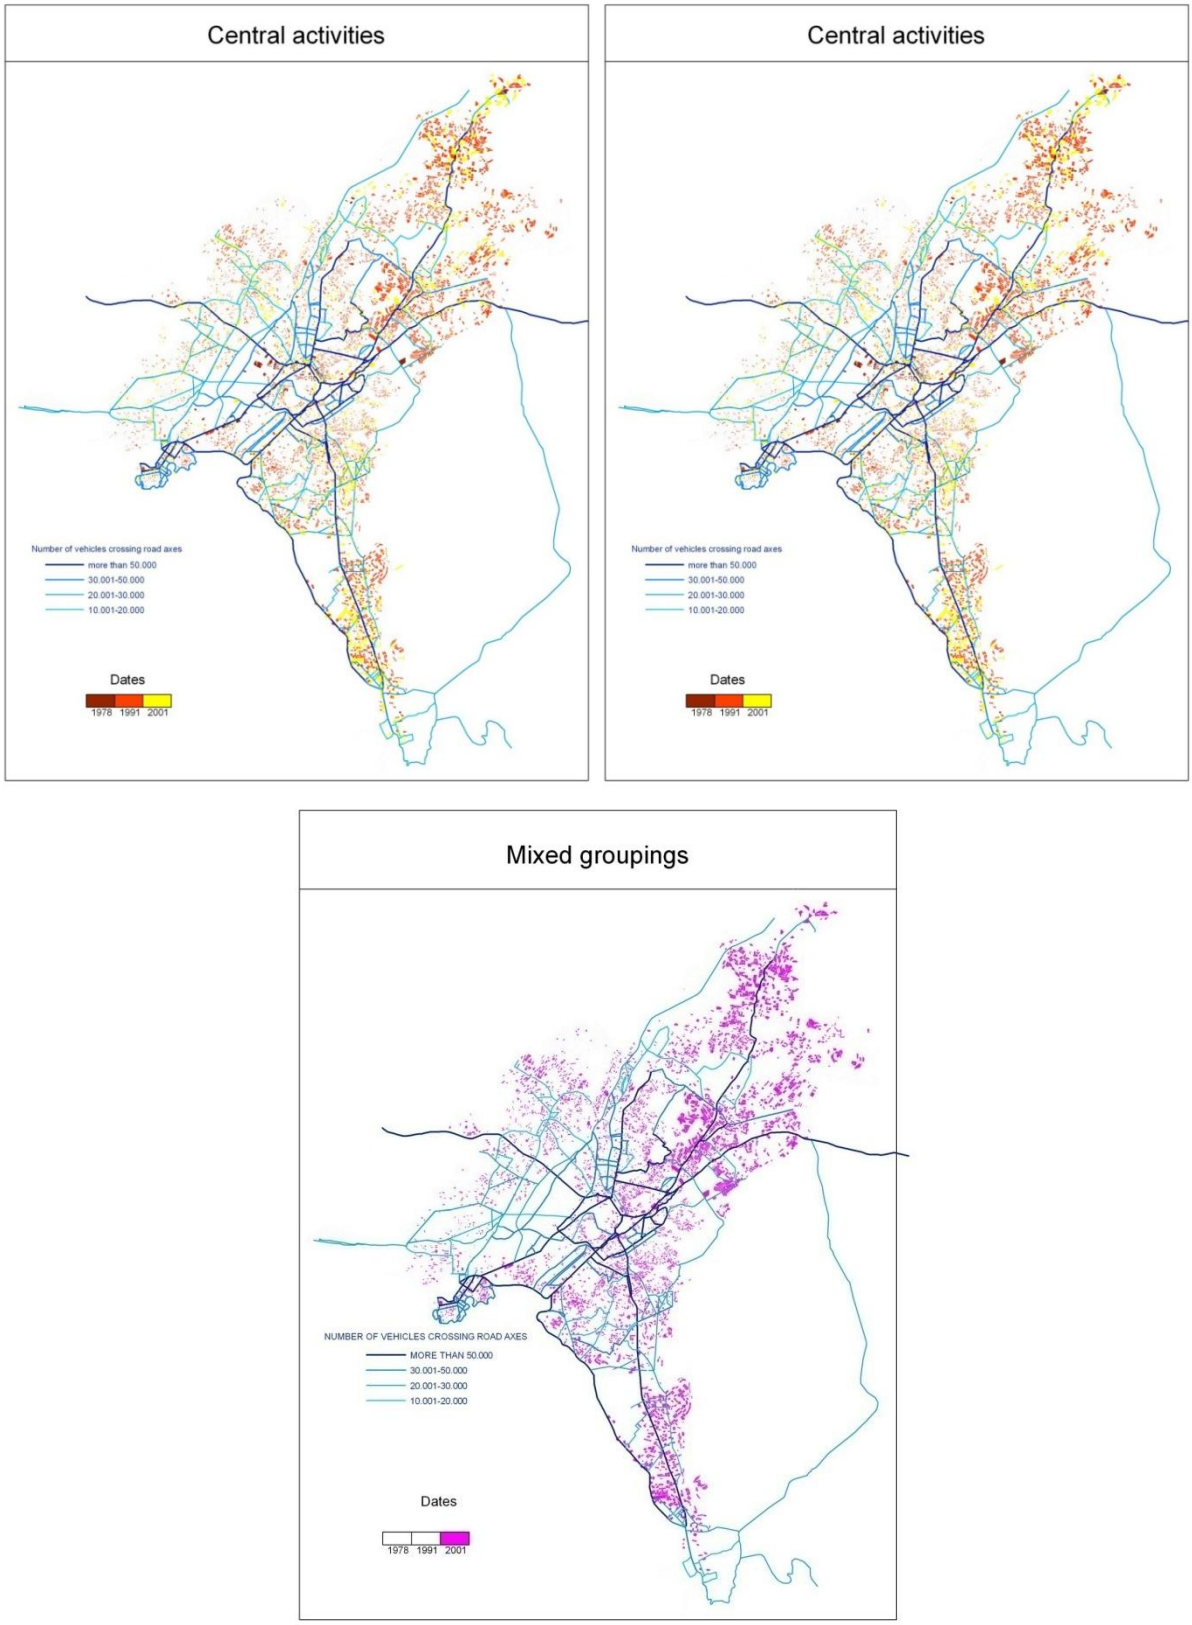
Table 4.

The areal investigation of land uses behavior shows that:

As for central functions, in 1978, the first grouping is allocated in the central core of the basin while other central functions cores and autonomously functioning sectors have not yet been created. In 1991, the central functions are allocated not only in the existing since 1978 core, but have extended on axial form on avenues that lead and cross high-income suburbs. In 2001, central activities are allocated with scattered form in the basin's total, more intensively in the south, north and east basin and will less intensity in the west. We conclude that the existing central functions cores are expanding with different intensity, towards all areas, so autonomuslly functioning central cores are created and that the basin is totally served (Map 1).

As for industrial and manufacture functions, the initial cores that were allocated in 1978 in the basin's total, were extended in 1991 in wider regions and more intensively in the west basin, that still remains the traditional industrial degraded area. In 2001, the mapping of the industrial and manufacture groupings show that they have remained steady in the same areas, as they have not extended or shrinked (Map 2). Therefore, although the employment in this sector has increased it is still concentrated in the same areas, co-existing with tertiary activities. It is concluded that the segregation of uses and the creation of functional zones with specific functions is not created while on the contrary everything is allocated everywhere but with some restrictions regarding not the existing plans, but the optimum service of the urban areas criterion that provides the best profit for these activities.

In 2001, the majority of the recorded cases shows that tertiary and manufacture activities are more intensively mixed. Therefore, the thematic mixture of land uses remains random in the majority of the recorded cases. In the north south and east basin in 2001 the new mixed uses groupings are scattered in all areas where intense central functions groups are also allocated. It seems that the activities of this grouping, that are mixed in a random way, are allocated with the criterion of the maximum coverage of the until then not satisfactory served areas. Therefore, new enterprises of all kinds avoid the congested center and prefer areas that had not until then developed functional centers but had increasing population. So, autonomous areas have started to develop, concentrating all kinds of functions. This auto-regulation that is not exactly following the legislated plans, that tend to sub-centers creation, show that traffic minimization has up to a point been achieved, while autonomously functioning sectors are created with a big degree of randomness. It is concluded that a thematic and areal balance has not yet been achieved. This phenomenon is related to the constant employment and population increase of many areas assisted by the freedom that is provided by the existing legislative framework.



Maps 1-3.

6 CONCLUSION

The subject of the current conference, as posed, leads to the search of the way of grouping of the land uses into the urban body. The structural investigation of an urban body formed during almost a quarter of a century without practically any interference shows clearly that the expected groupings are not steady but for different reasons they change adjusted to the total urban function. Again we are facing the Heiraclitus

famous saying "everything flows". We cannot compare directly the three structures because they result from three different matrices that contain different data from three dates that cover 23 years of the city's life. Our comparison will be nominally and conceptually only from the results of the revealed structures level.

The revealed parts of the city (groupings of land uses) in the three examined dates aim to the regard that the land uses are grouped according to their arising urban functional relavance and simultaneously according to their own optimum function in the total city's frame. Initially it is not possible to imagine a completely clear and rational layout of the thematic and areal defined "parts" of the city. This happens because the city's function is very complicated and also it is accumulatively developed. The revealed results of the analysis are constituting the creation of new theoretical dimentions, namely new parts of the city's function which present the best possible areal distributions. These "parts" are composed by phenomenically random groupings of the recorded urban functions. They result from a numerical classification, based on their linear relations and show that there is a phenomenically random allocation of the urban functions anywhere and anytime. The mapping of these "parts" shows on the contrary that they are areally mixed not randomly but according to a certain URBAN FUNCTIONAL AUTO-REGULATION.

Looking for New Ideas of Public Space – Public Space Projects in Gdansk Reinforced by Art Activities

Magdalena Rembeza

(Magdalena Rembeza, MArch PhD, Technical University of Gdańsk, 80- Gdansk, ul.Narutowicza 11/12, magrembe@pg.gda.pl)

1 ABSTRACT

Revitalization of public open spaces is a complex enterprise in Poland in terms of the art, cultural and information aspects of this process. Simultaneously the public space should play an important role when building the quality of revitalization programs and the quality of city development. The new art and cultural activities are the revitalization tools, which are also the good examples of bottom up ideas helping to start a process of change in the degraded urban areas.

The art and cultural projects, both in Young City of Gdansk (former shipyard areas) or in the Dolne Miasto (historical, degraded city centre district of Gdansk) shows that it is a real need of implementing such ideas and treating them as an important urban operational tools of the revitalization program.

The Wyspa Progress Fundation and the LAZNIA Center for Contemporary Art are very interesting initiatives which not only enable to transform the public space but also help to bring art into the urban space. The Wyspa Institute of Art is located in the building of the former Basic Shipbuilding School in the Gdansk Shipyard. It has become a home of the Wyspa Progress Foundation, an innovative artistic organization combining the presentation of contemporary art with reflections on the shape of social culture.

LAZNIA Centre for Contemporary Art is an animator of a new artistic project whose aim is to create a permanent collection of artworks in the urban space, called the Outdoor Gallery of the City of Gdansk. It is supposed to act as a stimulus to change the character of the district, where the institution is located. It should join the process of social and architectural transformation of this run-down district of Gdansk, called the Dolne Miasto, cooperating in a long-term revitalization plan.

Both projects (The Wyspa Progress Foundation and the LAZNIA Centre for Contemporary Art) are starting to be the catalyst of change in the revitalization areas of Gdansk. Due to revitalization process the degraded urban structure should be closer to meet the needs of people in their everyday life.

2 THE ROLE OF ART IN A PUBLIC SPACE WHEN CREATING THE REGENERATION PROGRAMME

2.1 Public space as an important element of building the regeneration program

The public space should play an important role when building the quality of revitalization programs and the quality of city development.

The public space and the whole strategy of building public space are a key element of regeneration programs. Building these programs is a multi-dimensional task based on spatial projects as well as on the „soft“projects related to local community. It is essential that designing the attractive public space for revitalization program is one of the most important factors that decide about its success. The attributes of a good public space like aesthetic and compositional attractiveness should have decisive role when creating city regeneration program (Zuziak p. 28-38).

The mentioned public space could not be only a showroom but should fulfill a further more important role – should be the heart of urban activities, determinant of local identity and a key element of structural conjunctions. Only this kind of space could be important for the local community (the actor of urban regeneration program) and have the significant role in the whole regeneration process.

2.2 Why exactly art in a public space

Speaking about public space it would be essential to understand what is the relationship between the public art initiative and urban regeneration program.

Commonly known examples of the artistic district (South Houston – Soho in New York, Marais in Paris, El Raval in Barcelona) demonstrate how art is important when creating the identity of degraded urban space. These districts attract the artistic bohemia, architects, and designers. The built-up area, former degraded, receives a new architectural value by converting into artist work-rooms, mansard roofs, galleries or museums.

Worldwide there is also the action of implementing the pieces of art in a public space. The actions organized by the Public Art Fund in New York (Manhattan, Rockefeller Center) or creating a permanent collection of art in Potsdamer Platz in Berlin or in Liverpool could be a good representation of it. What is more, Public Art Fund in New York has been committed to working with emerging and established artists to produce innovative exhibitions of contemporary art throughout New York City. By bringing artworks outside the traditional context of museums and galleries, the Public Art Fund provides a unique platform for an unparalleled public encounter with the art of our time.

It should be underlined that art in a public space is also an alternative for art in galleries and is a chance for artists to obtain a mass consumer as well as capture the individuals that do not have contact with art in their everyday life.

The types of public art involved in urban regeneration programs depend very much on the type of regeneration programs. For example Tim Hall and Iain Robertson demonstrate that we can recognize a broad distinction between flagship, or prestige, revitalization projects and communal regeneration projects. These have been summarized by the Policy Studies Institute as:

- contributing to local distinctiveness
- attracting companies and investment
- having a role in cultural tourism
- adding to land values
- creating employment
- increasing the use of open spaces
- reducing wear and tear on buildings and lowering levels of vandalism. (1994,p. 38)

3 PUBLIC SPACE PROJECTS IN GDANSK REINFORCED BY ART ACTIVITIES

3.1 Revitalization of Dolne Miasto in Gdansk through the art

The Dolne Miasto in Gdańsk is a historical, degraded urban district which is located in the close neighborhood of city centre (Głowne Miasto) however isolated. The Dolne Miasto is indicated as a pilot revitalization area due to its high cultural values. Furthermore it is the only part of a historical downtown that was not destroyed during the war. The second important factor is the necessity of immediate renovation activities in this area. The district of Dolne Miasto has got a specific genius loci because of its urban blocks, historical buildings (great examples of architecture dates to XIX century), characteristic public spaces. However the area is degraded and its state is becoming exacerbated. This situation ultimately affects social processes.

The stimulus of change in Dolne Miasto is LAZNIA Centre for Contemporary Art. It is an animator of a new artistic project whose aim is to create a permanent collection of artworks in the urban space, called the Outdoor Gallery of the City of Gdansk. The collection of the Gallery is supposed to be created by years and the works of arts are chosen in the international competitions. The important works which have already appeared in Dolne Miasto are: LKW Gallery by Daniel Milohnic and Alexander Rijkers from Germany, Staging Anonymous by Dominik Lejman, Invisible Gate by Front Studio from New York or Untitled by Esther Stocker from Austria.

The LKW Gallery by Daniel Milohnic and Alexander Rijkers is the lorry in a viaduct, a symbolic representation of mental barrier between Dolne Miasto and the rest of the city. Due to its construction it is easy accessible and simultaneously it is a place where workshops for children, exhibitions, concerts are being held. As authors say the LKW Gallery shall help to build a passage at Szopy-road, between Dolne Miasto area and the centre in order to integrate the district into the city of Gdansk. Furthermore the passage shall be an impulse for further artistic work and creation. The non-area under the bridge is transformed into a place of communication.

In December 2009 a new installation called the Invisible Gate design by Front Studio from New York won the competition. This is an urban, monumental project that has got influence on a city scale. Moreover the

Invisible Gate is characterized by a wide symbolic meaning thanks to the form of mirrors, reflections and pictures of architecture, people and river giving a wide range of interpretations.

The Outdoor Gallery of the City of Gdansk is an important and necessary element of the revitalization of the Dolne Miasto and plays a great role in eliminating social problems - through the art. Competitions of the Outside Gallery of the City of Gdańsk are a part of actions of the artistic practice as well as they are creating social behavior. The project is the part of the wider program which helps to improve living conditions in the housing areas. It also enables to change a character of the district and helps to create a unique collection of art in the urban space.

Fig. 1: The Invisible Gate design by Front Studio from New York. Photo by Anna Szynalewska

3.2 When the art becomes too difficult

Broadly promoted strategy of revitalization of Dolne Miasto through art is one of the most important issues related to LAZNIA activities. When presenting the program for 2010 there were a lot extreme opinions about the entire project: from the full of hope beliefs that Dolne Miasto will be a social laboratory to the very critical ones.

What is even more interested the inhabitants itself do not pay so much attention to the project.

When reported by Weronika Korbal, the respondents were rather insensible to theatrical character of installation by Dominik Lejman or other works presented by The Outdoor Gallery.

On the other hand the workshops for children organized by LAZNIA (e.g. architecture for the youngest or workshops with Front Studio) were very much approved by the local community.

This example shows that the art in public space, as a revitalization tool, will have a proper meaning only then when it will involve the local community.

3.3 The Wyspa Progress Foundation on the post- shipyard areas

The Gdansk Shipyard is a significant place, simultaneously symbolic in a mass memory of polish people. It is a place of freedom and place of birth of Solidarity in 1980 as well as the place of difficult experiences of transformations. In 1990 when the shipyard was adjudged bankrupt the city decided that on the post-shipyard areas will be a new city centre district called Young City of Gdansk. To start a process of change and revitalization of the area the artists were asked to liven up the space. The aim was to create the cultural space open for the city.

Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

Fig. 2 : The Wyspa Progress Foundation. Photo by: Joanna Kurkowska

In 2004 the Wyspa Progress Foundation was founded by Grzegorz Klaman and Aneta Szyłak in the building of the former Basic Shipbuilding School in the Gdansk Shipyard.

The Wyspa Progress Foundation is an innovative artistic organization combining the presentation of contemporary art with reflections on the shape of social culture. There is a place for workshops, library, club and exhibition. The artistic actions and exhibitions can be also found in the open space of Gdansk Shipyard.

Fig.3 : The Young City of Gdansk and the Wyspa Progress Foundation (IS WYSPA). Source: www.mlodemiasto.pl

But first of all the Wyspa Progress Foundation is a bottom up idea helping to start a process of change in the degraded urban area. However this process is not easy. The field researches led by Professor Joanna Tokarska Bakir (2008) show the differences in understanding the space of transformed shipyard by the social groups. For the artist this space is connected with symbols, history and the magic of post-industrial area. In the contrary the former shipyard workers emphasize the economical and the political context. In the same time both groups are afraid of the new investments and criticize the commercialization of the Young City project.

4 CONCLUSIONS

Public art can help alleviate a wide range of urban and social problems. In the same time it can be a good revitalization tool only then when it will involve the local community in the process of change. Both Gdansk' projects (The Wyspa Progress Foundation and the LAZNIA Centre for Contemporary Art) shows that revitalization process can be started due to art . It is also important that this kind of initiatives should have the wider context as well as they should reflect the processes of revitalization of the degraded urban substance.

Memorable Square: Identities, Meanings and the Production of Urban Space in Yogyakarta, Indonesia

Dyah Widiyastuti

(ST., MCP Dyah Widiyastuti, TU Dortmund, August-Schmidt-Strasse 6, 44229 Dortmund Germany, dwidiyastuti@yahoo.com)

1 ABSTRACT

Traditional space in Yogyakarta Indonesia is called alun-alun. It takes form as a square, which is located in front of the palace and is surrounded by essential buildings. Taking all into account, alun-alun is located in the area, which represents the power and civilization symbol. The initial function of alun-alun was not intended to serve royal purposes and show the grandeur of sultanate. Through history, alun-alun has been changing its role and becoming merely to be public space. It has experienced various tensions over its reproduction and control ranging from the issue of privatization, commercialization, and misuse to the tension between modernization and conservation. The mushroomed of street vendor and the absence f institution and management together with the lack of planning regulation have been declining the importance of alun-alun. Waiting for the ideal form of future alun-alun through debates among stakeholders has been creating negative impact and left this place abandoned.

2 ALUN-ALUN IN THE EARLY FORMATION OF KASULTANAN YOGYAKARTA (1755-1880)

2.1 Introduction

The establishment of Yogyakarta city was initially begun with the construction of the king's palace (kraton), while its architecture reflects the Javanese view of the cosmos. Within this overview Yogyakarta and its kraton is considered to be the imago mundi, the replica of the universe, where maintaining the balance between macrocosm and microcosm was fundamental. At the core of Javanese philosophy is the concept of dualism that shows the balance through dialectical interaction of opposites, such as interconnection of mountain and sea, solid and void and north and south. Two other important Javanese philosophical concepts are symmetry and hierarchy. Symmetry relates to the design and layout of buildings, while hierarchy could be seen in the arrangement of each building components and its relationship to other parts. These concepts of dualism, symmetry and hierarchy are strongly reflected in the layout of kraton and its two open spaces.

Spatially, kraton is a residence complex of the reigning king of Yogyakarta Sultanate. Taking a form of Javanese house, kraton contains series enclosures which each encircled by wall and a main gate. Each enclosure consists of courtyard with several open and closed pavilions. A pavilion without wall surrounding it is called bangsal or tratag, while the closed one is called gedhong. According to this Javanese house pattern, a large open space adjacent to bangsal could be considered as the courtyard of kraton complex. It has two open spaces on the northern and southern parts following the north-south axis, which are called alun-alun. The words alun-alun at least is interpreted in two ways. It comes from word 'alun' or the wave since it is an open space which is covers by sand like an ocean. Other believes it comes from words 'alon-alon', which means 'walk slowly' due to old Javanese custom. In the past, people who would be facing the king in the sitihinggil has to prepared themselves, started from alun-alun they had to walk slowly and set the pace in connection with royal procedures.

2.2 Alun-Alun Under Sultanate Power

The concept of hierarchy has put northern parts of kraton as the front and considered more important, while southern parts were considered pengkeran or the backside.Northern alun-alun covers an area of 310x 280 m2 which is bigger that southern alun-alun which only covers an area of 160x160m2. It took form as an open square located in front of bangsal pagelaran. The illustration of early kraton and northern alun-alun could be interpreted from a sketched by A. de Nelly in 1771 (Figure 1). Southern alun-alun was encircled by tapered wood fences called pinacak suji and guarded by Javanese royal soldiers armed with keris, a javanese dagger, and spear. Those indicated the importance of this space.

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)

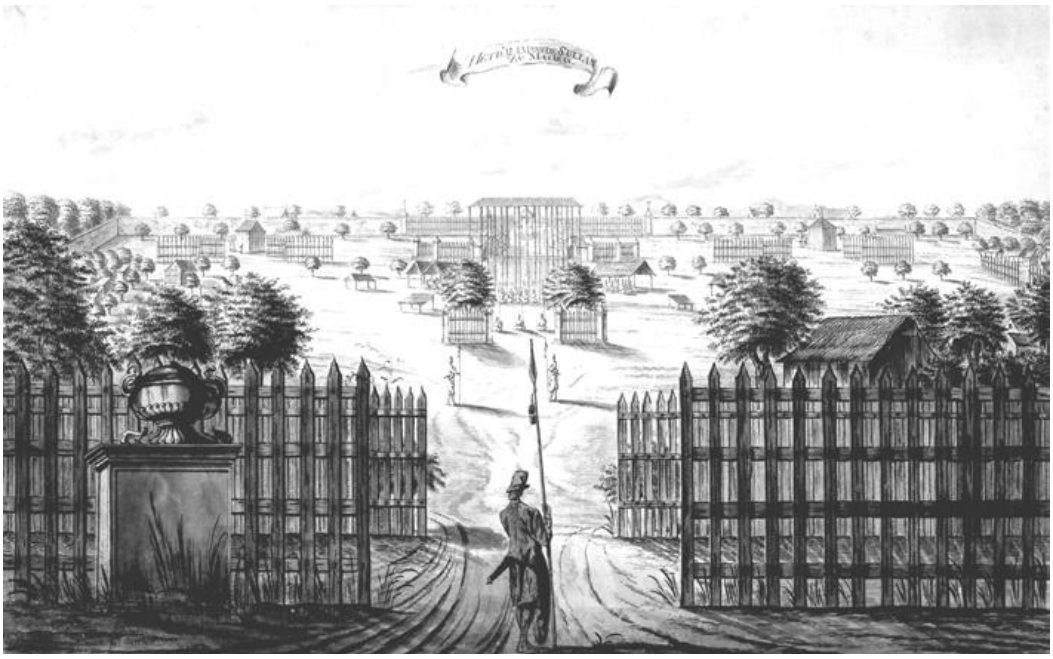

Figure 1. View of the Yogyakarta kraton from the northern square (alun-alun) sketched by A. de Nelly, one of Johannes Rach's pupils, in circa 1771.Source: Courtesy of the Rijksmuseum, Amsterdam as cited in Peter Carey 2008.

The surface of northern alun-alun was covered only by fine sand represented the shorelesss ocean which in turn is a universal image for the infinity of God. The center of square was completely released which make two banyan trees dominated the view. A pair of banyan trees called Kyai Dewandaru and Kyai Janandaru represents the idea of macrocosm and microcosm. Kyai Dewandaru represents the union of sultan and God, where dewa literally means god and daru or andaru symbolizes wahyu (divine radiance). Kyai Janandaru represents the unity of sultan and his subjects, where jana literally means human to characterize humanity in general and the population of sultanate in particular. Together they represent the two aspect of the Javanese doctrine of 'manunggaling kawulo lan gusti' (the unity of servant and lord). While the two banyan trees at center of alun-alun are primarily a symbol of mystical knowledge and the infinity of God, sixty-two banyan trees represented the age of Prophet Mohammad when he died also surrounded it. The boundless ocean and mystical union represented by twin-fenced trees at the center realizes the essential unity of creator and the created.

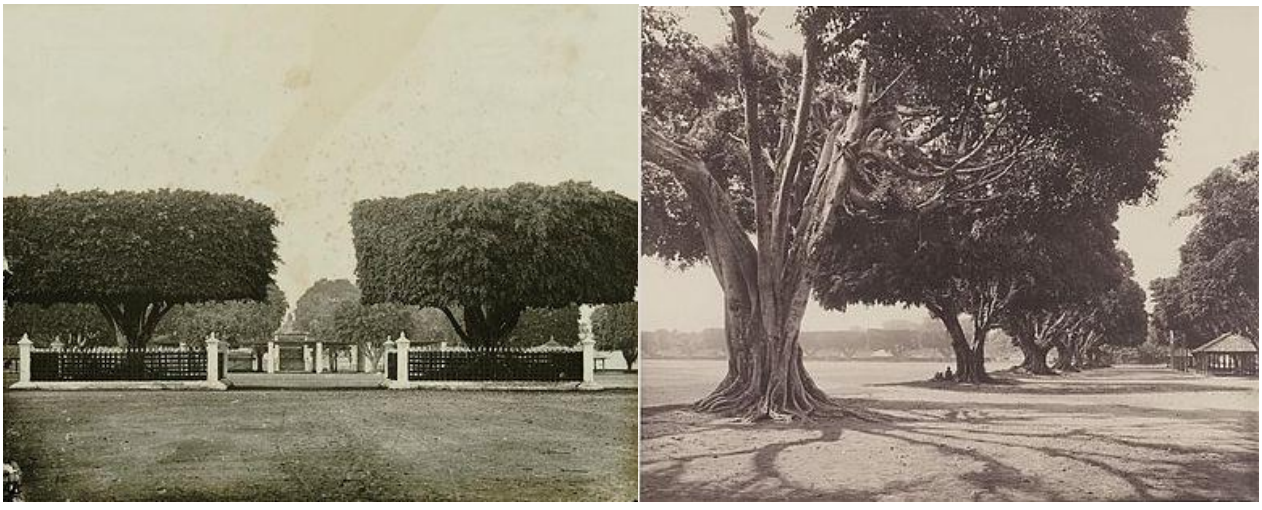

Figure 2. Banyan trees in northern alun-alun in year circa 1990. Source: Courtesy of KITLV/Royal Netherlands Institute of Southeast Asian and Caribbean Studies

Northern alun-alun was encircled with some important buildings in term of its size and function. The main building around northern alun-alun is pagelaran kraton (palace hall) which functioned as the main audience hall of the kraton and a transition space before entering a space for the throne of sultan. Along the western edge there is a complex which belongs to masjid agung (great mosque). Great mosque is separate component

of kraton compound but play strong role to legitimate king position where sultan as the representation of God is the head of religion. The square was surrounded by tall banyan trees and several pavilions called pekapalan which come from word kapal means horse or a place to tighten horse while the rider take a rest. Pekapalan was a rest place for bupati (regent) from Kasultanan Yogyakarta territory, when they had to face the king. Other buildings on the edge of northern alun-alun were tiger cage and pamonggangan, a place to store gamelan. King used to conserve wild animals like tiger and elephant, which symbolize his strong sovereignty (Lombard 2008).

Despite the strong presence of dominant power, historically alun-alun was central to both the physical and cultural lives of its people. Alun-alun was the only space of the palace that was publicly accessible. While it did not function as a democratic space, it nonetheless had a more civic nature than its surroundings, although this was rather symbolic. This space functioned as an arena for public activities sponsored by the ruler and the religious ceremonies to celebrate the ruling power of the king. Among various royal ceremonies, there were garebeg and sekaten.

The garebeg was a ritual of veneration, which includes praying, offering, and distribution of gifts and alms. It is held three times a year according to three major Islamic festivals that are Mulud, Poso and Besar. Garebeg Mulud commemorates the birthday of Prophet Mohammad, while other garebegs celebrate the end of the fasting months (Garebeg Pasa, Bakda or Shawal) and great Eid (Garebeg Besar). The ritual of garebeg consisted of a procession of royal troops, nobles and abdi dalems (retainers) bearing pusaka (heirlooms) and gunungan (a rice-mound) moved out of the inner complex of kraton towards the great mosque. Food offering are given to the mosque officials and other abdi dalem, and each of sultan subject should receive a portion of gunungan. The garebeg was importantly the occasion upon which taxes owed to the royal center were collected from all territories. It was on Garebeg Mulud that kraton claimed its share of harvest and collected taxes from the people. Hence, Garebeg Mulud could be considered as a symbolic form of sacrifice in which the farmers in hierarchical agrarian society would pay tributes to their ruler in exchange for divine blessing producing fertility in their crops. Garebeg was also a chance for people to see their king. Sultan appeared out of the place accompanied by high-rank royal families and officers sat on his throne while his subjects converged in northern alun-alun to worship their king. The coming of people in northern alun-alun implied loyalty and devotion of the people to their king, which in turn was also meant as recognition of king' power and authority over them. The combination of mystical union and the garebeg are thought to establish the prosperity, social and spiritual tranquility of the state and to define ideal social relationship in term of union of servant and lord.

Sekaten was the series of Garebeg Mulud held a week precede it. The fundamental parts of Sekaten was the appearance of two set of gamelan, Kyai Nogowilogo and Kyai Gunturmadu in the great mosque which are played simultaneously three times a day within a week. Besides the gamelan performance, sekaten is an annual event to provide public entertainment and a night fair runs enliven it for a month. Sekaten fair was not only to attract people from village, but also to provide entertainment to those who came to pay their taxes.

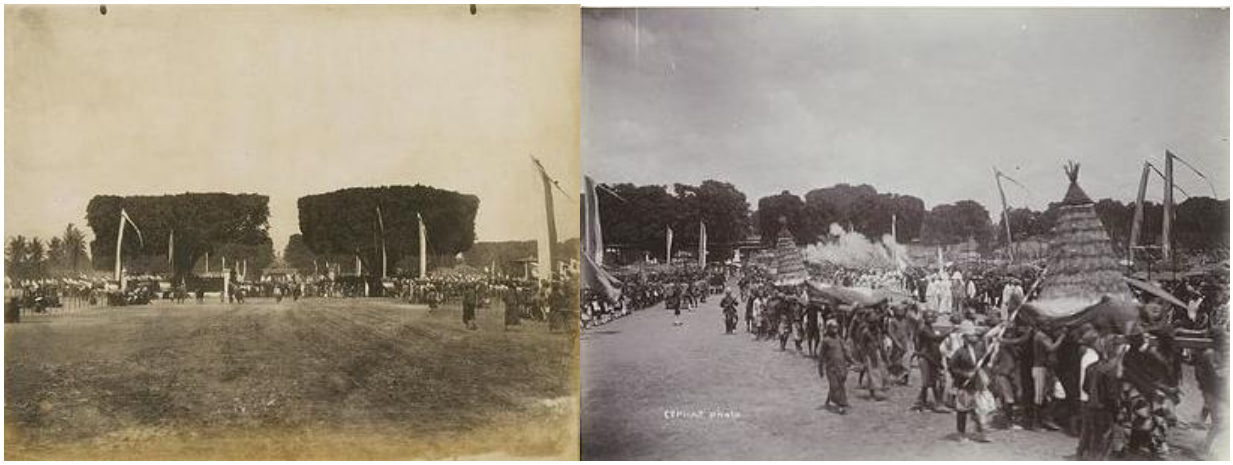

Figure 3. Garebeg procession in northern alun-alun Yogyakarta in the early 1990s Source: Courtesy of KITLV/Royal Netherlands Institute of Southeast Asian and Caribbean Studies

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print) Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

In the eighteen and early nineteenth century, the participation of the troops in the procession was a clear symbol of the sultan's military power. The sultan troops were at the time more than a symbol. They provided security and posed a clear threat to real and potential rebels and to the Dutch. The celebration was marked by the obligatory attendances at court of all the provincial nobility and all the kingdom officialdom. Participation in the ritual was an act of political submission and those who refused to attend could be executed for treason (Woodward 2011). Garebeg in the eighteen century was also arenas for elite political competition precisely because all of the contending factions were required to appear at court. Indeed, it was at this celebration that the unity of the kingdom was determined and reaffirmed precisely by the differential attendance of the provincial elite alongside the elite of capital.

3 ALUN-ALUN IN THE ESTABLISHMENT OF COLONIAL STATE (1880-1940)

The role of both alun-alun was closely related to the role of kraton as the center of political, military and ritual activities of Yogyakarta Sultanate. The balance between these organizational principles has shifted along with the political fortunes of the Sultan. There were massive changes happened in Kasultanan Yogyakarta in the early 20th century. VOC (Dutch East India Company) went bankruptcy in year 1799 and Royal Dutch Government took the control over its colonies. The arrival of Daendels, the Dutch governor general in 1808 marked the start of new and more aggressive policy toward the court. It placed the court in clearly subordinate position to European government. Since then the inharmonious relationship between sultan and Dutch came into surface. The renovation of most buildings in kraton complex shows the attempt of sultan to restore his cultural dignity in the midst of his decreasing political roles. Bangsal Pagelaran became the façade of kraton and marked the changing orientation of kraton to be more open. It followed with the construction of Sono Budoyo Museum and Soboharsono Theater surrounding northern alun-alun. The sacredness of kraton as well as alun-alun is gradually decreasing and becoming more public.

The changing political role of sultan in early 19th was also evidenced in the activities, rituals and processions taken place in alun-alun. In earlier time, the role of southern and northern alun-alun was related to the role of kraton as the center of political and military activities of Yogyakarta Sultanate. By the early nineteenth century, many of the functions of royal bodyguard regiments were of a ceremonial nature, although they still take to the field. The demise of the political authority and military power of the sultanate in the nineteenth century led its military, political functions to be redefined as ritual.

As Dutch colonial power grew, Kasultanan Yogyakarta became more and more of a theater state in which ritual replaced military and economic power as the foundation of royal prestige and authority. These political changes also impacted on the role of alun-alun as the space for conducting and representing the grandeur of kraton Yogyakarta. This is evidenced in the activities, ritual and procession taking place in alun-alun which was still a place for holding kraton rituals such as garebeg and sekaten although their message was fundamentally changed. The Garebeg as the grand gathering is no longer a state rite that unites the entire regions through a ceremony of gratitude for a bountiful harvest and the spreading of blessing from their king. The ritual and procession had been simplified and military parade was just the part of ritual. It is rather a cultural ceremony that its symbolic role is limited to the religious realm and the preservation of tradition, although it is argued that during the colonial period state ceremonies were used as a mode of symbolic resistance of colonial hegemony. Royal ceremony and ritual could not be used to show his authority, when royal military troops was eliminated to be just a ritual during garebeg. This aspect of ritual is subject to almost constant change. The number of gunungan decreased which could be interpreted as the sign of decreasing wealth and teritory, although the obligatory attendance at the court of all the provincial nobility was maintained until 1939s. Kasultanan Yogyakarta lost most of his outer territories while inner territory was shared with other court, Pakualaman in year 1813.

The role of both alun-alun was closely related to the role of kraton as the center of political, military and ritual activities of Yogyakarta Sultanate. The balance between these organizational principles has shifted along with the political fortunes of the Sultan. There were massive changes happened in Kasultanan Yogyakarta in the early 20th century. VOC (Dutch East India Company) went bankruptcy in year 1799 and Royal Dutch Government took the control over its colonies. The arrival of Daendels, the Dutch governor general in 1808 marked the start of new and more aggressive policy toward the court. It placed the court in clearly subordinate position to European government. Since then the inharmonious relationship between sultan and Dutch came into surface. The renovation of most buildings in kraton complex shows the attempt

of sultan to restore his cultural dignity in the midst of his decreasing political roles. Bangsal Pagelaran became the façade of kraton and marked the changing orientation of kraton to be more open. It followed with the construction of Sono Budoyo Museum and Soboharsono Theater surrounding northern alun-alun. The sacredness of kraton as well as alun-alun is gradually decreasing and becoming more public.

The changing political role of sultan in early 19th was also evidenced in the activities, rituals and processions taken place in alun-alun. In earlier time, the role of southern and northern alun-alun was related to the role of kraton as the center of political and military activities of Yogyakarta Sultanate. By the early nineteenth century, many of the functions of royal bodyguard regiments were of a ceremonial nature, although they still take to the field. The demise of the political authority and military power of the sultanate in the nineteenth century led its military, political functions to be redefined as ritual.

As Dutch colonial power grew, Kasultanan Yogyakarta became more and more of a theater state in which ritual replaced military and economic power as the foundation of royal prestige and authority. These political changes also impacted on the role of alun-alun as the space for conducting and representing the grandeur of kraton Yogyakarta. This is evidenced in the activities, ritual and procession taking place in alun-alun which was still a place for holding kraton rituals such as garebeg and sekaten although their message was fundamentally changed. The Garebeg as the grand gathering is no longer a state rite that unites the entire regions through a ceremony of gratitude for a bountiful harvest and the spreading of blessing from their king. The ritual and procession had been simplified and military parade was just the part of ritual. It is rather a cultural ceremony that its symbolic role is limited to the religious realm and the preservation of tradition, although it is argued that during the colonial period state ceremonies were used as a mode of symbolic resistance of colonial hegemony. Royal ceremony and ritual could not be used to show his authority, when royal military troops was eliminated to be just a ritual during garebeg. This aspect of ritual is subject to almost constant change. The number of gunungan decreased which could be interpreted as the sign of decreasing wealth and teritory, although the obligatory attendance at the court of all the provincial nobility was maintained until 1939s. Kasultanan Yogyakarta lost most of his outer territories while inner territory was shared with other court, Pakualaman in year 1813.

4 ALUN-ALUN IN THE EARLY INDONESIAN INDEPENDENT ERA (1940-1990)

Kasultanan Yogyakarta underwent significant changes during this period. Internal transformation had started after Hamengkubuwono IX ascended the throne in year 1940. Dutch authority on Yogyakarta was taken over by Japan in year 1942-1945. Although Japan did not explicitly take over the political agreement between sultan and Dutch government, the system of indirect rule over Yogyakarta was maintained. Kasultanan Yogyakarta had independent authority to regulate and manage its territory under the supervision of the colonial government. Dutch colonial government called these territory as zelfbestuurende lanschappen while Japan colonial government as kooti. Soon after the defeat of Japan, Indonesia declared its independence on 17 August 1945 and Kasultanan Yogyakarta joined to Republic of Indonesia on 5 September 1945.

During the early years of its independence, the position of this new republic was not yet fully stable, coupled with the intention of Dutch to recapture its former territories through military aggressions. Kasultanan Yogyakarta as a more well established court took important role in defending the sovereignty of Republic of Indonesia. In this revolution period, the center of Indonesian government who was formerly in Jakarta was relocated to Yogyakarta under warranty from Hamengkubuwono IX. Kraton Yogyakarta became the center of Indonesian revolution. In the early period of Indonesian independence, Yogyakarta also became a place for national revolution when it became the capital of Indonesian Republic in year 1946-1949. Yogyakarta became a special region in Indonesian Republic largely because of the central role that Hamengkubuwono IX played during Indonesian revolution. Northern alun-alun became a site for Indonesian independence movement and activities related to nation building were echoed from this square. Indonesian national army was formed in year 1946 and the parade was held in northern alun-alun led by first president Soekarno. Northern alun-alun was strategic place for mass mobilization such as political oration by Sukarno during the celebration of international Labor Day in year 1948.

Figure 4. Indonesian national movements in northern alun-alun in year 1946 Source: Collection of IPPHOS, Indonesian National Archives.

The next transformation was on the royal ceremony and rite. Hamengkubuwono IX viewed splendor through party and ceremony as a colonial legacy, where Dutch colonial power let the king and nobility to be complacent in luxurious life (Soemardjan 2009). The important rites were simplified without reducing its cultural, religious and magical significances attended only by officials and members of royal families. Hence the essence of each ceremony is retained but its pomp and splendor had been uninstalled. Among others, jamas pusaka (ritual of heirlooms bathing) is maintained but conducting without lavish and outstanding ceremony as the earliest times. Even the luxurious garebeg has been reduced to normality. Its Offerings and praying remained to be conducted in accordance with tradition, without compulsion for the local officials to be present and pusaka was no longer displayed during the procession. Garebeg were continues to be held three times a year where a lot of people came to watch the procession from sitihinggil to great mosque and scrambled the gunungan as a sign of king' blessing (Figure 6-21). The absent of local officers attendance was a result of government system, where their presence and homage from were no longer a symbol of loyalty to the king.

The event of sekaten had also changed its form. During previous years, at least until the period of Hamengkubuwono VIII, sekaten was originally seen as a means of supporting garebeg. At the beginning of Japanese occupation in year 1942, sekaten was installed with other shows and government stands also took part. This night market and exhibition lasted until the Indonesian post-independent in year 1950 when sekaten was held for thirty days instead of seven days duration. Along with garebeg, the festive of sekaten provided popular entertainments for people where gamelan sekaten was played. Northern alun-alun turned into a night market, in where a variety of performances such as shadow puppet and magic shows were held. The crowd created opportunity for selling food, either selling in temporary tent or hawking. There are many food and beverage stalls and merchants selling goods ranging from agricultural tools to clothing, cooking utensils, toys and souvenirs. If there is a common rule concerning this element of Sekaten, it is that whatever form of entertainment is currently popular is included.

Under Hamengkubuwono IX, kraton Yogyakarta has opened its door to local as well as global changes. The kraton complex which for years could only be entered by the nobilities and high rank officials has been opened to public. It began with the use of bangsal pagelaran for student lectures. Gadjah Mada University was established in year 1949, the lectures were temporary held in bangsal pagelaran and in the buildings around it before it had an official campus on the southern part of the city. Allowing commoners, students and teachers, to enter a sacred area of sitihinggil was a radical departure of Hamengkubuwono IX's redefinition of the concept of kingship.

What had been considered sacred and private space became more profane and public space. Surrounding the square is encircled with two-way streets along with sidewalk adjacent to the series of buildings on the edge. These streets were paved in the mid 1970 to provide access for people to enter kraton complex and its surrounding kampongs. A space that once was sacred is becoming a mere part of a transportation network dominated by vehicles. Furthermore, some parts of kraton complex were opened to Indonesian and foreign tourist. Kraton began to attract visitors and daily visited by people from rural sides and surrounding town within Central Java (Soemardjan 2009). Cultural attraction, important royal ceremonies and rites, has been

installed and wrapped for tourist purposes. There are daily wayang show (shadow puppet), gamelan performances along with offering lessons in gamelan play and classical dances for free of charge.

Out of special events like garebeg and sekaten which was held only three times a year, other activities which attended by mass of people had appeared in northern alun-alun. This area became the center of public activities. Students used to have outdoor activities, such as exercising and scouting while civil officers used to have offices around the square. During daytime a lot of tourists come to visit kraton building and Sono Budoyo and they used northern alun-alun for parking. Along with the increasing number of visitor, people who live surrounding kraton took opportunities for earning additional income by selling goods or offering services. They sold their goods in temporary kiosks, tents or in peddlers while other became tour guide, becak driver or parking attendant.

5 ALUN-ALUN IN THE CONTEMPORARY ERA

Northern alun-alun is considered as a place which has historical and cultural significances. A site of massive rallies contributes significantly to the political development in local and national levels. During political crisis of May 1998, northern alun-alun, which had been a cultural space, became Yogyakarta and Indonesian political space. When the legitimacy of the government of republic Indonesia came into question, the sultan rethought his position and became a national political figure. He devotes to Indonesian nation and willing to employ traditional Javanese notions of kingship and authority when the republic is in danger. Indonesia was hit by economic crises that began in year 1997 led to widespread students demonstration, violence by mob and security forces and demand for an end to the New Order government. The kraton of Yogyakarta played significant role in averting violence that is more tragic and facilitating the end of New Order. Yogyakarta as the symbolic center of Indonesia, were combined in the political dramas of 1998 and 1999 that led to the fall of the Soeharto government and the rise of Sultan Hamengkubuwono X as an important and powerful national leader. Socio-cultural aspects of massive moral movement of Yogyakarta community gathered in the square in front of Sultanate Palace to meet with Sri Sultan Hamengkubuwono X demanding political reform in Indonesia without violence. On 20 May 1998, Hamengkubuwono gave oration to call Soeharto to resign. He stood in front of people in northern alun-alun and spoke of the need of reformation. . Although sultan had significant political role, being part of Indonesia has redefined kraton functions as cultural and ceremonial instead of political space. Kraton had appeared to rely on their rituals to project their significance and relevance as a cultural center and tourist attraction. Although the essence of royal ceremony and ritual has been preserved, they have been experiencing commercialization as the impact of tourism development.

Figure 5. Northern alun-alun in year 2011 Source: observation

Sekaten as a series of garebeg ceremony has been experiencing fluctuation in meaning. At first was intended to celebrate the birthday of Prophet Mohammad along with religious activities. At this stage has been converted into means of income generation for various parties, especially when duration of sekaten was extended from seven days to a month. In year 1991, sekaten is enlivened with kraton festival where the culture of kraton has been compromised by the existing nature of modernity. This effort is a logical consequence of the discourses of tourism development endorsed by city government and Kasultanan Yogyakarta. The format of sekaten was changed into cultural and handicraft exhibition in year 2004-2005, called JES (Jogja Expo Sekaten). A professional event organizer organized it and the purpose was to promote tourism as well as to attract potential buyers and investor. Northern alun-alun was transformed into a modern expo arena with luxury booths and air-conditions system. Visitors had to pay entry ticket and traditional merchants were excluded, which was protested by public since it was considered disrespectful to tradition. Sekaten was long believed to be a folk market, where traditional merchants were prioritized and every person

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

has the right to come at no charge. Sekaten then has returned to its original format as a folk market. On sekaten fair 2011, the center of northern alun-alun became a bazaar area with numerous stalls and vendors, while government institutions also participated for socializing their programs. The spaces for sekaten event were divided into plots for merchants and for government institutions with different rates. The visitor also had to pay entry ticket of 3000 IDR (approximately 25 EUR). Space for sekaten has been commercialized, without changing the meaning of its ritual which takes place in the great mosque. This division led to assumption that garebeg was maintained as a sacred activity while sekaten is becoming more profane. Hence people who want to see garebeg or gamelan sekaten in the mosque were still free of charge, while those who want to see sekaten had to pay entry ticket. At the fair, there were rides such as Ferris wheels and mini train, which were simply meant to provide entertainment and fun. Joy rides and food stalls have become a feature in sekaten fair. Sekaten which was dominated by traditional merchandises, has been gradually replaced by popular entertainment and contemporary products. Traditional food traders are rarely seen and the nuance of tradition is almost imperceptible.

Figure 6. Gunungan and garabeg procession in year 2011 Source: observation

The major activities take place in northern alun-alun relate to the role of kraton complex as the major tourists destination in Yogyakarta. There are at least nine tourist objects inside kraton walls which consist of kraton main building, Tamansari water castle, old mosques, museums, birds market and traditional kampongs (Department of Tourism, Arts and Culture Yogyakarta 2007). Northern alun-alun becomes a gateway to kraton and surrounding tourist destinations. Thousands of people come to alun-alun to watch the garebeg procession and when many tourists come to visit kraton, alun-alun is used for parking. During tourist high season, the square is utilized for parking by private cars and tourist buses, while becaks (rickshaw) and horse-carriages are lined up next to the entrance of bangsal pagelaran (Figure 7-). All types of vehicles, ranging from bus, car, motorcycle, becak to horse-carriage are passing through the streets on its perimeter that becomes traffic artery and connects area inner to outer kraton wall. The atmosphere of alun-alun comes alive with growing number of people visiting during day and night and people began to take advantage from this festive by establishing their petty business. Street vendors are taking a chance by selling good to these visitors. Street vendors are visible almost everywhere in northern alun-alun where there is a high concentration of people- the streets, parking lots, street junctions, sidewalks and the center of the square. Various types of street vendors exist here (Figure 7-). Either some are stationary and operate in certain locations, with permanent structures such as warung or kiosk, or non-permanent structures such as gelaran (mat) and tent that are easy assembled and dissembled. Some street vendors are ambulatory which continuously moving about to a place where there are many people to sell their goods or offer their services. These ambulatory street vendors are using gerobag (pushcart), pikulan (yoke) or bakul (basket) which sometimes are installed on a bicycle or a motorcycle. Alun-alun has evolved into area where small-scale trading and bazaar occur. There are at least 470 street vendors and hawkers in northern alun-alun. Their informal status are not fit with the image of cleanliness and order which becoming the eyesore of alun-alun.

6 CONCLUSION

The aforementioned historical account visualizes how alun-alun has catalyzed the formation of collective urban images, which are transmitted from generation to generation creating a corpus of inter-subjectivity. This allows the square to maintain its role as a place for the collective expression of discontent and hope for better times.

The examination of alun-alun reveals of pattern of gradual change and transformation, which is tandem with the significant historical events and changes in cultural setting of the society. Changes are manifested in the

physical, social and symbolic pattern, which occur in response to events, actions or polices introduces in different historical periods. From physical perspectives, alun-alun has witnessed reorganization where some uses added and some modified, or eliminated along with the changes in political and major political holder. The reorganization of its morphological pattern resulting in the increase in density and shown in the changes of enclosure elements, building addition and general visual character. From social perspectives, alun-alun has witnessed changes in patterns of access and social character. It is however, from symbolic perspective that alun-alun has witnessed greatest changes. Alun-alun continues to be a venue for massive events ranging from cultural, social to political. Although alun-alun is still a venue for cultural ceremonies, the messages is fundamentally changed. They would rather a ritual, which symbolic roles are limited to the religious realm and the preservation of tradition. On other side they have experienced commercialization as the impact of tourism development. The agglomeration of commercial activities encouraged the growth informal sectors, which show the gradual decline of its importance divergence between the real lived space and the representation of space has increased.

Administration System	**Characteristic**		
	Arrangement of space	**Primary uses of space**	**Accessibility**
Traditional authority (1755-1880)	- Center is a sacred space - Periphery is profane	- Military activities - Royal ceremonies	- Restricted area and strictly controlled
Dutch colonial administration (1880-1940)	- Center is less sacred - Periphery is profane	- Royal ceremonies - Cultural activities - Social activities	- Partial restricted area and less controlled
Indonesian early independent (1940-1960)	- Center and periphery are profane	- Royal ceremonies - National movement activities - Economic activities	- Open area
New Order (1960-1990)	- Center and periphery are profane	- Royal ceremonies - Religious activities - More economic activities - More social activities	- Open area
Modern 1990- 2012	- Center and periphery are profane -	- Ritual ceremonies - Religious activities - Political activities - More economic activities - Social activities - Traffic thoroughfare	- Open area

Table 1. Characteristic of Public Space through Changing Administration System Source: Author

Alun-alun that was previously used only for a formal ceremonial meeting place between sultan and his subjects has evolved into area where small-scale trading and bazaar occur as well as special outdoor cultural events. The square that has an important historic and symbolic function, linking sultan and his people has evolved into a visitor attraction as many domestic as well as foreign visitors go there during the day and evening to browse among the stalls. On special occasion, elaborate court and religious ceremony take place in alun-alun, they have become cultural attraction in their own right.

1 ABSTRACT

The choice of location for a residence or a business is usually an important, long-term decision requiring a high level of investment of capital. With this in mind, such decisions should be considered together with their consequences, both for the individuals and the city as a whole. "Mobility Pass for Residential Real Estate" is an online tool which investigates the relationship between the selection of the location and the mobility behaviour, showing the effects of mobility time, mobility costs, CO_2 emissions and possible accident risks. Therefore the "Mobility Pass for Residential Real Estate" will be developed for the specific tenant or buyer, for the real estate agents (as a more specific marketing instrument) and for public administration, concerned with the allocation of housing subsidies.

The "Mobility Pass for Residential Real Estate" is designed as a free online tool available on the website www.mobilitaetsausweis.at. This paper deals with the multitier architecture, the basic data used and the routing network to calculate the trips which is the basis for the estimation of the mobility costs.

The project is funded within the IV2splus programme (ways2go initiative) of the Austrian Federal Ministry for Transport, Innovation and Technology (BMVIT). The programme management lies at the Austrian Research Promotion Agency (FFG). The project consortium consists of CEIT Alanova – Central European Institute of Technology, Institute for Urbanism, Transport, Environment and Information Society (lead partner), HERRY Consult GmbH (Consulting in Transportation Planning), Austrian Road Safety Board (Kuratorium für Verkehrssicherheit - KFV) and the University of Applied Science of WKW – Institute for Real Estate Management (Institut für Immobilienwirtschaft der FH Wien – Studiengänge der WKW).

2 RESEARCH BACKGROUND

In Austria, about 10 % of the population changes their home every year, in 2009 that was about 875,000 people. Nearly 80 % (680,000 people) residence changes occur within one or between neighbouring municipalities in Austria. Austria is a country greatly affected by urban sprawl; land purchase is much cheaper in not urbanised areas but infrastructure, from the school bus to the waste disposal, is paid by the public sector.

The population in Austria has increasingly moved outside the main municipalities. Located beside of the city centre most people move around by car and the commuting flows are increasing. It has been stated by the VCÖ (Verkehrsclub Österreich/Association for Transportation and Sustainable Mobility in Austria) that in all Austrian provinces transport is one of the main concerns as the emissions from traffic have increased since 1990 from 33 % to 71 %. The impacts of transport are also reflected in high economic costs, as in Austria every year more than 7.6 billion euro is spent in accident costs and infrastructure.

Looking at the individual scale, the location of the residence has a direct impact on the overall transport behaviour. Already in the 1970s, Torsten Hägerstrand dealt with an analysis of spatio-temporal behaviour of individuals and the depiction of human action in "time paths" (Hägerstrand 1975). The constraints identified by him through the spatial structure result in a manoeuvre, which are crucial to the design of the mobility possibilities and therefore to the possible needs. The "Mobility Pass for Residential Real Estate" shares the same theoretical approach and creates a more transparent and comparable free online tool for those looking for a new house and for the real estate business.

Direct and indirect costs follow the mobility trends, but so do time, CO_2 emissions and accident risk, all strictly related to the distances travelled. The medium and long-term consequences of most people's travelling patterns are still hard to estimate. Most times decisions are made on the basis of short-term decisions such as the price of the rent or for the purchase, the quality of the living according to the available

facilities and so on, without taking into account the costs associated to forced mobility related to going to work or to leisure activities.

While the prices of the rents or purchase and energy costs can be calculated rather easily, the costs and the CO_2 emissions related to the mobility are quite hard to estimate for most people, but often count up for a large part of the household's budget. It was estimated that in 2010 a household in Austria spends EUR 5,240 on average on mobility. A recent study by the VCÖ shows that compared to year 2005, that Austrian households spend EUR 330 more on mobility. The VCÖ indicates that people living in Vienna are paying the least on mobility (VCÖ, 2011). On the other hand, commuters who use public transport to work spend on average EUR 1,800 per year less on travel costs than those who travel by car.

This is why the "Mobility Pass for Residential Real Estate", with the calculation of mobility cost, mobility time and risk of accidents and giving a transparent view of the environmental impact by indicating the CO_2 emissions will help users rethink their habits in a more economic, safe and environmentally friendly way. In the following section the implementation of the "Mobility Pass for Residential Real Estate" concerning the 3-tier architectur and the tool itself will be explained.

3 IMPLEMENTATION

3.1 3-tier architecture

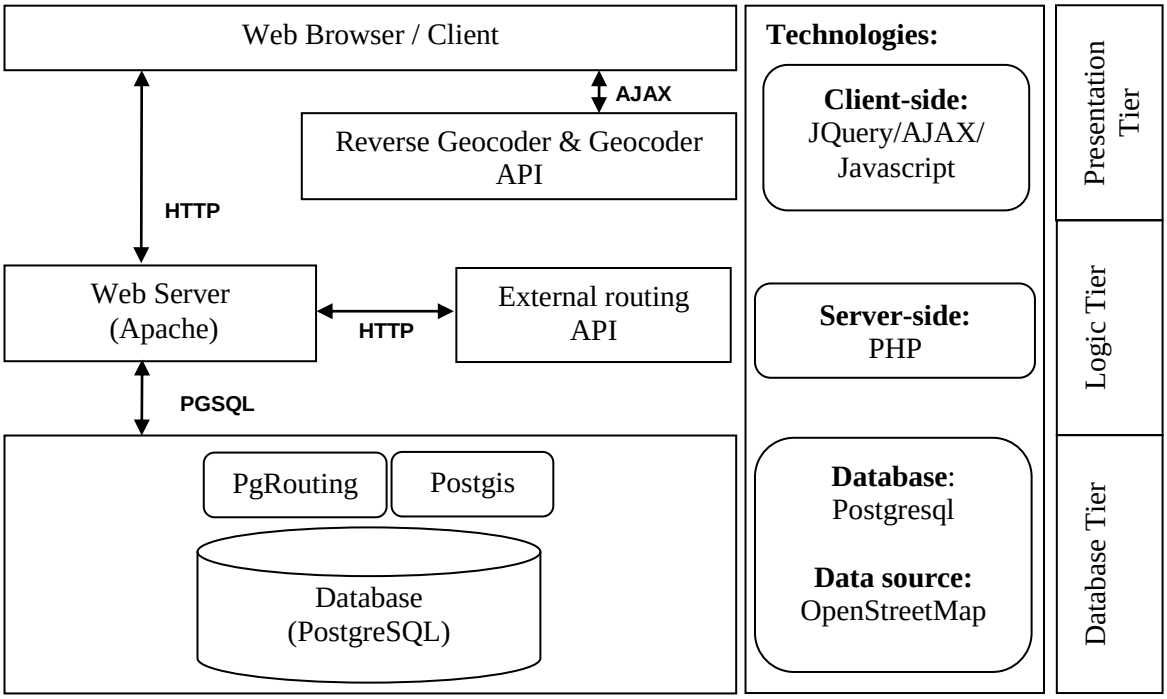

Fig. 1: 3-tier architecture of the "Mobility Pass for Residential Real Estate"

The presentation tier contains the web browser and uses a reverse geocoder and geocoder API to locate the different activities of the user. These interfaces are used to locate the activity places via a map or alternatively by street names. The used technologies for the dynamic components of the online tool are JQuery, AJAX and JavaScript.

The logic tier of "Mobility Pass for Residential Real Estate" provides the intelligence of the application towards the client. For this section the Apache web server with the server-side programming language PHP is used. An external routing API is used to get routing information in foot, bicycle or public transport, which are used to calculate the mobility costs.

The database tier contains the open source relational database management system PostgreSQL and its two extensions. PostgreSQL is extended by PostGIS, which enables the database to support and store geographic objects. With this extension it is possible to store Simple Features (points, lines, polygons) defined by the Open Geospatial Consortium (OGC). The second module PgRouting is used to extend the geospatial database with the functionality of routing.

3.2 Basic Data

The idea for the "Mobility Pass for Residential Real Estate" is to integrate an open and extensible data source. In a prototype version of this tool the individual vehicle transport should be calculated by the street data of Open Street Map (OSM). Open Street Map has the goal to collect all kind of data on a map, like streets, railroads, points of interests, rivers and topographic objects, which are collected under a public license domain. The main advantage of the Open Street Map data are the open source license and the community is updating the map continuously. Open Street Map uses a data model which makes use of topology.

The second data for calculation of the mobility behaviour, which is involved in this project, is the connection to the interface of AnachB.at. The interface is used for the calculation of the route trips of foot, bicycle and public transport and has a multimodal graph. The underlying routing graph of this interface is more detailed than commercial ones and includes live traffic information (Floating Car Data, Traffic Messages …). It gets permanently updated, because it was developed for E-Government and public administration (PRIKOSZOVITS, 2010). The figure 2 shows the online tool of AnachB.at.

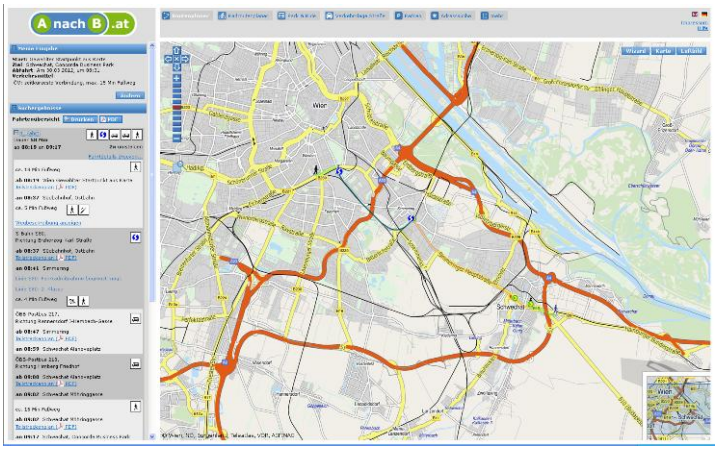

Fig. 2: AnachB.at online routing tool (http://www.anachb.at)

3.3 Routing network and algorithm

The basis for the calculation of the mobility costs are the driving distances between the different activity locations with their different modes of transports. For this the database of the "Mobility Pass for Residential Real Estate" includes a routing network, which consists of a weighted, directed graph. A graph is a non-empty set of vertices where the vertices are connected by edges. The extension of a directed, weighted graph means that every edge is represented by a direction and every edge has a weight assigned. The edges in the routing network represent the road segments and the vertices are made out of the intersections of the road network (DOMSCHKE, 1995).

The weights in the implementation of the routing network of the "Mobility Pass for Residential Real Estate" are defined as the time in seconds needed to pass the road segment, to get the fastest route from one node to another. The seconds are calculated based on the length of the segment and a defined travel time for the individual transport. The tag <highway> defines the different types of roads which exist in the Open Street Map dataset. In a first version only highway tags which are important for car routing are used to define the routing network (motorway, trunk, primary, secondary, tertiary, road, unclassified, residential, living street, service, track, path and the appropriate links). Therefore a travel time matrix was designed in according to the list of street categories.

In Austria, there are fixed general speed limits defined for the different types of road categories. These speed limits are not useful for route calculation, because in the real traffic it is not possible to reach them constantly. Therefore a travel time matrix was designed according to the reference point of the speed limits. Additionally there is a difference of these speed limits in the urban area, which has to be integrated in the routing graph of the "Mobility Pass for Residential Real Estate".

For this purpose, with the help of CORINE Land Cover 2006 data set, there is an attempt to have a delineation of inner-city and non-urban roads. The CORINE Land Cover data set consists of 44 classes (28

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

of which occur in Austria). The delineation from the city streets, the main class of "built-up area" and its subclasses are used.

At the preparation of the OSM import data every road segment is spatially analysed via the database. The road segments are intersected with the CORINE Land Cover data set and the definition of an urban road in the "Mobility Pass for Residential Real Estate" is fulfilled if more than 50% of the length of this segment is within the built-up area. The results are all the road data, which exist within the built-up area. With this gain of information, the travel time within the road segments of the built-up area can be adapted for the urban area.

The algorithm which is used for the calculation of the route is the Dijkstra algorithm. This algorithm finds the optimal route between two vertices in a graph. That means the solution is based on the weights the graph is using. Weights can be the length, cost, time, or other things that can be defined on the edges. As above said the "Mobility Pass for Residential Real Estate" uses the time to pass one road segment, so it finds the fastest path from one vertex to another. The idea of the Dijkstra algorithm is to start at the source vertex and searches all next nodes for the fastest edge to the target vertex. The result node is saved permanently and to find the next fastest segment, only the next nodes from the source node or the permanently marked nodes are scanned. If the algorithm reaches the target node it finishes. This algorithm is useful to get the optimal path with a little effort. If the graph is extremely intermeshed, this route calculation algorithm is not the best solution, because it gets slow and it cannot use negative weights, this results into not optimal route outputs. (Universität Oldenburg, 2012)

But also the Dijkstra algorithm is only as good as the graph. For every routing algorithm the database must be defined accurately and updated. In the case of a street routing graph for example it is also important to handle the one-way streets in a pleasant way for the used algorithm. In the routing network of the "Mobility Pass for Residential Real Estate" the edges of one way segments are weighted with extremely high time costs, so that the algorithm never uses them to find a route.

The routing graph of the individual vehicle transport of the "Mobility Pass for Residential Real Estate" covers the whole region of Austria. For the other types of transport modes (foot, bicycle and public transport) the route calculation via the interface of AnachB.at is used.

4 ONLINE TOOL

There are two different versions of the online tool (basic; advanced) which provide different information about the mobility costs. The basic tool should give the user a very quick and rough estimation of the mobility costs and the other output results of an household. An advanced tool also uses the route calculation (Open Street Map, AnachB.at) to get more exact results on the mobility costs, time consumption, CO_2 emmissions and accident risks for an household for a potential new housing location.

The basic tool is designed for people who want to find a rough result with only a few input variables. This tool is only based on standardised statistical mobility patterns. For that reason, a lifestyle matrix was developed out of the micro-census gathering made by Statistics Austria. Based on these statistics, 7 different lifestyle-types could be identified for Austria. In relation to the 4 residential locations (urban, semi-urban, peripheral and 4 cities with special transport infrastructure), 28 lifestyle groups have been established. After that mobility patterns could be classified and assigned to the different lifestyle groups.

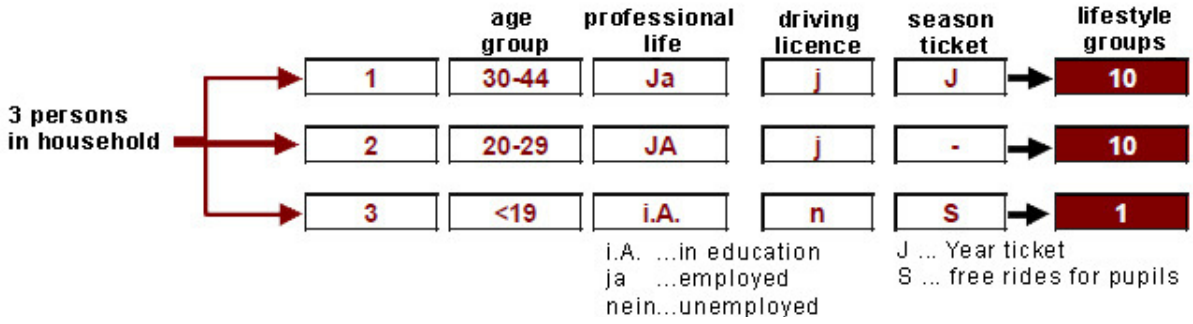

Fig. 3: Lifestyle group classification

Figure 3 shows an abstract assignment of the personal information to a lifestyle group.

The advanced tool of the "Mobility Pass for Residential Real Estate" consists of the created routing network and the external interface of AnachB.at. For the routing calculation, the user has to give information about the different work and weekly regular leisure sites of every person which lives in the household. The locations of the different places can be put directly onto a map or reference them through the input of an address. To any of these locations the user has to select the mean of transport. The kilometers of the different means of transport give the base for the calculation of the different output costs.

Additional in the advanced tool the user has to give some explicit information about the real estate of the household location. For the real estate information the user can choose between a rental object or an object of purchase. Due to this user inputs the tool calculates the annual costs of the object and the user has the possiblity to compare them with the mobility costs. (SEDLACEK N., 2012)

4.1 User Interface

The user interface of the simple tool only offers a few input parameters and a classification of them into three parts. The parts are the area for information about the household location, the mobility information area and personal information area of the household.

The user interface of the advanced module of the "Mobility Pass for Residential Real Estate" is shown in figure 4.

The website is divided into serveral areas. On the top of the tool there is the navigation. The user has the possiblity to calculate two different calculations and compare them against. The current selected site is marked in a different color. Furthermore the main part splits into two parts. The left part is reserved for the input parameters. For the clarity of the various input parameters the area for the information about the real estate location site and the household information are separeted by colors. The advanced tool makes use of a dynamic interface. Due to the inputs of the user new input areas are shown up, so that the user isn't overstrained by the great number of input variables.

The right side of the website contains a map, so that the user can see the different selected site locations.

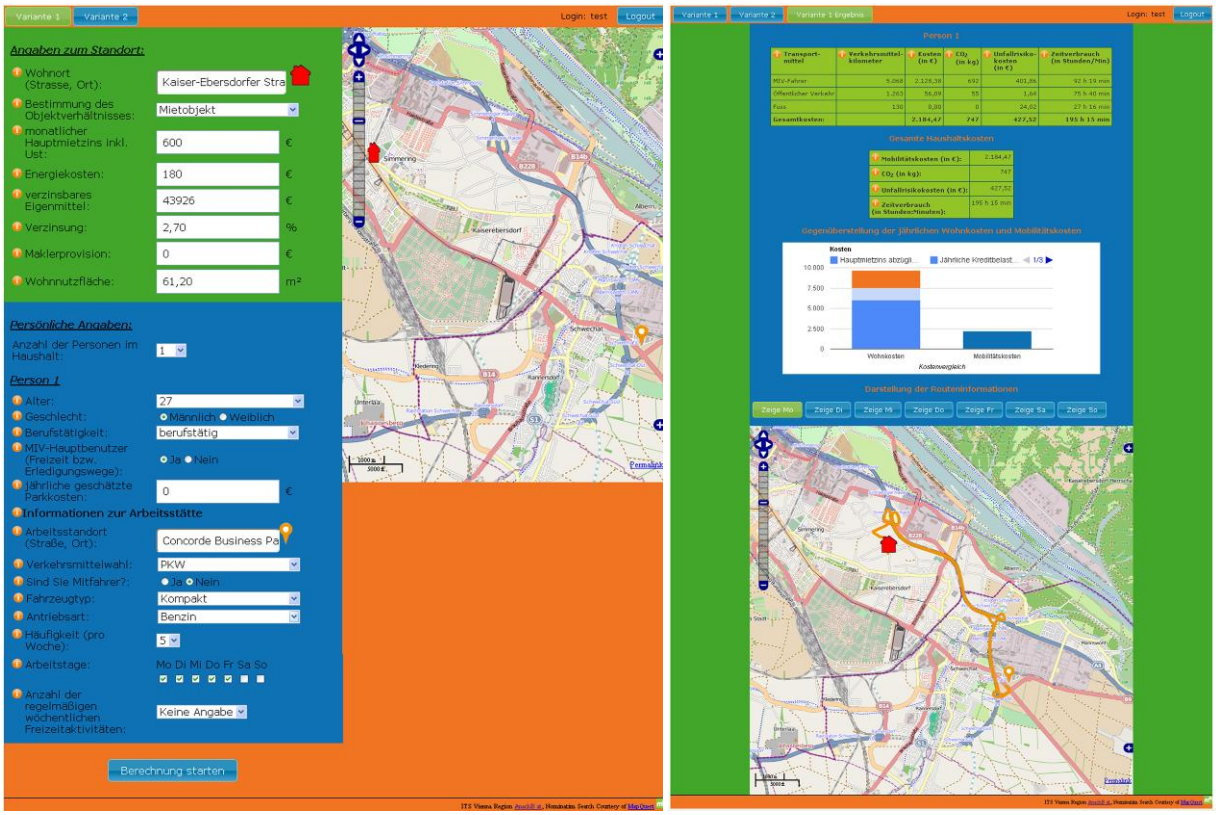

Fig. 4: User Interface (l.) and Result Interface of the advanced tool of the "Mobility Pass for Residential Real Estate" (r.)

4.2 Results

The result mask of the online tool gives information on distance traveled, transport costs, CO_2 emmisions, monitized accidential risk and transport time per transport mode in total for the household. The base for these

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

types of costs are the covered kilometers of the overall day trips (work, regulary weekly leisure activities and every day ways) per year. The costs are divided into different groups of transport.

The accident risk describes the calculation of the probability of accidents of certain groups (stratified by age, gender and transport mode) and the determination of a risk score with the help of economic costs of accidents. The variables are not considered isolated but take into account their mutual interaction.

The estimation of the CO_2 emissions in the advanced tool will be calculated on the base of the used transport modality and the distance with the different means of transports. The calculation gives the user a better understanding for his own carbon footprint. Furthermore the advanced tool in addition calculates the annual real estate costs, which gives the user the possibility to compare annual mobility costs with annual real estate costs. The user has also the possiblity to have a look at the calculated routes of this result on an "on the fly" map. The different ways of the various person are colored on a map to get an overview of the ways split day by day (figure 4). The "Mobility Pass for Residential Real Estate" provides the opportunity to compare the result information based on different chosen residential locations and their different mobility costs.

5 CONCLUSION

The "Mobility Pass for Residential Real Estate" is a free online tool, where the results of this tool should give the user a comparison of the rental with the added energy costs of their living place and the user-defined mobility costs. Furthermore additional information about the mobility time, CO_2 emissions and possible accident risk costs are presented to the user. The use of OSM data offers a great source for creating a routing graph with the possibility to integrate continuously updated open source data and it gives the possibility to extend the routing graph to other different modes of transport.

In addition to the mobility tools the tool calculates the CO_2 emissions of the household. Carbon footprints and their calculations have recently drawn attention as they can limit CO_2 emissions of individuals and households based on house, car, and other consumption-related measures. When considering CO_2 emission related to mobility a very important factor to be considered is the residence location.

The important added value of "Mobility Pass for Residential Real Estate" is that it is a combination of a footprint calculator and the calculation on costs, time and accident risk based on mobility. The use of OSM data offers a great source for creating a routing graph with the possibility to integrate continuously updated open source data and it gives the possibility to extend the routing graph to other different modes of transport. The use of the external interface to AnachB.at gives the possiblity to get the calculate routes from a multimodal routing network which is planned to extend of the whole region of Austria. The further development of the "Mobility Pass for Residential Real Estate" can be the optimization of the OSM routing network, the integration of POIs in the map, the improvement of the geocoding service and the integration of ticket prices of public transport.

1 ABSTRACT

The decreasing financial resources of many Styrian municipalities, particularly the small ones, lead policy makers to rethink funding allocations. Policy makers considered the inter-municipal use of public utility providers as well as the creation of regional authorities. These arrangements should provide for a more efficient and cost reduced usage of public utitlity providers. Due to these facts, the division 16 of the provincial government in Styria launched the project "Modelling the coverage of public utility providers". Within the scope of the project an ArcGIS Plugin was developed for modelling the coverage as well as for modelling the degree of capacity utilization of public utility providers in Styria. The results of the analysis provide transparent information about an optimized spatial distribution of public utility providers which creates the base planning criteria for the intended inter-municipal use of these facilities.

2 INITIAL SITUATION IN STYRIA

"Among all Austrian provinces, Styria has the smallest community structure: 76 municipalities have less than 500 residents, 196 fewer than 1000 and 407 municipalities have less than 2000 inhabitants. In 2009, approximately 200 municipalities attained negative annual accounts. This has to be equalised by funding allocations. The majority of these municipalities are small." (www.kleinezeitung.at, 16.12.2010).

Policy makers need to rethink funding allocations because of the decreasing financial resources of many municipalities in Styria. Already in 2006, the inter-municipal use of public utility providers as well as the creation of regional authorities were considered by different projects. Regional authorities are meant to consist of small adjacent municipalities with a corporate administration. In 2011, an administrative reform started with the scope to achieve sustainable cost and spending reductions. Until now, planning and spatial distribution of public utility providers was done by Styrian municipalities on their own. In the future it will be necessary to achieve planning as well as usage of public utility providers on an inter-municipal basis. This will lead to an optimized spatial distribution and furthermore to cost and spending reductions. An essential part to realise these reforms sucessfully is to actively involve the affected population as well as the policy makers in all major decisions. The results of the analysis provide transparent information about an optimized spatial distribution of public utility providers which builds the base planning criteria for the intended inter-municipal use of public utility providers. These transparent results should assure the arrangements will be widely accepted by the population.

3 MODEL FUNDAMENTALS

The model is based on the data of three main input parameters. The first parameter contains information about the capacities of public utility providers for different domains e.g. kindergarden, primary school, hospitals and so on. The second main parameter consists of demographic characteristics which are represented by a grid dataset with a spatial resolution of 250 m. The third main input parameter is a street graph which was exported from the GIP (Graph Integration Platform). There is one optional parameter for the analysis, i.e. named regions. These regions are used to distinguish between travel times depending on the spatial structure.

3.1 Public Utility Providers

This parameter contains information about the capacities of public utility providers for different domains which are a matter of public interest, e.g. kindergarden, primary school, municipal office, hospitals and so on. This information is provided by a component of the spatial information system Styria which is still under

construction and is stored in a point dataset. At present the capacities represent the current ones which are in use instead of the actual available ones.

3.2 Demographic Characteristics

This parameter consists of demographic characteristics which are represented by a grid dataset with a spatial resolution of 250 m. It is also necessary to use demographic characteristics with a spatial resolution on a local level for data preparation due to the data privacy policy. Both datasets are provided by Statistik Austria. On the level of the grid dataset demographic characteristics like age groups will be provided if there are more than 31 principal residences. In Styria the majority of the 250 m grid cells do not hold any detailed information about demographic characteristics. Due to this fact it is necessary to generate a hybrid dataset based on the grid dataset as well as on the local level dataset. The calculation of the number of people per age group and grid cell with less than 31 principal residences is shown in Figure (1).

$$A_{i,k_y} = \left(\frac{A_{i,y} - \sum_{l_y=1}^{n} A_{i,l_y}}{\sum_{k_y=1}^{m} H_{k_y}} \right) * H_{k_y}$$

A_i ... number of people per age group i
k_y ... grid cells < 31 principal residences of municipality y
l_y ... grid cells ≥ 31 principal residences of municipality y
H ... principal residences

Fig. 1: calculation of the number of people per age group and grid cell with less than 31 principal residences

3.3 Street Graph

The street graph represents the area-wide, homogeneous motorized as well as the non-motorized individual transport. This dataset was exported from the Graph Integration Platform (GIP). The street graph has to be slightly modified to be used within the model.

3.4 Regions

The spatial density of public utility providers depends on the area. In rural areas there are not as much public utility providers as located in urbanized areas. Because of this the spatial structure can also be involved for the calculation. There are three main areas: inner alpine, outer alpine and central area.

4 MODELLING THE COVERAGE OF PUBLIC UTILITY PROVIDERS

4.1 Model Algorithm

The model algorithm is based on the calculation of service areas for the different public utility providers and the spatial distribution of demography of the domain specific population group inside this calculated service areas. Depending on the reviewed domain it is important to distinguish between the accessibility and coverage of public utility providers. For example the domain “education” focuses on accessibility whereas the domain “public order” which covers the topics “police”, “fire departments” as well as “ambulances”, focuses on the coverage. As part of the model, service areas as well as origin-destination cost matrices are calculated on the base of the modified street graph. The calculation itself is based on the Dijkstra alogrithm (Dijkstra 1958). The centroids of the grid cells which provide demographic data are the origin or destination points, depending on the preselected domain. Another input dataset contains the point locations of public utility providers.

It is an iterative process. There are several steps:first, the algorithm chooses the grid cell with minimum travel time. Second the algorithm subtracts the number of people that need to be supplied from the total available capacity of the assigned public utility provider. Third, the remaining capacity is stored temporarily. Forth, the algorithm assigns the classification value of the coverage of public utility providers to the currently processed grid cell. The workflow of the algorithm is shown in Algorithm (1).

grid cells outside service area: coverage = not supplied
sorted cost matrix, travel time ascending
for travel time w = 1 to n of grid cells R of public utility provider I_y
if capacity of $I_y \geq$ *number of people need to be supplied in R: coverage = supplied*
else if capacity I_y *=0: coverage = inadequate supplied*
else: coverage = partially supplied

Algorithm 1: Assignment of the classification of the coverage of public utility providers per grid cell

The algorithm distinguishes between four different classification values: a grid cell is classified as "not supplied" if it is outside any service area. A grid cell is classified as "supplied" if it is inside of a service area and the public utility provider has enough capacities to supply this grid cell. If a grid cell is inside of a service area but the underlying public utility provider's capacity is equal to zero, the grid cell is classified as "inadequately supplied". Last but not least, if a grid cell is inside of a service area but the public utility provider has not enough capacities to supply this grid cell although the capacities are greater than zero, the grid cell is classified as "partially supplied".

4.2 Software implementation

With the release of ArcGIS® Desktop 10 the concept of Add-Ins was established. This concept allows easy distribution of self-developed Add-Ins via shared folders, e-mail or download link. The conceptual model was implemented as an ArcGIS Plugin for the release of ArcGIS® Desktop 10. The implementation was done in C# on the basis of the Microsoft.NET 3.5 Framework.

The calculations are mostly based on the functionalities of the ArcGIS® Geoprocessing library. The calculation and classification of the coverage of public utility providers is based on the self developed and implemented algorithm, shown in Algorithm 1. The methods and functionalities of the ArcGIS® Network Analyst library are used for the creation of the network dataset, as well as for calulation of the service areas and cost matrices. The service areas and the cost matrices are based on the GIP street graph which will be periodically updated.

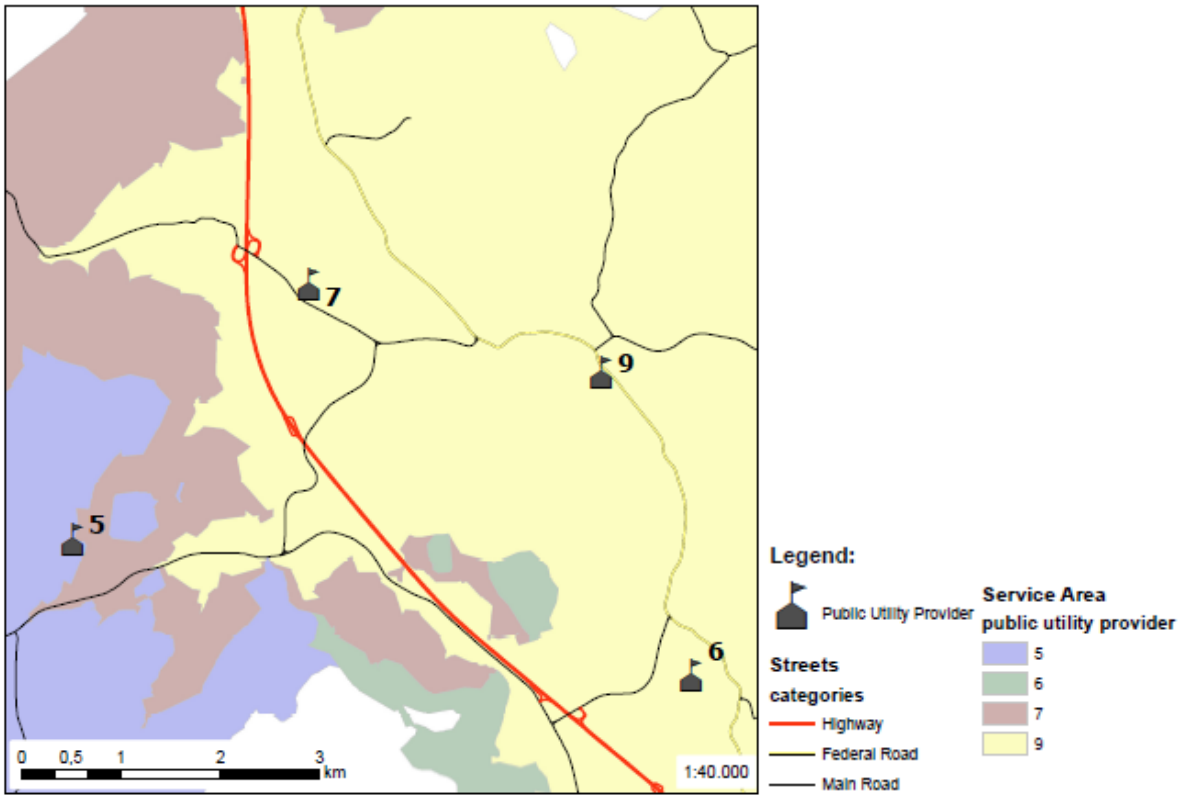

Fig. 2: Service Areas of kindergarden in Kalsdorf near Graz

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

4.3 Results

The results of the executed algorithm are a grid dataset representing the degree of capacity utilization with a spatial resolution of 500 m, as well as the capacity utilization of each individual public utility provider. In addition, the service areas are also available. The following figures show the results of the calculations. The example is chosen from the domain "education" – "kindergarden". The region is located in Kalsdorf near Graz. The configurable parameters are: 5 minutes driving time (individual motorized traffic) without any regionalization. The result showing the calculated service areas is shown in figure 2. The result containing the degree of capacity utilization is shown in figure 3.

As shown in figure 2, the service areas are overlapping each other. Although, as shown in figure 3, not all of the demographic micro cells are supplied. Most of the micro cells have no demand which means that there are no children aged 3 to 5. These cells are shown in grey. Some of the demographic micro cells are inadequately supplied or partially supplied, shown in orange and yellow. The farthest micro cells are not supplied, shown in red.

Fig. 3: Classification of capacity utilization of kindergarden in Kalsdorf near Graz

5 CONCLUSION

First estimations and evaluations of the employees of the provincial government in Styria determined that the developed tool is feasible and offers new opertunities for the intended inter-municipal planning. Due to the fact that the spatial information system Styria is currently under construction, not all public utility providers are digitally represented yet. Furthermore, the recorded capacities represent the current capacities in use, not the available capacities. For this reason it is essential to analyze the results critically. However, the employees of the provincial government in Styria can use this interactive tool to generate transparent information about an optimized spatial distribution of public utility providers which builds the base planning criteria for the intended inter-municipal use of public utility providers.

1 EINLEITUNG

Trotz der Entwicklung neuartiger planungsextensiver Bepflanzungsstrategien, wie Staudenmischpflanzungen (z.B. BDS 2009; FENZL & KIRCHER 2009; LWG 2007), die ein geringeres Maß an Arten-/Sortenkenntnis voraussetzen, war und ist das Wissen über den grünen Baustoff der limitierende Faktor bei der Planung, Anlage und Unterhaltung von öffentlichen oder privaten Grünflächen. Eine von der Hochschule Anhalt durchgeführte Umfrage bei Landschaftsarchitekten, Ingenieurbüros dieses Fachgebiets, Garten- und Landschaftsbauunternehmen sowie Grünflächen-/Gartenämtern zum Thema Wissen und Erfahrungen in der Pflanzenverwendung zeigt ein deutliches Ergebnis: Die häufigsten Planungsfehler oder Probleme bei der späteren Unterhaltung von Grünflächen sind insbesondere auf Defizite hinsichtlich der fachgerechten (standort- und funktionsgerechten) Verwendung bzw. Auswahl von Pflanzenarten/-sorten (Pflanzentaxa) zurückzuführen. Fachliteratur, Leitfäden, Pflanzenenzyklopädien und „Gartenbücher" bieten jedoch heute für Profis und Laien eine umfangreiche Unterstützung bzgl. der für eine fachgerechte Pflanzenauswahl zu prüfenden Parameter (BÄRTELS 2001; BORCHARDT 1999; DUNNETT & HITCHMOUGH 2004; FLL 1999; HANSEN & STAHL 1997; ROBINSON 2004; SCAREFONE 2007 etc.).

Unzählige Gartenbesitzer in Deutschland wählen die Pflanzen für ihren Garten nach eigenem Geschmack und weniger nach standort- und funktionsgerechten Gesichtspunkten aus; und nicht wenige Gartenliebhaber erweisen sich diesbezüglich sogar als äußerst beratungsresistent. So erfolgt die Auswahl von Stauden, Sträuchern, Bäumen etc. meist im Werbeprospekt, Einzelhandel oder auch zunehmend im Internet, losgelöst vom eigenen Garten. Die Folge sind mitunter teure Fehlkäufe, denn der tatsächliche ästhetische Effekt oder die Größenwirkung von Pflanzen weichen im eigenen Garten häufig von der persönlichen Vorstellungskraft ab. Weiterhin treten bei der Kaufentscheidung die visuellen Kriterien gegenüber den zu beachtenden Standortfaktoren des Gartens in den Vordergrund, da sie unmittelbar erfahrbar sind. In vielen Fällen erzeugen die so erworbenen Produkte über kurz oder lang Unmut im eigenen Garten.

3D-Gartenplaner für den computeraffinen Hobbygärtner geben zwar eine einfache Hilfestellung, doch sind fotorealistische Darstellungen ebenso unmöglich wie die fachgerechte und produktgenaue Auswahl von Pflanzentaxa. Branchenapplikationen für den Garten- und Landschaftsbau erlauben eine fotorealistischere Visualisierung von Vegetation und Gartenausstattung mittels Fotomontagen. Ihre Erstellung erfolgt jedoch losgelöst von der fachgerechten Auswahl der Pflanzentaxa, die hier nur teilweise durch externe Pflanzendatenbanken unterstützt wird. Fotomontagen stellen nur spezifische Ansichten des zukünftigen Gartens dar. Für jeden Blickpunkt muss eine neue Fotomontage erstellt werden, was die Kosten für Planung und Beratung steigen lässt. Der Aufwand wird in vielen Fällen nicht durch die nach HOAI üblichen Sätze vergütet bzw. sind Visualisierungen eine „Besondere Leistung" (WERNER & WALTER 2009). Der erforderliche Ressourceneinsatz macht die Erstellung von 3D-Visualisierungen im Rahmen einer durchschnittlichen Planungsaufgabe im Verhältnis zum erwarteten Gewinn schnell unrentabel.

Aktuell verfügbare Profisysteme zur Planung und 3D-Visualisierung von Vegetation, wie CAD-Fachapplikationen für die Landschaftsarchitektur (z.B. 3ds Max) sind in der Anschaffung sehr teuer und ihre Bedienung erfordert Spezialkenntnisse, möchte man akzeptable Ergebnisse erzielen. Das Gleiche gilt auch für die RealTime-Visualisierung von Vegetation mit entsprechenden RealTime-3D-Engines, wie Quest3D oder LandXplorer. Zwar bieten RealTime-3D-Visualisierungen zahlreiche Vorteile für die Planungskommunikation, da sich der Anwender frei in einem 3D-Modell bewegen kann, jedoch ist diese Technik momentan noch sehr zeit- und kostenintensiv. Denn das komplette Modell inklusive Bestandsobjekten muss als 3D-Modell konstruiert werden. Außerdem ist die Verknüpfung von Visualisierungstechniken mit Mechanismen zur fachgerechten Pflanzenauswahl in Softwaresystemen für Laien oder Professionelle bisher in den wenigsten Fällen realisiert oder fachlich schlecht umgesetzt.

2 ZIELE

Ziel des geplanten Forschungsprojekts der Hochschule Anhalt soll daher die Entwicklung und Erprobung eines „mobilen Planungs- und Beratungssystems für die Pflanzenverwendung“ (MobiPlant) sein, indem zur Unterstützung einer funktions- und standortgerechten Pflanzenarten-/-sortenauswahl neueste Techniken zur Visualisierung (Augmented-Reality) und weitere aktuelle Informations- und Kommunikationstechnologien (IKT) zum Client-Server-basierten Informations- bzw. Datenaustausch miteinander verknüpft werden (siehe Abbildung 1 und 2). Hierbei wird der Anwender jederzeit in die Lage versetzt, den Grad und die Tiefe der gewünschten Entscheidungsunterstützung selbst bestimmen zu können.

Die wirtschaftliche und anwendungsorientierte Nutzung von Augmented Reality (erweiterte Realität/ Filmtechnik) und mobilen, internetgestützten Technologien sind derzeit sowohl für Profis als auch für Laien in der Pflanzenverwendung unterrepräsentiert. Durch die innovative Kombination bzw. Verknüpfung von Augmented Reality mit web-basierten Geographischen Informationssystemen (WebGIS), Global Positioning System (GPS), Online-Datenbanken und weiteren Internettechnologien kann ein System geschaffen werden, welches mittels einer mobilen Benutzerschnittstelle, z.B. in Form von Tablet-PCs, Handheld-PCs und Handys mit GPS, Videokamera und Internetanbindung, bedient werden kann.

Abbildung 1: Prinzipskizze zur Funktionsweise eines Planungs- und Beratungssystems (vereinfachte Darstellung): v.l.n.r. Der Anwender plant auf einer Grünfläche Gehölze zu pflanzen (1); über die Kamera eines mobilen Endgeräts wird das Live-Video aufgenommen, mittels GPS und weiterer präzisen AR-Tracking-/Registrierungsverfahren werden Position und Ausrichtung der Kamera ermittelt (2), der Anwender wählt Pflanzenarten aus, Billboards/3D-Modelle der gewählten Pflanzenarten/-sorten werden maßstabsgerecht in das Videobild projiziert (3). Der Anwender hat nun die Möglichkeit, die Pflanzenauswahl aus visuell-ästhetischer Sicht zu beurteilen.

Dazu müssen die aktuellen fachwissenschaftlichen und fachpraktischen sowie informationstechnischen Belange des Bereichs Pflanzenverwendung interdisziplinär und praxisnah analysiert und zur programmtechnischen Umsetzung aufbereitet werden. Sie fließen unter Beachtung aktueller Normen und Standards in die Konzeption, das Prototyping und die Erprobung des mobilen Planungs- und Beratungssystems für die Pflanzenverwendung ein. Alle ermittelten und analysierten Maßgaben des Fachgebiets Pflanzenverwendung sind einerseits textlich und grafisch zu fixieren, andererseits erfolgt die Dokumentation des Systems und seiner Komponenten (für Tablet- oder Handheld-PCs sowie Mobiltelefone, die mit GPS und einer Videokamera ausgestattet sind) plattformunabhängig durch die Unified Modeling Language (UML) und die Nissen Information Analysis Method (NIAM). Dadurch werden die notwendigen Voraussetzungen für die zukünftige Nutzung der Forschungsergebnisse durch IT-Unternehmen geschaffen, gleich auf welchen konkreten Technologien ihre bisherigen Produkte basieren.

Der Fokus der fachwissenschaftlichen Fragestellungen liegt dabei auf der:

- Ermittlung und Analyse aller relevanten fachwissenschaftlichen und fachpraktischen Maßgaben und Parameter, die bei der Umsetzung von Programmroutinen und Funktionalitäten zur Unterstützung der Anwender bei der fachgerechten Pflanzenarten-/-sortenauswahl zu beachten sind und die Umsetzung und Evaluierung ihrer korrekten Implementierung;
- Entwicklung einer benutzerfreundlichen und intuitiven Benutzeroberfläche einschließlich einer fachgerechten und ansprechenden AR-Visualisierung von Pflanzenarten/-sorten verbunden mit der Durchführung von Anwendertests zur Praxistauglichkeit und Benutzerfreundlichkeit des Systems; sowie auf der

- fachspezifischen Nutzung verschiedener Technologien (AR/VR, GIS/WebGIS, Web-Services, verteilte Systeme etc.) bzw. ihre technische Verknüpfung zur Umsetzung von IKT-gestützten Komponenten zur Unterstützung der Anwender bei der Pflanzenarten-/-sortenauswahl.

Durch die Nutzung moderner IKT und der gleichzeitigen Verknüpfung aktuell getrennt gehaltener Daten zu nutzbaren Informationen kann das System zukünftig als Werkzeug zur Unterstützung einer funktions- und fachgerechten Pflanzenauswahl und zur Optimierung von Planungs- und Beratungsprozessen in der Pflanzenverwendung geeignet sein.

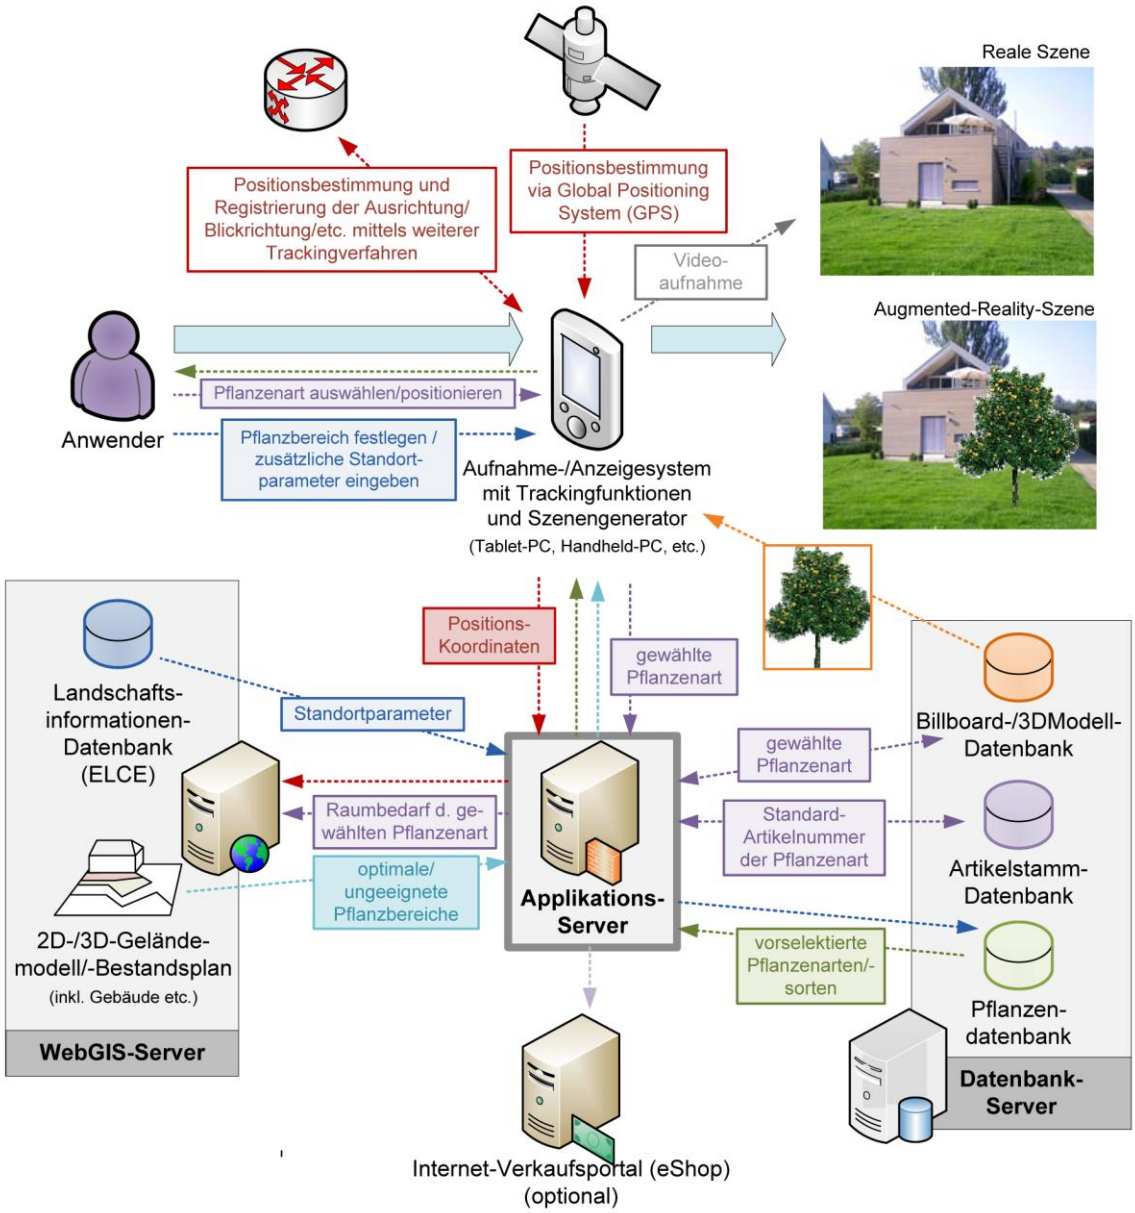

Abbildung 2: Vereinfachte Systemskizze zur Darstellung der Funktionsweise des mobilen Planungs-/ Beratungssystems für die Pflanzenverwendung, sowie das Zusammenspiel der einzelnen Systemkomponenten (ohne Auswahl der Lieferqualität einer Pflanzenart durch den Anwender, z.B. Hochstamm 12-14 mit Ballen, etc.).

3 FUNKTIONSWEISE

Die Unterstützung des Anwenders des mobilen Planungs- und Beratungssystems bei der Auswahl der Pflanzenarten und –sorten wird durch die Kombination von verschiedenen Technologien und die Verknüpfung von aktuell weitestgehend getrennt gehaltenen Daten und Informationen realisiert. Der Fokus sollte dabei auf der Umsetzung von drei Funktionalitäten/Komponenten (s. u.) zur Unterstützung bei der Auswahl der Pflanzenarten und sorten liegen, die in einem Gesamtsystem kombiniert werden und sich wechselseitig beeinflussen. Zur Umsetzung der Komponenten zur Entscheidungsunterstützung müssen die

jeweiligen fachlichen Maßgaben und Parameter ermittelt, analysiert, aufbereitet und programmtechnisch implementiert werden. Ihre fachlich korrekte Implementierung wird begleitet und abschließend evaluiert.

1) Visuell-ästhetische Entscheidungsunterstützung

Mittels der Umsetzung einer Visualisierungskomponente auf Basis der AR-Technologie wird der Anwender in die Lage versetzt, die Eignung von Pflanzenarten/-sorten aus visuell-ästhetischer bzw. gestalterischer Sicht durch Inaugenscheinnahme zu beurteilen. Via GPS, digitalem Kompass und weiterer präziser optischer Tracking- bzw. Registrierungsverfahren aus dem Bereich der AR-Technologien (z.B. Marker) werden die Position und die Ausrichtung des mobilen Endgerätes bestimmt. Optische Trackingverfahren liefern die Positionsdaten, indem per Echtzeit-Bildverarbeitung aus speziellen Bildmerkmalen im Videobild der Kamera die relative Lage des mobilen Endgerätes bezogen auf die reale Bildszene ermittelt wird. Hierbei werden Genauigkeiten im Zentimeterbereich angestrebt.

Im Moment der Aufnahme werden virtuelle Daten (sogenannte Billboards oder 3D-Modelle der gewählten Pflanzenart/-sorte, Markierung von geeigneten/ungeeigneten Pflanzbereichen etc.) in das aufgenommene Live-Videobild der Freiraumsituation maßstabsgerecht und in Echtzeit an die gewünschte Position projiziert. Es wird also ein kombiniertes Bild aus Wirklichkeit und künstlicher Umgebung auf dem Bildschirm des mobilen Endgeräts angezeigt (siehe Abb. 1). Bei Kamerabewegungen werden die virtuellen Modelldaten ständig aktualisiert. Dadurch erfolgt eine permanente und lagerichtige Anpassung der generierten AR-Visualisierung im Videobild an den realen Raum, d.h. an die Position und die Blickrichtung des Anwenders oder besser die Aufnahmerichtung der Videokamera.

Die Daten zur maßstabsgerechten Projektion des Pflanzen-Billboards/-3D-Modells werden aus einer Pflanzendatenbank ermittelt, sodass automatisch eine Anpassung des Pflanzen-Billboards/-3D-Modells hinsichtlich Wuchshöhe/-breite in verschiedenen Lebensstadien ermöglicht wird. Durch die Bereitstellung und Projektion unterschiedlicher Billboards können auch notwendige Differenzierungen hinsichtlich des spezifischen Habitus einer Pflanzenart in unterschiedlichen Lebensstadien vorgenommen werden. Für den Benutzer wird es somit auch möglich sein, unterschiedliche Entwicklungszustände im Lebenszyklus (langfristige Dynamik) und darüber hinaus im Jahresverlauf (kurzfristige Dynamik) der Pflanzenart/-sorte auszuwählen, um diese in das Live-Videobild zu projizieren und zu beurteilen.

Durch die AR-Visualisierungskomponente wird der Anwender bei der Entscheidung für eine bestimmte Art/Sorte aus visuell-ästhetischer Sicht unterstützt. Er wird in die Lage versetzt zu beurteilen, inwieweit die zuvor ausgewählten Pflanzenarten/-sorten aus visuell-ästhetischer bzw. gestalterischer Sicht für die Freiraumsituation geeignet sind. Dabei können die Pflanzenarten auch synchron geändert oder ausgetauscht werden, um verschiedene Varianten zu vergleichen.

2) Berücksichtigung des notwendigen Raumes zur art-/sortenspezifischen Entwicklung von Pflanzen

Eine weitere umzusetzende Funktionalität des mobilen Planungs- und Beratungssystems unterstützt den Nutzer bei der Beachtung des notwendigen Platzbedarfs von Pflanzenarten/-sorten, damit sich diese hinsichtlich ihres Wuchses art-/sortenspezifisch entwickeln können. Dazu wird ein Modell/Plan des Geländes (inkl. Gebäude, Grundstücksgrenzen bzgl. Nachbarschaftsrecht, bereits vorhandene oder geplante Vegetation und weitere Objekte) auf einem WebGIS-Server bereitgestellt (siehe Abb. 2: 2D-/3D-Geländemodell/-Bestandsplan).

Wählt der Anwender eine Pflanzenart aus, so wird auf Basis der Daten aus einer Pflanzendatenbank (Wuchsgröße/-breite, Wuchsform etc.) ein 2D- oder 3D-Modell der Pflanzenart/-sorte berechnet. Mittels GIS-Operationen bzw. Geoverarbeitungsfunktionen (z.B. Buffer, Select etc.) werden auf einer zuvor ausgewählten Fläche die Bereiche ermittelt, an denen eine Pflanzung der gewählten Art/Sorte mit dem Ziel einer art-/sortenspezifischen Entwicklung nicht sinnvoll ist oder aber Bereiche ermittelt, die geeignet sind. Die so ermittelten Bereiche werden dann als AR-Visualisierung, z.B. als halb-transparente Einfärbung in Echtzeit, in das Live-Videobild projiziert (siehe Abb. 3).

Der Anwender wird somit bei der Auswahl der Pflanzposition unterstützt. Optische Trackingverfahren liefern zentimetergenaue Positionsdaten der Kamera als Grundlage zu einer sehr genauen AR-Visualisierung der Pflanzbereiche im Live-Videobild. Die Position der Kamera wird per Echtzeit-Bildverarbeitung aus speziellen Bildmerkmalen im Videobild der Kamera, bezogen auf die reale Bildszene, ermittelt.

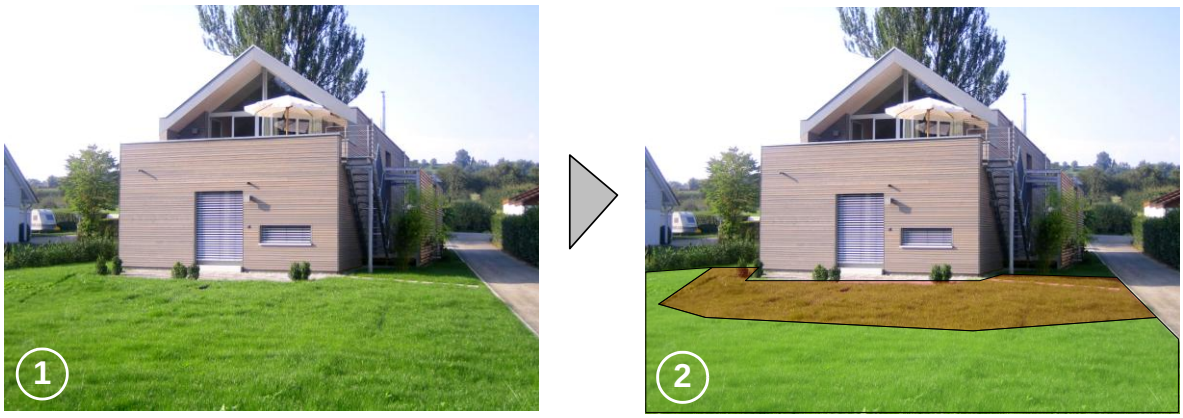

Abbildung 3: Prinzipskizze zur Funktionsweise einer Funktionalität, die den Anwender bei der Positionierung einer Pflanzenart hinsichtlich der Berücksichtigung des art-/sortenspezifischen Wuchsraumes unterstützt. Bild 1 zeigt das mit der Kamera des mobilen Endgerätes aufgenommene Live-Videobild. In Bild 2 werden dann nach der Auswahl einer bestimmten Pflanzenart in Echtzeit die Bereiche markiert, die hinsichtlich einer Positionierung der Pflanzenart geeignet (grün) oder ungeeignet (rot) sind. Der Anwender kann nun, unterstützt durch das System, eine geeignete Pflanzposition für die gewählte Pflanzenart bestimmen. Danach wird ein Billboard/3D-Modell der Pflanzenart an der gewählten Pflanzposition eingeblendet (siehe Abb. 1)

Wählt der Anwender des Systems einen Pflanzbereich aus, der hinsichtlich seiner Größe und seines Zuschnitts grundsätzlich nicht für bestimmte Pflanzenarten/-sorten geeignet ist (z.B. ist der Bereich zum Pflanzen einer Baumart zu knapp bemessen), so können bestimmte Arten/Sorten nicht mehr ausgewählt werden. Diese Funktionalität kann durch den Anwender wahlweise aktiviert werden, da in bestimmten Fällen ggf. auch wissentlich die Pflanzung einer Art/Sorte geplant wird, auch wenn diese dann nicht den optimalen Platz-/Raumbedarf vorfindet. Die so bestimmten Pflanzpositionen können dann als 2D-Bepflanzungsplan an einen ausführenden Betrieb übergeben oder zur weiteren Bearbeitung in ein CAD-System importiert werden. Für die Umsetzung der Komponente zur Unterstützung des Anwenders bei der Beachtung des notwendigen art-/sortenspezifischen Wuchsraumes liegen bereits einschlägige Erfahrungen und Ergebnisse aus einem abgeschlossenen FuE-Projekt vor, die entsprechend angewandt und/oder weiterentwickelt werden können.

3) Standortgerechte Auswahl von Pflanzenarten/-sorten

Die Funktionalitäten zur Unterstützung einer standortgerechten Auswahl von Pflanzenarten/-sorten werden bei Bedarf ebenfalls auf dem AR-Aufnahmesystem angezeigt, d.h. als Benutzeroberfläche zur Verfügung gestellt. Mittels GPS, digitalem Kompass und weiteren, noch präziseren optischen Tracking- bzw. Registrierungsverfahren aus dem Bereich der AR-Technologien werden die Position und die Ausrichtung des mobilen Endgerätes bestimmt. Die Genauigkeit von AR-Verfahren zur Positionsbestimmung liegt im Zentimeterbereich, somit sind diese für ein derartiges System geeignet (TÜMLER et al. 2008). Durch die bestimmte Position des Endgerätes in Kombination mit der Landschaftsinformationen-Datenbank (WebGIS-Services) erfolgt der Zugriff auf standortspezifische makro- und mesosystemische Informationen über die Klima- und Bodenverhältnisse (Winterhärtezone, durchschnittliche Niederschlagswerte, Lufttemperatur etc.) bzw. Informationen über die ökologischen Raumklassen.

Zusätzlich hat der Anwender die Möglichkeit, manuell weitere Standortinformationen für bestimmte Bereiche einzugeben/zu ergänzen (Lichtverhältnisse, Lebensbereiche nach HANSEN und STAHL 1997 oder KIERMEIER 1995, Bodenart etc.), die im Videobild markiert werden und dadurch als Attribute, z.B. von GRID-Zellen oder Vektoren in ein 2D-/3D-Modell übertragen werden, das auf einem WebGIS-System bereitgestellt wird. Die makro- und mesosystemischen Informationen können so bei Bedarf präzisiert werden, sollten die durch das WebGIS automatisch bereitgestellten Standortinformationen nicht genügen.

Diese dann im System vorhanden Informationen bilden die Grundlage zur standortgerechten Vorselektion von Pflanzenarten und -sorten durch eine weitere Systemkomponente – einer Online-Pflanzendatenbank.

Durch die internetbasierte Verknüpfung des Planungs- und Beratungssystems mit der Artikelstamm-Datenbank (siehe Abb. 2) können die Produktdaten der ausgewählten Pflanzenarten/-sorten an ein ebenfalls mit dem System verknüpften Warenwirtschaftssystem oder Internet-Verkaufsportal gesandt werden. Sollen Pflanzenarten/-sorten verwendet werden, die hinsichtlich ihrer Standortansprüche von den bestehenden

Standortverhältnissen abweichen, könnte ein derartiges System zukünftig auch dazu befähigt werden, Maßnahmen zur Standortverbesserung oder -anpassung (Substrataustausch, Mulch, künstliche Bewässerung etc.) vorzuschlagen und die dazu erforderlichen Leistungen als GAEB-konforme Daten auszugeben/weiterzuleiten oder Bestelllisten für die dazu benötigten Produkte zu generieren.

4 ARBEITSPROGRAMM

Zur Strukturierung des geplanten Vorhabens wurden zwei Arbeitsprogrammschwerpunkte (APS) formuliert. Durch die Kombination der Ergebnisse der APS entsteht ein Gesamtsystem, welches die Funktionalitäten zur Unterstützung einer funktions- und standortgerechten Pflanzenauswahl bereitstellt und dazu die in Abbildung 2 dargestellten Systemkomponenten bzw. entsprechende Daten/Informationen Web-basiert verknüpft. Im Folgenden werden die wesentlichen Aspekte der zwei APS kurz umrissen.

APS 1: Pflanzenverwendung und verteilte Web-basierte Informationssysteme

Der Fokus des ersten APS liegt auf der Bearbeitung der fachwissenschaftlichen und praxisbezogenen Fragestellungen innerhalb der Themen Pflanzenverwendung bzw. funktions- und standortgerechte Pflanzenauswahl sowie der Nutzung aktueller Informations- und Kommunikationstechnologien (IKT) zur Umsetzung und Web-basierten Verknüpfung der notwendigen Systemkomponenten. Im Vorhaben sind die fachlichen Maßgaben zur Umsetzung von Programmroutinen zur Entscheidungs-unterstützung (Unterstützung bei der fachgerechten Auswahl von Pflanzenarten/-sorten) zu ermitteln (Statusanalyse), durch eine Expertenbefragung zu verifizieren und als Maßgaben für die Entwicklung und Erprobung des mobilen Systems in einem Pflichtenheft zu definieren.

Die technischen Parameter zur Einrichtung und/oder Verknüpfung der folgenden Systemkomponenten: Applikations-Server, Pflanzen-datenbank (Kopie), Artikelstamm-Datenbank, Billboard-/3D-Modell-Datenbank, 2D-/3D-Geländemodelle/-Bestandspläne (WebGIS), Landschaftsinformations-Datenbank (ELCE, WebGIS) sind zu ermitteln. Dazu werden entsprechende Recherchen (Statusanalyse) sowie Expertenbefragungen durchgeführt und die Ergebnisse ebenfalls in einem Pflichtenheft dokumentiert. Weiterhin umfasst dieser ASP neben der Einrichtung/Anpassung/Verknüpfung von Systemkomponenten auch die Programmierung von Funktionalitäten zur Unterstützung der Pflanzenarten-/-sortenauswahl, sowie die technische und fachliche Evaluierung der Umsetzung der im Pflichtenheft definierten Kriterien und Parameter bei der Entwicklung des mobilen Systems.

APS 2: Visualisierung und Interface-Design

Der zweite APS umfasst die zu betrachtenden Aspekte der Visualisierung in der Landschaftsarchitektur bzw. speziell von Vegetation und widmet sich der Konzeption und Realisierung der AR-Umgebung und eines benutzerfreundlichen und intuitiven AR-Userinterface. Dazu werden im Vorhaben durch eine Statusanalyse alle fachlichen Parameter zur Visualisierung sowie zur Gestaltung und Bedienung der Benutzeroberfläche des AR-Aufnahme-/-Anzeigesystems ermittelt, durch eine Expertenbefragung verifiziert und in einem

Pflichtenheft als Konzeption zur Entwicklung und Erprobung (Evaluierung) definiert. Der Fokus liegt auf einem anwenderzentrierten Design von benutzerfreundlichen und intuitiven Interfaces (Schnittstellen, Interaktion, Benutzeroberflächen etc.) zur Administration der Systemkomponenten und insbesondere zur Bedienung des mobilen Planungs- und Beratungssystems.

Weiterhin sind Arbeitspakete zur Aufbereitung von Billboards und/oder 3D-Modellen sowie beispielhaften 2D-/3D-Bestandsplänen und ihre Bereitstellung durch die dafür vorgesehenen Systemkomponenten geplant. Weitere Schwerpunkte liegen auf der Begleitung der Programmierarbeiten und der Evaluierung des AR-Aufnahme-/-Anzeigesystems (AR-Umgebung) hinsichtlich einer fachgerechten sowie den Nutzeranforderungen entsprechenden Visualisierung von Vegetation sowie bzgl. der Umsetzung eines benutzerfreundlichen und intuitiven AR-Userinterface. Zur Ableistung der notwendigen Programmierarbeiten (Umsetzung des AR-Aufnahme-/-Anzeigesystems und des AR-Userinterface) ist eine entsprechendes Unternehmen in das Vorhaben einzubinden.

1 ABSTRACT

Der Anteil der Bevölkerung, der an der Planung und Entwicklung des eigenen Lebensumfelds mitgestalten und mitbestimmen möchte, ist in den letzten Jahrzehnten stetig gestiegen. Die Realisierung von Infrastrukturprojekten ist nur noch möglich, wenn möglichst gute Lösungen erarbeitet werden, die auf ausreichende Akzeptanz bei allen betroffenen und beteiligten Akteurinnen und Akteuren treffen – und dies bedarf eines professionellen, effizienten und konstruktiven Partizipationsprozesses.

Mit Hilfe des Partizipationstools (entstanden aus einem ways2go-Forschungsprojekt, bmvit) wird erstmalig ein optimales Zusammenspiel von technischen und nicht-technischen Methoden in Partizipationsprozessen über ein technologiebasiertes Planungswerkzeug zur Reduktion von planungs- und prozessbezogenen Barrieren und zur Unterstützung bzw. signifikanten Verbesserung der Bürgerbeteiligung in Planungs¬prozessen ermöglicht. Das Partizipationstool baut auf den existierenden Methoden der Partizipation, dem rechtlichen und wirtschaftlichen Rahmen, den Erkenntnissen aus der Praxis der Partizipation und den Anforderungen aller in Partizipationsprozessen beteiligten Personen, Personengruppen, Institutionen, Unternehmen etc. auf.

Das Partizipationstools besteht aus zwei Teilen: Das Frontend enthält sämtliche Online-Applikationen, die direkt im Partizipationsprozess eingesetzt werden können. Diese umfassen die Darstellung von Dokumenten jeder Art, von Personen, Gruppen und Terminen, ein Kommunikationsforum, die Möglichkeit zu Stellungnahmen etc. - das Frontend entspricht damit dem im Partizipationsprozess nach außen sichtbaren Teil des Partizipationstools. Das Backend stellt die Verwaltungsebene des Partizipationstools und damit des gesamten Partizipationsprozesses dar. Hier wird die Gesamtarchitektur der Partizipation verwaltet, werden alle Online-Applikationen betreut sowie alle Offline-Methoden und die Schnittstellen zwischen „online“ und „offline“ organisiert. Das gesamte Tool ist modulartig aufgebaut, um damit (je nach Bedarf eines Partizipationsprojekts) unterschiedliche Varianten bezogen auf Methoden und Umfang realisieren und anwenden zu können. In Summe wird mit dem Partizipationstool bidirektionale Kommunikation zum jeweiligen Projekt ermöglicht und im Kern die Komplexität von Partizipationsprozessen eingefangen, systematisch dargestellt und damit greif- und bearbeitbar gemacht.

Vom Einsatz des Partizipationstools profitieren alle beteiligten Personen Personengruppen, Institutionen, Unternehmen: Beteiligungsverfahren werden konstruktiver und effizienter (Zeit- und Kosteneinsparungen), die Planungssicherheit steigt, die Planung und Durchführung von Partizipationsprozessen wird klarer und professioneller und die Akzeptanz für erarbeitete Lösungen und die Barrierefreiheit im Zugang zu Partizipationsverfahren wird deutlich erhöht. Das Partizipationstool kann in Beteiligungsverfahren im Rahmen von Infrastrukturprojekten auf kommunaler, regionaler, nationaler aber auch internationaler Ebene eingesetzt werden. Neben der öffentlichen Verwaltung und der Politik zielt das Partizipationstool auch auf Infrastrukturprojekte ab, die von privaten Unternehmen umgesetzt werden.

2 AUSGANGSLAGE

Infrastrukturprojekte stellen einen wesentlichen Konjunkturmotor dar und sind entscheidend für die langfristige Lebens- und Standortqualität. Der Anteil der Bevölkerung, der an der Planung und Entwicklung des eigenen Lebensumfelds mitgestalten und mitbestimmen möchte, ist in den letzten Jahrzehnten stetig gestiegen. Die Stufen bzw. Ebenen der Information oder Konsultation werden jedoch seitens großer Teile der Bevölkerung als nicht mehr ausreichend erachtet – die Forderungen nach Kooperation, nach einer professionellen Mitgestaltung und Mitbestimmung, sind in nahezu allen öffentlichkeitsrelevanten Projekten sicht¬bar.

Die Realisierung von mobilitätsrelevanten Infrastrukturprojekten bedarf nicht nur bei der betroffenen Bevölkerung einer ausreichenden Akzeptanz. In vielen Fällen stellt sich die Herausforderung, mit Ziel- und Interessenskonflikten zwischen der Öffentlichen Hand, projektwerbenden Unternehmen, Interessengruppen und Verbänden, Planungsbüros und den betroffenen Bürgerinnen und Bürgern umzugehen. In der Praxis der

Partizipation lässt das Maß an konstruktivem Miteinander noch sehr viel Spielraum zur Verbesserung. Oft wird die Möglichkeit der Mitgestaltung und Mitbestimmung als Plattform des Widerstands um jeden Preis genutzt. Die Konsequenz daraus ist, dass viele Infrastrukturprojekte kaum noch eine Chance auf Realisierung haben und die Bereitschaft seitens Unternehmen, Politik und Verwaltung zu einer ehrlichen Einbindung der Bevölkerung teilweise wieder rückläufige Tendenzen aufweist. Einen beträchtlichen Anteil an diesem Umstand hat die Art und Weise, wie Partizipation in vielen Fällen von Infrastrukturvorhaben in der Praxis umgesetzt wird. Die Entwicklung (und darauf aufbauend der Praxiseinsatz) eines Partizipationstools sollte hier die Möglichkeit schaffen, planungsprozessbezogene Barrieren zu reduzieren und damit eine signifikante Verbesserung der Bürgerbeteiligung in mobilitätsrelevanten Planungsprozessen hin zu einem konstruktiven, ehrlichen und effizienten Miteinander zu erreichen.

Es gibt eine sehr große Anzahl und Vielfalt unterschiedlicher Methoden der Partizipation. Diese teilen sich auf in traditionelle (nicht technologiebasierte) Methoden wie Konsensuskonferenz, Planungszelle, Zukunftswerkstatt, Kooperativer Diskurs, Mediation, Runder Tisch, „Open Space“, Neo-Sokratischer Dialog, Workshops jeglicher Art, Bürgerforen, Bürgerversammlungen, Bürgerbeiräte etc. und internet¬basierte e-Partizipationsmethoden wie Online-Befragungen, Internetforen, Chats, e-Petitionen etc.

In der derzeitigen Praxis hängt die Auswahl der Methode vom jeweiligen Projektvorhaben, der Erfahrung und dem Wissensstand der Projektverantwortlichen und der gewünschten Intensität der Partizipation und Mitbestimmung ab. Dies führt dazu, dass nicht immer die „optimalen“ Methoden aus dem Pool existierender Methoden Anwendung finden und sehr selten eine „Gesamtarchitektur“ aus „Online-“ und „Offline-Elementen“ eines Partizipationsprozesses erstellt wird. Welche Methoden wann optimal zum Ein¬satz gebracht werden können, bedarf einer genauen Analyse der jeweiligen Situation resp. der Beachtung relevanter Auswahlkriterien.

Technologiebasierte Methoden werden in den meisten Fällen gar nicht oder nur sehr eingeschränkt eingesetzt. Als Gründe dafür werden meist die Nachteile von unpersönlichem Kontakt und das Nicht-Erreichen von Teilen der Bevölkerung (Coverage-Probleme) genannt. Ein umfassender und jeweils optimierter Einsatz von bereits bekannten und erprobten technologiebasierten Methoden sowie innovativen Ansätzen, findet somit derzeit nur selten statt. Die Konsequenz daraus ist, dass jeweils eine nennenswerte Anzahl an planungsprozessbezogene Barrieren nicht oder nicht ausreichend überwunden werden können und damit keine optimalen oder oft auch gar keine Lösungen erarbeitet werden.

3 INTERNATIONALER KONTEXT

Beteiligungsverfahren werden bei Infrastrukturprojekten weltweit durchgeführt. Allerdings werden hier auch international selten bedarfsgerechte Kombinationen aus Methoden (online- und offline Services) angewandt, auch wenn insgesamt die Nutzung von e-Partizipations-Services weltweit auf dem Vormarsch ist. Bereiche, in denen e-Partizipations-Services von Bürgerinnen und Bürgern besonders genutzt werden, sind Umwelt, Gesundheit und Bildung. Laut dem aktuellen „United Nations E-Government Survey 2010“ steht im Vordergrund zwar das Verbreiten von Informationen, doch immer mehr Regierungen nutzen auch Web 2.0 Anwendungen und soziale Netzwerke wie facebook oder twitter um Bürgerinnen und Bürgern die Möglichkeiten zu geben, am politischen Gestaltungsprozess teilzuhaben – und dies vor allem auf lokaler Ebene. Wenn es darum geht, Entscheidungsprozesse mit zu beeinflussen, sind Regierungen noch zurückhaltend. Nur 9% aller Länder erlauben und nutzen e-Petitionen – führend ist hier Großbritannien.

Wie in „United Nations e-Government Survey 2010“ betont, ist es für den Erfolg von e-Partizipation wichtig vor allem auf Sprache, Form, Inhalt und Zugangsmöglichkeiten zu achten. Um hier alle Bevölkerungs-segmente zu erreichen, sollte ein Methodenmix angewandt werden. Laut dem Bericht hat sich gezeigt, dass Top-Down Ansätze oft erfolglos bleiben. Bürgerinnen und Bürger nutzen dann e-Partizipation, wenn sie bereits in den Planungsprozess vor der eigentlichen Umsetzung des e-Services eingebunden sind. Auch zeigt sich, dass eine gleichberechtigte Teilhabe von Männern und Frauen nur möglich ist, wenn gender mainstreaming ernst genommen und entsprechende Ziele und Strategien bereits im Planungsstadium sowie in der weiteren Durchführung berücksichtigt und verankert werden. Dies gilt genauso für Strategien des Diversitätsmanagements.

Zu ähnlichen Schlüssen kommt auch die europäische Kommission. Im Rahmen des EC „e-Participation Programme“ werden verschiedene Projekte innerhalb der EU gefördert. Ziel ist es neue Verfahren zu

entwickeln und innerhalb der EU zu verbreiten. Ein Blick auf die geförderten Projekte zeigt jedoch, dass keines der Projekte versucht ein Verfahren zu entwickeln, dass es ermöglicht bedarfsgerecht Methoden (online oder nicht online basiert) auszuwählen und anzuwenden. Es werden hauptsächlich vereinzelte Methoden getestet und dies vor allem im Bereich der Gesetzesentwicklung. Thematisch scheinen Umweltthemen, vor allem Klimawandel und die spezifische Beteiligung von Jugendlichen von Interesse zu sein. In der Entwicklungszusammenarbeit werden seit Jahrzehnten partizipative Methoden getestet und erfolgreich angewandt. Auch wenn die Nutzung konventioneller Methoden (offline) im Vordergrund steht, gibt es hier verschiedene interessante e-Partizipation Pilotprojekte.

Österreich ist weder auf EU-Ebene noch in der internationalen Debatte führend - laut der UN-Studie scheint es hier noch einiges an Nachholbedarf zu geben. Während Österreich 2008 im e-Participation Ranking noch auf Platz 20 lag, hat es sich 2010 nicht unter den Top 20 halten können, weder bei e-Government, noch bei e-Partizipation. Das Ranking wird von Südkorea angeführt. Von den EU Ländern befinden sich mit Spanien (Platz 3) und Großbritannien (Platz 4) zwei unter den ersten 5. Weiterhin sind Estland, Dänemark, Deutschland, Frankreich, Niederlande, Belgien, Litauen und Slowenien unter den Top 20.

4 DIE ÜBERWINDUNG VON BARRIEREN – EINE HERAUSFORDERUNG

Das Überwinden folgender Barrieren muss Ziel jeder Partizipation sein – damit sollte auch das Partizi¬pations¬-tool hierzu einen wichtigen Beitrag leisten.

- Die Einbindung einer kleinen Minderheit von Betroffenen (aktiv Beteiligte) ohne die Sicherheit, die Meinung, Bedürfnisse und Interessen möglichst aller Betroffenen im Verfahren vertreten zu haben;
- Keine ausreichende Barrierefreiheit im Zugang zum gesamten Partizipationsprozess;
- Keine zeitlich und räumlich unabhängige Möglichkeit der Mitgestaltung innerhalb des Partizi¬pations-prozesses;
- Der Missbrauch von Partizipationsverfahren als Forum des Widerstands gegen nicht projektrelevante Personen, Einrichtungen, Parteien, Haltungen, Werte etc. und damit eine destruktive Haltung im Verfahren selbst;
- Geringe zeitliche und finanzielle Effizienz der Partizipation, vor allem auch über die Möglichkeit, das Partizipationsverfahren zeitlich zu „verschleppen“;
- Keine ausreichende Übersicht und Klarheit über alle projektrelevanten Daten und Informationen (Ausgangslage, Zielsetzung und einzelne Sichtweisen dazu, Handlungsspielräume, Planungs-grundlagen, Planungsstand, Planungsunterlagen, beteiligte Gruppen und Interessen, einzelne Sicht-weisen und Standpunkte zum Projekt selbst, Planungsabläufe, Entscheidungsabläufe, rechtlicher Rahmen etc.)
- Keine oder unprofessionelle Begleitung von Rückbindungsprozessen von Delegierten in die jeweiligen Herkunftsgruppen;
- Keine ausreichende Trennung zwischen den Interessen und Bedürfnissen von Privatpersonen bzw. Vertreterinnen und Vertretern von Gruppen;
- Ineffiziente Schnittstellen zwischen dem Partizipationsverfahren und dem jeweiligen formellen Verfahren (Verwaltungsverfahren zur Genehmigung etc.);
- Keine ausreichende Planungssicherheit für Projektwerber;
- Keine ausreichend repräsentative Erhebung des Meinungsbilds aller Betroffenen als Grundlage für eine Entscheidung bzw. demokratietheoretisch bedenkliche oder nicht transparente Entscheidungs-prozesse.

Die Herausforderungen in der Erarbeitung des Partizipationstools lagen vor allem auch in dem Zusammen-spiel von technischen und nicht-technischen Methoden für mögliche Anwendungsfälle einer Partizipation, um damit möglichst einen Beitrag zur Überwindung der genannten Barrieren zu leisten.

5 PARTIZIPATIONSTOOL – DER AUFBAU

Das Partizipationstool soll als ein technologiebasiertes Planungswerkzeug ein optimales Zusammenspiel von technischen und nicht-technischen Methoden in Partizipationsprozessen zur Reduktion von planungs- und prozessbezogenen Barrieren und zur Unterstützung bzw. signifikanten Verbesserung der Bürger¬beteilung in Planungsprozessen ermöglichen. Diese Unterstützung sollte nicht nur in der Durchführung des Beteiligungs-prozesses, sondern einerseits auch in der Planung, der Dokumentation und dem Monitoring stattfinden und andererseits auch die Analyse und Evaluierung eines Prozesses begleiten (siehe Abbildung 1).

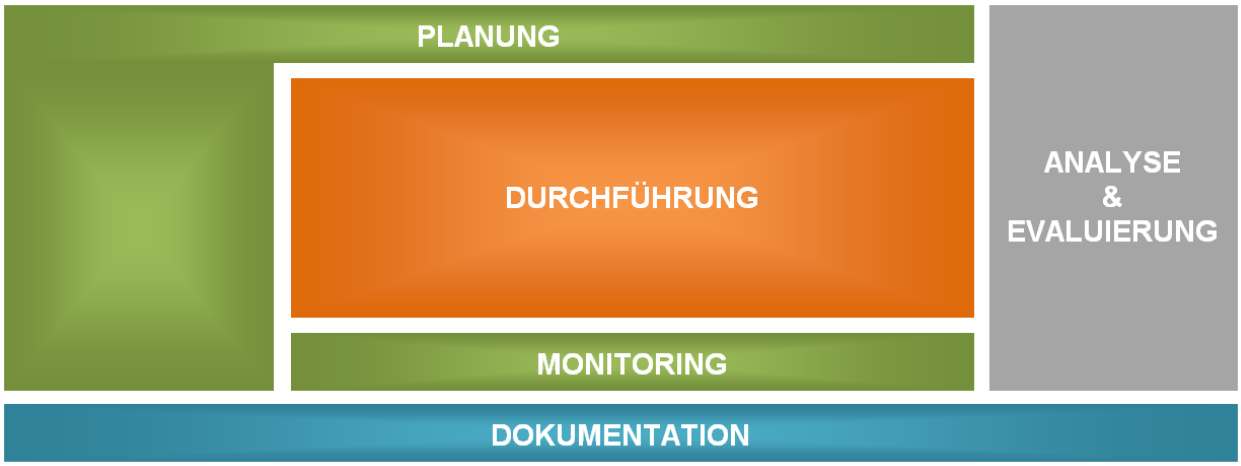

Abbildung 1: Einsatzbereiche des Partizipationstools im zeitlichen Ablauf einer Beteiligung

Das Partizipationstools besteht aus zwei Teilen: Das Frontend enthält sämtliche Online-Applikationen, die direkt im Partizipationsprozess eingesetzt werden können. Das Frontend entspricht dem im Partizi¬pations-prozess nach außen sichtbaren Teil des Partizipationstools und umfasst unter anderem ein inteligentes Dokumentenmanagementsystem, die Möglichkeit der Darstellung von Personen und Gruppen, von Ereignissen (Begehungen, Versammlungen etc.), Kommunikations-, Mitbestimmungs- und Mitgestaltungs¬tools etc. – im Kern wird dies über die vier Teile/Elemente „Personen“, „Gruppen“, „Events“ und „Dokumente“ abgebildet (siehe Abbildung 2), die jeweils untereinander verknüpft sind. Das Backend stellt Verwaltungsebene des Partizipationstools und damit des gesamten Partizipationsprozesses dar. Hier wird die Gesamtarchitektur der Partizipation verwaltet, werden alle Online-Applikationen betreut sowie alle Offline-Methoden und die Schnittstellen zwischen „online“ und „offline“ organisiert. Das gesamte Tool ist modulartig aufgebaut, um damit (je nach Bedarf eines Partizipationsprojekts) unterschiedliche Varianten bezogen auf Methoden und Umfang realisieren und anwenden zu können. In Summe wird mit dem Partizipationstool bidirektionale Kommunikation zum jeweiligen Projekt ermöglicht und im Kern die Komplexität von Partizipationsprozessen eingefangen, systematisch dargestellt und damit greif- und bearbeitbar gemacht.

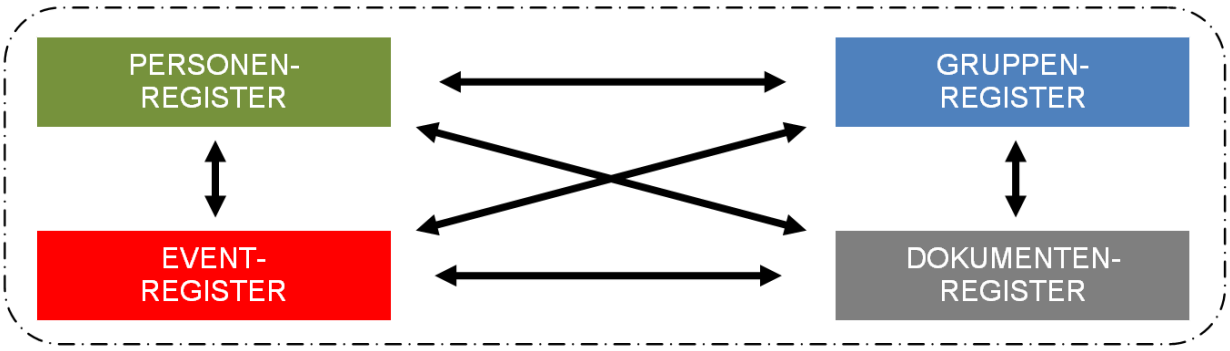

Abbildung 2: Grobstruktur / Elemente des Partizipationstools

6 PARTIZIPATIONSTOOL – DER NUTZEN

Der Einsatz eines Partizipationstools soll auf jeden Fall das Erreichen folgender Ziele unterstützen bzw. erleichtern:

- Einbindung von Meinungen, Bedürfnissen und Interessen möglichst aller Betroffenen in Planungsprozessen, unter besonderer Berücksichtigung von Gender und Diversitätsaspekten;
- Barrierefreiheit im Zugang zum gesamten Partizipationsprozess und zeitlich und räumlich unabhängige Möglichkeit der Beteiligung;
- Reduktion des Missbrauch von Partizipationsverfahren als Forum des nicht-projektbezogenen Widerstands hin zu einem konstruktiven, gemeinsamen Gestalten
- Erhöhung der zeitlichen und finanziellen Effizienz der Partizipation;
- Verbesserung der Übersicht und Klarheit über alle projektrelevanten Daten und Informationen;
- Passende Trennung zwischen den Interessen und Bedürfnissen von Privatpersonen bzw. Vertreterinnen und Vertreten von Gruppen;
- Ermöglichung effizienter Schnittstellen zwischen dem Partizipationsverfahren und dem jeweiligen formellen Verfahren sowie der Planungssicherheit für Projektwerber;
- Darstellung eines repräsentativen Meinungsbilds aller Betroffenen bzw. demokratie-theoretisch unbedenkliche und transparente Entscheidungsprozesse.

Damit kann einerseits eine bessere Daten-, Interessen- und Bedürfnisgrundlage für Planungsanwendungen ermöglicht werden und andererseits ein Werkzeug eingesetzt werden, das in Partizipationsprozessen zu einer optimierten Wissensbereitstellung und Wissensanwendung sowie zu einer besseren bidirektionalen Kommunikation beitragen kann. Das Partizipationstool kann in Beteiligungsverfahren im Rahmen von Infrastrukturprojekten auf kommunaler, regionaler, nationaler aber auch internationaler Ebene eingesetzt werden. Neben der öffentlichen Verwaltung und der Politik (Bund, Land, Bezirk und Gemeinde) zielt das Partizipationstool auch auf Infrastrukturprojekte ab, die von privaten Unternehmen umgesetzt werden.

Aufgrund der Online-Applikationen des Partizipationstools und der effizienten Verwaltung der Schnittstellen zwischen den Online-Applikationen und den Offline-Methoden ergibt sich außerdem eine verstärkte Effizienz, Kosten- und Zeitersparnis. So erlaubt es das Internet z.B. umfangreiche Planungsunterlagen, unabhängig von Öffnungszeiten und ohne Kopier- und Versandkosten bereitzustellen. Fragen, Meinungen, Anregungen, Petitionen etc. können von den Betroffenen/Beteiligten einfach online eingereicht werden oder auch direkt in die Planungsunterlagen eingetragen werden. Die Beteiligten können die Online-Applikationen des Tools nutzen, wann immer es ihre Zeit erlaubt. Damit können breitere Bevölkerungsschichten erreicht werden, was zu einem Abbau der genannten Barrieren führt. Weiters können bestimmte Bevölkerungs- bzw. Interessensgruppen wie Migrantinnen und Migranten, Jugendliche etc. gezielt angesprochen, ihre Meinungen abgefragt und in den Planungsprozess einbezogen werden.

7 WICHTIGES ZUM SCHLUSS

Das Partizipationstool kann und soll immer nur eine Ergänzung und Unterstützung von physischer Begegnung sein. Ein guter Planungs- und auch Beteiligungsprozess steht und fällt mit der Qualität des Planungs- und Moderationsteams – das Partizipationstool alleine kann und „will“ gar nichts leisten. Die Begleitung und Unterstützung des Gesamtprozesses über das Partizipationstool kann jedoch zur Förderung von Kontinuität, Vertrauensbildung und Transparenz beitragen und damit einen wichtigen Beitrag zur Verbesserung der Beteiligung von Bürgerinnen und Bürgern in Infrastrukturprojekten leisten.

„Pedestrianize Your City“ – Elemente und Vorteile einer Fußgängerstrategie sowie eines Fußgängerchecks für Ihre Stadt

Dieter Schwab, Martina Strasser

(Dipl.-Ing. Dieter Schwab, walk-space.at – der österreichische Verein für Fußgänger/-innen, dieter.schwab@walk-space.at)
(Dipl.-Ing. Martina Strasser, walk-space.at, martina.strasser@walk-space.at)

1 ABSTRACT

Eine Stadt, die sich der Nachhaltigkeit und „(Wieder)-durchmischung“ widmet, ist eine Stadt die, Fußgängerstrategien schon heute umsetzt, eine Tradition darin hat und bzw. oder gewillt ist den Anforderungen in der Zukunft gut gewachsen zu sein.

Welche Elemente eine effiziente Fußgängerstrategie beinhaltet und welche Vorteile dies bringt, und was es für die Lebensqualität in einer zukunftfähigen Stadt bedeutet, wird im Rahmen dieses Beitrags aufgezeigt und im Referat behandelt. Aus den Projekterfahrungen von walk-space.at – dem Österreichischen Verein für Fußgänger/-innen können unter anderem Ansätze für ein Strategie-/ einen Masterplan Gehen/Fußverkehr vorgestellt werden. Internationale Beispiele, so wie die Fußverkehrsinitiativen in Deutschen Städten oder die schweizer Strategie zur Forcierung des „Langsamverkehrs“ geben Anregungen für nachhaltige Stadtstrukturen.

New York:. If you can do it there, you can do it everywhere (vorher/nachher).

Fußgänger/-innen beleben den urbanen Raum – stärken die Nahversorgung und sind ein großes Potenzial verstärkt zu lokalen Kreisläufen zurückzukehren. Sparsam im Flächenverbrauch, nahezu lautlos und sehr CO_2-neutral trägt der Fußverkehr wesentlich zur Wohn- und Lebensqualität einer Stadt bei. Urbane Räume, die qualitätsvolle Fußwege bieten und öffentliche Räume als „Wohlfühloasen“ in Mitten des oft hektischen Alltags, tragen zu einem lebenswerten Wohn-, Arbeits- und Erholungsumfeld bei. Straßenraumumgestaltungen wie beispielsweise die Begegnungszone mit Tempo 20 nach Schweizer, belgischem und französischem Vorbild, oder „Shared Spaces“ sind erfolgreiche Beispiele für ein positives Miteinander aller Verkehrsteilnehmer/-innen.

2 WICHTIGE ELEMENTE EINER FUSSGÄNGERSTRATEGIE

Fußgängerfreundliche Strukturen: bringen alle Gelegenheiten – ob Versorgung, Erholung, soziale Beziehungen, Dienstleistungen, etc. wieder in die Nähe!

Mit dem demographischen Wandel, den Auswirkungen des Klimawandels und des Mobilitätsverhaltens als auch des Gesundheitszustandes jetziger und künftiger Generationen kommt eine zunehmende Bedeutung

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

dem Fußverkehr zu. Die Schweiz hat dies schon frühzeitig erkannt und bereits 1979 Grundlagen zur Förderung des Fußverkehrs geschaffen und auch beschlossen (Verfassungsartikel für die Planung und Erhaltung von Fuß- und Wanderwegen). Eine der wesentlichen Gleichstellung des Fußverkehrs zum motorisierten Individualverkehr ist das Modell der Begegnungszonen und das Agglomerationsprogramm, welches nur dann das Förderfüllhorn öffnet, wenn das Fußwegenetz klar ersichtlich und Teil der Gesamtplanungsvorhaben sind.

Auch in Deutschland will man künftig den Fußgängern/-innen mehr Aufmerksamkeit zukommen lassen. So wurde 2011 eine Fußverkehrsstrategie für Berlin beschlossen (siehe dazu Wohlfahrt von Alm in www.walk-space.at/images/stories/projekte/seminare/CD_Fachkonferenz_2011_Salzburg.pdf).

Im Rahmen des Vortrags bei der CORP werden internationale Beispiele aber auch Prinzipien und Maßnahmen für den Fußverkehr für Österreich vorgestellt. Aufgrund der umfangreichen Thematik einer Fußverkehrsstrategie für Österrreich seien im Folgenden einige wichtige Elemente dargestellt.

2.1 Bewusstsein-(sbildung)

Neue Transformationsprozesse des öffentlichen Raumes wecken einen Trend zum zu Fuß gehen durch die räumlichen Qualitäten und Verbesserungen in Form von Koexistenz statt Dominanz einer Mobilitätsform.

Pilotprojekte in Österreich, wie „Begegnungsraum Maxglaner Hauptstraße“, „Shared Space“ in Gleinstätten oder Neugestaltung des Sonnenfelsplatzes in Graz (siehe dazu auch Newsletter 3 2011 Walk-space.at) sind für diesen Entwicklungsprozess wichtig, weil sie u. a. durch positive mediale Berichterstattungen eine Öffentlichkeitswirkung erreichen und einen Umdenkprozess in Gang setzen bzw. verstärken. Konzepte wie die Begegnungszonen (www.begegnungszonen.ch) aus der Schweiz, oder das Koexistenzprinzip (http://www.bve.be.ch/bve/de/index/strassen/strassen/berner_modell.html) stellen für Fußgänger/-innen gute Lösungen einer qualitätsvollen Stadtgestaltung dar.

Besonders in urbane Räume ist der Fußverkehr effizient, energiesparend, umweltgerecht, gesund und kostengünstig, dennoch wird sein Stellenwert oft noch unterschätzt. Werden allerdings die Anzahl der Wege (Etappen) betrachtet, so sind die Anteile des Fußverkehrs am Modal Split am höchsten.

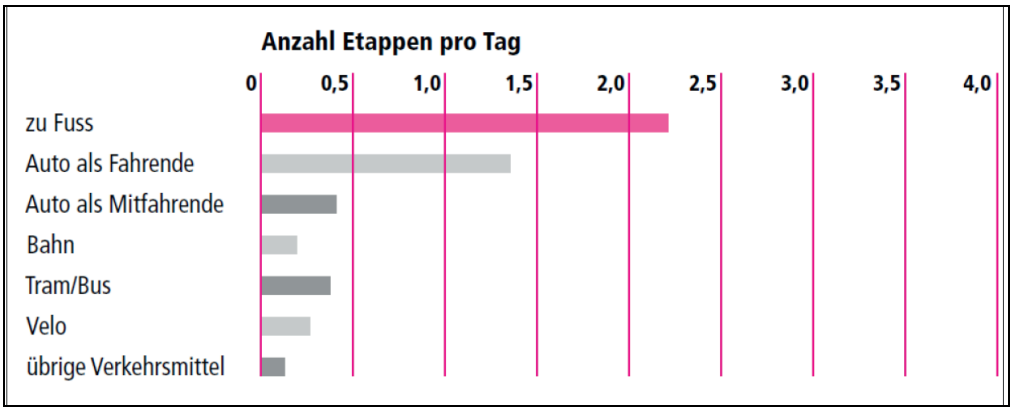

Fig. 1: Unterwegszeit in der Schweiz; Bucheli, D., „Elemente einer Strategie zur Förderung des Fussverkehrs in der Schweiz”, 5. österr. Fußgängerfachkonferenz „Green Mobility – zu Fuß im Alltag“ 10.11.2011.

Um Fußgängerstrategien realisieren zu können, muss daher in erster Linie ein Bewusstsein auf politischer Ebene und in der Öffentlichkeit geschaffen werden. Gehen ist nicht etwas, dass v.a. arme Leute tätigen. Gehen sowie die dafür notwenigen Komfort- und Qualitätsausstattungen gehören zu einer zukunftsfähigen Stadt, die sich durch Wohlfühlfaktoren kennzeichnet und nicht durch Staus und verparkte öffentliche Räume. Dazu ist es wichtig, dass ein Bewusstsein für die Relevanz und Notwendigkeit in der Umsetzung in Verwaltung und bei politischen Vertretern existiert oder durch **laufende Informationsprozesse** auch in der Bevölkerung geschaffen wird. Konferenzen**, Tagungen und Projekte sowie Netzwerkinitiativen** können im Sinne eines „State oft he Art-Austausches" diesen Prozess in der Fachöffentlichkkeit gut unterstützen.

2.2 Image-(kampagnen)

Angesichts der klaren Vorteile, die der Fußverkehr im Rahmen der Möglichkeiten (Streckenlängen, Infrastruktur, in der Wegekette) mit sich bringt, ist Gehen in vielen Fällen, die am klügsten gewählte Fortbewegungsart. Dieses Bewusstsein gilt es bei Politik, Verwaltung, Kommunen aber auch der allgemeinen Öffentlichkeit zu schaffen und zu erhöhen. Fußgängerfachtagungen (http://www.walk-space.at/fussgangerseminar/fussgaengerseminare.html) aber auch Preisauszeichnungen wie der „Walk-space AWARD für gute Fußgängerlösungen" (http://www.walk-space.at/Walk-Space-Award/der-walk-space-award.htm l) tragen in Österreich bereits dazu bei. Kampagnen, die die Vorteile des Gehens kommunizieren und die Zusammenhänge bewusst machen, erhöhen nicht nur die Chance zum Umsteigen vom Kfz auf das Gehen (+ÖV+Rad) sondern leisten auch einen Beitrag zur Gesundheitsprävention.

Kreative Imagekampagnen wie das Projekt „Die Stadt liegt Dir zu Füßen" der Stadt Graz, die Schülerrkmpagne von Perchtoldsdorf oder die südtioler Kampagne „Innichen – gut zu Fuß" wecken die Lust auf das zu Fuß gehen. Weitere Beispiele sind die niederösterreiche 10.000 Schritte Aktion „Los geht's! Jeder Schritt tut gut!" oder die Straßenmalaktion "Blühende Straße" im Rahmen der Europäischen Mobilitätswoche aber auch verschiedenste Beispiele vieler Straßenraumfeste in Österreich, die den Verkehrsraum in einen (grünen) Freiraum temporär transformieren.

2.3 Dialog und prozesshafte Maßnahme

Ein gutes Fußwegenetz orientiert sich an den Bedürfnissen von Frauen und Männern, jungen und älteren Menschen wie auch mobilitätseingeschränkten Personen.

Ein wichtiges Ziel ist daher, Qualitätsverbesserungen im öffentlichen Raum bereit zu stellen, insbesondere hinsichtlich:

- Lebenswerte Straßenraumgestaltungen
- Verweilmöglichkeiten (auch ohne Konsumzwang)
- Ruhemöglichkeiten, Sitzgelegenheiten
- Sozialraum: Begegnungen
- Freiraumqualitäten, Schatten, Pflanzen
- Sicherheit, Sichtverbindungen
- Wegeverbindungen, Orientierung
- Schnittstellen mit Qualitäten zu anderen Verkehrsmitteln v.a. zum öffentlichen Verkehr, Radinfrastruktur

Um möglichst vielen Menschen das Gehen zu ermöglichen – vor allem auch jenen Zielgruppen, die auf das Gehen angewiesen sind (Kinder, ältere Menschen, etc.) braucht es Voraussetzungen bezüglich Komfort, Sicherheit, Ästhetik, Leichtigkeit und Flüssigkeit. Es ist daher wichtig die Bedürfnisse der Nutzer/-innen des lokalen Fußwegenetzes einzubeziehen.

Ein wirkungsvolles Instrument dafür stellt der „Fußgänger-Check“ dar.

Der „Fußgänger-Check“ für Städte und Gemeinden

Wer viel zu Fuß unterwegs ist, ärgert sich über Schwachstellen des Wegnetzes. Bei fehlenden Straßenübergängen oder Behinderungen des Weges kann es zu gefährlichen Situationen kommen. Der „Fußgänger-Check“ für Städte und Gemeinden zeigt die Möglichkeiten zur Verbesserung der Qualität um für die Fußgänger/-innen das Umfeld so attraktiv und sicher wie möglich zu gestalten.

Eine qualitätsvolle Fußgängerplanung bezieht nicht nur punktuelle Verbesserungsmaßnahmen ein, sondern schafft ein engmaschiges Fußwegenetz ohne Hürden und Unterbrechungen. Verbesserte Querungen, geöffnete Durchgänge, kurze Wege und gute Orientierungsmöglichkeiten sind einige der wesentlichen Anforderungen an ein gutes Wegenetz für Fußgänger/-innen. Mit ununterbrochenen Fußgängernetzen und dem Mut, Straßenfläche für Fußgänger/-innen umzuwidmen, kann nicht nur das Gehen, sondern auch die Verkehrssicherheit, die Umwelt und das gesamte urbane Leben, gefördert werden.

Der „Fußgänger-Check“ bringt Fußgänger/-innen mit verantwortlichen Behörden zusammen und schafft so den Rahmen für einen Dialog und Maßnahmensetzungen. Mit der Einbeziehung jener Personen, welche das Gebiet täglich als Fußgänger benutzen, können lokale Erfahrungen und regionales Wissen in den Prozess einfließen.

Herzstück des Vorgehens ist eine gemeinsame Begehung, bei der die spezifischen Bedürfnisse im Wegenetz der Fußgänger/-innen vor Ort gesammelt werden. Die gemeinsame Arbeit mit der jeweiligen Nutzergruppe ermöglicht klare Prioritäten festzustellen. Ziel dieses Prozesses ist, gemeinsam realisierbare Maßnahmen zu finden und eine rasche Umsetzbarkeit erster Resultate zu erreichen. Das Instrument bietet eine „maßgeschneiderte Vorgehensweise“, um den finanziellen und personellen Aufwand gering zu halten.

Bis zu 50 Prozent der Kosten (des Fußgängerchecks selbst – aber auch der Umbaumaßnahmen!!) sind via klima:aktiv mobil, in Abhängigkeit von den erzielten Umwelteffekten, förderbar. Die bisherigen Projekterfahrungen u. a. aus Salzburg, St. Pölten, und anderen Gemeinden, wie z.B. Perchtoldsdorf in Niederösterreich oder in Graz zeigen die Chancen und Potenziale des „Fußgänger-Check“ für Städte und Gemeinden auf. Details dazu: http://www.walk-space.at/service/fusscheck.html

Einbeziehung besonderer Gruppen – es geht um die Menschen

Angesichts der demografischen Entwicklung in den Kommunen Österreichs und der zunehmenden „Überalterung“ der Bevölkerung, sollte bei Maßnahmen für den Fußverkehr der Zielgruppe „ältere Menschen“ besondere Bedeutung zukommen. Die Zahl der Menschen im höheren Alter wird mittel- und langfristig stärk ansteigen, weshalb dieser bevorstehende Alterungsprozess eine der größten gesellschaftlichen Herausforderungen der Zukunft darstellen wird. Je älter wir Menschen werden, desto mehr

sind wir auf das Transportmittel „Füße“ wieder angewiesen. Damit steigt jedoch auch der Anspruch an eine qualitätsvolle Verkehrsinfrastruktur, an ein gutes Fußgängernetz.

Doch das zu Fuß gehen im Alter hält auch fit! Eine umfassende Übersicht über die daraus folgenden Veränderungen und Anforderungen an ein Verkehrssystem der Zukunft, sowie Verkehrssicherheitsaspekte und das Mobilitätsverhalten älterer Menschen ist in der Broschüre "Zu Fuß im höheren Alter" im Detail dargestellt: http://www.walk-space.at/zu-fuss-im-hoheren-alter/zu-fuss-im-hoeheren-alter.html

Dialog Rad /Fuß

Dialog ist insofern dort besonders bedeutsam, wo es um das Erlernen von Mobilitätsmustern oder ein verbessertes Miteinander der Verkehrsteilnehmer/-innen geht – wie beim Thema Radfahren und zu Fuß gehen. Der „FAIRness AKTIONstag“ am Donaukanal in Wien bot unterschiedliche Angebote für ein faires Miteinander. Walk-space.at sammelte gemeinsam mit IGF u. a. Verbesserungen zur Begegnung von Radfahrern und Fußgänger/-innen.

Aufgrund der Erfahrungen aus dem Pilotprojekt „Gut Zu Fuß in St. Pölten“ - Fußnah wird die Bedeutung von Mobilitätssensibilisierungen von Schülern/-innen samt deren Eltern deutlich. Siehe auch: http://www.walkspace.at/pages/projekte.htm

3 SCHLUSSFOLGERUNGEN/CONCLUSION

Fußläufige Qualitäten sind die Voraussetzung für zukunftsfähige Städte und eine (Wieder)-Durchmischung, - die für alle Akteure zu einem lebenswerten Leben nötigen Ziele (Versorgung, Erholung, Beegnung, Sozialräume, etc.) werden wieder in die Nähe gerückt.

Im Vortrag werde ndazu internationale und österreichische Good-practice vorgestellt, werden Fragen diskutit wie es optimal gelingen die Stadt der kurzen & qualitätsvollen Wege zu realisieren – den menschlichen Maßstab wieder gut herzusellen.

People Articulating "the Urban" in Serbia: On-line Platform for the Dialog about Public Spaces, their Availability and Public Usage

Marija Cvetinovic, Dobrica Veselinovic

(PhD student Marija Cvetinovic, Ecole Polytechnique Fédérale de Lausanne, EPFL CODEV CM 2, 1015 Lausanne, Switzerland, marija.cvetinovic@epfl.ch)
(Dobrica Veselinovic, Civic Initiatives, Simina 9a, Belgrade, Serbia, dobrica.veselinovic@gmail.com)

1 ABSTRACT

This paper elaborates on the collaborative on-line platform for spatial resources in Serbia. This is an existing solution for the bottom-up involvement of stakeholders and communities in the revivification of non-functioning public spaces, a hideous legacy of the communist past and transitional present times. This idea of collaboration by means of a virtual resources data base actively uses the technological advances of modern times and enables a passive spectator-urban actor to take an active part in the creation of their environment. This thus provides them with an adequate framework for their spatial and social endeavours with regard to existing built structures in the current urban context.

Generally speaking, any built environment always reflects political and economic processes, especially in turbulent social times such as the disintegration of Yugoslavia's socialist system. These circumstances led to the destabilization of the institutions and the social value system in Serbia, depriving an average citizen of sufficient information about "the urban" and the possibilities and tools for action in their immediate surroundings. In this respect, this sort of on-line, participatory, user-friendly activity constitutes an incessant quest to examine and evaluate urban structures and related practices. It motivates inhabitants to develop an understanding of public spaces, the built environment and a variety of urban settings and trends, which thus become endowed with clear meaning and a positive purpose. This process means that public spaces are therefore eventually adapted to meet human needs.

This collaborative on-line platform launched a website in 2009 as a community-driven initiative to challenge uniform and centralized decision-making processes regarding the availability of special resources. The objective was to gradually and systematically change policies and attitudes within Serbian society, to raise people's awareness of their spatial needs and to enable them to engage in the public life of their cities. In other words, this exposes inhabitants to the reality of urban problems and encourages them to take an active part in the decision-making process of their cities' genesis. Moreover, this campaign ensures direct cooperation among urban stakeholders and informal groups concerning space utilization data, procedures, and practices. Every single case is tackled so as to have a clear and actualized presentation of each urban conflict. The site contains sections for mapping, two-way collaboration and discussion on focal spatial issues. To date, this service contributed to reviving more than 1500m2 of space in Belgrade. Similar initiatives have spread in 20 other towns in Serbia.

In short, this introduction of "the urban" as a tool for action-orientated public critique through modern means of communication such as the Internet, places urban patterns and structures in a positive flux. Citizens are stimulated to react to spatial conflicts. This then galvanizes them into positive action by proposing social practices to invest the space with beneficial social purposes. This activity transforms urban structures which are examined once again and subject to initiative-driven change. The question of space customization becomes a dynamic circle, forming a common meeting ground between actors and space. The rise of urban conflicts in daily life that are beyond the citizens' grasp can thus be prevented.

2 INTRODUCTION

2.1 Public Space in terms of the Serbian Transitional Arena

As in other post-socialist, transitional societies in Central and Eastern Europe, the urban transformation of Serbian cities witnessed dramatic social, economic and political deterioration at the end of the 20th century. The abrupt shift from a communist regime to that of a neo-liberal economy hindered urban development in Serbia and led to political instability, convergent socio-economic forces and inconsistent planning systems. Top-down urban planning procedures and strategies, inherited from the communist era, were rendered inefficient in addressing urban conflicts at all spatial levels. If you add to this the failure of successfully replicating more advanced models of western neo-liberal economies, it became clear that a fragmented,

small-scale approach to spatial and social conflict could achieve more long-term consistent and far-reaching results. An informal, problem-solving strategy will thus focus on public space. This is not only an essential prerequisite of social cohesion but also a common denominator of urban issues in a broader context.

Public spaces in Serbia nowadays suffocate under the weight of the neo-liberal dictates of profit as people strive to implement western models, fulfil market economy targets and redefine their national identity. Conversely, in socialist Yugoslavia, public space was defined as a venue for actions and interactions among individuals, yet it was controlled by one actor only: the state, the sole decision maker and executor of spatial strategies and actions. When the dismantlement of the socialist regime in Yugoslavia and Serbia started at the end of the 1980s, and when widespread public space became instrumentalized and reduced to a source of profit; leading to the collision of public and private interests in the 1990s, the most powerful economic actors usurped public space.

Within such a confusing social and political system, citizens are neither well informed about their rights nor conscious of their responsibilities towards the public and social good. Citizens are not aware that they should be the actual builders of the city. Their activities in public spaces could be practical examples of individual expressions of freedom and responsibilities. They would thus rise up beyond the negative influences of transition to build their immediate surroundings and take an active part in the development of their city, impacting on its overall constitution and appearance. Thriving public space allows the formation of social capital, the rooting of participative democracy and the determination of economic development. In other words, public space provides a solid base and an active framework for intensive, durable and mature social interactions in the city.

3 PEOPLE ARTICULATING "THE URBAN" IN SERBIA

Started as a small-scale joint action between social activities and virtual networking and collaboration, the "Openly about Public Spaces" campaign and on-line platform for dialog about public spaces aimed primarily to increase the citizens' awareness of public spaces, to give them the tools and information to address each case and officially claim their right to use these spatial resources. Tending to gradually impact the distribution of power and influence with regard to public space in a confusing transitional period aggravated by the ugly sequels of a 40-year period of socialism and totalitarianism, this carefully coordinated action not only increases the consciousness and democratic potential of Serbian society, but also brings it closer to modern trends by its use of low-budget, popular technological means and gimmicks (such as the Internet).

The idea was to create a virtual register of all public spaces in public ownership so as to map their distribution, identify the interest of urban actors or civic groups in using them, and define legal procedures to obtain them. This collaborative approach is particularly important as a community-driven initiative to allow informal groups to obtain access to spatial resources obstructed by blurred procedures, conditions, institutional responsibilities and lack of information. Citizens can therefore increase their awareness of public space in general, local initiatives to access this space can be strengthened, and information can be spread to all interested parties, enabling them to form a common front to pressurize institutions into addressing the largest number of focal points.

3.1 The Campaign: Dialog about Public Spaces, Their Availability and Public Usage

After the Law on Free Access to Information of Public Importance was enforced in 2004, and the Law on Public Ownership was proposed in 2009, the Civic Initiatives Youth Programme launched an official appeal to all municipalities and cities in Serbia, asking about the assets they had and how young people could access them. This campaign aims to ensure:

- Direct cooperation with NGOs and local communities to raise awareness of the issue of space utilization
- Dialog and cooperation with institutions concerning the collection of data, procedures and practices
- Public discussion on every single case in order to acquire a clear and updated presentation of every urban and spatial conflict.

The official record of municipal assets was the first hurdle to be overcome. It turned out that all property was owned by the government authorities, and that municipalities and cities were the sole administrators of said

property. On the other hand, before the adoption of the Law on Public Ownership (September 2011), a great many assets and public spaces were 'lost' and became privatized.

The Civic Initiatives Youth Programme first had to focus on areas where different groups and organizations (youth in particular) had already started an initiative to obtain space. By constant connection, dissemination of information, workshops, official and unofficial meetings, presentations of regional experiences, they tried to inaugurate another campaign pillar and bolster all formal and informal groups, organisations and individuals, who had started space acquisition initiatives.

Thanks to consulting, directing, helping in strategy making, negotiating with local authorities, and conducting actions for the revival of public spaces, the positive results of good practices started to emerge. Once a group has identified the public space which they want to 'conquer', they start to negotiate with the local authorities or they appropriate the space immediately (by arranging it, gathering in it, conducting various artistic activities in that space). It is most important not to give up in case of defeat, failed negotiations or disapproval, because it requires continuous action, ideas and persistence to unlock public space and obtain it for public usage.

3.2 The "Openly about Public Spaces" On-line Platform

The initiatives described above revealed that the local authorities (municipalities) do not have an official register of the public property in their ownership. "Openly about Public Spaces" supports the idea of giving abandoned or non-used public spaces to citizens, artists, youth organizations and NGOs. To classify the information obtained and better manage the development of the project, it was agreed that the abundance of information on different public spaces be gathered in a register. This would include mapping the spatial distribution of „public spaces", and collecting relevant data about public spaces, the legal framework to obtain them, their physical state and social interest in their revival.

Current trends of virtualizing social life via the World Wide Web and Web 2.0 bring into perspective the production of an on-line platform to enable average urban actors to discuss these issues., Two key elements/factors have modernized and simplified the participation of citizens in matters of spatial resources in Serbian cities: the fact that this information can be accessed through Internet, and that users can instantly communicate regarding eventual focal points.

While preparing the on-line platform, it was important to achieve maximum impact and to develop an effective map with a minimum of expended funds. The technical platform itself is set up with free software (Ushahidi) and free editable Google Maps. Ushahidi is an open-source platform designed for different types of mapping and data collection. Due to the needs of the local community, the software has been translated into the Serbian language and implemented in a very simple and clean graphical interface.

The platform is very simple, to allow the average user to better understand its content. It consists of informative and communicative parts. The informative section contains a virtual map of Serbia, where all identified public spaces are located and marked according to the category to which they belong, and a data base of textual, graphical and legal information about each space. Communication within the platform is enabled through a message-contact option, news feed and blog.

New public spaces are added to the map as soon as the information about them is validated and they are classified. To date, the platform has identified public spaces in more than 30 cities and towns in Serbia. According to physical and functional characteristics, these public spaces are divided into 3 categories:

(1) Unfinished urban structures

(2) Abandoned buildings and places

(3) Public spaces which have been partly used with non-used facilities

These categories were defined to clarify and streamline the actions to obtain the public spaces thus defined, which are themselves subcategorized in the same manner depending on their physical state: good, bad or very bad physical condition. The latter helps potential users of the space to plan their actions and the specific usage of the selected space.

In addition to mapping, the communication part of the platform is concentrated around a dialog box in which site visitors can type in locations and receive information should anyone else enter data on the map related to that particular location (comments and discussions). The overall idea is to carefully examine, tackle and

3.3 Activities in Concrete Space: Solved cases

The platform's on-line activity resulted in practical commitment through the Civic Initiatives Youth Programme's "Openly about Public Spaces" campaign. Armed with collected, classified data and willing to collaborate with institutions and diverse stakeholders, this programme gained significant success in its first 2 years of existence.

One of the first cases was the 100 m2 public space in the "Studentski Grad" local community in New Belgrade. This was successfully allocated to the "Context" and "ApsArt" associations and the "Carina" informal scene, which belong to "Cultural Network of New Belgrade" Association (NBKM), for their artistic activities from September 2011 until February 2012. What is more, they are released from having to pay all the costs related to the space. The associations decided to furnish the Municipality of New Belgrade and NBKM with quality artistic programs and advanced cultural activities. The broader social purpose was to create new cultural value at the local and municipal levels through an independent cultural scene.

The other project was the "Bezistan" Street Gallery, launched by the "MicroArt" organization, which highlighted the problem of abandoned space and its untapped potential. It was an abandoned and devastated street passage in the city center of Belgrade - and "MicroArt" proposed its reconstruction as a venue for cultural and artistic productions. "Bezistan" Street Gallery is a unique project in the way in which it refers to

the physical disposition of the elements in space as well as in its program of gallery activities, which consists of engaged art that addresses vital social issues. The cooperation of city authorities, municipality and citizens' associations established a new model of dealing with neglected public spaces in order to set up the innovative and unique principle of the displacement of the Arts in public spaces for cultural purposes.

All of these actions were launched by individuals, informal groups and associations ,through coordinated action with the Civil Initiatives Youth Programme using the "Openly about Public Spaces" campaign and on-line platform. These actions respond to the lack of public space for individuals and groups involved in community, educational, cultural, artistic, recreational and social activities, and to the lack of venues for interaction among these individuals and groups.

4 CONCLUSION

Encouraging the average urban actor to take an active part in social affairs can be but positive, for it reduces their passive roles as mere consumers of a growing, global mass culture, and endows their urban existence with an active purpose: the design of their urban environment and the control of their urban experiences. Therefore, the idea of collaboration on public space issues strengthens the social impact of these organizations and individuals, thus extending the influence of all urban actors, and calls for the legal responsibility of all institutions and stakeholders involved in the process.

To sum up, the objectives reached by this campaign may be identified as follows:

- Demystification of public space issues
- Relocation of issues about public space from the spheres of business, politics and potential corruption, to the spheres of public interest and the common good
- Enabling public accessibility to information and data about public space, real estate ownership, state property and their status and the possibility of leasing
- Increasing the availability of public space for citizens and associations, with an emphasis on youth organizations, groups and initiatives
- Increased transparency regarding the work of institutions and public authorities in relation to public spaces
- Increasing awareness by citizens of their opportunities, rights and responsibilities with regard to public space in general

Finally, this virtual participation tool represents a new interpretation of cities, their design, social and spatial development. The importance and expressive power of culture and the arts have been revealed in the hitherto undertaken actions of the "Openly about Public Space" project on spatial resources, their revival and design. Art in public spaces has always had the power of transmitting the message of the community, promoting social and cultural values, and embodying the ideas of a collective consciousness. In other words, this project proves that a set of prepared, organized cultural and artistic activities, supplied with the very resources for their implementation, is also a tool for political promotion and communication between the authorities and the public in order to establish a new and improved social order.

Recognition of Sustainable Approaches in Urban Structure of Historical Cities in Iran

Alireza Soltani

(Alireza Soltani, Educational Center of Tabriz Municipality, Tabriz, Iran; alirezasoltani10@yahoo.com)

1 ABSTRACT

Throughout history, most traditional cities and building practices evolved out of necessity and not a supply-driven ideology. Therefore, their sense of sustainability emerged from having found resonance with nature, human-environment interaction, its pace and cyclical progression and that's why they have withstood the test of time and appealed to a variety of functional needs. Much of their charm was a product of the way they related to the character of the neighborhood and allowed for democratic expressions.

The patrimony of indigenously designed and developed urban places and spaces is a clear fact; built environments which are culturally rooted, locally produced, and technologically adapted in time and space. Their potential responsiveness to the needs of a changing social and functional world was achieved through mixed activity patterns, organic geometry and human-environment interaction.

Historic cities of Iran were no exception and have evolved out of an unique sustainable ideology allowing resonance with nature, human-environment interaction as well as creating socio-cultural patterns for a satisfactory urban life. This sustainable approach has been manifested in characteristics such as direction to prevailing wind and sun, utilization of vegetation and other natural elements, vernacular materials and so on.

In this paper the intention is to analyze the conceptions of sustainability in urban structure of Iranian historical cities.

2 INTRODUCTION

Cities can be seen as expressions of mankind's cultural, economic and social evolution, and at the same time they are the stage on which people develop their own futures and in this process, urban life will exert pressure to evolve physically by expansion outwards, upwards, downwards or in increased density [1]. Cities of the great early civilizations which developed by incremental growth from a historic nucleus adopted common spatial or physical features with orientation to the path of sun and prevailing wind as well as encircling fortifications. Hierarchy, geomancy and cosmology were among the most influential planning and design concepts that were seen in almost all ancient civilizations. Besides, since the earliest of times, political, religious and other vested interests have been glorified in cities and, often, physically raised [2]. The 'historic center' of city encompasses architectural, social, urban, environmental expressions which are recognized as relevant and which express the social and cultural life of a community. From an urban point of view, historic center or district is the oldest nucleus of a city which has evolved in centuries and contains best examples of most precious monuments of the city.

The concept of sustainable development is steadily approaching recognition, if not full disciplinary autonomy, becoming the focus of new theoretical and normative reflection. However, the same cannot be said of a more specific field of application of that same concept - the urban environment. In our opinion, this has been hindered until recently by some unresolved problems - of definition, methodology and epistemology - intrinsic in the more general concept, and also by some specificities of the urban case especially the historic district of city that have not been sufficiently borne in mind. A city is, by nature, a manufact, an almost entirely artificial object, constructed for historical goals of socialisation, synergy, increase of knowledge and social wellbeing. A weak concept of sustainability, which permits ample substitutability between production inputs and utility function inputs, is almost impossible to avoid. When considering the problem in its entirety from an urban point of view, we must combine the socio-cultural, economic and environmental elements, which all go towards the construction of that complex set of relations we call city. Sustainable urban development may be defined as a process of synergetic integration and co-evolution among the great subsystems making up a city and its history (economic, social, physical and environmental), which guarantees the local population a non-decreasing level of wellbeing in the long term, without compromising the possibilities of development of surrounding areas and contributing by this towards reducing the harmful effects of development on the biosphere.

With the current size and foreseen increase of the world's population living in urban areas, supplemented by insufficient policies to recognize and facilitate sustainable use of heritage assets, pressures on historic cities

will continue to rise, making historic urban landscape conservation one of the most daunting tasks of our time. As a direct consequence, the time allocated at World Heritage Committee sessions to debating the impact of contemporary development in or adjacent to World Heritage designated cities has increased dramatically. Ranging from traffic and tourism pressures, to high-rise constructions and inner city functional changes, the issues negatively affecting the protection and conservation of World Heritage sites are numerous and often inter-related. However, in the case of threats to the universal value and integrity (physical or visual) of historic urban landscapes, and as opposed to uncontrolled urban development or large-scale planned development, there's a clear emphasis on urban heritage and urban landscape in historic center of cities to attract attention, investment and visitors.

Urban areas act as population centres providing goods and services not only for its population, but also for populations worldwide. Urban ecosystems can no longer be considered as a separate entity to the environment as they have direct and indirect impacts on the immediate and wider environments. Many of the environmental problems faced today (eg global warming, water and air pollution and inadequate access to safe drinking water) can be traced back to cities and lifestyle choices. With urban population levels expected to reach 60% in the next 30 years and the majority of urbanisation to occur in developing countries, urban environmental management is being increasingly important.

Ministries of Culture across the world and Organization of Cultural Heritage, Handicrafts and Tourism in Iran have been the pioneers to establish and monitor the norms, regulations, strategies and actions regarding identification, registration, conservation and restoration of historic buildings and quarters. In Iran, historic centre of 90 cities with a total area of 16000 hectares have been identified and registered by the organization of cultural heritage, handicrafts and tourism revitalization projects with diverse characters and frameworks have been planned and implemented in these areas which are in different stages due to historical, cultural and political priorities.

Historic centers of cities in Iran which had been built during history in response to economic and social life of this territory were considered as dominant pattern of their frames until the late Ghajar era. Primary changes in these centers were accomplished when Iran was settled in the world capitalism chain in the last years of Ghajar era. Entrance of the first automobile and propagation of western culture were two important factors to change the structure of Iranian cities environmentally. Some of major characteristics of historic urban environment in Iran which contribute to urban sustainability are as follows.

2.1 Existence of Cultural Heritage

Historic district of each city possesses the best examples of cultural, historical, urban and architectural heritage of the city. From this perspective urban heritage exposes itself mainly as a collection of monuments and landmarks: honourable relicts of the past, symbolizing our history, giving meaning to our cultural identity and embellishing our lives. In most cities of Iran, most precious examples of mosques, tombs, palaces, public bathes, urban squares and Bazaars, symbolizing historical, cultural and architectural identity of the city are located in the historical centre of each city. These monuments along with some visual and/or verbal documents about past can provide us with enough information enabling simulation of ancient urban characters. Besides, the built heritage of each city creates the best opportunities for tourist attraction leading to economic benefits to the area. In Iran, more than 27000 monuments located in historical center of cities have been registered as national heritage by organization of cultural heritage, handicrafts and tourism. Most of these monuments are symbols of old architectural and urban design styles and are considered to be major sources of urban tourist attraction. Existence of these monuments which are always located in inflection points of urban texture, make any intervention a challenging one. Since these monuments can not be replaced or displaced, the geometry of new interventions and urban projects, especially streets and intersections need to be aligned with the location of monuments which in some case makes almost impossible to reach and acceptable level of intervention. In most case, location of a monument in historic district has made new intervention incapable of providing suitable vehicular access into the area.

2.2 A Source for Continuity of Culture

Historic urban environments and spaces sustain social structures of human societies and ensure their continuity. Environment plays a significant role in socialization: from the very babyhood, individuals experience an impact of the native settings. Specific environmental characteristics – geomorphologic

features, spatial structures, scale, rhythms, textures, light, colors and similar – are gradually imprinted in human mind, creating a sense of sympathy with the native environment, as well as preferences for specific spatial and other physical patterns. This way environment transfers culture of an ethnic, a nation, a class, or a similar social group from generation to generation. Sometimes 'a silent language' of environment is more suggestive than words, because it is less intrusive and does not moralize, as it sometimes happens with verbal socialization. Thus, historic urban environment plays a significant part in cultural development – it acts as a carrier, a sustainer, and a transferor of traditions. Factually, this is the main role of historic environment, and local people understand this perfectly well – intensifying grass-roots movements or spontaneous resistance of local population against a new development – are clear evidences of this phenomenon. It is always very hard to disconnect a community from its cultural identity.

2.3 Pedestrian Spaces and Environments

In the ancient city, pedestrian circulation was the dominant mode of circulation and therefore, dimensions of all public spaces were adjusted for pedestrian movement. The human dimensions and scale of these spaces led to sense of safety and comfort for pedestrians creating opportunities for pedestrian activities [3]. On the other hand, a major layer of urban structure that has developed in the recent decades can be defined as the network of motorways and other high speed traffic routes. The development of this layer has had a clear impact on both the global structure of the city and on the local urban systems. The new structural layer, emphasizing on car based global movement, has not improved overlapping and interconnection of the local urban areas. The continuity of the older urban texture has been further interrupted, resulting in a vulnerable global urban structure characterized by very low integration and intensive dependence on limited links of a network of highways. In this process the self-contained housing estates developed in the previous periods have become more segregated in the global spatial system of the city [6]. In cases with no urban intervention, due to dimensions of open spaces, lack of enough space for vehicular circulation and parking has created lots of problems and inconvenience for residents.

2.4 Climatically Responsive Spaces and Environments

In traditional cities of Iran, like other old civilizations, overall configuration of city was organized depending upon orientation, sun light and prevailing winds of each area and the effects of urban morphology on the urban microclimate and, therefore, on energy consumption can not be ignored. The physical parameters that could affect the urban microclimate were size of city, density of built-up area, land coverage, building height, orientation and width of streets, and building-specific design details affecting the outdoor conditions [4]. There exist enough documents indicating that designers and builders of ancient cities in Iran were well aware of strong correlations between urban street configuration and wind flow and sunlight direction, therefore, pollution dispersion and human comfort. This direction was called Roon. Besides, there was a subtle knowledge in street design which aimed to maximize ventilation, dispersion of pollutants and solar access, while not compromising shelter and urban warmth. They were based on relationships between these factors and urban geometry towards finding a 'zone of compatibility' for all inhabitants. Uniform structures of contemporary city regardless of local climate and natural ecosystems of each city have disrupted the traditional and organic harmony of natural and built environment leading to a sense of discomfort for occupants of new buildings.

2.5 Visual Integrity

The intimate and cohesive quality of the urban spaces in old city depended on homogeneous building materials and on the uniform proportions and heights of the buildings. These elements come together in a subtle interplay between the occasional landmarks and the simple and uniform residential structures, the walled and covered alleyways (called Sabat) and well-organized open public spaces (called Arsan), and the striking climatic features integrated into built elements, for example Badgir (wind catcher) in central regions of Iran creating a delicate balance, and one that can be easily thrown off [5]. In historic center of most cities in Iran, many traditional buildings, particularly along the main routes have maintained their architectural features and details. Many others, however, were shelled and have been left in a state of ruin, or hastily and poorly reconstructed, or radically transformed during the immediate aftermath of the deterioration. Lack of visual relationships between old buildings and new constructions has disrupted the integrity. New building design, height and bulk relationship of facade parts, scale and massing of large buildings an urban projects,

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

size and massing of new additions, cornice heights, roof shapes, reconstruction of building components, prevailing setbacks, building widths and spacing, stoops and porches, garages and driveways al have led to a visual chaos in most historic cities of Iran. New buildings need to be designed to strengthen the unity of the existing streetscape, and should follow the design principles of historic architecture. But in some cases, these buildings which merely imitate the forms and materials of historical buildings dilute the quality of existing historic structures.

3 CONCLUSION

In the case of urban sustainability dealing with historic centers of cities in Iran, it has been recognized over the last decades that these areas are not constituted only by material and physical heritage – buildings, streets, squares, fountains, arches, and sculptures – but also include the natural landscape, and above all, its residents, customs, activities, economic and social relations, religious ceremonies, beliefs, and urban rituals all of which must be considered in any restoration or revitalization project aiming at urban sustainability. Due to high complexity of revitalization in historic centers it is necessary to compile comprehensive strategies covering diverse aspects of the task. Therefore, existing processes and methods applied to heritage cities, while helpful, are insufficient to meet contemporary and emerging needs. In response to these needs the following strategies can provide the basis for a comprehensive sustainable approach.

- Improving the conditions of pedestrian access with the least intervention with vehicular circulation by provision of suitable street network, intersections, parking lots and public transportation facilities.
- Improving and rehabilitating old residential buildings and motivating residents to live there while improving and upgrading basic infrastructure and municipal service.
- Promoting and selecting a variety of economic and commercial activities that are compatible with the historic context and can meet part of the maintenance and development costs of new projects and conservation of historic monuments, the cultural and urban heritage, making, if necessary, adaptive re-uses for adequate maintenance and economic gains.
- Modifying and easing the regulatory, administrative frameworks for land use and use of open spaces for new constructions and projects while respecting old architectural and urban texture of the area.
- Planning and executing tourism attraction policies and visitation to reinforce sustainable and human development by enhancing and protecting monuments and archaeological sites.

1 ABSTRACT

Social and urban stratification can pose a serious threat on attracting the masses into urban spaces, hence on sustainable existence of urban fabrics. This can further develop into possible safety and security risks on their dwellers and users. It may happen directly or indirectly by intensifying the visible or invisible boundaries between the cities and their outskirts, as well as those between the districts, boroughs, and neighborhoods within the cities. This is because those intensified boundaries physically restrict future developments and predispose them to failure even before gestation.

Traditionally authorities in larger cities have learned to deploy 'inclusiveness' so that the development plans can be carried out under a larger yet more unified umbrella of planning and managerial tasks. Quite the contrary, the smaller cities in most cases cannot come into the same point of agreement to make a coalition work, due to decentralization prescriptions along with many other reasons e.g. limited human resources, budget and time.

This paper aims to investigate Orange County in Southern California as one of the most successful regions in overcoming the aforementioned problem. The paper starts with an analytical history of demographic and geographical changes in the region. Contemplating on potentials of the region, it will then discuss how the entire region has been shaped based on the coalition at the scale it was formed. Finally, it concludes with a coalition model for regional planning and suggests its application to the similar situations for acquiring a record of success in regional developments.

2 INTRODUCTION

Social and urban stratification can pose a serious threat on attracting the masses into urban spaces, hence on sustainable existence of urban spaces and urban fabrics likewise. This can further develop into possible safety and security risks on their dwellers and users. It may occur as a result of assimilationist policies and urban gentrification, intensifying the visible or invisible boundaries between the cities and their outskirts, as well as those between the districts, boroughs, and neighborhoods within the cities. This is because those intensified boundaries restrict future developments and predispose them to failure even before gestation.

More recently, social and urban sustainability debates have concentrated on issues related to the terms incorporation and multiculturalism – or as a normative precept: mixed societies. Conversation about multiculturalism is of particular significance as a mode of inclusion (Kivisto and Faist, 2007); thereby having (re-)mixed city. Despite varied and contested meanings of multiculturalism, there is a general consensus that involves valorizing ethnic, cultural diversity, accessibility of resources, social mobility and avoidance of social stratification. Glazer (1997) asserts that 'we are all multiculturalists now' – even if it has not been translated into official policies (Favell, 1998, Modood, 2001, Pearson, 2001, Kivisto, 2002, Joppke and Morawska, 2003, Kymlicka, 2003). Kivisto and Faist (2007) however believe that 'more recently the view has been challenged by those who contend that the multicultural moment is over as state policy, social practice, and perhaps as theoretical construct as well' (See Delanty, 2000, p.104; and also Barry, 2001; Kelly, 2002; Wolfe, 2003; Joppke, 2005).

Mixed society and mixed city in practice go beyond implementing and maintaining mere social practice, cultural features, and state policy. It is a complex, multi-layered and multi-dimensional practice which engages every social structure of city actively and effectively. The mixed city could be achieved, even if partially, by giving weight to diversity of economy, ethnicity, language, etc. This diversity can be reached by adopting diversifying policies in all respects including spatial and physical planning.

Contrary to the fact that the United States is accused of being an *assimilationist model of melting pot*, State of California's Orange County with 34 cities, is a highly demanded and a growing county, which can pride itself on embracing diversity and multiculturalism. This county has successfully enhanced the idea of

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

diversity through what we shall call *'mixing the cities'*; by mixing many social, cultural, economic, and spatial aspects of planning within urban contexts. The post 1994 bankrupt Orange County is now considered a successful model not only for attracting investments or for its flourished urban attractions, but for making the proper and balanced urban atmosphere – where almost everyone could feel at home; what is crucial for social sustainability and a sustainable growth.

This paper aims to provide an analysis of the current condition of the County, portraying the success of this region that stems from its diversity beyond its mere geopolitical and climate advantages. The paper starts with the regional and demographic analysis that points out the diversity of the region. Investigating the potentials of the region, it will then discuss how the spatial planning has facilitated the diversification within the entire region through the coalition between the cities of the county, each of which playing a crucial but complementary role to the others which is substantial to the success of the County. Finally, to achieve diversity successfully, it concludes that, in similar cases, the idea of 'mixed city' ought to be replaced by an all-inclusive region including 'mixed cities' which utilizes a model of regional coalition; a model of Mixed-Cities Coalition and Competition (MCCC).

3 URBAN PLANNING AMBIANCE IN THE UNITED STATES

"Every time Treasury changes the Tax Code, every time Congress alters a welfare program, every time the Defense Department awards a military contract, urban policy is being made" (Donna Shalala). According to US Bureau of the Census (1997) 87504 units of government were identified and listed in 1997 in the United States. In that year, there were 3043 counties, 19372 municipalities, and 16629 townships. Increasing number of the government units has led to intergovernmental problems (Cullingworth, 2003).

On the other hand, not only hardly do American cities make comprehensive plans, but they also never lend themselves to carrying out those plans. Moreover, in the planning system neither does the country come to an agreement with its organizations upon the content of 'public interest', nor does it permit the centralization needed to carry a plan into effect (Banfield, 1961). However, Campbell *et al.* (1976), amongst many others, proclaim that citizens' familiarity with current political events and issues is severely limited.

The institutional framework, that defines the legislative body responsibilities, 'blurs the distinction between policy making and policy applying, and so enlarges the role of the administrator who has to decide a specific case' (Mandelker, 1962).

Domination of the law and lawyers over planning issues, limited allowance for discretion, zoning as the focus point of planning actions, regulatory barriers etc. are just a few problems facing the planning agencies in the United States. Furthermore, those agencies are facing a myriad of social and technical problems e.g. decayed inner-city, urban sprawl, urban and environmental contamination, along with problems of race, sex, social class and poverty, which in turn call for public policy, new regulations, and regulatory and control mechanisms at federal and states levels.

In such a complex planning system, where discretions should be kept to bare minimum, decision making is a tough job. Orange County and its associated cities are no exception. The demographic and related information, which follows in this paper however, support the hypothesis that multiculturalism in this region is historically very well-established. The subsequent analysis of findings will help cast light on more facts which will help argue for this hypothesis. The following section will discuss the demographic and monetary diversity for which the region is renowned. Despite what was just pointed out there are some exception which will help prove the rule; some cities lacking some of what attributes as multiculturalism. In other words, some cities in OC are providing diversified urban context that fills the existing gap in other cities, for unified multicultural region.

4 INCORPORATIONS, DEMOGRAPHIC AND AVERAGE INCOMES IN ORANGE COUNTY

Orange County (OC) is located in Southern California and has more than 3 million populations, 34 incorporated cities and is spread over a total area of 947.98 square miles (2,455.3 km^2), as of March 2012 (see Fig 1).

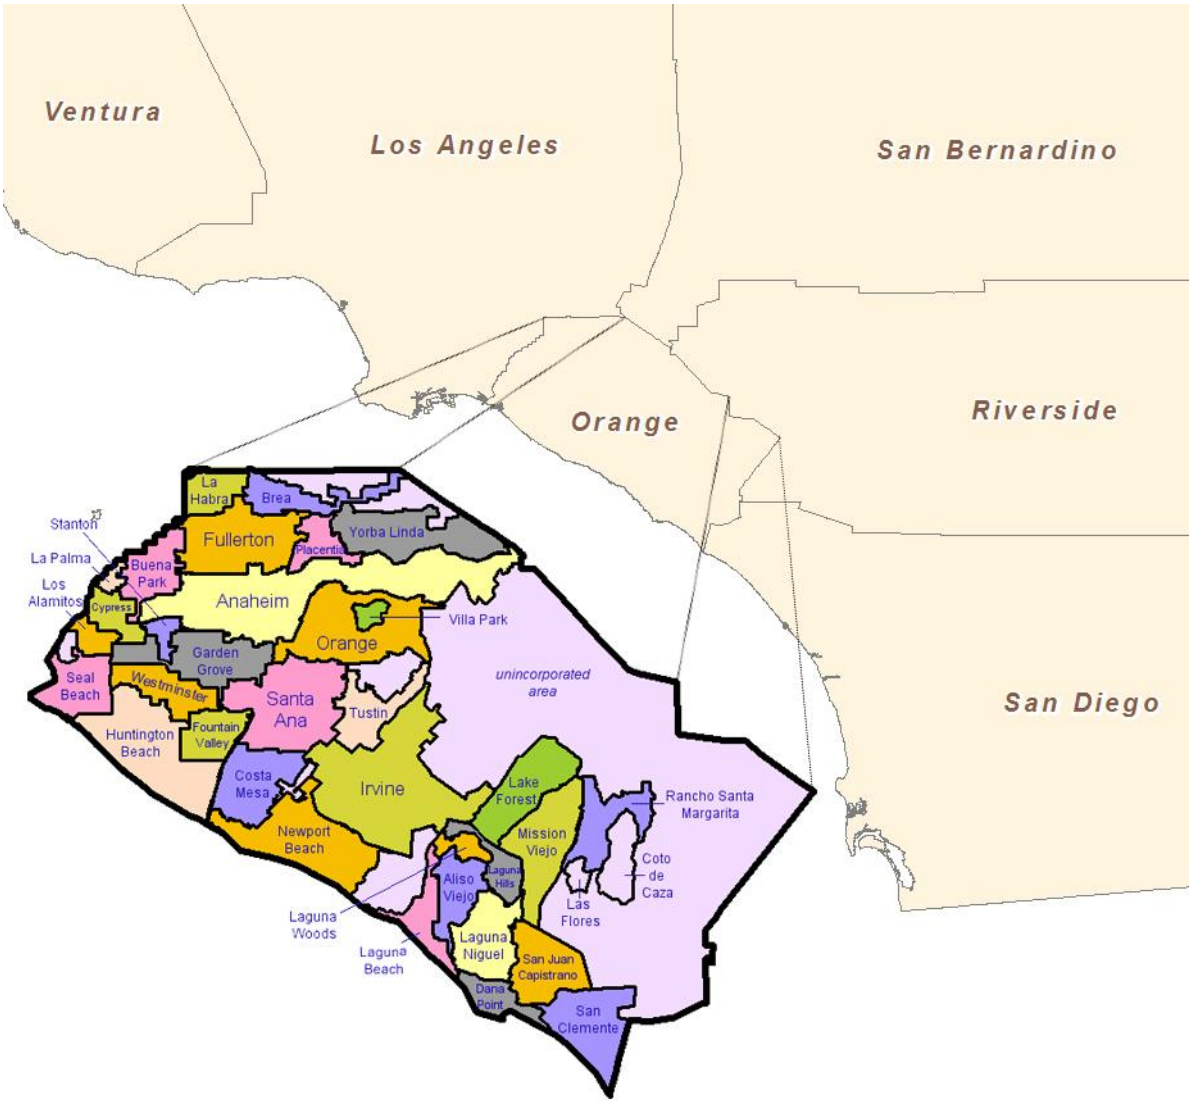

Fig. 1: Orange County and its neighboring counties

The county was incorporated in, but received separate political entity from Los Angeles County in 1889, based on three cities: the city of Anaheim established in 1870; Santa Ana in 1886; and Orange in 1888. In chronological order, Fullerton, Newport Beach, Huntington Beach (originally known as Pacific City), Seal Beach, Brea, La Habra, Placentia, Laguna Beach, Tustin, San Clemente were incorporated and joined the county between 1904 and 1927; and the rest between 1953 and 2001. The newest city is Aliso Viejo. The city of Santa Ana accommodates the governmental bodies of the county (see Fig 2).

According to County of Orange (2012), the county consists of 5 districts; each of which is overseen by a board of supervisor elected by the voters of their district for a four-year term. The general mission of the board is described as "Making Orange County a safe, healthy, and fulfilling place to live, work, and play, today and for generations to come, by providing outstanding, cost-effective regional public services" (County of Orange, 2012).

4.1 OC Chronological Development Provides Specific Characteristics for the Cities

Enough free land ready to be used for new developments with no major environmental risks or any other serious limitations has provided the county with an opportunity to expand in different periods for the past 110 years. The County records show that, in every major period prior to and during the twentieth century, a number of cities have been established and officially joined the county. This implies that incorporated cities have had ample of time not only to be developed and adapt, but also to find their unique role in the region, and to develop the characteristics of their own. The core cities have maintained the very sense of their downtowns and in their further development phases, some new characteristics have adjoined what was already present there. Anaheim, for example, as the oldest city in the region, by hosting Disneyland Park in

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

fifties, has gradually turned into a tourist hub of the region and beyond. City of Irvine, renowned as a preplanned city in the entire United States, has hosted the prestigious *University of California Irvine (UCI).* Subsequently accommodating numerous entrepreneurs, businesses, and headquarters, over the last three decades, Irvine has announced herself as a reliable economic region, serving Southern California and creating numerous jobs. This chronological development allowed the county to take the opportunity to contain a variety of cities providing people with various atmospheres, and lifestyles, with different living budgets.

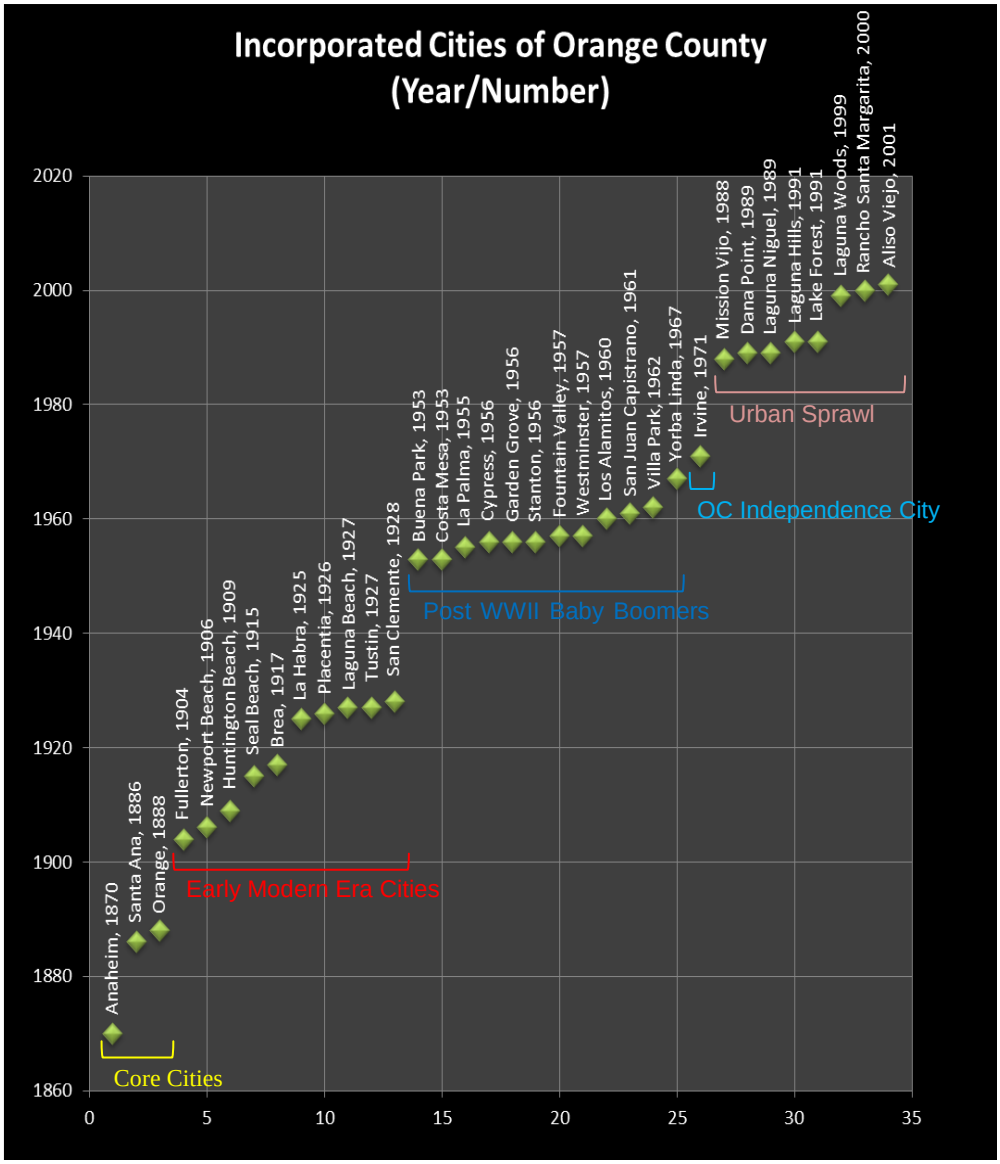

Fig. 2: Incorporated cities of Orange County

4.2 Diversity of Incomes

The high cost of living in OC —from property and gas high prices through to sales tax, and maintenance costs—, certainly, makes the residents to think about their expenditure carefully. However the differences are obvious from place to place. The fact is that in a number of urban parcels —urban segments with specific income, race, education or age characteristic— in the area even families in lower incomes bands can reside. The accommodation and other costs, in such parcels, dramatically are lower than the others. In fact, although the overall income of the region is higher than average in the United States and also higher than the neighboring counties, the statistics derived from census 2010, show that the county contains a variety of parcels where household incomes range from the lowest to the highest in the country. This is considerable

because some cities like Newport Beach and some districts —which are not part of any other cities yet like Coto de Caza —are free from some parcels with families in lower income brackets.

In fact, most parcels with higher incomes (per household) are concentrated in a limited number of cities and independent areas. The average household income of the county in shown in Fig. 3.

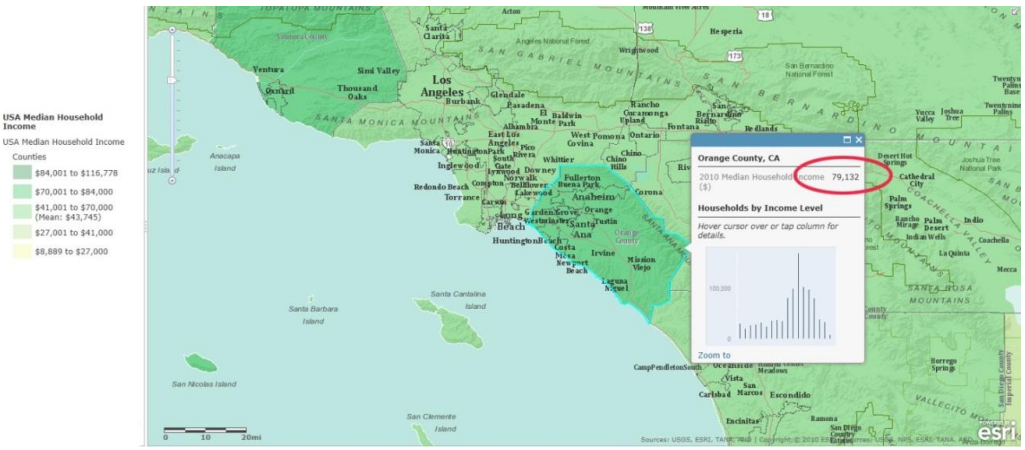

Fig. 3: Average household income of Orange County (and the counties around)

Color-coded inspection of income bands shows the distribution of household income with their sample parcels in Figs. 4 to 8. This reveals that the parcels accommodating families with varied incomes spread throughout the county with 25 cities already accommodating more than 2 brackets. However this range varies from city to city.

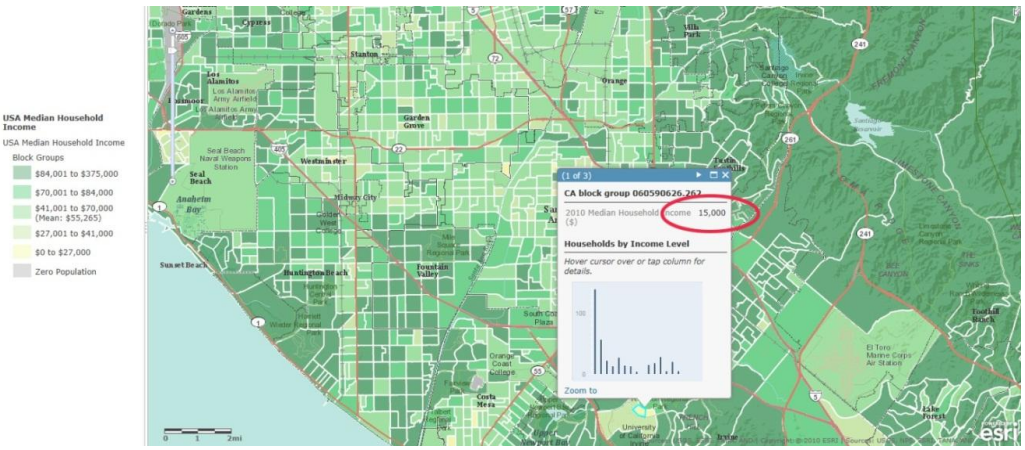

Fig. 4: Sample parcel with average of lower household income

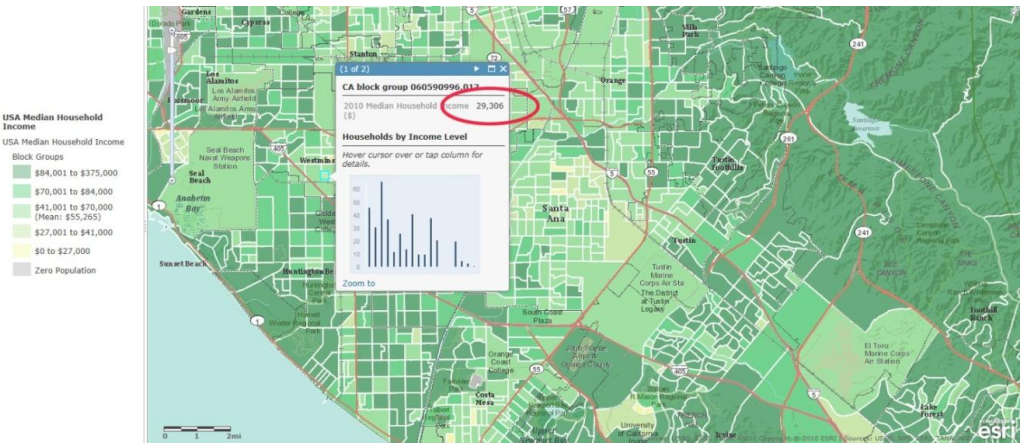

Fig. 5: Sample parcel with average of lower-middle household income

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)

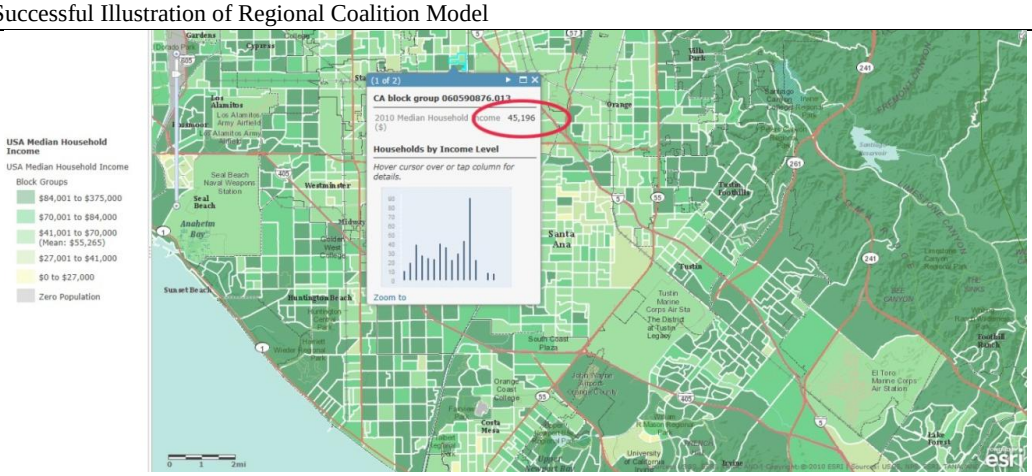

Fig. 6: Sample parcel with average of middle household income

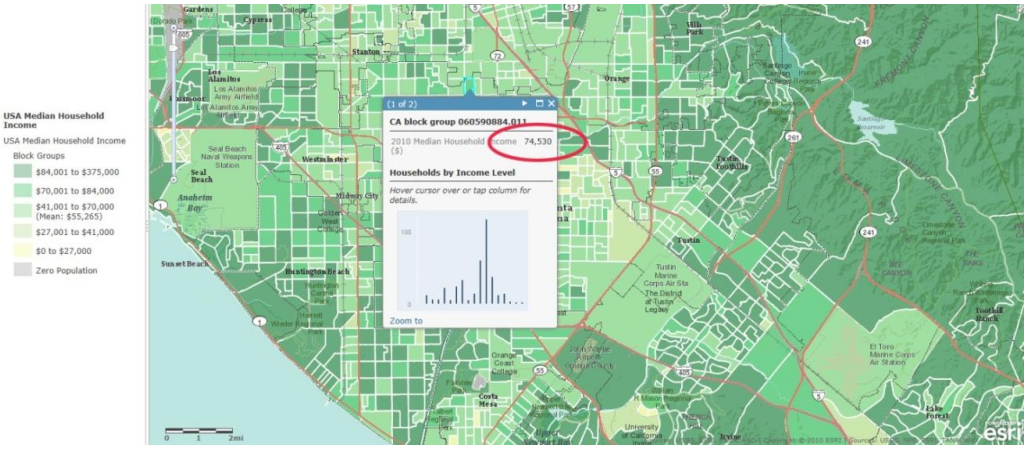

Fig. 7: Sample parcel with average of upper-middle household income

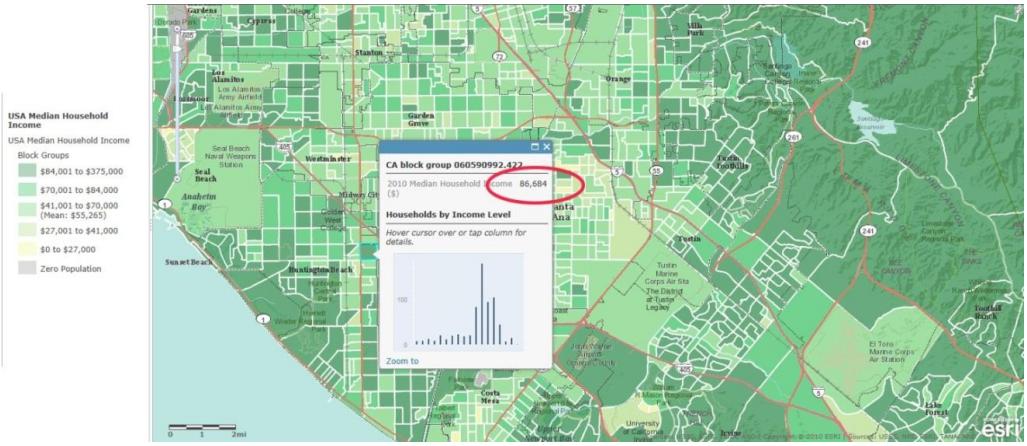

Fig. 8: Sample parcel with average of upper household income

Although the cost of living in this area is fairly high, there are a number of urban parcels carrying different costs of living. They can suit a wider range of families with various incomes. Even if the household income changes, the family can still find a place in the region to fit their budget to stay in, should they choose to. In other words, if cities like Irvine, Newport Beach or Laguna Niguel are accommodating middle-upper and upper class families, there are still other cities which comprise urban parcels accommodating lower and middle-lower class families.

4.3 Home to Diverse Ethnicities

About 60 percent of the population in OC has white backgrounds. However, the adjacency of California to Mexico and some other historical and geopolitical ties have given the county a unique ethnical diversity. A considerable one third of the population is of Hispanic —or Latino— backgrounds settled in different areas

of the state, specifically in the south. They form the first majority in cities like Santa Ana, Anaheim, and Stanton.

Adding to this, the county is also very well-known for being the home to a large population of people with Asian backgrounds. According to census 2010, more than one sixth of the county's population has Asian ethnicity. In Westminster and La Palma, Asian communities are the most populous communities in the cities. In Irvine 40 percent; Garden Grove 37 percent; Fountain Valley 33 percent; Cypress 31 percent of the cities' populations are having Asian backgrounds (See Fig. 9 for more Information).

Despite the overall majority of white backgrounds in the county, people from various ethnicities can still find the communities where they feel at home: the cities with multicultural nature. This diversity helps various ethnicities to gradually become a part of a larger society by experiencing mixed-culture cities and communities.

Apart from these major ethnicities, a considerable portion of population belongs to other ethnicities in the region, e.g. African Americans, Native Americans, Pacific Islanders, as well as people from two or more major ethnicities. This mixture of people from various backgrounds makes the communities and the entire county more viable and livable place for a larger spectrum of citizens than any other single-ethnicity society. This represents an alternative way towards a more sustainable society that can properly and proactively responds to the needs and wants of any multicultural region not only in California but throughout the entire country.

5 MIXING THE CITIES OF MIXED CITIES

The aforementioned analyses along with many others —like age and education— imply that the diverse atmosphere of the county has formed, been fostered and flourished over the years. This is because of the socio-historical sequences, and was reinvigorated by exerting official policies; a mixture which has proven to work effectively. In fact, what is obvious is that the *mixed cities* which accommodate and serve the people from various backgrounds, race, sex, and age and attempt to respond to their dwellers properly and proportionately, cannot be achieved by simple and single urban task forces in a limited time frame and in a single city with such a size. It means at township scale attaining an all-inclusive urban functionality is possible neither rationally nor practically, unless the city —or town— scales up enough for taking up such a task. One of the benefits of mixed city is to keep people visiting different places of the city. This helps people to get more familiar with various places of the city and keep involved with each other. Logically and rationally, small cities cannot contain all different types of buildings and complexes — also known as urban functions – for keeping their dwellers and spatial users satisfied. Lack of enough space for such ambitious intentions, the unreasonable cost of maintenance that imposes to the city, and the occupancy/use rate, are only some major reasons.

Therefore, to properly achieve the objective of a mixed city, depending on the scale, sometimes combining the cities and achieving mixed city at a higher scale may be inevitable; what we shall call *mixing-cities*. At a regional scale, this act should be considered to maintain and enhance a multicultural society.

But the question remains to be "how this is achievable and if spatial organization of urban functions within a city can facilitate the concept of 'mixing the cities'"?

5.1 Competition

Every city in Orange County, like any other city in the country, has a unique budgeting mechanism, and city management system as well as its very own priorities, concerns, problems and needs. This means the cities are in a hidden-and-obvious competition with each other. They attempt to attract young professionals and families form higher incomes brackets as a major driver for change and a long-term reliable source for further urban development, at a rate comparable or higher than their other rival cities.

While larger cities have logically, traditionally and organizationally been familiar with centralized decision making for each borough/district, the smaller cities, even those incorporated with a region/county, have been engaged with intracity competitions and in many cases have struggled. Under such circumstances, wasting financial resources on rework and duplication, as a result of lack of attention to the already developed opportunities within close or neighboring cities, is very likely and prevalent. In addition, successful patterns of development and popular characteristics and functions in a city can stimulate duplication and

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

multiplication of the processes in other cities; what in return, can lead to unjustified results or weakens the potentials of development based on any other intact characteristic within the region.

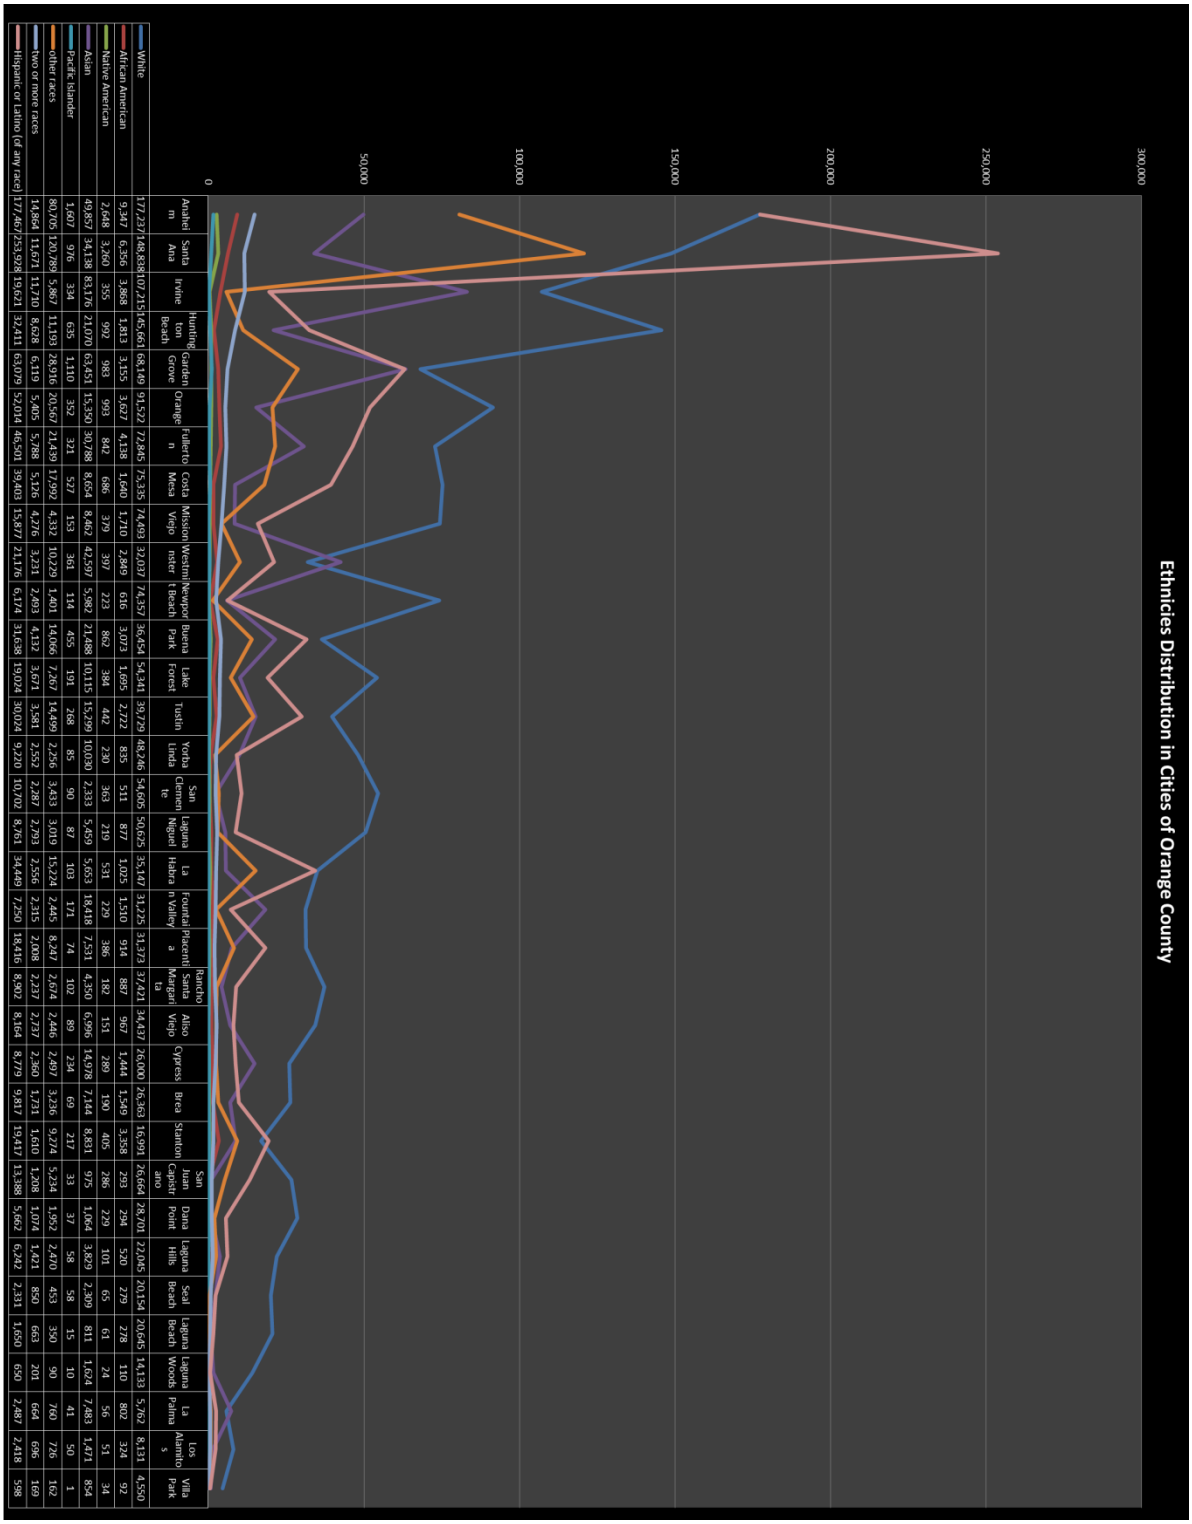

Fig. 9: Main ethnic groups in 34 major cities of Orange County

5.2 Cross Functional Cities: Major Urban Functions Attributed to Different Cities

Tourism industry stands at the third place, after business —tax revenue of the businesses— and shopping, and forms a vital source of income for Orange County's economy. Average annual temperature of 68°F (20°C), beautiful beaches, as well as outstanding and vivid inland sceneries of the County, accompanied by exceptional urban attractions, have provided a vibrant combination of possibilities for almost all tastes and preferences.

Most cities in Orange County are acting as a role-player in the development process of the region:

- The pre-planned and young city of Irvine as the home of Fortune 1000 headquarters for Allergan, Broadcom, Edwards Lifesciences, Epicor, Standard Pacific and Sun Healthcare Group and as the city hosting a number of thriving businesses and start-up companies founded by young entrepreneurs, in Southern California, provide a proper place for business. In addition, the well-known schooling system of the city and hosting the accredited University of California in Irvine (UCI), constantly invite younger generations and their families to relocate to the area. All these are accompanied by other unique facilities of the city like Irvine great park home of sustainability and a number of social and cultural events as well as William Woollett Jr. Aquatics Center (WWJAC), etc.
- Having an old town accommodating a number of historically well-known buildings in the area and the only international Airport of the county —John Wayne Airport—, Santa Ana hosts governmental bodies of the county, and play a key managerial role in the region.
- Anaheim works as a tourist hub for the County and hosts Disneyland Park; the second largest theme park in the world. The city with its theme park and many other historical attractions works at national and international levels and invites people from various background and with different expectations.
- The city of Costa Mesa, hosts a number of major buildings and complexes. South Coast Plaza shopping center —originally designed by Victor Gruen— with an approximate 24-million visitors per year, Orange County Fair with more than 1.3 million visitors per year and Segerstrom Center for the Art as a performing art complex and offering world's leading performances are some those attractions.
- Orange County Museum of Art and upscale-luxury Fashion Island open air mall —main buildings designed by William Pereira and Welton Becket— as a part of Newport Center, Both are located in the city of Newport Beach.
- Numerous art galleries of Laguna Beach, offering the world's leading fine art works have rendered the this city as the art hub of the region. Producing a fascinating atmosphere in the city, those galleries lay over the flattering sceneries of the Pacific coastline (see Fig. 10).

In addition, Cristal Cathedral — designed by Philip Johnson— and International Center for Possibility Thinking —designed by Richard Meier— in Garden Grove, and numerous seasonal events like Dana wharf sport fishing, whales and dolphins cruises, wild river water park, air combat center, and many others have been spread in the entire county, working as interlinking functions. This dispersion of urban functions ranging from those needed for everyday life to those known as a place for entertainments or occasional events keep everyone, both residents to visitors likewise, busy and happy to move from one location (city) to another in almost all four seasons of the year.

Each major city of the region has a number of urban attractions and key function(s) that cannot be agglomerated in a single city. This has resulted in a region composed of built-up areas on a *cross-functional* network of correlated urban nods.

Building a cross-functional region is an objective that is achieved by cultivating the major urban functions, across the region. Not only does this approach facilitate the process of establishing specific characteristics for each city, but also expedites the intercity and intracity mobility of the dwellers and users of the different urban spaces which assists the process of mixing various group of spatial users. This causes the development of the dialog between different types of users—from different races, ages, backgrounds and social classes—with each other and with the urban fabrics of the host cities. To the contrary of an experience of an *all-inclusive* and *all-in-one-place cities*, like what can be gained in Las Vegas, in cross-functional-cities model, the citizens, visitors and tourists require commuting from one city to another within the region to arrive at the places they would like visit. This will initiate them into getting familiar with the culture, and some hidden attractions while bringing about their own culture to the heart of the cities. It will also help them learn more about the region and its social dimensions, which in return, makes the mixing procedure smoother and more enjoyable (see Fig. 11).

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

In such an atmosphere, the mixing process flows well beyond enacting mere official policies. It turns into being the social practice innate to the daily life of people. As a result, this also resonates with other aspects of social process of mixing cities; acknowledged formally even the governmental bodies.

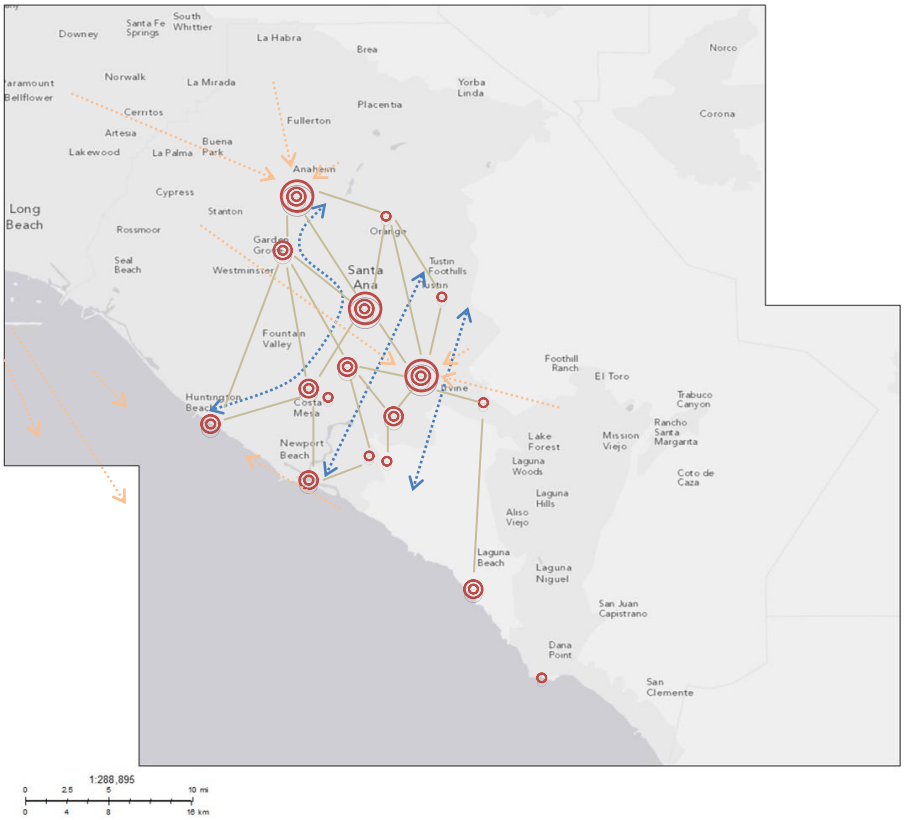

Fig. 10: The spread out urban functions in the cities of Orange County

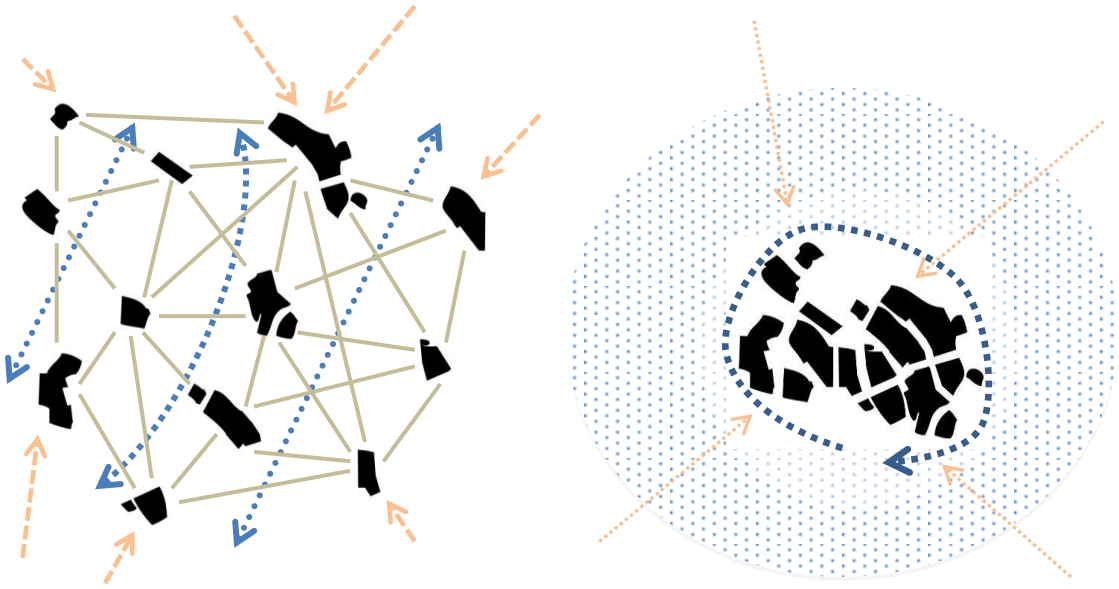

Fig. 11: Reviving urban life in connecting corridors and interfacial urban fabrics in cross-functional region versus all-in-one-place city

The cross-functional region —versus all-inclusive city—, which is heavily based on decentralized governments, holds the *mass-response* characteristic on one hand, and on the other, reinforces the

constructive competition between cities as independent urban entities through which each city attempts to achieve the best position among the others, with regards to its own characteristics and attractions.

6 MODEL OF MIXED-CITIES IN COALITION AND COMPETITION (MCCC)

A cluster of smaller cities, with fully separate authorities, provides decentralized urban management and decision making systems. If, at the same time, the cities are incorporated with their region and are able to work through the regional issues under a regional supervision via the organization whose role is to merely moderate and facilitate the negotiation between cities, they can come into a regional coalition which not only enhances the chance of equal opportunities offered to various cities and the richness of regional diversity, but it also helps the cities work out their chance if they attempt to achieve positions, to propose genuine urban functions or to warrant specific funds at a regional scale. It means, in this coalition system, each city has its own characteristics, yet the entire region, will have the exclusive characteristic that does not exist solely in any of those cities. In this model, the region —according to Gestalt and Systems Theory— is more than arithmetic sum of all participant cities. Fig. 12 indicates how the decision process works in a corss-functional region, using a MCCC model, compared to a traditional model in a large centralized city.

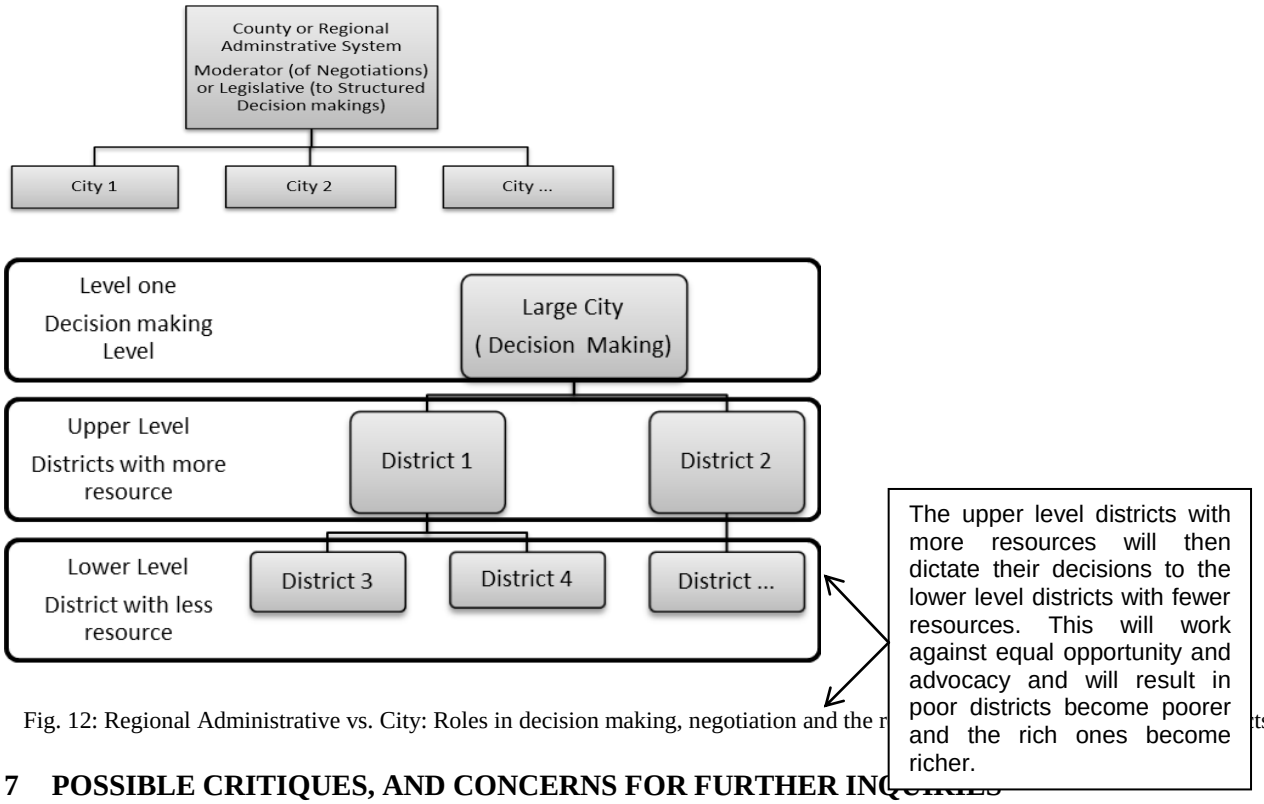

Fig. 12: Regional Administrative vs. City: Roles in decision making, negotiation and the r ts

7 POSSIBLE CRITIQUES, AND CONCERNS FOR FURTHER INQ

This model provides a solution to zoning problems which limit people movements within the city and may act against the notion of mixing city. Allocating similar urban functions in one place, zoning policies in most cities in the United States, encourage people to have linear inner-city trips between some major city hotspots of their owns: home, work and leisure. The question that will remain is: what if the similar zones of different cities are allocated close to each other? This also needs to be considered in the framework of MCCC model.

On the other hand giving a proponent role and characteristic to the smaller cities through applying cross-functional model to low density/low rise cities, the issue of urban sprawl can be addressed and gradually alleviated. Therefore the model itself can provide some proper responses to the issue of urban sprawl. However the further concerns of producing new urban sprawl around the major cities of the region will remain valid. In case of Orange County, the fresher incorporated cities are experiencing the same problem: the cities which have no specific characteristics of their own at the regional scale as yet. To tackle this problem, the process of following the model should be seen far from being an end state; it should reiteratively and reflectively be reviewed, reframed, reconsidered and remodeled.

One of the most important concerns is that at which distance (radius) the expansion and inclusion should happen where the urban functions spread out. If the radius is so large, it may endanger the usage of public

transportations or bikes, as the most sustainable transportation alternative to commuting with cars. This may also compromise overall sustainable life of the region which can face the entire model with serious challenges. Therefore, establishing an assessment method that can help evaluate the factors and deliver the proportionate radii of expansion and inclusion needs to be considered for further research and enquiry.

The last concern is about the managerial aspect of launching, maintaining and enhancing of MCCC, if it is supposed to be pursued through a structured method. First, if a region was not diversified enough from various points of view, is the development of the cross-functional region model prior to other socio-cultural policies? Second, because of some legal issues pertaining to decision-making in the United States, is there any way to legalize this coalition and push it to go beyond the simple negotiations and conventional agreements between cities?

8 CONCLUSION

Orange County as a highly demanded region in Southern California has been inviting diversity in various aspects. Although some cities of the county are not considered as mixed cities, but at a larger scale, the county is a mixed region. The process of mixing the cities by spreading the urban functions in different cities turned out into a cross-functional cities/region model.

Traditionally and logically, larger cities' authorities have learned to deploy —at least, to some degree— 'inclusiveness' so that the development plans can be carried out under a larger yet more unified umbrella of planning and managerial tasks: what shall be called *all-inclusive mixing city*. Quite the contrary, pursuing the same strategy for smaller cities are not financially and rationally justified. The smaller cities naturally cannot exist and develop based on an all-inclusive mixing city scheme. Small city as a parcel of the region undertaking a regional dialog with its context has an alternative way of carrying out coalition with other small cities to achieve mixing the cities.

If the coalition model is applied to the region, the separation of the cities can be used as an advantage compared to large city systems. Not only does this provide the required platform for exercise and flourish decentralization, but it also offers a competitive atmosphere between the cities that adds flexibility and dynamicity to the whole region.

The model, which we have called Model of Mixing-Cities Coalition and Competition (MCCC), proposes all-inclusive regions —attaining cross-functional cities— where independent cities come to a regional coalition while the intracity competitive ambiance can be used as the major source of motivation for further development.

Remixing Music in the City and Music online: How Listening to Music Changes because of Piracy

Olivier Lefebvre

(Dr Olivier Lefebvre, Olivier Lefebvre Consultant, 4 rue Rollin 75005, Paris, France, o.lefebvreparis05@orange.fr)

1 ABSTRACT

Music has often changed, from a social point of view, and also the relationship between music and the city. This paper attempts to describe how music changes under the impact of Internet. Are concerned the milieu of musicians and the audiences. The economic model of music has not burst into pieces, but it has deeply changed. There is a trend to pure consumerism thanks to Internet (probably the sales of downloaded music will become more and more important). Also, independent artists can use Internet and have a livelihood (fat tail phenomenon). Therefore the diversity of music can be preserved. Concerts (music in the city) allow escaping from the losses of money because of piracy. There are several experiences for listeners, which are possible, some of them involving going to concerts and festivals.

2 INTRODUCTION

Mutations of music, and also of the relationship between music and the city, have been described by some sociologists. For instance, Adorno, in his famous book on the sociology of music, has shown how the dominance of recorded music occurred. Till the 19th century, music lovers were people performing it. They were aristocrats or people having a job allowing leisure (like doctors). Recorded music allowed anybody listening to the best musical performance. But listeners were no more people performing music. According to Adorno, the companies editing recorded music have a control over the public's taste. Hence a decline of good taste. Music becomes a commercial good. Composers prefer to compose music for movies to have a livelihood. Honegger wrote: "the musician has to be a craftsman". Also, from Stravinsky: "any reaction is good" (meaning that any demand from the public is a good thing). At the opposite, Schoenberg was always an inflexible composer.

The American sociologist Howard Becker tells another story. He describes the ordinary jazzmen (not the "stars" of the milieu) in the USA. The condition and the outcome of their activity is the repertoire. In the first half of the 20th century, it was called the "Great American Songbook". The knowledge of the repertoire allowed jazzmen who were not accustomed to perform music together, succeeding in doing it. The repertoire was a living one (songs becoming out fashioned, other appearing). This music was performed in public places (ballrooms, cafes, restaurants etc.) or in private parties (ceremonies, marriages …). All that changes in the fifties when FM radios appeared (allowing diffusion of precisely defined genres like rock, soul, country music, dance music like sambas, bossa novas etc.), and also TV (changing the way in which people spend their leisure time, they are more and more in their houses and less in public places). Schools for jazzmen appear. Before, they learned pieces of music listening to radios or buying scores (called "lead sheets" or often "fake books" because they were pirated). Now they listen to web radios or streaming sites, can download sores on Internet. It is cheap to record a Compact Disc (used to show the talent of a musician or a band to a possible employer). One can use a home recording studio. Even, some musicians are teleworkers. Also, more and more electrical material is used by instrumentalists. There is a Computer Aided Music. Internet has become a tool for musicians.

In this paper, we shall attempt to describe the current impact of Internet on music. In particular, we examine the consequences of piracy. Bur first, we have to quickly describe what piracy is and what the response of the Majors of music is:

A few words on piracy. There are "amateur pirates" and "professional pirates". The last are an organized community. They have their own definition of performance or feat, their own hierarchy of talents. They meet in some places (they organize congresses). The framing to examine this milieu should comprise the warders. There is the role of social interaction. For instance, the beginners are initiated by those who know the tricks to escape from the warders. Or there is a competition to accomplish the most spectacular feat. The contempt they trigger can influence their behavior (Becker, 1995). This idea on deviance comes from Howard Becker. It is the main idea in the theory called "labeling theory". According to this theory the means used on Internet called "shaming" should not be efficient (note that we speak of the "professional pirates", not of the "amateur pirates"). There are "moral careers": one can stop, go on or … pass to the other side, the warders

Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

'one, the ability in computing serving the security of firms and administrations. Let us recall that for some, piracy is their livelihood. One can be sure that this kind of piracy will last.

The response of the Majors of music. The economic consequence of piracy is that demand decreases, and also the profits of the Majors (even if other activities than recorded music, like music diffused on radio or TV chains, in nightclubs, or concerts, are not vulnerable to piracy). They have to make economies. They sign fewer contracts with artists. Before, they could sign contracts with beginning artists, being in the role of an insurer. They no more do it, hence some danger for the future of music (Lefebvre, 2008). But now the selection of notorious musicians, among the beginners, occurs on the social networks like Facebook. Once a musician is notorious (thanks to the free diffusion of the music he or she performed on Facebook) he (she) becomes an independent artist or accepts a contract with a Major. The Majors struggle against piracy, using all means they can use (pedagogy, legal punishments …). But if Internet is really a global phenomenon, reflecting the human nature, amateur piracy will be uneasy to eradicate: human nature is made up of Desire (desire of "free lunch") and Reason (acceptance of the economic exchange). Amateur piracy is the consequence of the "appalling popularity of music", to use the words of Constant Lambert.[1] Concerning professional pirates, they will continue. Paradoxically, they do not "steal" the musicians, since they download files illegally only because it is a feat: if they were not pirates, they should not buy the files they download. But they "steal" the telecommunications operators, saturating their networks. Of course, we do not speak of these professional pirates who allow amateur pirates to illegally download pieces of music, thanks to sites they control (they may make money or not). What has been the response of the Majors of music? Their ability to cope with crises is legendary (Lefebvre, 2008). Their response has been to merge and to have branches organizing concerts (since concerts escape from the consequences of piracy).

We shall describe the effects of Internet on the musicians, on the audiences and on the diversity and the evolution of music. Note that the last topic has not only economic and technological aspects, but also social and aesthetic.

3 THE IMPACT OF INTERNET ON THE MILIEU OF MUSICIANS

We can distinguish three categories:

(1) The "stars". Once one of them is notorious thanks to the social networks, he (she) signs a contract with a Major. This company manages his (her) career, including concerts. It is the realm of culture industry. The place is large cities.

(2) Independent artists. They use the social networks and blogs to reach recognition. To have a livelihood, they bank on concerts (and sometimes on teaching). Also, they can use micro labels (to sell Compact Discs) or Net labels (small labels on Internet, allowing downloading music for free or at a very low tariff). They escape from the influence of Majors, which have strong requirements concerning the musicians who have contracted with them. They have a direct control over the link between themselves and the public. Thus Internet allows the "fat tail" phenomenon. Diversity of music is preserved.

(3) Ordinary musicians. They record music rarely, indeed just when they are at the top of their career: at this time they record several Compact Discs and make tours far away from their region. They can sell a few Compact Discs to listeners when they perform music in a concert. In general, they perform music in public places (ballrooms, cafés). They have a livelihood but are not affluent people. They prefer to perform the music they like, but it is not always possible. According to the French sociologist Perrenoud, who has studied this milieu, there are three possible situations. When they give concerts the music they perform is of a good quality. In the case of "entertainment" (balls, feasts …) the audience is a partner and there is an interesting stake for them, since they have to understand the desires of the customers and to satisfy them. In a third situation, it is Eric Satie's "musique d'ameublement" (music like furniture) or background music. For instance the musicians play jingles during a ceremony, or they perform music in a casino. The public is indifferent, or they do not listen to music at all. If it is boring for musicians, it is … lucrative. According to Perrenoud, these musicians participate in "local networks" while the "stars" participate in "cosmopolitan networks". The American sociologist Robert Merton has characterized the "local networks" as relying on personal relations, and the "cosmopolitan networks" as relying on competency. The "cosmopolitan networks" are present in the large cities, where culture industry is located.

[1] Already in the thirties, there were attempts to diffuse music thanks to loudspeakers in the streets of some British cities.

4 THE IMPACT OF INTERNET ON AUDIENCES

There are three categories. They can be described in terms of listener's experience:

(1) Pure consumerism. These listeners follow fashion. They often listen to a small number of "blockbusters", but changing. If they are young, they listen to music freely (often they access social networks, by means of mobile phones). The sales of downloaded music are increasing, as it is shown by the success of I-Tunes. Internet is favorable to this kind of consumption: practical, allowing teasing the desires of listeners, entertaining. Of course, "amateur piracy" is a limit, but let us recall that at the time of discs and CDs, there was some piracy, also. Legal downloaded music is more and more in accordance with the needs of this audience. These listeners can go to concerts given by the stars they like. It is the kind of concert in a large hall or outdoors, gathering thousands of people. It is attractive not only because of music but also because of the spectacle and atmosphere. But even if this case, there is a substitute: the music video. Music videos are a great success. They can be bought on Internet. Also, one can view them on some TV chains (MTV is the most famous).

(2) Tribal listeners. It is another experience of listening to music, that of listeners fond of a particular genre. They use social networks, Internet and go to concerts. They are a tribe, a "group of peers", to use the words of the American sociologist David Riesman. Often, these musical tastes are linked to other tastes, or behaviors (clothes, politics …). This passion can lead to attempt to perform music. Often, a beginning musician passes from a "group of peers" to a professional way of life (Perrenoud, 2010).

(3) "Interested amateurs". These listeners build up their own experience in an autonomous way. They want to understand some aspects of the music they listen to, its evolution etc. They make experiments. They use all the means to listen to music: Internet, independent medias (like France Musique and TSF Jazz, which are radio chains in France) , concerts … From an economic point of view, it is interesting for those whose livelihood is music: these various means of diffusing music can be combined to obtain "synergies", that is to say to boost sales. For instance, a radio chain informs that on Internet one can obtain rebates to go to some concert, make advertising for clubs organizing concerts, broadcast discussions triggering the purchase of CDs by listeners etc. Here, there are two opposite points of view. According to Adorno, these listeners are in "secondary roles". According to the musicians described by Howard Becker all those who are not musicians are "squares" (meaning philistines). But some think that there is room for a middlebrow art. We deal with this topic, now.

5 THE IMPACT OF INTERNET ON DIVERSITY OF MUSIC AND TASTES

According to Constant Lambert, there is a highbrow art, a middlebrow art and a lowbrow art. Lowbrow art is popular art (pop music, songs which are "blockbusters" etc.). Middlebrow art is more sophisticated. One often quotes Offenbach, Cole Porter, Duke Ellington and Kurt Weil. Note that the line between middlebrow and highbrow music is not so clear: Sibelius composed for circus, Schoenberg, Webern, Ravel (and others) composed waltzes à la Johan Strauss … But what is highbrow art?

Let us start from the Impressionist Revolution in painting and music. Around 1900, occurred the "painter's rebellion" according to André Malraux in his book "Le musée imaginaire". The topic disappears. Instead, the way in which the painter looks at the world, is interesting. Perspective and horizon disappear. Color is dominant, not drawing. According to the French sociologist Francastel, Cézanne "paints the color" (not adding color to drawing), creating an impression of depth with color. On the painting, large colored areas suggest mutual links between things or human beings. The end of successive planes removes sacredness (our environment is not always submitted to hierarchies). But emotion does not disappear. There is color and atmosphere. Also, it is a fleeting instant, as when the modern citizen understands what he (she) has around him (her) thanks to his (her) saturated senses (Mac Luhan thought that we understand our environment thanks to synthetic images). The evolution is from the meticulously built up spectacle, to poetic atmosphere. From structured spectacle, with particular areas on the painting, to a single space pervaded by an atmosphere (at this time, the French sociologist Tarde wrote that diffusion is space is a universal notion). In music, traditional form (symphonies of the 18th century, Liztian symphonic poem) is dynamited by Debussy, Stravinsky and Schoenberg, before the First World War (Lambert, 1948). Curiously, the origin is … Oriental music, with Glinka. Form is replaced by frantic rhythm and successive surprises. Through the Russian musicians, Chabrier, this influence reaches the music of Debussy, Stravinsky and Schoenberg. What was

efficient to remove traditional form was not so much nationalistic music but exoticism (Glinka composed music in the Spanish style). Finally a list of innovations was accepted (pentatonic scale, all tone scale, atonal and serial music, rhythmic innovations coming from ethnic sources etc.). After the First World War an era of pastiche begins. The major influence is "barbaric rhythm" suggested by jazz, but no highbrow composer will seize the opportunity. An era of experiments (like concrete music initiated by Georges Antheil or electronic music) begins. Constant Lambert deplores the lack of middlebrow composers.

Let us sum up the characteristics of lowbrow and highbrow art:

Lowbrow art	*Highbrow art*
Specialized (idiomatic)[2]	Universal (cross border)
Unambiguous	Ambiguous
Redundant	Full of surprises
Oriented towards the person's universe	Abstraction, intellectualism[3]
Not technically sophisticated[4]	Technically sophisticated

Now we can describe towards what fate the "interested amateur" is driven by his (her) experience. Either we describe this experience in the words of marketing. Brands allow the customer's experience. They choose a theme, and then freely propose videos on social networks or Internet (on particular regions, on trips, on "stars", on sports …) or give advices, display cooking recipes etc. The idea is to fashion the customer's experience to trigger the purchases of the brand's products. In this case, the "interested amateur" is in a "secondary role". But he (she) can also reflect on music in an autonomous way. There are many questions deserving reflection:

- What is the better music, the exotic or the nationalistic?[5]
- Do we need middlebrow composers and to do what?
- What is the role of technology?[6]
- What is the evolution of music?
- Etc.

The French specialist of Medias (and musician who invented "concrete music") Pierre Schaeffer wrote: "on music anybody tells anything". Therefore there is room for the "interested amateur" reflecting on music in his (her) own way.

Howard Becker has described these groups giving support to an artist (or several artists) attempting to change conventions and aesthetic choices (Becker, 1988). An "interested amateur" should belong to a group of this kind.

6 CONCLUSION

The city is no more the place where notorious musicians are selected (it is done on the social networks[7]), or where the tastes are fashioned, but it remains a place where music is diffused, listened to. After all, the city and music have something in common. For instance, the both allow "time travelling" (to use the Constant Lambert's words). The atmosphere of ancient quarters in cities gives the impression to make a trip in time. It is the same when one listens to ancient music, perhaps played with ancient instruments. It is emotion thanks

[2] Idiomatic is the word used by Perrenoud to characterize the genre that tribal listeners listen to.
[3] According to Mac Luhan, modern art wants to understand the aesthetic effects. It is more difficult to understand the effects (backward, from the effect to the cause) than to observe the effect (forward, from the cause to the effect).
[4] Some innovations coming from highbrow music can pervade lowbrow music after some time: thus the pentatonic scale is used by the rock music. But even the rhythms of lowbrow music are less complex than those of highbrow music (as the rhythms coming from the Hindu tradition used by Olivier Messiaen).
[5] Nationalistic music sticks to folklore melodies and rhythms, and even can be played with authentic, traditional instruments. Representatives are Albeniz and Bartok. Now it is called "world music".
[6] In the case of "electronic music" there are no more instruments. Music is diffused through loudspeakers. However, it is played. Tunings are made by the composer, who is also the Disc Jockey. Software is used.
[7] It is different for classical music. The career involves studying in a conservatory, participation in international competitions, then recordings and concerts.

to a travel in time. One can taste the both: visiting the French Quarter in New Orleans and listening to jazz dating from 1900. Cities propose many ancient places where one can listen to music: churches, cloisters, palaces, old plazas etc. There are also industrial buildings which have been revamped, opera houses, classical concert halls, modern auditoriums … Only the modern auditoriums are really adapted to the sound engineers 'tricks to obtain a sound of good quality, and modern orchestras. In other places there is a dilemma: one can use the sound engineers 'tricks to obtain a sound of good quality, but the original atmosphere is lost, or one keeps the ancient atmosphere but the sound is not perfect. In any case, recorded music is of good quality, no matter the place where it is recorded.

The presence of music in cities is often subsidized: it is the case for opera houses, conservatories, sometimes some bands. The ordinary musicians are paid indemnities if they do not earn enough fees in one year (in France and other European countries). In large cities, the stake is the image of a city. In small cities, support is given to festivals. Essential are events (like the presence of famous artists) and the peculiar atmosphere which is liked by those going to festivals. Settings have to be pleasant thanks to historical, architectural or natural features. The success of festivals depends on their reputation.

There is not a revival of concerts, but the dominance of recorded music is not absolute. One of the reasons is that concerts escape from the consequences of piracy. It is better from the point of view of the musicians 'livelihood.

There are several experiences of listening to music, some of them involving going to concerts.

Ten or fifteen years ago, Internet appeared as very much adequate to distribution of music. It was flexible enough to distribute music in these two situations: either the public is large and unknown, either it is small and known (Becker, 1988). But one can apply this idea from the French social thinker Proudhon to Internet: any important social progress has its other side, is also a cause of problems. Internet generated piracy. The economic model of music has not exploded. But musicians are more interested in concerts, since their revenues from recorded music are often threatened by piracy.

Remixing the (Suburban) City – Institutional Frame, Strategies, Projects in the Vienna Region

Andreas Hacker

(Dipl.-Ing. Andreas Hacker, Metropolitan Area Management Vienna/Lower Austria, Schwartzstraße 50, 2500 Baden, sum.sued@stadt-umland.at)

To understand regional development /spatial planning in the Vienna Region …

Metropolitan Area Management Vienna - Lower Austria

To understand regional development /spatial planning in the Vienna Region …

- The legal frame and the laws of regional/spatial planning are regulated by the "lands" in Austria. In the case of Vienna and Lower Austria, they are partly completely different which complicates co-operations.

Spatial planning of the local level

- The spatial planning on the local level is part of the autonomous competence of the municipality. Provincial government supervises the spatial planning activities of the municipalities. (local development scheme (örtliches Raumordnungsprogramm),land use plan (Flächenwidmungsplan),building regulation plan(s) (Bebauungsplan)

Vienna:

- Because of the status as a municipality and a land, Vienna has to fulfil the spatial planning on the local and the supra-local level in its autonomous competence.

Metropolitan Area Management Vienna - Lower Austria

To understand regional development /spatial planning in the Vienna Region …

- Due to the Austrian tax system municipalities try to improve their financial situation by creating new business and housing areas (financial compensation law, payroll (communal) tax: revenue depends on population size and number of working places)
- Favourite housing areas for Austrians are (still?) small villages near the cities, with „green" intact environment, good traffic connections – to use the economic, cultural infrastructure of the agglomeration area.

Metropolitan Area Management Vienna - Lower Austria

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

To understand regional development /spatial planning in the Vienna Region …

- Because of the fact that Vienna is a municipality and at the same time a provincial state the co-operation on the same level (Vienna with Lower Austria or Vienna with the surrounding communes) especially with the surrounding communes is difficult.
- Vienna and the communes of Lower Austria do not have a common inter-communal planning body because of political reasons, economic prosperity and rivalry between the city and the suburban area. Regional planning and planning between the city of Vienna and the municipalities of Lower Austria were mainly based on singular projects

Metropolitan Area Management Vienna - Lower Austria

Vienna region – structures for Cooperation

- The „Planungsgemeinschaft Ost (PGO)" is plattform of the federal states Vienna, Lower Austria and Burgenland to initiate and co-ordinate spatial-related activities. It was founded in 1978. It elaborates basic information, reports and concepts, mostly concerning the development of settlements, traffic and the preservation of green spaces.
- The association „Verein Niederösterreich – Wien, gemeinsame Erholungsräume" was founded in 1974, it aims at securing leisure related areas and at creating and financially subsidising leisure areas with supra-local importance.
- The Verkehrsverbund Ost-Region Ges.m.b.H. (VOR) co-ordinates tariffs, time-tables and information of public transport (train, bus, tramway, underground) of the Eastern Region of Austria and the Viennese metropolitan area (1984).Share holders: Vienna, Lower Austria , Burgenland
- A political upgrading of the intermunicipal co-operation has been realised by the institutionalisation of a common financed metropolitan area management / Stadt Umland Management (2006).

Metropolitan Area Management Vienna - Lower Austria

Stadt-Umland-Management Wien / NÖ

- Joint initiative of the provincial governments Vienna, Lower Austria
- „Political heads" are the members of the provincial governments in charge of spatial planning, regional development
- Steering comitee with administrative and political representatives
- Budget: approx. 200.000 € (for continuos activities)

Metropolitan Area Management Vienna - Lower Austria

SUM Region

„SUM region“ is not defined exactly (due to different functional linkages) …

but focused on this region.

Metropolitan Area Management Vienna - Lower Austria

SUM - Activities

- Cooperation and Intermediation
  - → activating the cooperation and harmonization of the involved Lower Austrian communities and Viennese districts and the two „Länder“ concerning regional planning matters as well as specific projects
  - → mediating controversial cross-border issues
- Plattform of Information
  - → serving as a plattform for information about topics of regional relevance
  - → organising exchange of ideas among the stakeholders with a focus on establishing an all-inclusive vision of the agglomeration
- Incentives and Management
  - → designing solutions for cross-border challenges together with the stakeholders to create added regional value

Metropolitan Area Management Vienna - Lower Austria

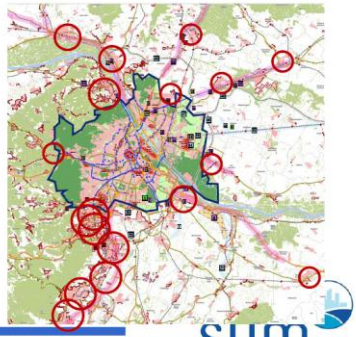
The agglomeration area Vienna – Lower austria

- metropolitan area with 2,6 mio inhabitants
- separated by the Danube River into „North" and „South"
- Vienna (1,7 Mio), surrounded by 13 small towns (10.000 – 25.000), many small municipalities (> 100) and large areas of precious nature and farmland
- radial structure, continuous settlement area along some axes (esp. to the south)



Metropolitan Area Management V ... Austria

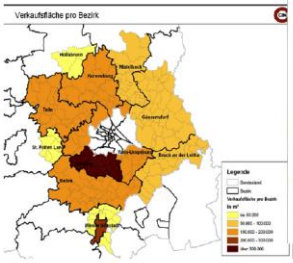
The agglomeration area in Lower Austria

- Concentration in the south of Vienna
- Biggest settlement area in Lower Austria
- Highest regional tax revenue
- Decrease industrial/producing sector
- Retail, logistics most important branches
- Problems concerning environment, traffic system, „life quality"
- New challenges for politician (new initiative groups versus traditional politician system, cooperation vienna – Lower Austria)

Metropolitan Area Management Vienna - Lower Austria

The agglomeration area in Lower Austria

Competition city versus periphery – for example: retail



Metropolitan Area Management Vienna - Lower Austria

Centre Areas in Lower Austria

www.raumordnung-noe.at

- Since December 2004 (14th amendment to the Lower Austrian Spatial Planning Act) municipalities have the possibility to zone "centre areas" in the land use plan. Zoning town centre areas is an important step towards an integrative strategy for the development of the town centre and retail structures.
- Inside centre areas – no limitation of sales area
- Inside housing area – max. 1000 m² floor space
- Periphery – max. 80 m² (except goods not relevant for centre areals like cars, furniture..)

Metropolitan Area Management Vienna - Lower Austria

Urban renewal in Lower Austria

www.dorf-stadterneuerung.at

As a result of the successful programme "Village Renewal", the programme „Urban Renewal" was started in 1992.

- people in the towns can take part actively in the life of the town and get involved in the discussion, decision and design process.
- Main goals:
  - more life quality in the towns
  - better communication of the citizens among each other
  - Rising its attractiveness and the economic potential
  - Co-operation of town and economic acteurs
- Always 18 towns can be active in the programme Urban Renewal at the same time
- financed by the government of Lower Austria and the municipalities

(Ramez Zabeh, M.A., Faculty of Architecture & Urban planning, Qazvin Azad university, Qazvin, Iran, ramez_62@yahoo.com)

1 ABSTRACT

City neighborhoods, despite its historical importance, today forming the pattern of urban living have little significance. However, in recent decades in the context of sustainable development, they have been re-emphasis on reducing. A vision of sustainable community development, the new approach will strengthen the city in which problems in returning to the neighborhood as the cells are thought to urban life. In the present study the recovery of new urban areas in terms of social patterns, has been

Elected in a district of Tehran) in a neighborhood of Tehran's Evin (the process of restoration and sustainable community development approach in the context of neighborhood functions and were analyzed Using the principles and indicators of sustainable community development and application perspective The depth interviews and focal groups were used to examine the mental impressions and opinions of residents In improving the spatial structure and the promotion of social capital by The results show Discontinuity in the spatial structure of communities and loss of physical identity Area residents and reduce the loss of social structure through continuous communication and interaction between people is The results showed that a strong social networks and groups in local communities And create the necessary background and contexts of communication between residents of Effective feedback can lead to problems of urban residents and improve the biological With emphasis on the spatial structure of the proposed sustainability indicators that are observed in the , Can be useful in improving social interactions and relationships between residents within the local communities approach the expected This indicates that the assessments These interactions in a reversible process leading to the improvement of the spatial structure of neighborhoods and strengthen the local identity.

2 INTRODUCTION

Residential neighborhoods in the cities of the distant past, as the cells have an essential role in the lives of residents of urban life they have.

Since, in urban neighborhoods, gathering place for people with specific ethnic, racial, religious, social and economic has been common, followed by accumulation in a range of individuals with common characteristics, the specific identity of parts of the city known it was for a cause other surrounding tissues were differentiated.

The operating range of identity in the cause and function spaces with specific functions that distinguish the tissue surrounding it returns the range. A certain lifestyle among residents in a neighborhood usually lead to common goals and interests among the residents of a neighborhood.

In recent decades, with dramatic changes in lifestyle and changes in community structure is established.

Meanwhile, with the vision of sustainable community development as the view that the current problems of cities and urban life in the group returned to the neighborhood knows, you can use the powerful forces of endogenous and social capital in its existing problems.

Accomplishing this is a neighborhood structure that distinguishes it from the adjacent neighborhood. These characteristics reflect the cultural, historical, social and neighborhood residents and neighborhood-level social network in which communication occurs in different forms.

In other words, a range in which the civic life and urban life in a neighborhood scale is now. And indicators of cultural, social, historic in scale, it may be possible.

Lack of local connections can cause rupture of the spatial structure of the residential neighborhoods that only the shadow of popular participation and improved results.

some people knows that, solutions of urban problems in return to the villages and rural life. And others unhappy with the phenomena of urban life, it also points out the pros and seek appropriate solutions to overcome these problems are.

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

Using the perspective of sustainable development can make sense for neighborhood residents and neighborhood culture and common sense in place of biological problems to achieve success.

This study has the potential within the urban areas, through building a powerful local groups and be active participants as social capital, deep and effective to use. So in addition to creating a better environment to live, work and play with the improvement of the spatial organization of urban neighborhoods where they play a fundamental role in establishing the identity.

The main questions this research include:

1. You can view the related theoretical concepts for sustainable neighborhood development, improve the spatial structure of urban neighborhoods of Tehran be used?

2. How can the social capital of local communities to improve the spatial structure be used?

In this study, the studied area is, Evin neighborhood,in Tehran. This area has a strong historical background, and has undergone new development, a municipality located in the region.

3 THEORETICAL FRAMEWORK

Neighborhoods and local communities:

Another element that must be evaluated in view of sustainable community development, neighborhood, urban life is a living cell. Generally, the neighborhood is part of the city in which spatial relations are facing as individuals. With respect to each aspect of the neighborhood may be defined:

1) The administrative relations: by borders and boundaries

2) aesthetics, features and history developed by

3) Social and saw the look of the area residents

4) Performance of services by

5) Environmental: by spaces with high quality traffic flowing smoothly and the environment.

((Neighborhood is an important part of the activities and work space in which citizens use it occur. Neighborhood is an important foundation for understanding the broad social mobilization of people and the people To enable, develop and defend those rights is that Not in the political sphere but also in the field of energy and material culture, economy and social life are.))

It is a neighborhood institution through which individuals and by the ability for early action by an effective interaction in individual and collective within or beyond it, to implement.

Generally, the neighborhood can be a predominantly residential area With specific and distinct identities and characteristics of the surrounding tissue as , Which usually includes the local service area for pedestrian and bicycle access and priority is.

Development of a sustainable community:

The cell with the neighborhood as "urban life" only to realize sustainable development in local development and local scale, and the idea of "think global, act local" was followed.

Because now more than 50% people live in cities, How can the macro-scale neighborhood development and success or failure of society to the problems of environmental, social, physical and ... To determine.

"A sustainable community development" is only a single type of neighborhood, neighborhood, town or region does not describe. Enables traders to activities of the citizens want and can give them stability, which may vary from one community to another community. Generally, a stable neighborhood, with consideration of potential environmental, social and economic needs of inhabitants, says the response. Development of a sustainable community can be as changes in local management practices to global environmental sustainability and at the same time also helps the local environment, natural and artificial, Be explained. Sustainable development by increasing local control over decisions and encourages consideration. Such a strategy requires the development of empowerment in decision making to the local level.

Aims to create sustainable neighborhoods:

The vision of a sustainable neighborhood development, the two main areas in the urban neighborhoods targeted for sustainable neighborhood development as:

1) The spatial structure and spatial identity

2) social capital

Generally, the main goal of a sustainable neighborhood development, Improve spatial structure and spatial identity through strengthening social institutions and social capital is in line to use. Location identification of biological To facilitate understanding of the meaning is one of the most important aspect of quality is a place. Spatial identification process and the environment and human interaction And human activities within this environment are considered.

For a range of residents, And length of stay or activity due to internal experiences, Observations or different memories, Sense of integrity and dedication to me as part of its social identity develop and strengthen the development of space systems alone can not be responsible for neighborhood development goals. Thus the space requirements needed to rebuild and revitalize and strengthen social networks, social interactions. Social interactions and social networks in urban neighborhoods with sustainable and their sense of belonging and responsibility among residents of a neighborhood were considered.

As was mentioned,the ultimate goal of a sustainable neighborhood development is the relationship between social capital and physical.

The concept of social processes, to improve the physical structure and the identity and capacity for future development are used.

Subjective impression of the neighborhood residents Evin:

Neighborhoods within its historical core of the relatively old Evin in Tehran is a city in central region that regular and irregular texture of chess in which the tissue is relatively modern.

Original inhabitants of this area of the Armenians have the use over time, the other residents who also compiled and mixed tissue formed.

The Community believes that strong social relationships is in the range has a spatial structure which integrated.

The range of elements that are symbolic and environmental perspectives in mind, people remain.

Opinions of residents in two areas of social and physical, is obtained through two techniques :

A) depth interview

B) discussions with focus groups

In the present study to collect data, Method and direct face to face interviews with neighborhood residents, Evin has been used. Chosen because this method and multi-dimensional extension of this research And the lack of practical and applied research in this field .

In this type of interview is a qualitative, response of the different spectra are chosen . Some officials in the municipal affairs of the municipal authorities, the Arts and Cultural Center ... , Local dignitaries and residents with the most basic form of the interviewee.

Factors such as intimate partner sexual diversity, age, duration of residence and has been involved in the selection of individuals interviewed.

Information and personal characteristics of interviewees:

Possible location of the interview with the relative dispersion in the study area has been. These variations cause variations in the results of the questionnaire has been.

As was predicted the willingness to participate, His sense of responsibility and sense of belonging among residents with higher residential And those who owned their own property More than all tenants and residents with residence history is less than 5 years.

Considering the physical and social issue in two main areas to be, Results obtained in these two areas mainly covers ,mental problems that you think people in their lives can be seen from the range include:

* Background Physical

* Traffic and access problems

* Local service problems

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

* The break in the spatial structure
* There are different types of pollution in the area
  * Social background
  * Lack of participation
* Lack of information about local groups
* Lack of adequate understanding of each other residents

4 CONCLUSION

Specific location and placement of these elements, and a member in its range, It caused a major role in the region in terms of availability and performance has been. The historical record shows four stages of change that caused a major change in the relationship between mass and space and the space and its users are.

Evin local axis passing through the one hand and increasing human population density and spatial structure and its social construction in this area led to the rupture. While the placement of the cross member of a neighborhood like Beheshti University, commercial office elements and ... Addition, all were due.

Characteristics and problems of study area,The two techniques of field and depth interviews conducted with residents. The results confirm the difficulties in their social context and the spatial structure. Discontinuity in the spatial structure and so weakened by the loss of physical identity and ultimately rupture in the social structure is. This break led to a decrease in social interactions among residents have been limited. The main results of the use of social capital in the potential range.

1 ABSTRACT

An understanding of the causes and the implications of land use and land cover changes and trends is a fundamental part of planning for sustainable development. As consequence, spatial information on land use and land cover become nowadays more and more available, sourced by regional, national as well as European iniciatives or programmes. Though, like in case of so much data in Europe, all these investments can run in the risk of losing the real impact due to incompatible data standards, decentralised data storage and high data complexity for operational assessments. The HLANDATA project aims to demonstrate the feasible European level harmonization of the land use and land cover datasets taking into account both the data categorization and the data models through the development of user oriented value-added services to streamline harmonized data exploration and analysis.

2 CONTEXT

2.1 Land cover or land use?

Land cover and land use and are amongst the most important geographic information themes today and an understanding of the causes and the implications of their changes and their trends is a fundamental part of planning for sustainable development. Land cover represents the biophysical state of the real landscape which means that it consists of natural, but also modified (cultivated) and artificial objects, as referred by the categorization such as artificial surfaces, agricultural areas, forests, natural areas, wetlands, etc.. Land use reflects the socio-economic purpose for which land is used (land function), either current or planned in future, as referred by the categorization such as residential, industrial, commercial, agricultural, recreational, etc. Together thus land cover and land use provide for the particular territory complementary information both on landscape potential and on realizing this potential - the characterization, which essential for many applications areas.

2.2 Need for harmonisation

Historically, land cover and land use information has been managed at various levels - from European to national, regional or even local one. The many activities producing information from European to local scale have been mostly developed independently, addressing specific requirements (i.e. information to be acquired, level of detail both geometric and semantic, updating periods, timelines, precision) of specific users. This has resulted in a suite of datasets, mainly not compatible with each other, not taking into account the interoperability of the information. However, in a context where related environmental threats (for example; climate change, biodiversity loss, and food security) become more and more global issue, there is a need to better integrate various sources of information at various scales. One of the succesfull long-term programme providing harmonized land cover and land use at a pan-European level is the European CORINE Land Cover iniciative [1], nowadays integrated (together with High Resolution Layers (HRL) and Urban Atlas components) in the initial operational phase of GMES programme framework [4]. Nevertheless, many parallel national, regional and local land monitoring activities still exist and need to be linked or integrated in order to achieve efficient land monitoring set up in Europe. Therefore, at present there is an urgent need for harmonization and standardization of land cover and land use information at various levels.

2.3 INSPIREd effort

The main European geographic information harmonization initiative, INSPIRE Directive, set up the rules for the implementation of the datasets included in INSPIRE's Annexes II and III which must be approved by the Member States, and to asure that the datasets owned by the different Member States will be implemented in order to allow their interoperability. All European Member States will have to make available their geographic information as established in INSPIRE, being land cover one of the themes included in the

Annex II of the Directive, and land use one of the themes included in the Annex III of the Directive. The INSPIRE Directive [3] is truly a key driver for the standardization and harmonization of land cover and land use information in the EU, but there is still a long process to reach this situation. Development of the respective INSPIRE Technical Working Groups (TWGs) has to be also regularly tested to assure the best use of the existing experiences in the land cover / land use mapping community. This is why, some initiatives have been / are being carried out which support INSPIRE in achieving its objectives. In prominent position, the HLANDATA project builts on experiences from various previous harmonisation activities and, in close cooperation with respective the INSPIRE TWGs, aims to demonstrate the feasible European level harmonization of the land use and land cover datasets taking into account both the data categorization and the data models through the development of user oriented value-added services to streamline harmonized data exploration and analysis.

3 HLANDATA APPROACH

3.1 Project background and objectives

HLANDATA,[1] lead by the Government of Navarre and TRACASA - Spain, is a European project supported by the ICT Policy Support Programme (ICT PSP) between March 2010 and February 2013. ICT PSP aims at stimulating innovation and competitiveness through the wider uptake and best use of information and communication technologies by citizens, governments and businesses. HLANDATA consists of 9 partners, i.e. public authorities, private companies and research institutes from 6 different European Union countries as well as one international planning organization. Primary goal of the HLANDATA project aim is to contribute to a common data sharing infrastructure, contribute and test TWG data specification to assure sharing land cover and land use data between different public administrations and other stakeholders on European, national, regional and local level. More, HLANDATA aims at fostering the use of land use and land cover data at a European level through the creation of value-added services beyond the traditional concept of land cover and land use data provision. The results are web services in different Pilots - different application areas and the support of awareness rising for data harmonization, data sharing, data exploration and analysis guiding holistic planning. The services are based on the development of one land cover and land use harmonization proposals (coordinated with INSPIRE TWGs) which takes into account already existing data models and categorizations as well as the specific requirements of the users.

3.2 Project phases

From technical point of view, the HLANDATA project is phased into following subsequent logical chain of activities (reflected also on organization level by Work Packages (Figure 1).

Diagnostic phase

The first phase - 'Diagnostic' consisted of assessment of the current European situation regarding the harmonization of the Land Cover and Land Use geographic information, taking into account the categorization and data model initiatives already ongoing in that field (i.e. SIOSE, LISA). Also, being HLANDATA focused on relevant value-added services, thorough assessment of the end users and their needs from the point of view of data harmonization i.e. kinds of users, user purposes and required functionalities for the high-level services was developed in the project.

Harmonization and development of common data infrastructure phase

In the second phase – 'Harmonization and development of common data infrastructure', based on the diagnostic results, a harmonization proposal for the land cover / land use geographic information was developed and provided to respective TWGs, both from the perspective of the data categorization and the data model (i.e. HILUCS for TWG LU). Fruitfull cooperation with INSPIRE TWGs is clearly one one of the achievements of the HLANDATA project.

[1] HLANDATA website http://www.hlandata.eu

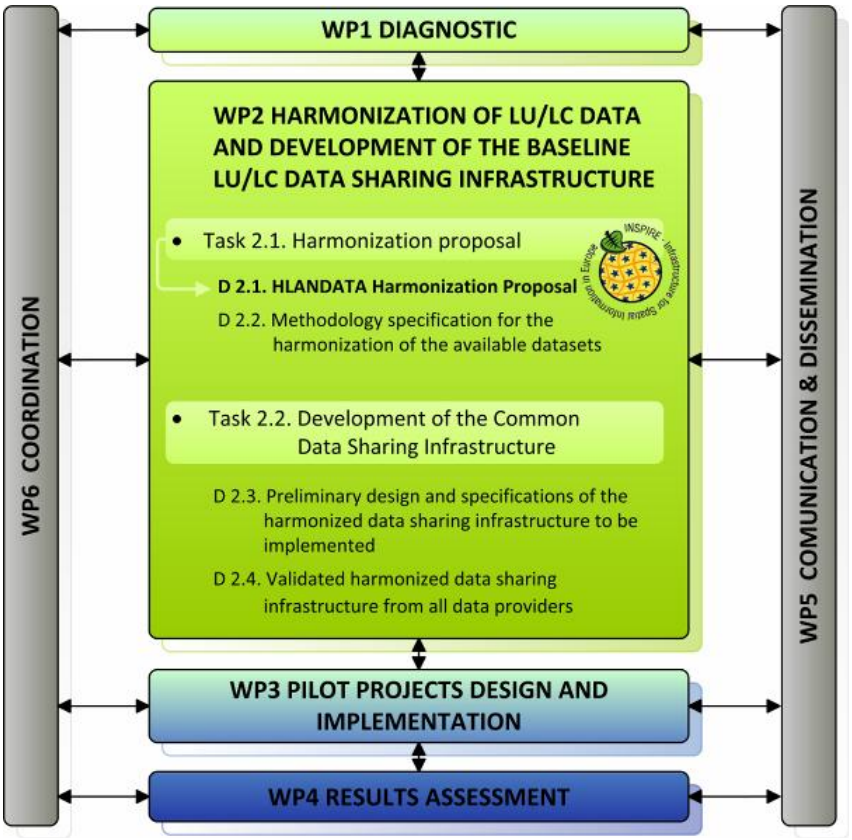

Fig 1: Phases / Workpackage structure of HLANDATA project

More, common data sharing infrastructure (CDSI) has been developed to support harmonised land cover and land use data stored and maintained in different sources across Europe. The HLANDATA geoportal provides a map viewer to overlay and compare spatial data, and a metadata catalogue that allows to search and to find available data. The HLANDATA geoportal follows the principle: one centralised access to decentralised data! The CDSI enables access to the harmonized data via WMS. A common functionality and requirements on WMS are defined, so that interoperability of WMS is given. The HLANDATA geoportal is the access portal to the CDSI and the harmonized WMS, and provides a viewer for mapping and overlaying data.

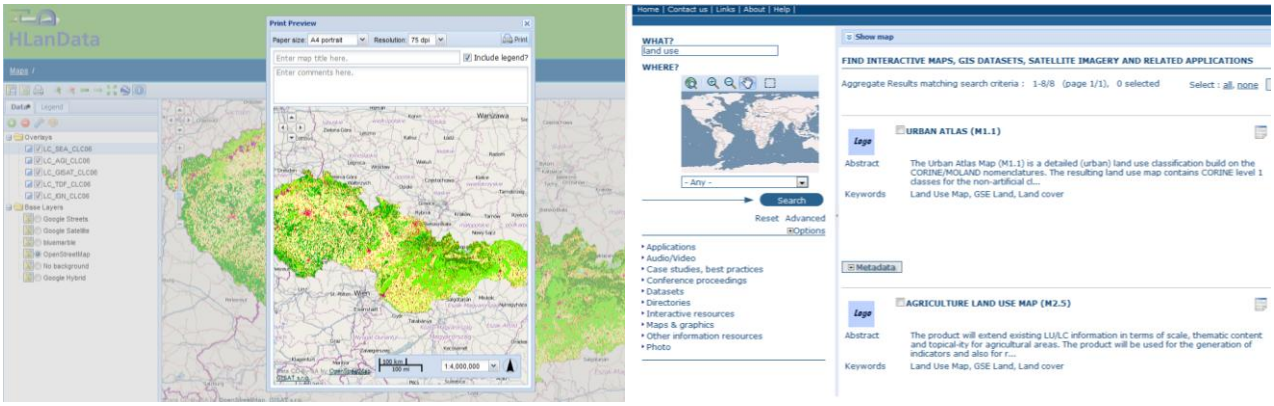

Fig 2: The HLANDATA Geoportal

Additionally a metadata search allows to access relevant information on the datasets according to one common metadata profile. The architectural design consists of a three tier architecture, which has the advantages of flexibility, good scalability and thin clients. The HLANDATA Geoportal is accessible on http://portal.HLANDATA.eu (see on Figure 2.)

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

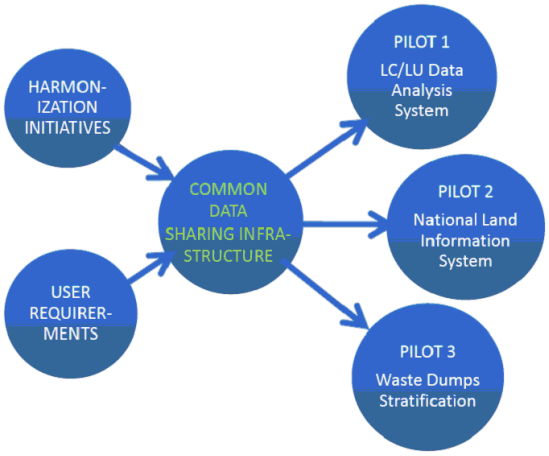

Fig 3: The HLANDATA Pilots and the previous project phases

Value-added web services implementation and validation

Finally in the third phase - 'Value-added web services implementation and validation', the HLANDATA common data sharing infrastructure (CDSI) is used and data harmonization potential is demonstrated using three specific value-adding thematic web based services (Pilots) developed for the selected users: LC/LU Data Analysis System (Spain), National Land Information System (Czech Republic, Lithuania) and Waste Dumps stratification (Slovakia) as seen on Figure 3. The value-added service within each of the pilot project is a specialized web-based map application that allows users to freely access it and to perform selected operations to obtain desired new information using harmonized land cover / land use data. These functionality is in most cases provided by using standardized web services (e.g. OGC – WMS, WFS, WPS) and standardized IT protocols and formats (REST, JSON, …). Contained map layers of each Pilot include harmonized WMS that were prepared at previous stages. Some of Pilots offers also additional value-added services based on functionality that needs availability of source data and/or some additional data – through a (geo)database. Both Open Source and commercial development frameworks have been tested in Pilot implementation. User utility assessment is also carried out within this phase to validate pilots design. Following chapter is focused on Pilot 2 - National Land Information System overview provided by GISAT.

4 PILOT 2 – LAND COVER / LAND USE DATA EXPLORATION WEBTOOL

In the frame of the HLANDATA project Pilot 2, GISAT and CENIA, which jointly serve as the National Reference Center (EIONET NRC) for Spatial Analysis and Land Cover in the Czech Republic work on exploring the potential of the setup of a national land information system and on the development of its trial which shall be demonstrated as the Czech pilot within the HLANDATA project. The project focuses mainly on technical, but reflects also organizational support required to set up data sharing cycle of the national mandated actors and data providers of partial land cover and land use data in a harmonized way.

Public administrations, decision makers, private companies, NGOs, researchers, planners, GIS analysts, the public, all these stakeholders and more require access to adequate and comprehensive data to achieve interdisciplinary and holistic analysis and planning activities, transparency and participation in decision-making, efficient integrated data management, and monitoring of changes for a sustainable development. Due to the harmonisation according to common standards, land use and land cover data across Europe can be shown on the HLANDATA geoportal together in one map, with one common legend, and therefore become comparable as a key input for cross-border analysis and integrated planning activities, e.g. in regard to environmental, mobility, economic, and social issues.

Nevertheless, The HLANDATA project aims even more by exploring potential how to turn data into standard information and provide user-friendly tools to explore, describe, compare and explain land cover and land use changes in socio-economic context. In order to achieve this level of flexibility and usefulness required by users, the service specification for the Pilot 2 goes far beyond the traditional concept of data provision. Inspired by the European Environmental Agency (EEA)'s the Land and Ecosystem Accounting framework [2], the Pilot 2 is based on an interactive web-based approach, where both spatial and socio-economical statistical data are delivered in an organized way, together with tools, in a fast and flexible

environment. This allows data to be easily viewed and analyzed in user-predefined themes (indicator views), as well as being further explored interactively. The webtool, based strictly on Open Source frameworks, integrates main standard presentation modes - maps, tables and graphs in an interlinked manner i.e. user-defined changes in/via one presentation mode are instantly reflected in all the others. User is also free to choose the most appropriate level of granularity for his analysis or define his own analytical units. Analytical views on data can be stored (using OpenID authentification) and/or shared with other users using URL link. Finaly, users can export of each webtool component (into PDF or images) to be used in user reports or assessments.

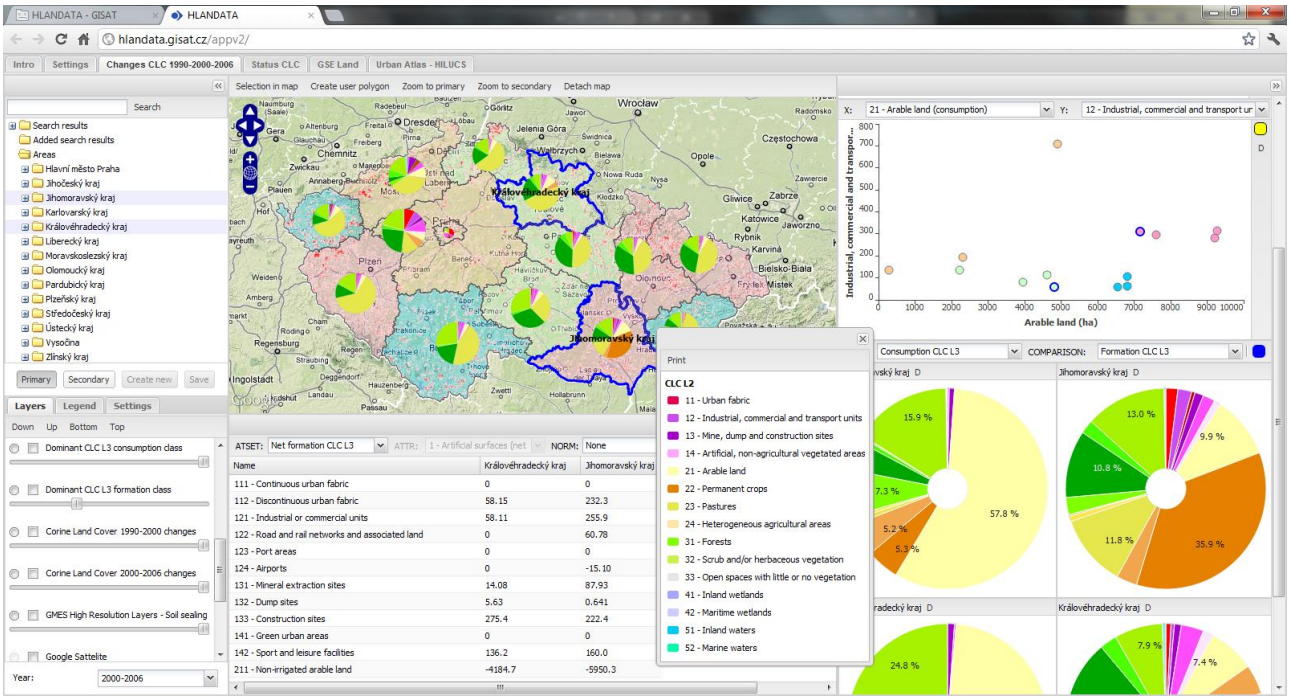

Fig 4: Example of the HLANDATA Pilots 3 – webtool interface

5 CONCLUSION

The HLANDATA project demonstrates advantages of current European effort for data harmonization of land use and land cover datasets within the INSPIRE context on example of user oriented value-added services streamlining harmonized data search, exploration and analysis. The web-based approach to the Pilot demonstrators developed within the HLANDATA project then shows not only potential of harmonised land cover / land use data, but also the power of new technological solutions to support the complex spatial information provision to the end-user. Intuitive, fast and user-friendly exploration and analysis webtool handling large spatial datasets integrated with traditional socio-economic statistical data can provide effective support to spatial planning on various administration levels and assure sharing the land knowledge on decision making level.

1 ABSTRACT

Vor dem Hintergrund der Notwendigkeit, den weltweiten CO_2-Ausstoß in den kommenden Jahren drastisch zu reduzieren, nehmen Städte eine wesentliche Rolle ein. Dies trifft im Besonderen auch auf Österreich zu, wo der Urbanisierungsgrad inzwischen 50 % beträgt und laufend weiter zunimmt. Nachhaltigkeit und Energieeffizienz sind die Werte, an denen sich heute die Zukunftsfähigkeit einer Stadt misst. Die Reduktion der Treibhausgasemissionen komplementiert Vorgaben wie Verkehrsdurchlässigkeit und Habitatsdichte als Ziel der Städteplanung. Es gibt keine lebenswerte Zukunft ohne Klimaschutz. Städteplanung und -entwicklung befinden sich weltweit in einem Wandlungsprozess, und eine neue „Gründerzeit" zeichnet sich auch in Österreich ab. Die Zukunft gehört ökologisch ausgerichteten Metropolen, die zwar dicht bebaut sind, aber dennoch sparsam mit Ressourcen umgehen, ihre Energieversorgung organisieren, Verkehrsströme begrenzen und die Landschaft und Arbeit zurück in ihre Mitte holen.

Genau hier setzt der Klima- und Energiefonds mit seinem Förderprogramm „Smart Energy Demo – FIT for SET" an. Mit diesem und weiteren Programmen in der Energieforschung und im Verkehr werden Fördermittel für die smarte Stadtentwicklung bereit gestellt, um österreichische Industrieunternehmen, Energieversorger und große urbane Zentren im internationalen Wettbewerb zu unterstützen. Gleichzeitig erhalten aber auch kleine und mittelgroße Städte Zugang zu intelligenten Technologien auf nationaler Ebene. Insbesondere bei der „Stadt als Testbed" sieht der Klima- und Energiefonds ein großes Potenzial: Österreichische Unternehmen sind in vielen Bereichen, von der Energietechnologie über Gebäudetechnologien bis hin zur Elektromobilität, internationale Spitzenreiter. Mit Unterstützung des Klima- und Energiefonds planen und realisieren diese Unternehmen wegweisende Demo-Projekte für eine weiterhin hohe Lebensqualität in Österreichs Städten.

2 SMART CITIES ALS BAUSTEIN FÜR ZUKUNFTSFÄHIGE WIRTSCHAFTSSTRUKTUREN

2.1 Nachhaltige Stadtentwicklung – Systemintegration und Systemoptimierung

Viele (Einzel-)Ergebnisse als technologische Basis für eine klimaneutrale Stadt sind vorhanden: Über das breite Portfolio des Klima- und Energiefonds mit den Schwerpunkten der vergangenen Jahren wurden bereits zahlreiche Ergebnisse initiiert. Eine der Hauptaufgaben der Planung neuer Siedlungsformen liegt nun in der Integration der Vielzahl innovativer, urbaner Einzellösungen – es stehen also Systemintegration und Systemoptimierung im Zentrum. Gebäudesanierung und effizienter Neubau, solare Technologien, Mobilitätskonzepte, Intelligente Verkehrssysteme, erneuerbare Energieaufbringung oder „Smart Grids" sind Bereiche, die vor allem im optimalen Zusammenspiel eine nachhaltige und klimaschonende Stadtentwicklung erlauben.

Das Förderprogramm „Smart Energy Demo – FIT for SET" zielt daher auf die Integration von mittlerweile meist sehr ausgereiften Einzellösungen ab. Die Verflechtungen der technologischen und sozialen Notwendigkeiten einer emissionsfreien Stadt sind Hauptzielrichtungen der Demonstrationsprojekte, die im Zuge von „Smart Energy Demo" geschaffen werden sollen. Der Anspruch der klimaneutralen und nachhaltigen „Smart Cities" soll insbesondere auch in Österreichs historischen Städten umgesetzt werden.

Die erste Ausschreibung hatte die Konsortienbildung und eine gemeinsame Visions- und Konzeptentwicklung (Roadmap, Actionplan) sowie die Vorbereitung der Antragstellung für die zweite Ausschreibung im Fokus, der zweite Call zielt auf großvolumige Pilot- und Demonstrationsprojekte im urbanen Kontext ab.

2.2 Smart Energy Demo – FIT for SET: Programmvision und -strategie

Die Vision des Klima- und Energiefonds für das Programm „Smart Energy Demo – FIT for SET" ist die erstmalige Umsetzung einer „Smart City" oder einer „Smart Urban Region", also eines Stadtteils, einer Siedlung oder einer urbanen Region in Österreich, die durch den Einsatz intelligenter grüner Technologien

zu einer „Zero Emission City" oder „Urban Region" mit hoher Lebens- und Wohnraumqualität wird. Bei der Betrachtung einer Stadt als (Gesamt-)System werden jene Themen in den Mittelpunkt gestellt, die dazu beitragen, die Rohstoff- und Energieversorgung, die Verarbeitung, Entsorgung und Wiederaufbereitung

von Ressourcen für „Städte der Zukunft" effizient zu gestalten. Demovorhaben, die durch den Klima- und Energiefonds gefördert werden, beinhalten daher insbesondere Technologieentwicklungen, die eine Interaktion und Vernetzung von einzelnen technischen Systemen ermöglichen, zwischen Systemen eine Schnittstelle bilden und damit die Einzelsysteme bzw. Einzellösungen optimieren;

„Smart Energy Demo – FIT for SET" ist darüber hinaus jenes Förderprogramm der Bundesregierung, das österreichische Unternehmen für die Beteiligung an „European Industrial Initiatives" im Rahmen des „SET-Plans" bereit macht. Die Programmstrategie orientiert sich daher auch an der Europäischen Forschungs-Strategie für „Smart Cities" („European Research Strategy") und deren strategischen Eckpfeilern.

3 TECHNOLOGISCHE BAUSTEINE EINER SMART CITY

Die richtigen Technologien sind von zentraler Bedeutung für die Lösung der Herausforderung, Städte fit für die Zukunft zu machen. Beispiele hierfür sind Gebäude als Kraftwerke, intelligente Energienetze (sogenannte Smart Grids), neue Speicherlösungen, multimodale Mobilitätslösungen sowie intelligente Informations- und Kommunikationstechnologien – all dies sind Bausteine einer „Smart City" mit hoher Lebens- und Wohnraumqualität.

Seit 2007 unterstützt der Klima- und Energiefonds mit seinen Programmen die Entwicklung dieser Bausteine in Theorie und Praxis mit mehr als € 600 Millionen. Mehrere Beispiele aus fünf Jahren Forschung zeigen einen kleinen Ausschnitt aus dem breiten Spektrum an technologischen Möglichkeiten.

3.1 Gebäude als Kraftwerke

In Österreich werden knapp 40 % der Endenergie in Gebäuden eingesetzt. Sie bergen das größte Verbesserungspotenzial im Bereich der Energieeffizienz, um die Belastung steigender Energiekosten ausgleichen und Treibhausgasemissionen reduzieren zu können. Gleichzeitig zeigen Untersuchungen, dass in einem urbanen Stadtteil eine 100 % Gesamtdeckung des elektrischen Energiebedarfs und sogar Überschussproduktion durch den Einsatz erneuerbarer Energie prinzipiell möglich.

Mit SmartCityGrid: CoOpt testet ein Konsortium unter Federführung vom Austrian Institute of Technology (AIT) die koordinierte Optimierung von erneuerbarer Energie in Netzen und Gebäuden anhand der ENERGYBase, SOL4. Es werden optimierte Regelstrategien entwickelt, welche vorausschauendes Reagieren erlauben. Dafür haben sich modelbasierte prädiktive Regelungen (MPC) bereits in industriellen Anwendungen bewährt (z.B. Kraftwerkstechnik). Durch die prädiktive Eigenschaft des Reglers kann auf zukünftige Veränderungen optimal reagiert werden. Dazu sind genaue Modelle und Vorhersagen, etwa von Energiebedarf und -erzeugung, Wetterentwicklung oder Benutzerverhalten essentiell.

Die Sanierung denkmalgeschützter Gebäude auf Aktivhaus-Standard untersucht die Stadt Graz im Rahmen des Forschungsprojekts denkMalaktiv. Die neuesten Technologien werden sondiert, teilweise weiterentwickelt und zu Sanierungskonzepten verknüpft. Die Umsetzung als konkretes Pilotprojekt für ein „Netto-Null-Emissions-Haus" erfolgt am Beispiel des Jugendstilgebäudes Sanatorium in der Schönbrunngasse in Graz. Der älteste Teil des Hauses stammt aus dem Jahre 1885. Das Gebäude vereint Historismus und Neorenaissance sowie einen Bauteil aus 1902-1903 mit ersten Jugendstilelementen.

Beide Projekte wurden im Rahmen des Forschungs- und Technologieprogramms „Neue Energien 2020" gefördert.

3.2 Smart Grids für smarte Märkte

Die Einführung von Smart Grids bietet Zugang zu einer sicheren, kosteneffizienten und nachhaltigen Energieversorgung. Österreich verfügt bereits über großes Know-how sowie Innovationen im Bereich der Smart Grids. Dank mehr als 18 Millionen Euro Forschungsförderung für Smart Grids im Rahmen von „Neue Energien 2020" liegt Österreich EU-weit im Spitzenfeld.

Im Forschungsprojekt ADRES wurde ein Autonomes Dezentrales Regeneratives Energie-System in einem ganzheitlichen Konzept entwickelt und erprobt. Ziel ist das Erreichen von Leistungsautonomie, also jenes Zustands, in dem ein Siedlungskollektiv nicht nur in der Jahressumme, sondern auch in Echtzeit

ausbilanziert ist. Das Projekt wurde interdisziplinär geführt mit dem Institut für Energiesysteme und Elektrische Antriebe der TU Wien als Projektleiter, dem Institut für Energietechnik und Thermodynamik der TU Wien, AIT, Austrian Power Grid (APG), Burgenländische Elektrizitätswirtschafts AG (BEWAG), Energie AG Oberösterreich, Energieversorgung Niederösterreich (EVN) und Wienenergie Stromnetz.

Die Ergebnisse des Projektes in Kurzform sind:

- Dezentrale autonome Energiesysteme sind möglich, aber die Kosten ohne Netzanbindung sind hoch, insbesondere da dann die Speicherung und Backup-Versorgung dezentral in der Siedlung erfolgen müssen.
- Voraussetzung für nachhaltig versorgte Siedlungen ist eine Effizienzsteigerung in der Endanwendung
- Minimale Speicherkosten entstehen bei Erzeugungsmix aus etwa 70 % Windenergie und 30 % PV.
- Tagesspeicher sind kostengünstig, Wochenspeicher und Speicher für längere Zeiträume sind unwirtschaftlich gegenüber einer Netzanbindung der Siedlungen.
- Biomasse eignet sich als Backupversorgung mit der Möglichkeit, Elektrizität und Wärme zu erzeugen.
- Photovoltaik ist zukünftig wirtschaftlich und „lastfreundlich" durch die Tageserzeugung.
- Windenergie ist nur in Großwindanlagen, nicht aber in siedlungsnahen Kleinwindanlagen wirtschaftlich.
- Neben Suffizienz und Energie-Effizienz ist auch Leistungseffizienz zweckmäßig, d.h. die Verbrauchsgeräte sollten in ihrer Spitzenlast möglichst begrenzt sein.

Die Salzburg AG nimmt die Herausforderungen einer integrierten Beatrachtung des Energiesystems an. Alle Projekte, welche die zukünftigen Anforderungen der Energiewirtschaft wie intelligente Netze und Zähler zum Thema haben, werden in der Initiative „Smart Grids Modellregion Salzburg" gebündelt. Für den gesamten strategischen Ansatz wurde Salzburg vom Klima- und Energiefonds als „1. Smart Grids Modellregion" ausgezeichnet. Alle Energieträger und Komponenten von Strom und Fernwärme über Mobilität und Gebäude werden zu einem horizontal und vertikal integriertem Gesamtsystem zusammengefügt. Energiewirtschaft, Wissenschaft, Industrie und Wohnbau ziehen an einem Strang. Dadurch entsteht ein breites Knowhow-Portfolio von technischer und wirtschaftlicher Expertise über Erfahrung bezüglich Nutzerverhalten bis zur Analyse sozio-ökonomischer Aspekte.

3.3 Multimodal ins 21. Jahrhundert

Einer der Kernbereiche einer „Smart City" ist ihr Umgang mit Mobilität und Verkehr: Hier sind neue, intelligente Strukturen notwendig, um die Lebensqualität der Menschen zu verbessern und dabei als Stadt Wirtschaftlichkeit zu garantieren. Die verkehrsbedingten Emissionen sollen laut „Weißbuch Verkehr" bis 2050 um 60 Prozent reduziert werden, konventionelle Autos zur Gänze aus dem Stadtbild verschwinden. Die Verlagerung des Verkehrs von der Straße auf die Schiene und die Integration intelligenter Verkehrskonzepte und -Leitsysteme in Städte und urbane Regionen werden vom Klima- und Energiefonds als Querschnittsthema durch mehrere Förderprogramme getragen.

Mit Projekten wie GIP (Graphenintegrationsplattform), GIP.GV (e-government Lösungen zur Wartung der GIP), VAO (Verkehrsauskunft Österreich) und den laufenden Demonstrationsprojekten wie EFM Modellregion Bregenzerwald, FCD Modellregion Salzburg und Testfeld Telematik wurden vom Klima- und Energiefonds bereits wesentliche Schritte in diese Richtung gesetzt. Das vom Klima- und Energiefonds 2011 gestartete Programm „Innovationen für grüne und effiziente Mobilität" setzt auf diese Vorarbeiten auf und unterstützt Intelligente Verkehrssysteme, die dazu beitragen, die Effizienz und Sicherheit des bestehenden Verkehrssystems zu erhöhen, die Verkehrsnachfrage in Richtung der stärkeren Nutzung umweltverträglicher Verkehrsträger zu beeinflussen und „grüne Güterverkehrskorridore" zu schaffen. Es leistet damit einen essentiellen Beitrag zur Gesamtstrategie für ein Intelligentes Verkehrssystem, das den europäischen Rahmenbedingungen und nationalen Vorgaben entspricht.

Die Einbettung von E-Mobilität in ein Gesamtverkehrskonzept wird im „Leuchtturm der E-Mobilität" eMORAIL aufgezeigt. An zwei Pilotstandorten in Österreich – in der Steiermark und in Niederösterreich –

wird ein integrierter Ansatz zur Verknüpfung des öffentlichen Verkehrs mit E-Mobilität- Services entwickelt, die Grundlagen für einen flächendeckenden Rollout werden geschaffen. Im Rahmen des Internationalen Eisenbahnenverbands in Europa nehmen die ÖBB damit eine Vorreiterrolle ein. Die Entwicklungsschwerpunkte im Projekt beschäftigen sich mit den Dispositions- und Abrechnungssystemen, den Kundinnen- und Kundeninformationssystemen und dem einfachen Zugang zu E-Mobilität für Nutzerinnen und Nutzer öffentlicher Verkehrsmittel sowie der Integration beider Verkehrsleistungen zu einem neuen integrierten Verkehrsangebot. Die entwickelten Lösungen sollen den Kundenansprüchen im hohen Maße entsprechen und den „Open Source"- nspruch erfüllen.

Mit dem Ziel, dass der öffentliche Verkehr noch umweltfreundlicher wird, haben sich die Wiener Linien, Siemens, Vossloh Kiepe, Rail Tec Arsenal und die SCHIG zu einem Konsortium unter Führung von der Technischen Universität Wien zusammengeschlossen. Bis November 2013 laufen Tests im Klima-Wind-Kanal sowie im regulären Passagierbetrieb. In der ersten Phase von EcoTram wurde ein Schienenfahrzeug in Hinblick auf dessen Energieeffizienz der Heizungs-, Klima- und Lüfungstechnik-Geräte durchleuchtet. Aktuell kamen bei einer Straßenbahn energieeffiziente Komponenten zum Einsatz. Sie verfügt über zahlreiche technologische Innovationen, wie eine Wärmepumpe oder eine frequenzvariable Ansteuerung. Die TU Wien entwickelte dafür ein Simulationsmodell für einen Regler, der selbständig den Heiz- oder

Kühlbedarf ermittelt. Bei einfachen Umrüstungen von den etwa 300 „Ultra Low Floor" Straßenbahnen in Wien wären Einsparungen von rund 30.000 t CO_2 pro Jahr möglich.

4 STÄDTE ALS TESTBEDS

Der Schwerpunkt des Förderprogramms „Smart Energy Demo – FIT for SET" liegt auf der Umsetzung im städtischen Kontext – sowohl seitens der Umsetzungsplanung als auch im tatsächlichen Umsetzen integrativer „Smart City"-Lösungen („Städte als Testbed"). Viele Städte Österreichs können hier bereits erste Ergebnisse vorweisen.

4.1 Linz setzt auf Energienetze

Linz ist mit 190.000 Einwohnerinnen und Einwohnern wirtschaftliches und politisches Zentrum von Oberösterreich. Die Industriestadt setzt seit Beginn der 1980er-Jahre energische Schritte zur Verbesserung des ökologischen Umfeldes. Ziel der Smart City Linz " High Level pproach Towards n Integrated Energy Vision 2050, Roadmap 2020 and Action Plan 2015" ist nun eine Bündelung der zahlreichen aktuellen und abgeschlossenen Klimaschutz-Projekte. Bestehende Initiativen zu Smart Metering, E-Mobilität, Energieeffizienz in Gebäuden oder Informations- und Kommunikationstechnologien werden vernetzt und zur Vision einer „Smart City Linz 2050" zusammengeführt. Roadmap und Aktionsplan beschreiben die Zwischenstationen auf dem Weg zur Verwirklichung der Leitziele.

Linz setzt klar auf intelligente Netze (Smart Grids), die auch die Einspeisung von Energie aus kleinen, dezentralisierten Produktionseinheiten (Solar, Wind, Geothermie, Biomasse) bewältigen. Dabei soll die Produktion durch Nachfragesteuerung, über verringerte Verteilungsverluste und verbesserte Koordination der Energieproduktion aus erneuerbarer und fossilen Ressourcen optimiert werden. Der Einbau moderner Informations- und Kommunikationstechnologie in die „intelligenten Netze" erlaubt dabei neue Lenkungs-möglichkeiten auf Nachfrageseite und hat mit dem größten österreichischen Roll-Out – rund 20.000 Smart Meter sind in Linz bereits installiert – vorangehend begonnen.

4.2 Smart Satellite City Deutschlandsberg

Nach der Fertigstellung der Koralmbahn 2020 verbindet der künftige IC-Bahnhof Weststeiermark den Bezirk Deutschlandsberg mit den Zentralräumen Graz, Wien und Klagenfurt. Bei täglich rund 3.000 Passagieren wird dieser Verkehrsknotenpunkt Brennpunkt eines künftigen Stadtteils, der zwischen dem neuen Bahnhof und der 6 km entfernten Bezirkshauptstadt Deutschlandsberg neuen Wohnraum für rund 10.000 Einwohnerinnen und Einwohner liefert. Im Zuge des „Smart Energy Demo – FIT for SET"-Programms wurde eine gemeinsame Vision und Roadmap für das Jahr 2020 und 2050 für Deutschlandsberg und den neuen Stadtteil rund um den neuen IC-Bahnhof entwickelt.

Das übergeordnete Ziel für die ganze Region ist es, zu einem „Greenfield for green jobs and green investments in a green valley" zu werden. So sollten bis 2050 80 % der CO_2-Emissionen von

Deutschlandsberg und der betroffenen Gemeinden reduziert werden. Das neue Siedlungsgebiet rund um den Bahnhof Weststeiermark ist als Null-Emissions-Best-Practice-Beispiel geplant.

Hauptpunkte sind Informations- und Kommunikationstechnologien (IKT) und intelligente Netze, in denen erneuerbare Energien und Speicher integriert werden. Bessere Wärmedämmung bestehender Gebäude und die Einführung von energiesparenden Baustandards soll den Wärmebedarf von Deutschlandsberg und der angrenzenden Energie-Region Schilcherland um 60 % bis zum Jahr 2050 verringern. Zudem soll solarthermische Energieerzeugung bis 2050 auf mindestens 80 % ihres Potenzials ausgebaut sein.

5 CONCLUSION

Seit mehr als vier Jahren arbeitet der Klima- und Energiefonds als zentrales Instrument der österreichischen Bundesregierung für Klimaschutz, höhere Energieeffizienz und den Ausbau von innovativer erneuerbarer Energie. Er hat sich in dieser Zeit als Impulsgeber und verlässlicher Partner für heimische Unternehmen und Institutionen etabliert, die durch gezielte Förderungen ihre starke Position im internationalen Wettbewerb ausbauen und nachhaltige Arbeitsplätze schaffen.

Der Klima- und Energiefonds wirkt mit seinen Förderprogrammen, weil in den Smart Cities mehr als 4,8 Millionen Menschen in Österreich täglich dabei unterstützt werden, eine nachhaltige Energieversorgung für ihre Region aufzubauen und klimaneutral zu leben. Mit diesen Fördermitteln werden heute intelligente Lebensräume skizziert und heimische Forschung und Entwicklung unterstützt, die die Erreichung der Klimaziele erst möglich machen und gleichzeitig die Innovationskompetenz am Wirtschaftsstandort Österreich stärken.

Spatial Planning and Open Space Integration in Urban Ethiopia: a Sustainable Accessibility Exegesis

Tendayi Gondo

(Lecturer Tendayi Gondo, Department of Urban and Regional Planning, University of Venda, Private Bag X5050, Thohoyandou 0950, Limpopo Province, South Africa, gondotee@gmail.com)

1 ABSTRACT

Urban planning practices of many cities are in constant mutation throughout the world. With sustainability as a goal, land use monitoring and regulation is becoming more in demand. This analysis seeks to assess the accessibility and attractiveness of public open spaces in a sample of cities and/or towns in Ethiopia. Specifically, it questions the extent to which Ethiopian cities are designed to human scale. The analysis utilizes data from a series of surveys conducted in four major cities and/towns. A econometric analysis was employed to pool the findings together. Results reveal that most public open spaces are less attractive and difficult to access. Absence of such recreational facilities in many neighbourhoods has seen some households travelling greater distances to access such facilities in other (often distant) neighbourhoods. Three major factors are to blame. These include absence of a land use (re)mixing strategy, weak development controls that have seen some open spaces giving way to illegal land uses and the general absence of quality infrastructure in existing open spaces. The most affected households reside in poor neighbourhoods. The scale of the challenges was also found to be much higher as one moved from smaller cities to much bigger cities. Only a spatial planning strategy that is guided by a known land use (re)mixing strategy would ensure improved accessibility to open spaces. Such an effort however needs to be complemented by strategies that strive to strengthen the current development control mechanisms and the fortressing of open spaces that are under immense pressure from other competing uses. A major facelift on the attractiveness of existing open spaces through the provision of quality infrastructure is also required.

2 INTRODUCTION

Urban planning practices of many cities are in constant mutation owing to a myriad of driving forces. Lifestyle patterns of many cities are shifting to those of a sustainable society (Chiesura, 2004; Burnett, 2007; Ioj˘a, 2011). One notable force is urbanization that has seen the distance between people and the natural space expand (Li et al, 2005). Increasing urbanization trends, have seen nartural ecosystems increasingly being replaced by urban development. One of the most affected component of urban landscapes is open space. Open spaces are part of the urban greenspace that form an important component of the complex urban system. Urban greenspace plays a crucial role through direct and/or indirect provision of essential ecosystem services (Costanza et al., 1997). Benefits that accrue to urban communities are many. Such benefits are often environmental, aesthetic, recreational and economical in nature (Bradley, 1995; Tyrv¨ainen, 2001; L¨utz and Bastian, 2002). Mahdavinejad and Abedi (2011) contend that urban openspaces have an exceptional environmental importance with regard to their contribution to the reduction of various types of pollution and to the improvement of microclimatic conditions. In addition to this role, they also make positive contributions to human health and well being. They also lead to an important contribution to human thermal comfort in exterior spaces (Aravadinos, 1999). Aspects such as “amount of public green spaces per inhabitant”, “public parks” and “recreation areas” are often cited in literature as important factors that make the city liveable, pleasant and attractive for its citizens (Mahdavinejad and Abedi, 2011).

With sustainability as a goal, land use monitoring and regulation of open spaces is becoming more in demand. This is because planning and management of urban greening is of utmost significance to urban sustainable development (Miller, 1988; Grey, 1996; Teal et al., 1998). With this new thinking, it is also strongly beleived that developing more sustainable cities is not just about improving the abiotic and biotic aspects of urban life, it is also about the social aspects of city life (Mahdavinejad and Abedi, 2011). Such a social focus encompasses among other aspects people’s satisfaction, experiences and perceptions of the quality of their everyday environments (Chiesura, 2004). This analysis takes this social inclination by assessing the accessibility and attractiveness of public open spaces in a sample of cities and/or towns in Ethiopia. Specifically, it questions the extent to which Ethiopian cities and/or towns are designed to human scale and/or aspirations. Public open spaces are in this analysis refer to recreational facilities such as public parks, playgrounds and amusement centers and residential gree space.

2.1 Open space management and accessibility issues

The design of public and green spaces has emmetrged and one importatnt area of particular interest for landscape architects and planners in recent years (Oguz, 2000; Chiesura, 2004). It is now beleived that sustainability indicators for urban development should include more parameters about public spaces and green open areas, as well as indexes reflecting citizens' satisfaction and perception of their living environments (Chiesura, 2004). Herzele and Wiedemann (2003) for instance developed an integrated indicator to assess the accessibility and attractiveness of urban greenspace in four Flemish cities. Pauleit et al. (2003) proposed a more flexible approach named Accessible Natural Greenspace Standards Model to promote the natural greenstructure of towns and cities and devised a decision-support framework for its implementation.

Cooper Marcus and Francis (1998) argue that aesthetics are a factor that affects use and enjoyment. Some critiques have argued that the aesthethic/design approach should also be based on function rather than aesthetics alone (Goliˇcnik, 2010). The the utility derived from the open space depends on the distance to and the size of the parcel (Anas, 1978; Wu and Platinga, 2003).

2.2 Spatial planning and open space management

A number of challenges that spatial planners and/or urban designers face in creating inclusive urban spaces for contemporary and future use have been noted by many research scholars (Ward Thompson, 2002; van Kamp et al., 2003; Maruani and Amit-Cohen, 2007; Matsouka and Kaplan, 2008). With regard to the planning and management of public open spaces Goliˇcnik and Thompson, (2010:38) beleive that urban designers are still far from finding answers to the following daunting questions;

- How well to predict the use of spaces they have created?
- How certain they can be that a place designed for certain types of activity and occupation will serve its users' needs well?

It is generally argued that the empirical basis for much of the decision making as it regards the creation of people friendly urban space is often lacking (Forsyth, 2007; Frick, 2007).

The notion that landuse planning could be used to determine appropriate levels of accessibility to different landuse functions is not new (Curtis, 2008). The bulk of such efforts have been encuspulated in discussions revolving around the area of land use transportation integration (Freilich and White, 1994; Kelly, 1994). While there is no concensus as to the ideal urban form – an urban morphology that would achieve sustainable accessibility, there is a general agreement among urban planners and designers that some urban forms are more sustainable that others (Williams et al., 2000; Sorenson, 2001; Hickman and Banister, 2002). It is believed that urban forms that are guided by a sound land use (re) mixing strategy promotes the achievement of sustainable accessibility to public open space.

3 MATERIALS AND METHODS

Since the study is largely an environment – behaviour research, the major research instrument employed in this study was observation. Such kind of studies have long history. Typical studies in the past have always used behavior mapping as a way of understanding the interaction between people and space (SeeIttelson et al. 1970; Bechtel et al. 1987). Such an approach is premised on the fact that there is less recorded on how people use green space and the kinds of dimensions and details that support different uses within such settings. (Lawson, 2001; PPS - Project for Public Spaces, 2005; Goliˇcnik and Thompson, 2010). In addition to observed behavior of space users as well as the recording of size and typology of public open space facilities, a questionnaire was administers to a smaple of random observed space users. This was done to comprehensively capture both that passive and active interaction between people and space. A total of 451 questionnaires were administered with the help of Urban Management Masters (UMM) students at the Ethiopian Civil Service University (ECSU) in 2009. Such a survey was conducted in four selected cities and/or towns – including the capital city of Addis Ababa, the city of Dire Dawa, and the two towns of Nekemte and Chancho. Sample charcteristics and a description of each study area chacteristics is summarized in table 1.

Name of City/town	Number of surveyed open space users	General characteristics of city/town	Urban landscape characteristics charcteristics
Dire Dawa	112 observed space users surveyed in the city's 5 out of 9 kebeles	It is the second bisggest city (after Addis Ababa – the capital). The total urban population is 232 854 inhabitants.	Dire Dawa covers a total area of 128 802 hactares of which 2 684 hactares is urban.
Nekemte town	100 observed space users surveyed in the twon's 7 out of a total of 12 Kebeles	It is the administrative capital of Wellega zone in Oromia Regional State. The town is 331km away from the country's capital Addis Ababa. Its population stood at approximately 76 817 in 2009.	According to the current urban master plan, the town occupies 3 192 hactares of land of whicxh 627 hactares is urban land. Urban agricutures constitute 1.24% of urban land; Urban forest 32.5 percent; Open space 5.6%, Sportfields 0.5%; the built environment 60.1%.
Chancho town	67 observed space users surveyed in the twons 3 out of a total of 5 kebeles.	It is the administrative capital of Gololcha Woreda in Oromia Reginal State. The town is located 307 km to the South-East capital city of Addis Ababa According to the CSA report of 2007, the towns gross population density stood at 1641.1 people per km^2.	The covers apprimately 493 hactares of land.
Addis Ababa	172 observed space users surveyed in a sample of kebeles of the city's 3 out of 10 subcities of Yeka, Lideta and Bole	It is the capital city of Ethiopia. The estimated total population of the city in 2008 was 2 738 248 (FDREPC, 2008).	?

Table 1. Sample characteristics and discription of study area

3.1 Model specifications

The logistic regression model was applied to determine factors that explained why some urban urban citizens define their surrounding public open spaces as accessible. When dealing with a dichotomous dependent variable - the main interest is to assess the probability that one or the other characteristic is present (Peng and So, 2002; Peng et al, 2002). The logistic regression model answers the question what determines the probability that the answer is yes, or no. The special features of the model guarantees that probabilities estimated from the logistic model will always lie within the logical bounds of 0 and 1. In other words the probability that an urban citizen picked at random is defines public open space as accessible is not a continuous variable but a discrete one. The logistic regression model can be expressed mathematically as follows;

$$Y = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + \cdots + \beta_n x_n + ui$$

Where

Y = is the dependent variable (i. e. probability that an urban citizen chosen at random is agrees that the surrounding public open spaces are accessible.

B_0 = is the intercept (constant) term

B_k = coefficients of explanatory variables

X_i = explanatory variables

The aggregate expression of the model can be summarized as follows:

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

$$Y = \beta_0 + \sum_{k=1}^{k} \beta_i x_i + ui$$

The selection of predictor variables was based on the review literature review on accessibility, spatial planning and green space management issues as detailed in the next section. Model variables were therefore defined as follows;

Y = Probability of an urban citizen agrees that the surrounding public spaces are accessible (i.e. probability/Agree = 1)

X_1 = Type of user (1 = occassional user; 10 = frequent user)

X_2 = Typology of public space (3 = public parks; 2 = playgrounds; 3 = residential green spaces)

X_3 = Size of parcel (1 = small; 10 = large)

X_4 = Observed open-space function (0 = serving its purpose; 1 = not serving its purpose)

X_5 = Income status (0 = low; 1 = high)

X_6 = Distance to open space facility (0 = next to neighbourhood; 10 = far away from neighbourhood)

X_7 = Size of urban area (population equivalent on a 5 point likert scale; 1 = small/Chancho town; 5 = large/Addis ababa)

X_8 = Aesthetic appeal/attractiveness of open space (0 = less appealing/attractive; 10 more appealing/attractive)

3.2 Selection of model variables

The choice of explanatory variables was made on the basis of a review of literature on accessibility, spatial planning and green space management. Many scholars beleive that accessibility to public open spaces is a function quality of spatial or land use planning (Hickman and Banister, 2002; Curtis, 2008). There is general consesus that spatial planning approaches breed different urban forms that ultimately govern the resultant level of sustainable accessibility (Williams et al., 2000; Sorenson, 2001). Delshammar (2005) maintains that spatial planning agencies may comprise a wide range of activities directed at open spaces and at users, both indirectly through work performed in public open spaces that users relate to and use and, more directly,through dialog and participation. To this end, increasing user information and participation is seen as central to making it easier for people to relate to and use public open spaces (Randrup and Persson, 2009). Although others beleive that user participation in open space management may be time consuming and expensive (Buchecker et al. 2002; Mabelis and Maksymiuk, 2009), reseaerch scholars such as Jansson and lindgren (2012) maintain that it can assist spatial planning agencies in fostering socially sustainable open space landscapes and processes.

Other research scholars beleve that it is the quality of created open spaces that determine their level of accessibility. Such open space quality attributes are quantifiable, through an assessment of citizen's satisfaction and the general perception of their living environments (Herzele and Wiedemann, 2003; Pauleit et al. 2003; Chiesura, 2004). Such a more aesthetically inclined approach is beleived to be a major factor that affects use and enjoyment of public spaces (Cooper Marcus and Francis, 1998)

Some critiques have however argued that a complete understanding of determinants of public open spaces accessibility should also be based on function rather than aesthetics alone (Forsyth, 2007; Frick, 2007; Goliˇcnik, 2010). The ultimate utility derived from the open space depends on the distance to and the size of the parcel (Anas, 1978; Wu and Platinga, 2003). Level of accessibility to open spaces is also believed to vary according to type of users. Such different user groups can be characterised by socidemographic variables such as gae and income, or whether they are actively or passively using spaces (Jansson and lindgren, 2012). Kaplain, (2001) defined passive users as urban citizens who experience the spaces mentally or visiually.

3.3 Model evaluation

Parameters in logistic regression model were estimated using the maximum likelihood method. The statistical significance of each coefficient was evaluated using the Wald test. In this analysis, the enumerated regression coeficients represent the change in the logit of the probability from a unit change in the associated

predictor, assuming other factors are constant (Gujrati, 2003). The goodness-of-fit test of the regression model in this study was analyzed using;

- The Omnibus test, which is a likelihood ratio chi-square test that test whether the coefficients of the variables in the model are all jointly equal to zero.
- The Hosmer & Lemeshaw (H-L) goodness-of-fit test, which examines the null hypothesis that the model adjust well to the data and
- The Cox and Snell (1989) and Nagelkerke (1991) – two descriptor measures that reveal the amount of variation in the outcome variable that is explained by the models (Long, 1997; Hosmer and Lameshaw, 2000).

The Hosmer & Lemeshow (H-L) inferential goodness-of-fit test yielded a Chi-square (7 degrees of freedom) of 9.296 and was insignificant ($p > 0.05$) suggesting that the model fitted to the data well. Two other descriptive measures of goodness of fit are R2 indices defined by Cox and Snell (1989) and Nagelkerke (1991). Results suggest 35.4% to 56.2% of variations in the outcome (i.e. the probability of a randomly chosen urban citizen agreeing that own public open space is accessible.

4 RESULTS

Results reveal that out of the 451 surveyed urban inhabitants in four smpled cities and/or towns of Ethiopia, a total of 80.3 % beleived that public open spaces were not easily accesssible. A number of constraining factors were discerned. Such constraints were analysed using the binary logistic model. Results are summarized in table 2. The positive beta estimate on type of user implies that people who regularly use observed public open spaces were 1.027 times (ie. Exp B = 1.027) more likely to agree that such facilities were easily accessible that those seldom use them. Such variation in access between active and passive public open space users were however not significant ($p > 0.5$). Accessibility to public open spaces was also found to vary significantly with the typology of public space ($p < 0.05$). The negative beta estimate reveals that public parks were dismissed as highly inaccessible (in relative terms) as compared to play grounds and residential green open spaces.

Another significant factor ($p < 0.01$) was the size of the observed size of the land land parcel. Large public open space facilities were largely dismissed as inaccessible when compared with small ones ($\beta = - 0.655$). Th major agument was that small public open spaces were in relative terms many than the larger ones which were mostly located in few far distant neighbourhoods. From the face value, this might be a reflection of hierarchical distribution of different sizes of open space facility. Further probing however revealed that this was largely a reflection of lack of capacity by planning agencies to provide an adequate supply of such open space facilities.

Study results also revealed that about 31, 9% of the total sample respondennts were using public open spaces where elements of serviing an unintended function were observed and recorded. Such unintended functions included illegal disposal of solid waste, unauthorized urban farming activities, illegal structures (housing and informal business) and livestock grazing. The binary logistic results revealed that respondents who were observed using public open spaces which had an element of not serving the intended purpose were 0.007 times more likly to dismiss the concerned parcel as inaccessible (refer to table 2). Such a finding was very significant ($p < 001$).

Access to public open space was also found to vary significantly with the income status of the user ($\beta = 2.837$; $p < 0.001$). Open space users who belonged to a low income bracket were 17.068 times more likely to dismiss the public open space more inaccessible than those who occupied the high income bracket. This is because the supply of such facilities was very limited in low income residential areas as compared to high income residential neighbouhoods. As expected, open space users who defined surrounding public open spaces as being far away from the own neighbourhoods were 0.082 times more likely to dismiss such facilities as more inaccessible than those who felt that such facilities were within reach ($\beta = -2.5$; $p < 0.001$). The size of the urban area from which the public open space user came from also mattered. Users from the much bigger cities of Addis Ababa and Dire Dawa were more likely to identify their publiblic open spaces as in accessible than those who came from the much smaller towns of Nekemte and Chancho. These results were however not significant ($p > 0.5$). Another significant factor ($p < 0.001$) was the attractiveness and/or aesthetic appeal associated with the concerned public open spaces. Many users felt that the public open

spaces were less attractive and aesthetially appealing. Since the beta estimate is positive, such users were 19.054 times likely to dismiss such public facilities as inaccessible more than those who thought otherwise. Several reasons were advanced. Most users felt that the bulk of public open spaces were not monitored and maintained regularly. Most facilities were characterised as dirty owing to indiscriminate disposal of solidwaste. The supportive infractructure such as access roads, equipment for public tolilets and water taps was also reported to be in dire state.

	B	S.E.	Wald	Df	p-value	Exp(B)

5 DISCUSSION

Despite their utmost significance to urban sustainable development (Miller, 1988; Grey, 1996; Teal et al., 1998), public open spaces are often poorly accessible to many urban dwellers in developing countries such as Ethipia. The use and enjoyment of public open space has been compromised by a variety of actors related to their accessibility. The aesthetic/design approach as expoused by Cooper Marcus and Francis (1998) was found to be a significan factor affecting access to and subsequently the use and enjoyment of public open space by urban dwellers. Most public open spaces in the sampled four towns are from meeting the minimum requirements of sustainable accessibilty as they are poorly designed and less aesthetically appealing. A more functionalistic perspective to utility derived by users of public open space (Goliˇcnik, 2010) revealed that a sizable number of parcels are not serving their intended purpose and are therefore (by implication) excluding other urban dwellers from enjting the benefits from such facilities. Such a challenge – of creating creating inclusive urban spaces for contemporary and future use is not unique to spatial planners and/or urban designers in Ethiopia. Many other research scholars concur that there is a generally high level of uncertainty among spatial planners and/or urban designers that the places they design for certain type of activities and occupation will serve the intended needs of users well (Ward Thompson, 2002; van Kamp et al., 2003; Maruani and Amit-Cohen, 2007; Matsouka and Kaplan, 2008; Goliˇcnik and Thompson, 2010). The mismatch between intended and actual use of public open space in the sample cases presented is largely as a result of weak development control mechanisms, whihas seen illegal land use activities competing for space. Contesting usesing have been in the form orm of waste disposal, illegal land use developments such as informal settlements, informal business, urban agriculture and livestock grazing.

The analysis concurs with findings from elsewhere that the the utility derived from the open space depends on the distance to and the size of the parcel (Anas, 1978; Wu and Platinga, 2003). The hierachical classification and distribution of public open space parcels was however not found to be a plausible expalnation to limited access to large parcels by many users. Rather, results revealed that most municipalities were failing to meet the minimum required ratio standard set by the National Urban Planning Institute (NUPI) a proffesional body for urban planners in Ethiopia. Such supply constraints are on one hand as a result of resource constraints and on the other hand as a result of rising urbanization rates which has seen the distance between urban populations and the natural environment expand in most cities around the world (Li et al, 2005).

The notion that different spatial planning approaches breed different urban forms that ultimately govern the resultant level of sustainable accessibility (Williams et al., 2000; Sorenson, 2001) is not misplaced. This analysis revealed that access to public open spaces in high income neighbourhoods whose urban mophorlogy

was better (in relative terms) when compared to those of low income neighbourhoods were more accessible. Such better urban forms are in part a reflection of the active involvemnt of high income residences in matters concerning the planning and management of public open spaces. Such involvement is crucial as it assists spatial planning agencies to fostering socially sustainable open space landscapes and processes (Jansson and lindgren, 2012).

If sustainable accessibity is to become a reality in urban Ethiopia, a number of interventions are required. At the more operational level, municipal officials should deal with all types of maintenance, upkeep and development of public open spaces. In addition to maintenace of vegetation, there is need for municipal authorities to engage in routine cleaning, installation and maintenance of equipment in all public open spaces. The installation aspect should also extent to creating physical security features that will fortress the bulk of public open space facility to avoid encroachment of other illegal land use activities. At a more strategic planning level and tactical levels, spatial planning agencies in Ethiopia, should encourage more collaboration with public space users so as to align their future spaces with user needs.

6 CONCLUSION

Urban planning practices of many cities today are in constant mutation as spatial planning and/or urban design authorities seek to find sustainable solutions in recreating inclusive urban spaces. Using accessibility to public open space facilities as a predictor variable, this analysi sought assess the extent to which a sample of four Ethiopian towns and/or cities were designed according to human scale and other aspirations. Results revealed that revealed that most public open spaces are less attractive and difficult to access. At a more general level, three major factors are to blame. These include absence of a land use (re)mixing strategy, weak development controls that have seen some open spaces giving way to illegal land uses and the general absence of quality infrastructure in existing open spaces. The most affected households reside in poor neighbourhoods. Only a spatial planning strategy that is guided by a known land use (re) mixing strategy would ensure improved accessibility to open spaces. Such an effort however needs to be complemented by strategies that strive to strengthen the current development control mechanisms and the fortressing of open spaces that are under immense pressure from other competing uses. A major facelift on the attractiveness of existing open spaces through the provision of quality infrastructure is also required.

1 ABSTRACT

Select The City of Bruck an der Mur is located in the alpine space of Austria at the convergence of the rivers Mur and Mürz. As an industrial and commercial centre of the region Bruck/Kapfenberg/Leoben in Upper Styria with a population of about 12.500, the city faces multiple challenges such as a declining population, a dwindling communal budget and competition for space. Therefore, the city council and the mayor of Bruck decided to engage in a multi-stakeholder process within the Fit4Set smart energy initiative (Austrian Klima- und Energiefonds). The objective of that process was to build a new image and work towards a smart city by taking a holistic approach emphasizing urban planning and quality of life aspects as well as energy and resource efficiency issues in order to achieve climate protection. About 30 stakeholders from universities, research institutes, the City of Bruck an der Mur, transport companies, industry, politics as well as non-profit organisations came together to develop the future of the city in an open, participative and creative process.

The stakeholder process was divided into 3 moderated workshops: in a first step, the stakeholders developed a vision as to what the city should offer in 2050. The stakeholders then developed a roadmap listing measures in all urban sectors nessecary to achieve a smart city vision. Lastly, participants drew up an action plan for the immediate future that enables the City to implement a number of innovative and integrated planning measures towards climate protection and a higher quality of life. Before, between and after the workshops numerous, very crucial bilaterial discussions took place between members of the consortium and project management in order to provide room for information exchange, critique and feedback. Project management kept the mayor of Bruck closely informed about all steps throughout the process.

This paper describes and analyses the stakeholder process and provides the lessons learned in the process. These include the importance of involving all relevant stakeholders, the crucial role of trust and open communication and the high value individuals place on quality of life issues and the adaptive approach required by all participants to carry such a process through to the end. The stakeholder process enabled the city for the first time ever to openly discuss critical topics in a large forum and to work toward the common goal of developing a smart city.

2 INTRODUCTION

Amongst other issues, the smart city concept advocates an integrated planning framework at an urban scale and aims at profiting from synergies between strategic measures in different fields of activity. The city of Bruck an der Mur is one of the cities selected for grants by the Austrian Klima- und Energiefonds in the Fit4Set funding framework.

Bruck an der Mur has a population of 12.500 inhabitants and is the district capital of an industry hotspot located at the confluence between Mur and Mürz rivers in Austria. Hence, Bruck an der Mur represents one of the most important traffic junctions in Austria. Its residential areas and industrial structures are strongly determined by its geographical situation, and characterised by great density and only little open space. Due to this situation, public facilities, residential and recreational areas for citizens, commerce and tourism as well as transport infrastructure need to coexist in a sustainable way with industrial and business facilities in a confined geographical area. Beyond this, Bruck an der Mur is confronted with a constant decline in population since the early 1970s. Hence, economics, urban planning and development, buildings, energy supply, mobility, supply and disposal systems as well as communication become central fields of action and need to be considered in an integrated way when it comes to decision making (DiNucci R., et al, 2010). To

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

date, the implementation of such integrated and interdisciplinary strategies has been impeded because of conflicting interests and the lack of coordination and communication rather than due to technological issues.

Therefore, a stakeholder process was initiated to involve all relevant local stakeholders including local authorities and administration, industrial representatives, representatives of local housing companies and political representatives in a process to shape a common vision for the future of the city and draft a set of measures and projects which would contribute to tackle the main issues Bruck an der Mur is confronted with. The aim of the paper is to introduce the stakeholder process which took place in Bruck an der Mur, highlight and analyse the different phases of this process and present some lessons learned.

3 STAKEHOLDER PROCESS

3.1 Role of Stakeholders

The smart city topic is highly integrative and deals with a broad set of issues. Because of its integrative character, many stakeholders from diverse fields and organisations need to be involved very early on in the process and motivated to participate and contribute. Therefore a large number of individuals respresenting a diverse set of organisations were invited to participate in the process. With that the process and decisions resulting from it are better legitimized and chances are much higher that innovative climate protection projects are realised (Nordström, E. et al, 2010). It is crucial to not only involve public authorities, but to also motivate those who will actually have to implement the projects. Those include representatives from industry, hospitals, public transit companies, residential construction companies, real estate companies and developers (Sinning, H. et al., 2011). The term stakeholder takes into account that stakeholders‘ specific interests and their options to act diverge (Albrechts, L., 2003).

The stakeholder process in the Smart City Bruck project included an all encompassing communication and coordination process with workshops and numerous coordination meetings. The following diverse set of stakeholders with different duties, responsibilities and roles was integrated in the process:

- Municipality and associated businesses: project coordination, making available information and documents for appraisals and analyses, critical reflection of the process, developing ideas and concepts
- Technical project team: Analyses, formulating technical requirements, designing communication and cooperation process, developing concepts
- Mayor and city council: political backing and decision-making
- Project Management: networking, organizing the communication and coordination process, lobbying and coordinating between mayor, stakeholder and the project team
- Stakeholders: generation of ideas, critical reflexion, feasibility
- Urban sociologist: motivation, formulating the guiding concept
- Moderation: designing the communication and cooperaton process and selecting methods and exercises for the workshops.

The involvement of these stakeholders in the different phases of the processes in Bruck an der Mur is visualized in table 1.

3.2 Methodology

The stakeholder process lasted about 6 months and consisted of several preparation and research phases and three one to two-day moderated workshops (see table 2) with the objective to develop a vision, a roadmap and lastly an action plan for projects in the City of Bruck an der Mur. In the workshops, most exercises were done in small groups of 5-8 persons and the results were then presented to and discussed in the plenary. Participants from the following organisations belonged to the core project team (Unversity of Leoben, AIT, the City of Bruck, Stadtwerke, Mürztaler Verkehrsbetriebe, verkehrplus GmbH, Voest Alpine Austria Draht, Norske Skog, LKH Bruck, Biomasse Heizkraftwerk). In addition to that, non-profit organisations, sociologists and members of city council also participated in the workshops. All participants acted as multipliers in their respective organizations and were instrumental in conveying the message to those who were unable to participate.

Most workshop participants demonstrated from the very beginning a strong interest in the process and a high desire to achieve results that would further the interests of each stakeholder and his/her organisation as well as the city of Bruck. Some participants initially were hesitant with their contributions and had to get used to working in this very open, participative workshop atmosphere. Discussions were at times highly controversial which is typical for stakeholder processes (Maguire, B., 2011). The mayor personally supported the process and participated part time in all workshops. The following table illustrates the main methods applied during the process.

Stakeholder process phases, dates and number of participants in the workshops	Municipality	Technical project team	Mayor	Project manager	Stakeholders	Urban Sociologist	Moderator
1 Coordination phase	■		■	■			
2 Kick-off Meeting	■	■		■			
3 Workshop 1, Oct. 3-4, 2011 (40)	■	■	■	■	■		■
4 Coordination phase	■	■		■		■	
5 Workshop 2, Nov. 10-12, 2011 (30)	■	■	■	■	■	■	■
6 Coordination phase	■	■	■	■		■	
7 Workshop 3, Dec. 20, 2011, (30)	■	■	■	■	■	■	■
8 Coordination phase	■	■	■			■	

Table 1: Integration of stakeholders

Workshops/Date	**Methods**
Coordination Phase 1	Data gathering, stakeholder coordination, workshop preparation
Workshop 1 - Vision, Oct. 3-4, 2011	'future conference'- holistic, systems-oriented, topics covering past (last 10 years), present, future **Small group sessions => vision**
Research phase 2	Data gathering, data analysis, energy and CO_2 emission modelling, bilateral discussions between project partners, interviews, sociological analysis, workshop preparation
Workshop 2 .- Roadmap, Nov. 11-12, 2011	Sociological analysis of Bruck an der Mur Energy demand and supply scenarios until 2050 and assessment in terms of CO_2 emissions Travel demand and traffic emissions model (CO_2) for all modes World Cafe, small group sessions **Assessment of all measures => roadmap**
Research phase 3	Bilateral discussion, needs analysis of town segments, workshop preparation
Workshop 3 – Action plan, Dec. 20, 2011	Presentations, small group sessions Determining requirements for all 5 geographic areas **Concretising of 5 project ideas => action plan**

Table 2: Methods applied during stakeholder process

3.3 Results

The results of the workshops as illustrated in table 3 below reflect the diversity of participants' backgrounds and interests. The holistic approach with the focus on achieving a high quality living and working environment in an attractive location for business, living and recreational activities was carried through the entire process. The overarching issues of a shrinking and ageing population and the high level of industrialisation were driving discussions and the need for changes in the urban environment. Energy and mobility issues were considered important, but only two of many topics that needed consideration. During the workshops, it repeatedly became evident that the smart city concept with its focus on integrated urban planning provided a very good basis for discussions and an opportunity to take into account a broad set of topics. Participants expressed the wish to implement many of the smaller project ideas generated during discussions even without external funding opportunities.

Workshops/Date	Results
Workshop 1 - Vision, Oct. 3-4, 2011	**Past and present**: major issues- demographic change, social and societal issues, economic needs and employment, traffic and mobility, energy, politics, financial markets, construction/living situation, health, quality of life **Future – Vision**: alternative forms of energy and combinations thereof, cultural and creative think-tank, excellent education opportunities at all levels, new living facilities, new mobility concepts, public participation, concept 'kurze Wege' (small distances), need for a change in values
Workshop 2 .- Roadmap, Nov. 11-12, 2011	**Guiding concept** – Lebens(t)raum am Fluss (living along the river – a dream come true)-all other issues were fit into this concept **Energy demand** and **supply scenarios** presented in terms of CO_2 emissions: Industrial energy use 8 times higher than residential energy use, separate scenarios for both sectors **Multi-modal traffic demand model** for Bruck an der Mur: CO_2 emissions for all modes presented **Measures for roadmap** developed and assessed in following areas: mobility/traffic, energy/energy efficiency, renewables, industry and urban planning
Workshop 3 – Action plan, Dec. 20, 2011	Bruck an der Mur divided into **6 geographic areas**: Grazer Vorstadt – smart economy, Altstadt – smart downtown, Bahnhofsviertel – smart mobility, neuer Siedlungsraum –smartest living, bestehender Siedlungsraum – smart living and Gewässer – smart streams – developed requirements and needs for each area Five **potential projects** discussed in-depth: -Eco-electricity for households: 100% of households obtain electricity from renewables -City reframing: telemetric approaches, public participation, public space central -Smart climate place: telemetric approaches, regional products -Mobility management: improve public transit connections, reduce automobile traffic, find innovative multi-modal options -LED for public streets: install LED in public places to improve lighting

Table 3: Results of Workshops 1-3

4 LESSONS LEARNED

A number of crucial lessons can be drawn from this stakeholder process and applied in similar activities in other communities. The outcomes may lead to concrete demonstration activities in the future. The stakeholder process can be considered successful for the following main reasons:

- Stakeholders: a large number of stakeholders from various different backgrounds and organisations were involved early on in the process, attended all three workshops and were very much engaged in the at times controversial discussions. This did not only guarantee that they felt included and could contribute, but it also helped legitimize the process and enabled stakeholders to bring in their individual knowledge and interests. During the process, it became transparent that a lot of ideas could not have been developed without the power of collective knowledge of all stakeholders. Because of an open and adaptable process design, stakeholders could also develop trust and become used to the process and each other.
- Professional moderation: the moderator provided appropriate and flexible methods depending on the needs of the stakeholders and the process in order to achieve the objectives set during the three workshops. She also set the stage for a very open and transparent process during all workshops.
- Project management: the project manager was highly engaged, professional and diplomatic and knew the city and ist political environment very well. He also was well-known in the community. He spent a lot of time in bilateral discussions between workshops with project partners to inform, gather data and develop project ideas. He also regularly informed the major about current project activities and new and potenially sensitive information to ensure project success.
- Sociological impetus: the stakeholders became highly motivated when an urban sociologist provided input to workshop participants as to how the city might be able to change its image from an industrial town to an attractive town along rivers and provide better access to them. He also emphasised the importance of public participation in the urban improvement process.

- Building on strengths: Bruck an der Mur benefitted from being able to build on existing activities. A lot of activities such as increasing the capacity of the biomass district heating plant, suggestions to improve energy efficiency from industrial partners, refurbishment of the train station and associated mobility-related project ideas as well as ideas to improve the attractiveness and livability of the town to turn it into a more viable business location had already been in discussion or under way.
- Focus on holistic, integrative urban redevelopment: issues surrounding the topics of energy and mobility only played a minor role. Those topics could have played a much more prominent role given the fact the project was mainly aimed at considering energy and mobility issues. Instead, it was much more important to all stakeholders to view the city as an urban environment with a broad set of issues that should all be looked at simultaneously in order to find viable long-term solutions. Participants wanted to work toward a higher quality of life in the face of a shrinking population, a dwindling communal budget and economic competitiveness in the region. During the discussions mobility and energy topics were woven into project ideas rather than being the drivers for specific projects.
- Funding impetus: it needs to be stated very clearly that this process and with it the opportunity to renew the city of Bruck would never have taken place without the funding impetus provided by the Fit4Set programme. Given the budgetary constraints in communities at the moment, initiatives such as this stakeholder process or the construction of demonstration projects would never have occurred.
- Large pool of project ideas: aside from the actual project ideas relevant for the next call, the stakeholders developed numerous project ideas that can be developed step by step in the future. They vary in size and financial volume and most of them will require additional public or private funding. Nevertheless, some like providing better access to the river Mur at some key access points could be implemented very soon. Both, big demonstration projects and small projects all work toward the common objective of achieving a high quality of life in a high quality environment where the rivers and streams play a much more prominent role.

5 CONCLUSIONS AND NEXT STEPS

The city of Bruck an der Mur is a highly industrialised city facing demographic problems such as a declining and ageing population, competition for space and budgetary constraints. In an effort to reduce conflicts and find viable, long-term solutions, the city engaged in a large stakeholder process involving a variety of local stakeholders including the city of Bruck an der Mur, city council, industry, business, energy providers, public transit companies, mobility firms, non-profit organisations, research organisations, and universities. In the course of the 6 months long stakeholder process dealing with urban development and climate protection issues, stakeholders developed a vision for 2050, a roadmap and an action plan for a smart city.

The smart city approach offered a new way to find integrated and interdisciplinary solutions to existing problems. The holistic approach allowed all stakeholders to develop interlinked ideas for the entire urban region and to take advantage of synergies when applying measures in different fields simultaneously toward the same objectives.

Lessons learned from this process are numerous and can and should be considered in similar processes in different communities. They include the important role of a diverse set of engaged stakeholders who have the opportunity to contribute in an open, engaging and trusting environment. Project management was instrumental in keeping all participants informed, passing along new and sensitive information when appropriate and involving key individuals. An urban sociologist provided highly motivating input and a guiding concept (Lebens(t)raum am Fluss) that was carried through the entire process and will certainly live on even beyond this project.

5.1 Next steps

Bruck an der Mur submitted a proposal in the second Fit4Set programme call which focuses on the historic town centre of Bruck an der Mur with its large urban development potential. The project „Smart historic site Bruck an der Mur“ will deal with climate protection and restructuring and refurbishing parts of the existing old town. An integrated planning concept with interlinked demonstration projects in the historic old town is supposed to show how climate protection measures and measures to improve quality of life can counteract

population decline. The following topics will be dealt with integratively in the project: mobility management, creating attractive public space, energy networks, communal supply and disposal systems, buildings as well as information and communication technologies. It is also planned to intensify communication with the population, because everyone's life style (consumer behaviour, mobility, leisure activities) determines the success of local climate protection and quality of life measures.

Sustainable Urban Development in Germany in the 1990s – a Situation Report after 20 Years

Axel Laistner, Hermann Laistner

(Dipl.-Ing. Dr. techn. Axel Laistner, axel laistner consulting UG(hb), Rosenstraße 6, 73466 Lauchheim, axel.laistner@laistnerconsult.de)

1 ABSTRACT

Already in the 1980s the subject of sustainable urban development was a recognised and coming issue. In this process significant research and development work was done by the now defunct company of POET GmbH and the IfEU GmbH first in West Germany and later also in the eastern parts of Germany. Coming from a solid engineering foundation of project work and research into the structure and efficiency, especially regarding energy and environmental issues, as well as the community political processes, they were among the pioneers of public-private-partnering in urban development. The two companies found themselves in a unique position to react to the German reunification and the ensuing period of transition, to use the unhoped for degrees of planning and development flexibilities.

Now – almost 20 years later – we can look at some of these research and development projects, and have a first discussion on their sustainability success. In this paper and the accompanying presentation, we will take a research project from western Germany (1986 to 1995), the developing understanding of which went directly into the design and execution of a real urban development project in eastern Germany (1991 to 1994), and look how the latter has stood the test of time over 20 years.

What can be learned when comparing the original thought processes with the current status of reality? All these projects were both situation driven (in time and in space), and implemented the developing knowledge on sustainability, as a methodology to ensure project longterm success.

Having been party to this process, as managing employees and researchers in these companies at that time, and having access both to the documentation and other then leading engineers and planners involved, the authors can give a unique perspective covering the whole time period.

At present a new relevance developes in this activity field. The current urban development schemes in China, India and many other places of the world are of such scales, that questions of doing it right, while doing it timely, are of prime significance. At the same time, we are facing a situation, in which within the coming 40 years the whole energy supply and distribution system of the world – including China and India – will need to be 100% restructured and reworked. We need a whole new quality of urban flexibility, and a resurgence of a full consideration of the human scale, even in gigantic projects, to achieve the path to urban sustainability.

Taking proven experience in sustainable urban development and engineering, what will be the tasking and quality expectation of urban design and development in the coming years and decades? System changes will require mental, philosophical, and educational changes in human minds, encompassing developers, planners, architects, and engineers. So, what do we need to learn, and how do we teach it, fast and to many humans, in a short time?

2 BASELINE THOUGHTS ON ECOLOGY IN URBAN DEVELOPMENT – A SITUATION APPRAISAL OF THE DEVELOPING UNDERSTANDING IN THE 1980S

Starting with the Club of Rome "The Limits to Growth"[1] in 1972 a period of developing consciousness on the unsustainability of western societies' urban developments ensued. This was characterized by a multitude of developing descriptions for problems, solutions, and designations for whole fields of interest. Nomenclature and its meaning was and is still in a state of partially defined flux – misunderstanding and misrepresentation abound(ed). Then in 1987, the world first learned the meaning of the word sustainability and the multitude of its facets in the UN Brundtland Report .

Words like "environmental", "ecological", and then even the then new "sustainable" were and are used sometimes interchangeable. Very often with different understandings of their meanings and definitions, especially as pertaining to different trades, and in different languages and cultures.

[1] for our pathway to experience see the reference listing on publications and projects provided for the subjects "sustainable urban planning and engineering" and "energy systems and waste management" at the end

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

For the reason of retaining a reflection of this state of affaires, in the following appraisal of the time, the words "ecology" or "ecological" have been retained – even though by today's understanding it would be more often be replaced by "urban sustainability", "environmental sustainability" or "sustainability" (without qualification).

During the mid 1980s Hermann Laistner approached the field of sustainable urban development with an interdisciplinary experience, gathered by actively developing the area of "energy efficiency consulting" through a series of research and pilot projects starting in the late 1970s. He was selected as the key researcher, developing the chapter on urban supply systems, within the team and scope of a German federal research project on "Ecology in Urban Zoning" (Ökologie in der Bauleitplanung) .

Within this technical field at that time, the traditional biological definition of "ecology" was found to be unsuitable to the application on human society and infrastructure. A new approach to the definition of "ecology" needed to be found and developed. Our situation appraisal and train of thought back then was:

The central European landscape, dominated by civilization, is endangered. The consequences of uncaring use of the available natural resources by the industrialized civilization are visible and undeniable. Even more troubling are the reactions of soil, water and athmosphere to the continuouse careless production of artificial products, with the most varied characteristics. It therefore must be the tasking of future human action to protect the still remaining resources from complete depletion and devastation. This demands a careful approach, and the limiting of needless use, as well as the reclaiming and reuse of our process materials.

The civilized landscape, created by humanity, is no longer capable to cope with the effluents of our industrial societies. Product and contamination concentrations in soil, water and atmosphere grow steadily, and our so called "clean-up measures" don't eliminate them, but simply transfer them from one carrier medium to another. Our aim must therefore be to keep the production of materials, and therefore the number of material transformation processes, at a low level. This is not the call for "back to the stone-age", but the tasking to our highly industrialized society to set it's aims towards preferably innovative and efficient future developments.[2]

From this analysis the technically founded working-definition of „ecological" became:

"Avoid and reduce the material transformation processes, while at the same time develop and strengthen mitigation mechanisms"

By now this has developed into the "mantra" of the energy managerment engineers:

AVOID – REDUCE – COMBINE

A principle just codified in the last two years in the ISO 50001 and EN 16001 standards on Energy Management Systems.

Back to our situation appraisal between 1985 and 1996. Upon closer inspection, the applications of this working definition onto the field of urban development were found to be many, and can only be charactericed in short hereafter.

3 OUR STARTING POINT – AN ECOLOGICAL EVALUATION OF PUBLIC SUPPLY/DISPOSAL NETWORKS – THEN AND NOW – A SHORT APRAISAL OVER 20 YEARS

Being engineers, trained in the technical aspects of urban and energy systems, our approach was to inspect our everyday technical supply system structur in a first step.

Starting with considering the aspects of soil protection, our attention was drawn to the there burried pipes and cables of public supply systems. Taking up the discussions on leakage and enroute losses, new demands on the line quality, leakage protection, as well as regular maintenance were developed as a first step. This however proved to be only an intensified system of fault detection and repair, of our urban buried systems, existing in general below our public roads and walkways. Overall, this encompasses not only operational pipe and cable systems, but a multitude of historical relics.

Digging up holes regularly seems to be an unavoidable result of this historically developed system.

[2] Citation from „Der moderne Infrastrukturkanal" published 14.04.1993. chapter 1. Einführung in das Thema – translated 2012.

3.1 Water Supply Systems

The existing system in many industrialized countries was and is largely non-sensical. It carfully extracts raw water out of the ground, streams and lakes, then processes and desinfects this raw water carefully to the highest quality potable water standards. Then we use it undifferentiated for hygienic and cleaning applications, as well as for toilet flushing, car washing, industrial applications, and irrigation, or fire fighting. The large majority of those applications do not necessarily need hygienic potable drinking water.

A differentiation according to water use is needed. This then leads to the installation of rainwater runoff collection in cicterns of single houses or whole developments. Or as very widely used in dry climates the grey water collection for black water flushing use. However driving this technology is the growing scarcety of water in ever larger areas of the world – not in, nor by, the still "water fat"[3] industrial countries.

3.2 Sewage and Precipitation Drainage Systems

Especially in southern Germany, the wide spread combination of sewage and rain water drainage in one pipe still existing is technically obsolete, but historically and fiscally at present not correctable. The separation and treatment of household black water from precipitation run-off must be instated now in accordance with law, while just 20 years ago this was just the reverse. In modern systems black water needs to be directed in as concentrated form as feasible to treatment plants, well contained and monitored. While precipitation runoff needs to be dealt with as local as possible. In principle precipitation water should be retained locally even in urban sealed areas. Meaning – as far as a suitable geology is present – soil infiltration or surface run-off in open ditch systems, preferably unpaved and planted, into natural run-off beds.

3.3 Waste Disposal

The undifferentiating throw-away and cover-up depositing of wastes of all kinds, still prevalent in Germany throughout the 1980s and 1990s has been replaced by a whole industry of waste processing, geared for profitable recycling of materials. However, as long as the so called "thermal reuse" of materials is classified as a form of recycling of materials at present, we have still have a ways to go. Only the non reusable waste components should be burned for heat and electricity generation. Burning it in our definition book means destroying any materials' useful characteristics – and that we don't classify as recycling unless heat energy it is the only useful characteristic remaining in a collected material.

3.4 Heat Energy Supply Systems

Historically one can see that the generation of heat energy came from old wood stoves, through the fossil fuels coal, oil, and gas and now increasingly returns to regenerative carbon e.g. wood pellet, bio gas, and solar thermal systems as heat source. This exemplifies the increasing importance of the renewable resource of our forests.

Using the heat potential of our excess heat in industry and in the generation of electricity has spawned both metropolitan urban district heating networks, but also smaller more rural network sizes fed by Building block heat-electricity co-generation plants. By now whole villages are being supplied with heat and electricity by such plants using biogas as renewable fuel. Currently a whole new structure of debates and applications develops in this area.

3.5 Electrical Power

Up until a few years ago, ever since the 1930s, industrial countries have developed a highly centralized electrical power production, and large interconnected distribution grid systems. Power plants were for a very long time thought to be only efficient and profitable, if they reached a certain economy of scale. Using our traditional system of economic evaluation – which blatantly disregards any and all environmental issues other than raw material extraction and those that produce an accountable bill – huge burdens coming from this scaling up were non-chalantly postponed into the future. World wide we still don't face up to the fact, that nuclear reactor waste is an as yet TOTALLY UNSOLVED engineering problem, with us for only 60 years now. The issue of fossil fuel induced climate change is just beginning to make headways into peoples minds.

[3] "water fat" is a wording created by Frank Herbert in his novel "Dune". It signifies the unconscious and uncaring dependency on the plentiful availability of water by a society and its members.

At present however, we see a wide scale restructuring of decentralized energy production happening in Germany and various other European countries. This actually mostly stabilizes the local electrical networks, as less electricity has to be transported to the consumers through the long cables from the central grid elements. However, localized and at times of low demand and high production of e.g. wind or photo voltaic generators, the electricity systems require a whole new system of grid management architecture.

3.6 Telecommunication

In the 1980s West Germany was just at the beginning of implementing the then "new" technology of cable TV. Telecommunication was solely copper cable based and for most of the country and the world limited to twisted pair analog telefone lines. In the 1990s it already became very clear, that with the coming IT network technology and the new glass fiber transmission technology a wholesale effort of "recableing" of Europe was needed.

Now we can use every cable and the "airwaves" for communication, and we have in many places a plethora of choice regarding providers and technology. In fact we see a return to the combined service provider of telephone, TV, IT and mobile communication in out technological societies. These competing communication companies now strive to cover economically as much turf = people and businesses as possible, driving again a recabling and growing antennae-jungles of multiplicity in the name of competition ideology.

Any understanding, that the product needs competion but the pathway doesn't, so prevalent in roads, rails, gas-pipes and electrical power grids, is totally lost on that business area of our societies. In effect – while the power consumption of our individual appliances has continually and significantly been reduced over the last 20 years, the IT revolution has ensured, that we still need more electricity than ever before – because we all need to have so many computers and IT gadgets more, to "survive" our daily toils nowadays.

3.7 Reviving an old idea – Utility Tunnels

Remembering the above definition of ecology, an observable, simple to check urban supply system should be our aim. And, not surprisingly such systems exist, and have proven their usefulness since the middle of the 19th century. They even have a name: UTILITY TUNNELS. Today they are mostly used in industrial facilities and within large public infrastructure like universities, airports, hospitals, or civic centers.

It is however noteworthy, that even though many such systems exist in the public spaces in the former eastern block countries, this subject has been virtually banned from the education and training of urban engineers and city planners. In all of Germany, Austria and Switzerland, to our knowledge, no focused academic courses are currently in existence on this subject. This serves to illustrate that the ecological working definition of avoid, reduce, and innovate has not yet even sustainably reached the academy.

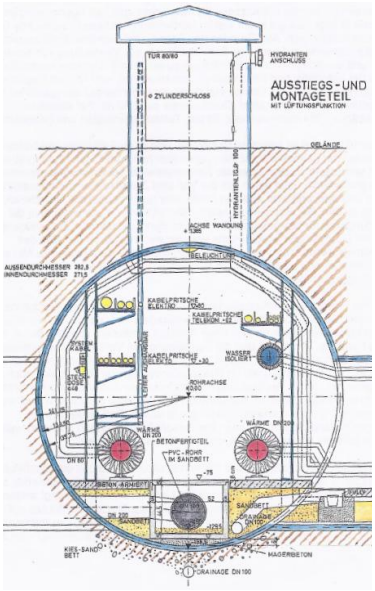

Fig. 1: Sustainable underground system development for urban development area = the utility tunnel picture excerpt from research final report Abb. 17,

Coming from the system analysis above, within the research project "Ecological Business Park Mainz-South" (Ökologischer Wirtschaftspark Mainz-Süd) executed for the Federal Ministry of Construction (BMBau) from 1986 until 1995, therefore not only sustainability aspects of the urban surface development were considered. A significant chapter was reserved on how to better, and more long-term sustainably, deal with all the "stuff" we burry in the ground. The old idea of the "utility tunnel" (Infrastrukturkanal, Leitungsgang, Werkleitungsstollen, Sammelkanal, Kollektor, urban galery, common duct, galerie techniques, just to cover some of this technologies' names in at least 3 languages) which has been successfully used since 1865 in Europe was reconsidered and creatively applied to the research project. To this and its effects see more in the presentation "Utility Tunnels – proven sustainability above and below ground" by us in these same conference proceedings.

Suffice it to say here – we've sucessfully achieved REAL NO DIGGING situations in urban development (meaning also – no horizontal boreholes), achieving longer road surface stability and other benefitial effects.

4 URBAN DEVELOPMENT – FROM "STRENGTHENING THE COMPENSATION FUNCTIONS" TO "SUSTAINABILITY DESIGN AND OPERATION"

Within the above cited federal research project "Ecological Business Park Mainz-South"5, the initial question was:

"Why do business and industrial areas so often degrade into industrial wastelands – which then have to be expensively cleaned up and recycled?"

The contrast to housing developments, which retain or even rise in value during their time of use, is evident and striking. In the process of developing the research project we went, together with the other involved partners, especially the City of Mainz Planning Authority, through various planned steps to come to valid results. Towards the midterm of the project a situation developed unexpectedly, called "the German reunification", that enabled us (POET mbH as Designers & IfEU mbH as Researchers) to implement the just gained insights in a real East German development project – the Business Park Wachau North – located now in the City of Markkleeberg, directly south of the City of Leipzig in Saxony .

This paper will in the following describe the considerations developed in Mainz-South, while the congress presentation accompanying it will show their implementation at Wachau-North and how the area has stood the test of time over 20 years. Short conclusions on the individual success or applicability at the Wachau project are the end of each chapter

4.1 Laying the Base – Understanding the Situation

The initial step performed in Mainz-South was an in depth ecological situation analysis performed by the project partners "ifp – Institut für Planungsdaten – Offenbach", "igi – ingenieurgeologisches Institut S. Niedermeyer – Westheim", and "IfEU mbH". An intensive involvement of many branches of the City of Mainz administrative offices brought to the table considerations and aspects of demography and statistics, economy, traffic and transportation, tourism and recreation and many more.

This in depth look at the whole area of the southern city and open areas up to the next built up neighbouring communities on all sides was the foundation of all future considerations.

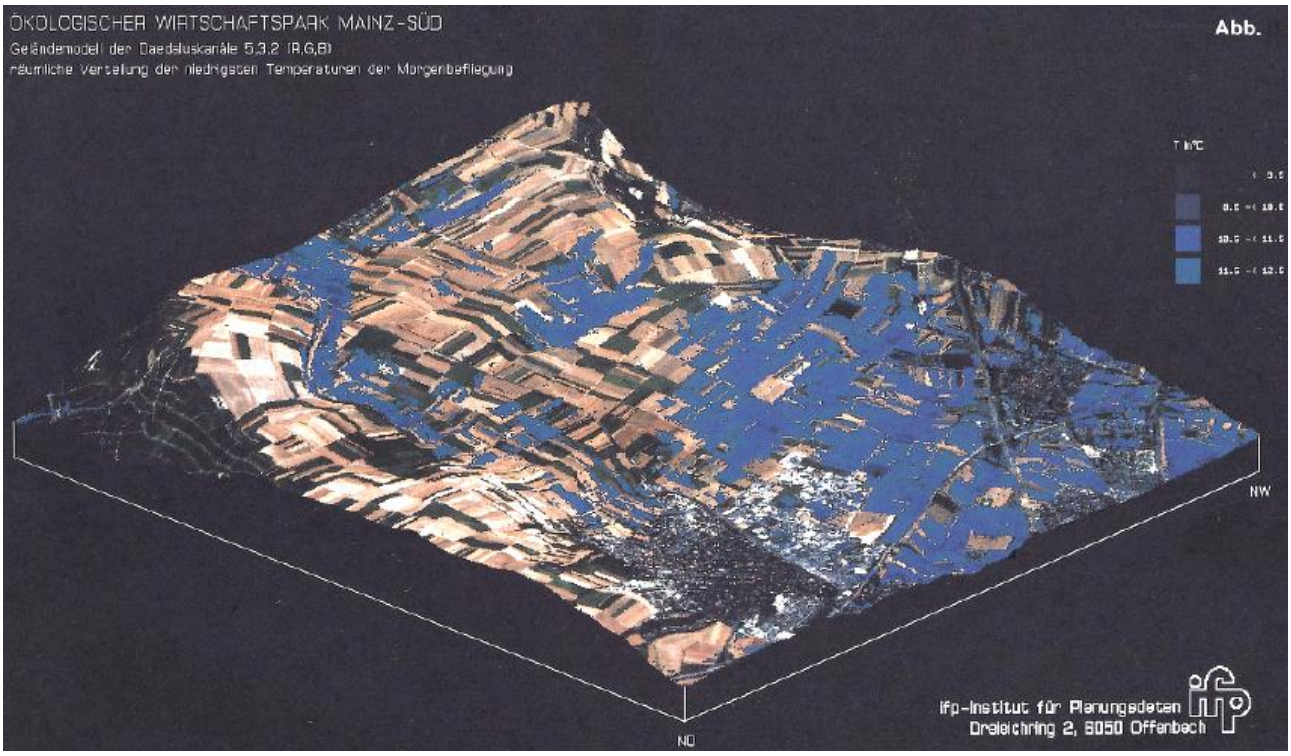

Fig. 2: Ecologically considered area in relation to identified urban business/industrial development area. sketch overlay on picture excerpt from research final report5 Abb. 3

At the time this was begun in 1986, this kind of initial study was not necessarily yet part of the normal process of developing an urban zoning at all. This research project was intended to produce an example documentation for others, later to be copied: how to conduct such an in depth effort. Therefore it was important to identify a complete situation picture regarding hydro-geology, climate impact on temperatures and ventilation, topography, biotopes and biotope potentials, and identification of possible business areas and compensating green or open areas to create a sustainable end solution. Nowadays this scope would still be widened by a consideration of endangered or protected species in the areas.

This is the only step that was not equally performed in Wachau, as by the time of our involvement the detailed development area there had already been defined and partially marketed to investors.

4.2 Sealing the Landscape = Contaminating the Ground

A first analysis came to the conclusion that the unattractive but “seemingly” practical approach of total surface paving had to be considered to be one of the main reasons for the business areas' decline into wastelands. It maximizes technical surfaces that need expensive maintenance (always in short supply in competitive environments). It also maximizes and focuses run-off, which in turn leads to both flooding effects downstream, and the concentration of contaminations at main leakage or seepage points. Rendering parts of the areas virtually useless because of "health hazards" after sometimes surprisingly short times. These effects are compounded by the VERY WRONG assumption of most people operating and working in such sealed surface areas, that "a little spillage is alright – it can't go into the ground anyway".

The longer this process, the worse, and worst of all – our long term involvement with sewage systems taught us – is the military operator. Regardless of nationality or ideology, they are closely followed by the energy production and chemical industries. National security and easy subsidized profits seem to trump all considerations – and the results are accordingly, as we've continuously found through all the various conversion, survey and design projects over now a 40 year plus period of engineering lifes.
This insight led us to the planning approach for the open ground – limited surface paving – conception of Mainz-South and the susequent execution of this at the Business Park Wachau-North.

4.3 Defining the Urban Structure and Access

As with any urban development an initial urban access structure was developed, considering transportation systems (road axes, public transport, parking), and urban gravity center structur.

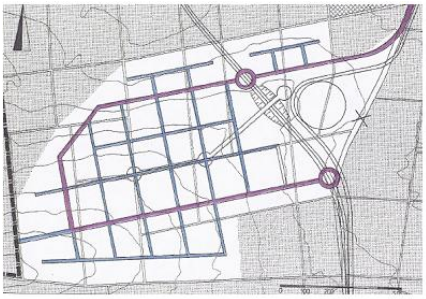

Fig. 3: road grid

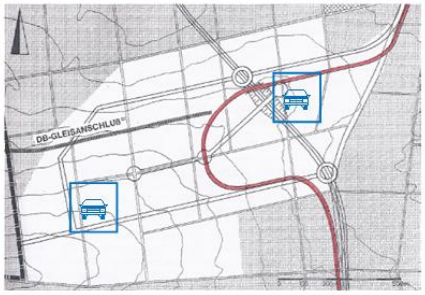

Fig. 4: public transport (rail) & parking

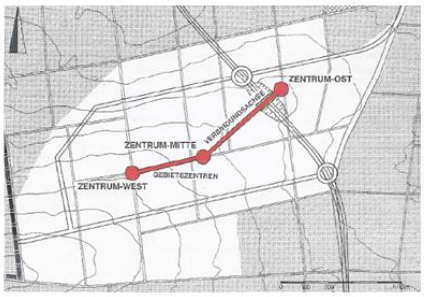

Fig. 5: centres structure

of the urban business / industrial development area
picture excerpt from research final report[5] Abb. 11, 12, 13, 19

An important consideration for urban sustainability, it turns out, is to consider the need of humans, to need places of "interest" to congregate. It helps to consider compatible and non compatible functionalities, and then develop focus points within the access grid, that are helpful to the users, e.g. to use sustainable transport, to switch from an access to area transport mode to an inside area transport mode, to find other facilities that enable secondary tasks like shopping for food on the way to/from work, etc.

Regarding the acceptance of urban mass transport or other public transport, understanding the "human" limitations on the acceptance of such systems, and the direct dependence of human decission making on the subjectively experienced level of comfort of the individual is crucial. To successfully develop a transportation access mix for any business or industrial area, which is not automatically heavily biased towards the use of cars for all other comers by the required road dimensions for trucking access is not a trivial issue.

Urban/rural comparative experience shows that car use for short to medium distances of travel correlates very closely with the availability of easy parking at both ends of the way. For people to consistently forego the use of their cars, requires parking problems at both ends, but ALSO very comfortable, preferably more direct public transport AND pedestrian routes to and from the stations. The later possibly at least with some consideration as to adverse weather conditions, the former definitely at an adequately cheap fare price in relation to the average income.

Only if MOST or ALL of these conditions are met, will people even consider to forego using or even having a car – if their affluent enough to own one. Building a public transport system with stops every few kilometers, at city quarters, without walkways and in subtropical climate – as can be observed lately in Dubai UAE – will not decongest the road system. While building covered and weather protected walkways through building blocks and independent from the roads, as can be seen in Montreal Canada for many years now, will keep people using urban transit even in the dead of a Canadian winter. So pedestrian ways need not and should not necessarily follow roads. As feet are not round – we should all know and understand this.

And in Wachau in 1991, we also were still relearning these facts. So while the internal pedestrian routes are adequate and both bus and tram access or border the area, most traffic there is still by car, but numbers of public transport users are slowly growing – both due to increasing economic difficulties of the population and due to service improvements by the public transport operators.

4.4 Using Green Elements

as Long-term Structuring Design Elements

by making a concious decission to integrate open surface – high quality green corridors as value retaining elements into the urban zoning design of a mixed business and small industry development.

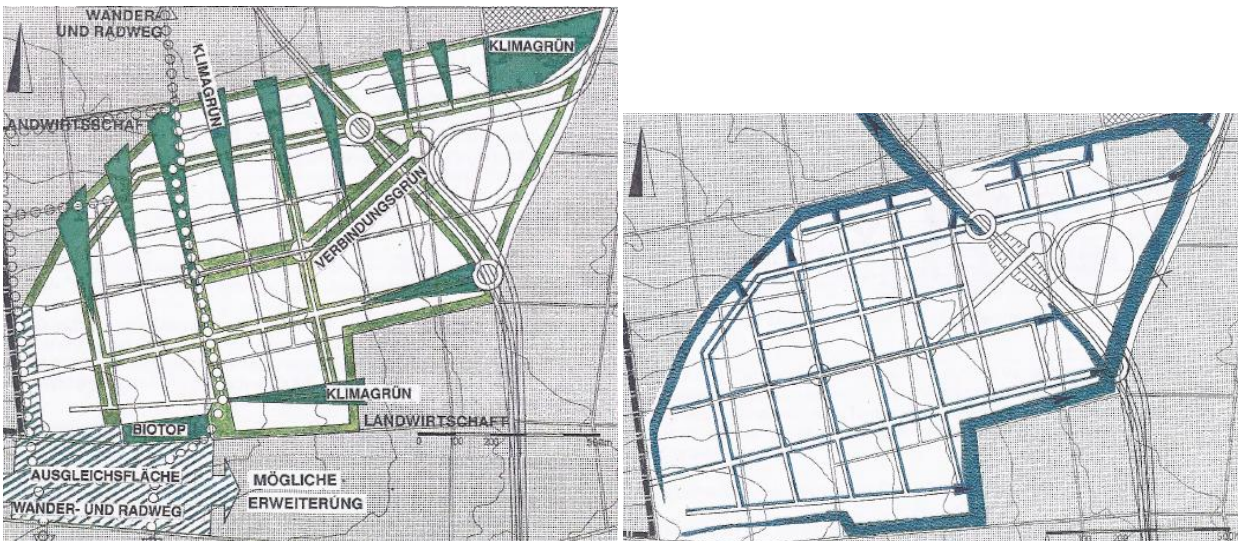

Fig. 6 (left): green zone grid, recreational – hiking and bicycling ways, of the urban business/industrial development area. Picture excerpt from research final report, Abb. 16, 18. Fig. 7 (right): Fig. 7: open ditch surface dewatering structure.

The research area – as can be seen in Fig. 2 above, was and to our knowledge[4] still is mostely used as farm land, and will remain also for a significant time in the future surrounded on all sides by farm land. It is situated right in between the city to the north and 4 or 5 smaller towns and settlements to the east, south and west. Accordingly both rural and farming traffic, as well as the recreational traffic of hikers and bicyclists, needs to be accommodated by the design of urban pathways with a rural "flair", to avoid untoward disruption of an important rural and recrational area close to the city.

The climatological analysis had shown that it is important to have "climate corridors" for temperature regulation, and to avoid undue wind turbulences as much as possible in the area. So the concept from the start girdled the whole area with a green zone, which also accomodates two main drainage ditches and facilities for surface runoff.

The road cross sections have been purposfully designed to have green stripes planted as boulevards, with trees and bushes on both sides, and ditches on either one or both sides. Parking is limited to one side on defined parking stripes only. Access to the individual business properties is limited to defined access points. Frontal parking areas, linking and paving building lines and road edges directly, are expressly prohibited by zoning rules application, and property sales contracts.

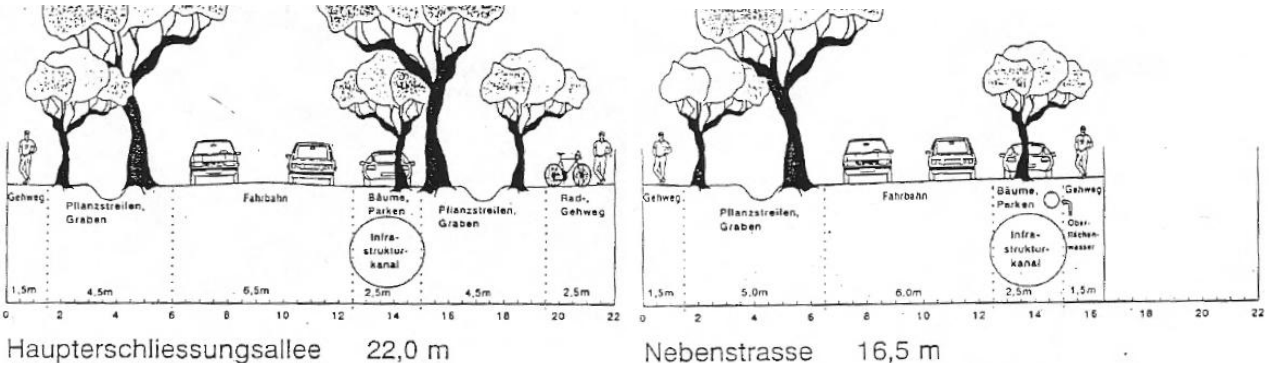

Fig. 8: standard road grid cross sections for main boulevards and side roads of the urban business/industrial development area

picture excerpt from research final report5 Abb. 15

This concept – which also has significant positive effect on the utility tunnel underground system and its surface penetrating elements – has been implemented in full, and enhanced by non-public, mandated green zones, and maximum property surface sealing limitation in Wachau-North. It has proven extraordinarily succesful there. The only comment by the manager of the still functioning development company there at a visit to the area in March 2012 was:

[4] according to Google Earth and Google Maps last checked on 22.03.2012

"Put curbstones on both edges of the roadsides – even the ditch side. Defined inflow-points to the green ditches limit the green area pollution with throw-away waste, and makes road sweeping easier for the sweeper drivers." – We took note, and learned.

as Economic Performance Enhancers

Both the open surface drainage in green ditches, open retention ponds with a continuous minimum standing water level, and the integrated planting, green zones, and roads structured as planted boulevards, create a green atmosphere in the business park. It was thought and hoped that this would have positive effects to:

- keep the area looking clean
- enhance level of moral with the employees in the area
- enhance corporate marketing and image building as well as client impressions when visiting

This design concept intended to test a possibly durable set of solutions has passed the reality check of time. In Wachau people have continuousely reported to prefer this working environment. With a short stroll, easily during break times or meal times, they can have their morning snack or lunch next to a "duck pond". This effect has been noticed by the business managers, who in turn report better performance and moral in their employees, as well as a very high marketing and client contact and recognition value effects for their businesses.

The aim to retain this green area character, and the property values continuously, has until now been achieved over the 20 year period. Properties of businesses that defaulted have easily, and at good value been resold. All lots but two are occupied, which is not at all the average for such areas in the eastern German states, even so long after reunification. Due to the attractiveness of the business park there are no empty buildings.

What we missed in Wachau's green areas according to local feedback were: spaces to place business location bulletain boards at the main road entries into the area

We've since applied this learned knowledge on urban design and successful elements to various other developments both of business and housing areas, small and large. We've continuousely found them to be an economic performance enhancer, starting with the property marketing at the beginning, and continuing on through the years, by keeping areas viable, values and supply level of service high, and maintenance an disruptions low.

Our overall conclusion on this is – humans are willing pay to have humane surroundings!

4.5 The Human Element in Urban Development

an integrated – target oriented, and feedback controlled, design & optimization process

Urban and regional planners, who are educated as such, have understood for a long time, that their field requires intensive coordination, balancing, and value choices between a multitude of hard and soft factors, impacting on any development situation and human society.

It is therefore only proper to demand such an integrated approach from the whole team of participating engineers, architects, planners, economists, investors and – last but not least – local politicians. And right there it starts to get difficult. Many interests create many interfaces, and not all are reconcilable.

We've found it highly helpful therefore to approach such projects with two main process instruments:

- comprehensive knowledge in the design team from day one onwards
- a known methodology, which we implement on the consent of our clients, and thereby create an operative framework of decision making, and target evaluation, with clear feedback mechanisms and consideration input of all involved parties.

We call this "integrated design in a network optimization process". It is based on developing a clear target canon, aimed to smoothly work within the legal framework of zoning and planning regulation. And to give due consideration to the political processes involved. While ensuring, that these are not hindered or interrupted for reasons of faulty, incomplete or unduely late design and document preparation.

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

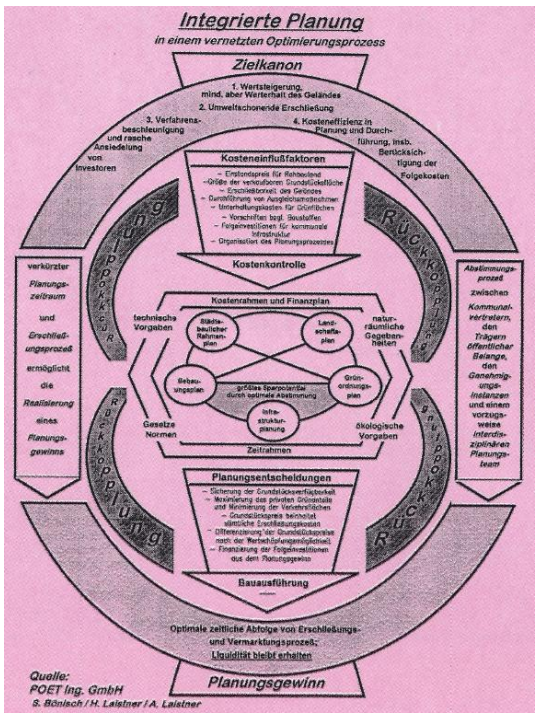

Fig. 10: integrated design – POET mbH company presentation

Our success at best in the Business Park Wachau-North development has been a fully completed legal zoning and development process within only 5 months between design contract and tendering of development construction works. And providing construction power to the first private property investor's construction site a scant 4 months after that.

4.5.2 - retaining knowledge and intentions by institutionalizing operations and their funding

Already prior to the research project Mainz-South, an increasing economic pressure started to develop within Germany regarding community finances. More and more the communities were suffering under an increased debt burden. When the opportunity came in the German reunification process to try something new, instead of the "old" strict public administrative structures and processes, we did. We used the idea of public-private-partnership structures. Instead of burdening newly created, understaffed village administrations in eastern Germany with all the ins and outs of a large development project, we suggested the creation of a privately structured, but in its majority publicly owned development company.

The relationship of 70% public ownership to 30% private ownership developed in Wachau from the fact, that the public side brought into the partnership both the property value, and all the public authority rights, while the private investor (one of the initial larger property investors interested in the area) supplied his organisation, banking and property marketing skills. This proportion proved to be fortuitous, as it created a situation in which, once profitability was achieved, the public side was the main beneficiary, as well as having "learned the business" so to speak. An unplanned withdrawing of the private investor, which in other PPP cases, so often leads to the public partner suddenly finding themselves teamed with a completely unknown new business partner, with completely new and different investment interests, did not happen.

Also the development concept from the start included a continuous income to the development company, from mainly two sources. Why – because we knew, that future upkeep was needed to ensure success – and at the time no public works structure was available. So why not build a development company into the kernel of a future public city works and supply company.

Its income to this day, is mainly generated from the sale of heating energy to the properties in the development area, and the sale of electricity to the grid through the open electricity market. To achieve this we designed and built a heat/power cogeneration plant in the development area. The secondary income is from the dues of an ownership cooperative of the property owners and users of the development area. All owners until now could be convinced, that this mandatory membership to enter the area, is worth its money – as this keeps the green areas, ditches and roads clean, the trees and bushes pruned and the marketing and property values up.

On the side – as operator of a heat/power plant the development company maintains the utility tunnel, the road surfaces and the street lighting. It has proven so succesful and effective, that when the village of Wachau was integrated into the City of Markkleeberg, the new city heads decided to turn over the development and operational works of a huge recreational lake and waterway development to the south of the city (slowly converting the old lean coal strip mining pits) to the development company – which is therefore currently designing and building a waterway lock for recreational ship traffic.

5 CONCLUSION AND OUTLOOK

It can be said, that the development ideas, which were developed in the late 1980s with the support of the German Federal Ministry for Construction, Zoning, Urban Development, the German Federal Ministry for Research and Technology, and many state and local authorities and research partners have passed their first stage test of time in the unforeseen but fortuitous implementation project at Wachau-North. While many of the research projects of the time were designated "Modellvorhaben = Demonstration Project", only few could be implemented against the inertia of the status quo, and the often uncoordinated pressures of investment and political interests. However – now we have this and other demonstration projects to study.

On the other hand, POET mbH and IfEU mbH did not arrive at this level of knowledge all at once. We went through a long process of idea development and successive implementation trial – one or two ideas at the time all through the 1980s and 1990s. The focus of this paper on only two projects – Mainz-South and Wachau-North – only reflects the unusual confluence of research and implementation chances taken – a rare situation for analysis of the development of ideas and their testing over time.

There is however the future to consider. And while – as an attendee to the realcorp now for quite some time – we realize that these ideas have spread, we do still percieve a pronounced lack of understanding for the human requirements and conditions. Especially, when confronted with large to huge to gigantic projects all over the world, we must state emphatically, that the universities and trade schools for engineers and city planners are NOT YET getting the message across.

We are still educating whole generations of architects, planners, engineers and economists who have not a clue what sustainability means. Above all else, and apart from all the many elaborated and sophisticated definitions that are put onto this single word:

Sustainability means – it has to last & humans have to like it to make an effort to make it last.

To get people to make the effort – the direction the finger is pointing could not not be clearer:

Start remembering, and take consideration of your and others' humanity, and integrate human and humane requirements into your technical, creative, administrative or economic thought processes.

Until and unless you do – nothing of you and your effort and work will remain in time.

The Effect of Fourth Dimension on the Behavior of Urban Dwellers

Anahita Mahmoudi, Shabnam Farboud

(Anahita Mahmoudi, Architect, anahita.mahmoudi@gmail.com)
(Shabnam Farboud, Urban Planner, shabnamfarboud@yahoo.com)

1 ABSTRACT

Although it seems that urban design is limited to three dimensions but in fact the factor of "Time" as a fourth dimension should not be ignored.

As Kevin Lynch said in urban spaces people feel passing time by two items; first, an organized repetition and second, estimated activities and Irreversible changes (instead of repeating).

We live in the places which have time in. Patrick Geddes mentioned that city is more than a place, but it's a show in time.

The first way of feeling passing time is to consider about environmental events repetition such as seasons or days and nights. The main life cycle is based on natural cycles. The effect of these natural cycles on human activities should be considered in urban design process. In different time of days and nights the urban spaces will be different either.

On the other hand, today the men's life cycle is not just depended on natural cycle .Sunshine and sunsets are not the point of start and ending. In parallel with breaking place limitation- with electronic communications- Krietzman believed that the past time limitations are now going to break. He also mentioned that it is not far to call these days society"24 hours society" and it is an introduction of "New World".

By the weakness of time structures, the"24 hours society" has been created, so the usage of timing and activities patterns increase or decrease in different ways . By having the time of night –which cannot be possible without electrical devices- we don't create more time but we can use the time more effectively.

breaking time limitation have been reached more freedom. If the differences between days and nights, work days and weekends disappear, what changes will be appear in the peoples life? More freedom and more diversity will be found which are confusing at first. In one "24hours society" the activities patterns and using urban spaces create based on demands and priorities of urban dwellers and it cannot be predictable easily.

The disadvantage of" 24hours society" is that it reduces people communications, so it leads the society to Individualism and reduces social connections which was formed in public places.

The urban designers should know the behavior patterns and activities. They should know how to increase some activities which occur in the specific time and recognized how to use some events in order to increase some specific activities.

Although many lines and political boundries has divided human society into different groups with their own nationality and culture , but the human nature is still similar.So it can say that most of the mens reactions in urban spaces might be predictable. Sice that the most of reactions rise from emotions and human nature.such as feeling fears, happieness,greif,tendency to be among the other people and communication.

But what will happen to them in "24hour city"? It is clear that multifunctional buildings, appropriate lighting and people appereance in urban spaces can be the structures of this society.

In this article we want to find out the effect of urban design on people behavior in 24 hours. We try to find normal and obnormal behaviors and propose some recommendation in order to avoid abnormal activities and increase the normal ones.

So to reach that, we analysis three public spaces in different times of 24 hours of one day and compare people behaviors in them and the reasons of their differences. It should be mentioned that in this article the emphasis is on urban users not only the spaces but finally according to the results, the new form for that urban space will be suggested and say that if the concept of 24 hour city is responsive for that area and if it can improve it or not. What happened after midnight? What about the first hours of the day?

Is it a good idea to encourage people to come out or just like the fairy tales after midnight there is no sign of living in the city? Should people conquer their fears and go out of their shelters or its better to keep their solitude?

2 THE DESCRIPTION OF BEHAVIOR

The method of doing an activity is called "behavior". The human behavior is an outcome from his needs and motivations, the environment potentials, the image of the world which caused by his perception and the meaning of this image (Lang, 1987). So an activity when effected by one of those iems will cause different behaviors. moreover behavior is strongly caused by culture and society (pakzad ,2009).

2.1 The effect of space on behavior

The environment is something which surrounds the people. The part that men reflect to, is called" behavior environment" (Lang, 1987).

The environment can be the source of perception, knowing, effectiveness, and spatial behavior. Two last items are completely influenced by the moral patterns .These pattern, have interaction with needs and human motivations. There are two viewpoints about the amount of environmental effect on the behaviors: first the opportunities of the environment (it means that people can choose among verified opportunities) and second one the existence of possibility in it (in a specific area, the possibility of some reactions than the other ones increase) (bell & the others,1990, portiens 1977).

The space as a physical part of environment can effect on the behaviors and control it .but about the activities the environment can just increase or decrease the possibility of doing some activities so the effect of environment on behaviors are stronger than activities. Its why that in design process,instead of activities , behaviors should be considered (pakzad ,2009).

Montgomery says that the soft infrastructures such as programs, activities, and verified festivals are as important as hard infrastructures (e.g. buildings and spaces). To encourage people for appearance in public spaces it is must to create attractive, functional and secure places instead of just increasing urban facilities (Montgomery, 1999).

As it mentioned above, the environment and users have mutual effect on each other. So it's obvious that the items which organized to create a 24hours urban space might be different by the others usual item. At least there would be some instruction for them. Therefore these items have their own effect on the space users. They can force some behaviors and activities. They can permit the user sit, or walk. Stay calm or play with a loud voice. Feel safe or walking fast to get away from that scary place. Besides the users have their own effect on the environment. Their cultures, traditions, their habits and hobbies can be effective on the form of urban space and sometimes the policy of government or the tendency of client for designing a specific area will change the design path.

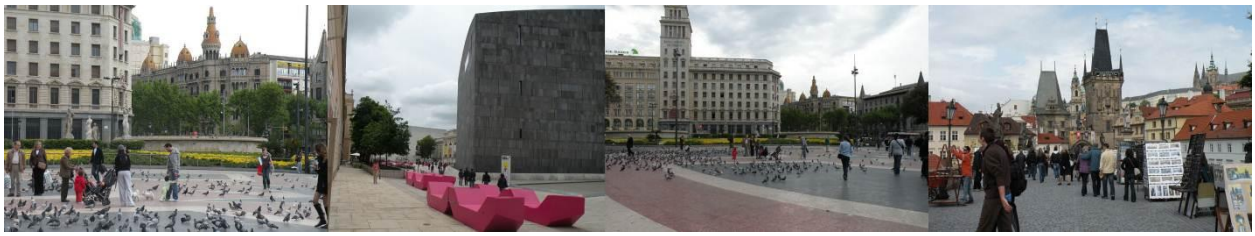
2.2 The Public Urban Space design and its impact on behavior

Kolkohn(1989) have two description for urban space: Social space and artificial(constructed)space. The artificial space is more about physical space, so what architects consider is "morphology of space". (The way that space effect on our perception and the meaning which can be found out) (Madanipour, 2008)

In a conference hall which the furniture have been placed formally there will be rarely conversation between people, while if the decoration changes, the result will be change either. This instance shows that design is an important item in space creating, but it is not the only effective item, since what happens in the spaces is mostly related to the users. Gans(1968) believes that there are differences between the spaces which have potential themselves and offer a spectrum of opportunities and the spaces which are created by usage and function of people.

The urban designers create the environment with potential in , while people create real environment. The urban designer is not the one who determine a specific activity and behavior ,but he is the person who provides the possibility of doing some behaviors and actions(Carmona, Matthew, 1996).

Public Space no. 1: Shiraz,Iran, Shahrdary Square Photographer:Anahita Mahmoudi, 2012



Public Space no. 2: Arranged right to left: Praha (Czech Republic), Barcelona (Spain) ,Bratislava(Slovakia), Vienna (Austria). Photographer: Anahita Mahmoudi, 2009, 2010.

Pubic Space no. 3: right to left: Praha (Czech Republic), Barcelona (Spain) ,Bratislava(Slovakia), Vienna (Austria), Istanbul (Turkey). Photographer: Anahita Mahmoudi, 2009, 2010, 2012.

Public spaces	Ledge design	Surrounding by buildings	Form	Lighting	Furniture	Perspective	Car passing
Public space no.1	no	No limitation, in the same level with street	line	adequate	Just one or two seat benches with long distance from each other	open	Motorcycles and biking in the side walk area
Public space no.2	no	yes	Square and rectangle	adequate	adequate	open	no (just tram and emergency cars)
Public space no.3	Multifunctional buildings, designed facades,	yes	Square, rectangle and line	adequate	adequate	open	no (just tram and emergency cars)

Public Space	fountains	Multi media	Integrated ** with third place	Possibility of public meeting	vegetation	Shopping area
Public space no.1	no	No (just some LCDs for advertisements)	no	yes	Seasonal trees	no
Public space no.2	no	no	yes	yes	no	yes
Public space no.3	no	no	yes	yes	no	yes

Aldenburg in his book (a good excellent place) mentions that third place is a friendly and informal public space where people gathers, far from work and home(1999). Third places are intermediate places between people and their society. Frequently these places are cultural and amusement, such as the cafes beside Paris street, or coffee shops in Wien, etc. (Carmona, Matthew, 1996).

3 SPACE AND TIME

By passing time, spaces are formed as the living place and the quality of passing time gives meaning to the spaces. Space and time are dependent together.

At the same time both the “change and stability of environment” are important. The urban designer should know how the environment change and find out which items stay calm and which ones change.

They should consider the effect of day-night cycle and seasons on men’s activities. In the different times of days and nights the perception and usage of the urban space is different either. It means that in different time of a day-or generally a year- the users and the way of their activities in urban space are different. for example in weekends one space specialized to kids and employment women and in the other days it’s a place for elderly and housewives. Of course there is no written low to limit the function of space for specific group or specific time, but its people which decide to use it in their own style. So it is reasonable that according to the time, the users change – in both aspects of amount and sort - and so do the activities (Carmona, Matthew, 1996).

One of the reasons that the “multifunctional” buildings and spaces suggested is the effect of them on creating more active and dynamic urban spaces. The key point is focus on putting different functions in one place.

Krietzmen knows the “one- functional buildings and spaces” as “one time spaces”. He mentioned about the spaces which are used in specific times of the day. He believes that in one 24 hours society the urban spaces should live 24 hours a day either (Krietzmen, 1999).

Among all thse 13 items which mentioned above, in authors opinion the factors of "lighting" and " surrounding" are more important than the others,since good and enough lighting makes the users fell safe and secure . places with enough lighting prevent the criminal activities or at least decrease them.

It seems that the public spaces which are just some straight lines decrease the communications and lead the users to individualism. especially when there are some seats in the place, people will sit down there and looking directly to the streets or the shops (depends on the side of seat) and usually not interested in new conversation with strangers, while on the other hand, in some places with the form of square or a closed loop people feels more comfortable, and the increasing of eye contact can make people close together or creates possibility of new communications.

Also the factor of surrounding area makes an important role to give the users the sense of place, since when people found themselves in an area which is closed by some buildings, some attractive functions, and beautiful view and landscape, inside, he feels belonging to place. By arrange some simple programs by urban managements in the public spaces strangers will know each other and so gradually the unpleasant sense of "strangers are scary" disappear. (like some common activities (playing in a team , singing a song together, doing some matches like kite running, or feeding animals, etc.). All of these activities can be some effected motivations to encourage people to appear in public places and act according to society accepted rules. Moreover the tangible and subtle control of polices and their appearance in public spaces make the environment safe.

These arrangements can make a pleasant evening and day for people. But what about nights? Two items make nights scary. First the lack of enough light (that increase the possibility of crimes) and second the lack of people. Except lighting which mentioned before, the 24hours functions make the place dynamic and alive during night time. Some functions such as super markets, hotels, restaurants, cinema and theatres, dancing clubs, are the places which most of the times have customer. Also some terminals (bus, metro, taxi, and airport) work until midnight and the appearance of passengers and the users help to make the area safe. It should consider that the dream of 24hours public spaces just limited into some places and not all the urban spaces. However they can design in an appropriate distance from the other regions and have this ability to provide facilities for their neighbourhood. It will be better if city divided in to some region. Each region has its own 24hours public space with its specific functions and facilities. Someway it will be the beating heart of the region. But it would be dangerous if all the consideration and designing just centralised in one place and besides the layers behind these ledges and out of this centre, everything drown in darkness and silence. Therefore its better that the major streets lead to somewhere near this centre (it increases the escape ways in a case of dangers), also an adequate lighting is not only for centre but also for all parts of the region is recommended.

4 CONCLUSION

It's clear that not only people effect on its surrounded area but also the evvironment has its own impact on people. This impact sometimes caused by social factors such as culture , government policy , traditions or sometimes it just caused by design of some place and the concept of designer in order to make people do some specific activities.besides some design points , the factor of time is considerable.

Most of the urban spaces during day hours are active and dynamic, but in the night time there are going to be some scary place and sometimes full of homeless, beggers and criminals. Some scences like that prevent the appereance of urban dwellers in night. To reduce these views, the exictance of some 24hours activity are necessary. In the weekends and summer nights, the people are in the street and public spaces over midnight but in winter and during work days, these appereance come down. Providing some facilities which are always entertaing and attractive for people improve the urban space. Also settlei down some functions which are 24hours open and service to users, such as terminals , stations, hotels , bars,clubs etc. Moreover its better that each region all around the city has its own 24hour public space that depended to the area of region the number of them can be different (between 1 -4).These spaces with reasonable distances by each other will be the beating heart of the region and make the area always active and safe. There are thirteen important items (such as ledge, form, multi media, lighting, furniture…) that considrating about them in urban design process make the urban space more pleasant and satisfied for the urban dwellers.

1 ABSTRACT

The third sector is essential for economic activity of cities and therefore needs to be provided with respective resources. Such resources are - among others - space of sufficient quality and the possibility for companies to pursue economic activity uninterruptedly. In many urban regions though, economic zones get under rising pressure from other uses and are deprived of the resources they need. They get pushed further and further to the margin of urban areas and onto lower quality sites. This trend is critical, as it aggravates urban sprawl, excessive land use, high transport activity and might even make companies migrate out to competing sites. In fact, it poses a risk to the quality of life and the competitivity of urban regions and therefore has to be banned.

So, the question is: How can areas that permit economic activities to be pursued in an undisturbed way be provided inside the urban compound in the long run? And how can good co-functioning with other urban uses be guaranteed?

This paper presents an innovative approach to this issue by describing the project "Resource-saving Enterprise Zone Liesing", which aims at not only preserving an existing industrial zone undergoing structural changes, but also at developing it into an attractive, future-proof and resource-efficient economic area. Structures and tools which foster its economic activity and minimise conflicts with other uses are provided. As a result, an appealing, high-end business quarter inside the urban compound is created and backed-up for the future.

2 THE PROJECT "RESOURCE-SAVING ENTERPRISE ZONE LIESING"

2.1 Project Background

The project area is 240 hectares large and comprises 563 companies of various sizes and branches. It is situated in the south of Vienna at the border to lower Austria.

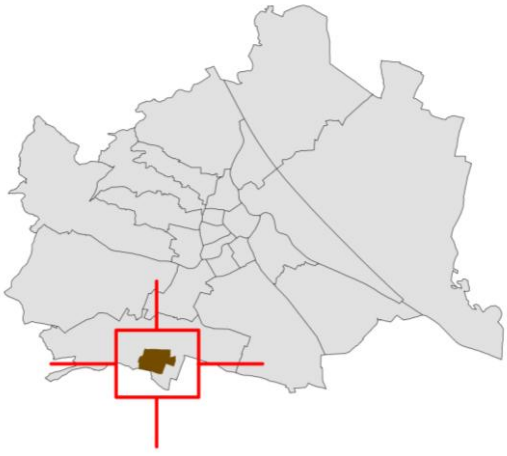

Fig. 1: Location of the Enterprise Zone Liesing

The area is widely known as „Industriegebiet Liesing" (industrial area Liesing), although just a small number of the enterprises can still be called industrial in the traditional sense. The number of trade firms, offices or transport companies is constantly growing in the zone. Besides that, an official set of development aims for the area or a targeted strategy for attracting businesses has not yet been developed. As a result, the area is very diverse and unstructured.

Concerning the physical appearance of the zone, it has to be stated that there is a lot of untapped potential. At the moment, the area lacks satisfying design of buildings, public space or green areas, especially in areas at greater distance to the main roads. There is also a considerable amount of vacancies and brownfields.

Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

Furthermore, the zone lacks specific identity among the local businesses as well as among the general public. Its identity as traditional industrial zone got lost when big industrial enterprises closed down or relocated. At the moment, the zone has no strong identity that it could use in competition against other zones.

As a consequence, the enterprise zone – despite favourable site conditions - lost importance for politics, administration and businesses. The main focus of their activities has shifted to exploiting free or unused lots without paying attention to the development of the business zone as a whole. As a result, the overall design is weak, the uses are very heterogeneous and some big key areas in the center of the zone are at risk of becoming shopping or housing areas.

To controvert these tendencies, to back up the zone and to develop it into an attractive and future-proof enterprise zone, the project described in this paper was launched. The focus on "resource-efficiency" was chosen because it is generally seen as standard for future-oriented, long-term urban planning. Furthermore, there are some main enterprises in the zone (e.g. bakery "Der Mann") which have already implemented innovative solutions for efficiency measures and can be used as beacon for the over 500 remaining businesses. Through using these model businesses as leading forces as well as working out spatial strategies for the development of the zone as a whole, a strong identity as resource-efficient enterprise zone shall be achieved and serve as attractor to new businesses.

The project is co-founded by the European Fund for Regional Development and lasts from 10/2010 to 12/2013. It is a clear aim to set up sustainable structures that persist beyond the formal end of the project time frame.

2.2 Project Aims

The operational aims of the project "Resource-saving Enterprise Zone Liesing" are the following:

- To establish a district management („Quartiersmanagement") on site as a service for companies
- To establish the brand „Resource-Saving Enterprise Zone Liesing" and to integrate the local companies into brand development
- To improve resource - efficiency on all levels in the zone
- To secure jobs in the zone and to attract new businesses
- To design a comprising masterplan and create an attractive urban environment
- To secure the enterprise zone as location also for companies with high emissions
- To foster cooperation of property owners, businesses, science and research
- To integrate the local companies and site owners into the process of decision making
- To develop suggestions for improving the infrastructure for employees as well as employers
- To develop suggestions for adjusting the legal framework of building and corporate law
- To stimulate the property market and improve the use of free spatial ressources
- To raise awareness for the enterprise zone among the inhabitants in the neighbourhood

2.3 Project Structure

To achieve these aims, the following work packages have been designed:

- Establishing and implementing a district management ("Quartiersmanagement")
- SWOT analysis of the area
- Establishing and implementing a brand and communications concept
- Stimulating resource-efficient economic activity
- Stimulating the real – estate market
- Developing a masterplan with resource-efficiency measures

By now, work package 1, 2, 3 and 5 have been successfully accomplished, 4 and 6 are ongoing. Work package 1, the district management, is the core of the project and lasts for its entire time frame.

In this paper, the focus lies not so much on describing the actual situation of the area or the work packages, but rather on the project`s integrative approach of adressing all relevant stakeholders in the process. Furthermore, a comprising picture of the numerous measures taken to turn the industrial zone into a resource-efficient, attractive business quarter will be given.

3 INTEGRATION OF ALL RELEVANT STAKEHOLDERS INTO THE DEVELOPMENT PROCESS

3.1 Cooperation on Political Level

For this project, the most important players for urban economic development of Vienna have joined in cooperation: the steering committee is made up by representatives of the Vienna Chamber of Commerce, the Vienna Business Agency and the City of Vienna (Municipal Planning Department MA 21B). This means that several different politic points of view as well as a large number of different stakeholders on municipal and district level are represented in the decision making process. As the three players are represented in the steering committee which decides unanimously, cooperative decision-making is fostered. This collaboration is of particular importance, because it creates the necessary capacity to act and to implement the project results.

3.2 The District Management ("Quartiersmanagement") as a service for companies

The district management ("Quartiersmanagement") is the core of the project. Through installing a district manager ("Quartiersmanagerin"), whose primary task is to serve as a pivotal point and service department for companies in the enterprise zone, a strong signal of support is sent to the companies. As it is a main aspect to integrate the businesses into the development process of the zone as much as possible, their opinions shall be heard and considered. This is the task of the district manager: motivate the business and land owners to participate in the development process and bring in own ideas, as it is them who will be the stakeholders of the zone`s development in the long run.

The district management office is located at the center of the zone and interested parties are welcome to drop by with any issue concerning their working and living in the area. It is designed as one-stop-shop providing information about funding, contact points, relevant developments, interesting events or research activities that might be interesting for companies and other stakeholders. It is the first place where business and land owners as well as inhabitants can carry their concerns and ideas to.

The manager herself initiates projects, discussions and networks and encourages relevant stakeholders to cooperate and become active in and for the zone. The main part of her work is to transfer knowledge and to stimulate communication and cooperation of all parties by establishing networks, developing and communicating new ideas and clarifying the way to their implementation.

Her main tools are information and discussion events, the homepage www.ig-liesing.at, periodical newsletters and personal interviews. Furthermore, specific surveys concerning sustainability in the area supply her with in-depth knowledge, and a brand and communications concept enables effective public relations.

This service is unique for business areas in Vienna and centralises the information flow for all the relevant parties, be it companies, land owners, project developers or district and government officials. It offers one main contact person for any issue relevant for the economic area. This shall provide support for the already located businesses as well make it easy and attractive for interested companies to settle in the enterprize zone.

3.3 A Broader Perspective: Integration of Neighbours and Companies outside the Economic Zone

To adress the development of the area in a comprehensive way, it is necessary to also take its surroundings into account. This means getting into contact with neighbours as well as companies located in the rest of the district or even further away.

As the enterprise zone is surrounded by housing areas, it is particularly important to get into contact with neighbours in order to prevent conflicts of uses. The neighbours` issues are analysed by personal interviews and by cooperation with local neighbourhood associations. The neighbours are being constantly informed by

press work and newsletters and invited to activities in the zone, especially when it comes to free space issues and temporary use, as the Enterprise Zone Liesing shall be a place for working as much as living.

Besides the neighbours, it is also advisable to have a broader horizon concerning the companies taken into account. It is a definite intent of the project to also cooperate with companies outside the industrial zone if they are willing to. That might be a neighbouring company participating in joint renewable energy use or a spatially more distant company cooperating in a research project.

4 RESOURCE-EFFICIENCY ON ALL LEVELS

4.1 Resource-efficient Design of the Area

As sustainability goes beyond the entity of a single company, a broad set of surrounding factors has to be considered when developing an enterprise zone in a resource-efficient way. These factors are, e.g., referring to transport, open and green space, architecture, the real estate market, social systems, structures of land use, local supply, contamination and brownfields, technical infrastructure or the image of the zone. To deal with these these factors in the project area, four studies have been contracted out:

- A detailed SWOT analysis
- A transport expertise
- An open and green space expertise
- A masterplan

In these studies, the aspects described above are dealt with in depth. At first, a detailed analysis of the strenghts, weaknesses, opportunities and threats (SWOT) of the zone is pursued and based on that, ideas and measures for the area are suggested and rated. These ideas will be comprised in a masterplan, which is expected for the second half of 2013 and will provide recommendations and sustainability guidelines for stakeholders in planning.

In the course of the studies, business and land owners as well as neighbours are adressed by interviews, workshops and other events. This is to constantly integrate the various players in and around the area into the analysis and the implementation process. The district manager has a catalyst function for the zone and the studies provide her with the necessary knowledge, but they also serve as tools for adressing the relevant players.

4.2 Resource-efficient Economic Activity

Besides the spatial approach, it is of course crucial to promote sustainability on the business level. To achieve this, businesses in the area are constantly informed about technological developments, funding opportunities, advice programs etc. by newsletters, events and personal consultation of the district manager. They shall be motivated to implement innovative ideas, draw from existing advice ressources and think beyond their own business unit.

It is a priority of the project to promote existing (often underused) expert consultation programs rather than to set up new programs. One of these existing programs is the ÖkobusinessPlan (ÖBP) Vienna, a service by the City of Vienna. It offers general advice as well as specific consultation concerning resource-efficient economic activities to companies. Results of ÖBP – related projects in the zone are, for example: halving the cutting loss of circuit boards or bringing down the water use in their production by 40%.

Before our project started, only 16 of the 563 companies in the industrial zone participated in the (subsidised) ÖBP. The aim is to raise that number to at least 100 consultations as well as promote the other existing consultation offers, e.g. state expert advice programs about mobility management. The part of the district manager here is to provide basic information about expert advice offers, to get the relevant players into contact and to support the business owners in implementing their projects.

Besides the single-business level, there is enormous resource-saving potential in the enterprise zone that could be adressed on the meso-level, that is by cooperation of businesses. Fields of cooperation are e.g. renewable energies, waste disposal or water and process energy use. Attractive for cooperation might be, for example, the solar energy field: forming a group of businesses that build a joint solar panel of considerable size and work out an energy contracting scheme to provide energy for parts of or the whole industrial zone.

To stimulate initiatives like this, ideas have to be substantiated, stakeholders have to be motivated and the path to realisation has to be made clear. This is the task of another study contracted out in March: it will identify specific projects, calculate costs and benefits of their realisation and show the necessary technical, financial, legal and organisational steps to implementation. The district manager again is the one to communicate the results of the study, get the necessary players together and provide support with implementation.

5 OUTLOOK

In 2011, the district management was installed and right now, it is at full service. The first public events have taken place, the website and newsletters have been worked out and the district manager is in permanent contact with the relevant players. In spring 2012, the SWOT analysis and the brand and communications concept have been completed.

During the months to come, the focus will be on intensifying the expert advice events concerning resource-efficiency for the companies and on getting company and land owners motivated to implement projects. The study about the resource-efficiency potentials in the area will serve as a basis for this task and be completed in autumn. Furthermore, joint work with research institutions will be intensified. Cooperation programs with the University of Technology and the University of Natural Resources and Life Sciences in Vienna have been set up and will be executed in autumn. Besides that, the public relations work will be increased, as the brand and communications concept is ready for implementation.

6 CONCLUSION

The project "Resource-saving Enterprise Zone Liesing" offers an innovative approach to the problem of fragmentation and out-migration of enterprise zones. Through the comprising measures of the project – with the district management at its core - high-quality space for economic activity is assured inside the urban compound, which offers security of investment and a long-term perspective for development.

The various actions towards augmenting resource-efficiency shall enable a development leap of the former industrial zone towards a future-oriented business area with a strong and attractive reputation. Furthermore, the explicit project aim of integrating business owners and other relevant parties into the development process shall guarantee the pursuing of the suggested path after the project deadline. Through this, conflicts with other urban uses are minimised and the companies are enabled to contribute their essential share to the functioning of a city in the long run. The result of the project will be a modernised, resource-efficient and stable business area that is attractive to innovative companies of various sectors.

The Walkable City – the Concept of Stockholm

Michael Erman

(Michael Erman, MSc. Spatial Planning, City of Stockholm, Planning Department, Strategic Section, michael.erman@stockholm.se)

1 ABSTRACT

This paper shows how the City of Stockholm currently works on the implementation of its new City Plan "The Walkable City - Stockholm City Plan 2010". The City's planning is subjugated to the norm of sustainability, a human oriented approach and the goals to create an open, connected and healthy city. The City's Vision 2030 provides the guiding thinking for important strategic planning issues[1] that laid the ground for the City Plan which contains four strategies for sustainable growth: strengthen central Stockholm, focus on strategic nodes, connect city areas and create a lively urban environment in all of Stockholm. Together with nine overarching focus areas of the plan, the strategies intend to make Stockholm denser, better integrated and functionally mixed. The City Plan has a new spatial approach in comparison to the former comprehensive plan of 1999 i.e. several previous planning principles had to be changed. The current implementation of the City Plan tries to find ways and acceptance of changing Stockholm's former distinct spatial patterns and develop new spaces for 150,000 people as well as many new infrastructure investments.

Three examples of strategically important urban planning approaches seen from a helicopter perspective are illustrated:

- The Royal Seaport project as an environmentally "world class" extension of central Stockholm
- Collaboration in Kista Science City as one of nine strategic nodes with ICT as a development engine
- A programme for connecting the nodes of Högdalen and Farsta as new form of planning

2 STRONG GROWTH NEEDS NEW CONCEPTS

In 2008 the City Council of Stockholm decided that it was time for a new comprehensive plan to be prepared. The old comprehensive plan of 1999 should be replaced as a strong growth and new challenges urged politicians and planners to come up with a new concept for Stockholm's future development. The City Plan "The Walkable City - Stockholm City Plan 2010" of course partly built upon the former plan but many guiding planning ideas have changed compared to former planning intentions. It also invents the form of continuous comprehensive planning i.e. thematic or geographic completions are made when necessary.

The comprehensive plan of 1999 was introduced as a plan that "has to build upon sustainable development and what was created by its inhabitants during several centuries".[2] The planners' intent was in first place to keep the city's existing morphology consisting of inner city and its clear distinction from various forms of suburbs (e.g. garden cities, metro suburbs). "An important starting point for the millennium shift's comprehensive planning is that the city shall develop with a maintained soul and its existing characteristics."[3] This rather conservative attitude has to been seen from a perspective of a decennium (1991-1999) of economic crisis and a modest population growth. Until that date Stockholm was internationally seen as a city with very clear spatial patterns. The overall planning goals of 1999 did not change that policy i.e. they did not require substantial spatial expansion. Existing built-up areas and infrastructure could be sustained without bigger extensions and new investments. The city should grow inwards and more or less keep its existing morphology.

In this respect, a very important decision of the City Council was made 1994 saying that brown field development has priority to the use of green areas.[4] Hammarby Sjöstad[5] has become a pioneering example for this planning perspective towards ecocycle thinking and sustainable development in Stockholm. With this guiding example, the planning approach of Stockholm has changed considerably compared to the 1990-context and principles. The new planning approach was also the starting point when preparing the current

City Plan. It became necessary in order to keep pace with high growth rates but also in order to implement the rising ambitions of sustainability and an increased influence of private stakeholders.

2.1 Demographic and economic growth – a reality to deal with

Stockholm is a strongly growing city, from 0.86 million inhabitants (density: 4,580 inh/km²) today to probably one million in year 2025, i.e. a growth rate of approximately 1.5 percent/year. This corresponds to the high growth rate in the Stockholm County in general, which is expected to grow from 2.1 million inhabitants (2011) to 2.6 million people in 2030.[6] Half the population growth is based on natural growth and half on an immigration surplus whereof immigration from abroad clearly dominates. Planning institutions on both within the county and the City of Stockholm recognise this development and handle it in an affirmative way in its planning efforts. This means that the City's planning has to assure 100,000 new housing units until 2030 i.e. approximately 5,000 units/year. Although this is a high figure it will not be enough due to an accumulated lack of housing. There have been big shortcomings in new production rates during the last 20 years where only one third of the needed new accommodations were built. The consequences are strongly raising prices for owner occupied flats (around 6 500 Euro/m² in central areas),[7] new production of mostly expensive housing projects, long queues to rental flats (currently 5-20 years waiting time depending on the list!), lack of ten thousands of student rooms, segregation and growing commuting distances.[8] The City's planning recognises these problems and has approximately 11,000 housing units in its current detailed plans ready for building. However the private stakeholders do not keep pace due to their foremost economic prin¬ciples of starting building projects only where high profits are to be expected. The City uses different tools to adjust that: dialogue, negotiations, different forms of contracts, using the own power as real estate owner. The City also tries to get a better geographical balance of new housing projects i.e. to start more projects in less attractive areas (suburbs, economically weak southern parts) and not only in central parts of Stockholm.

The immigration pressure is high due to a very positive economic development during the last few years where the global and European crisis luckily was not very marked in Stockholm. Stockholm can be described as the economic engine of Sweden, where the service sector strongly dominates (> 90%) and the innovation potential is high. Many head quarters of international enterprises, Governmental functions, big and stable clusters (ICT, clean-tech, life-sciences, financial sector, creative industries, tourism, etc.), high-quality universities and a well developed R&D sector but also stable framework conditions create good conditions for business and new jobs. It is estimated that the number of working places will grow from 1.1 million (2010) to 1.3-1.4 million in 2030 in Stockholm county[9] whereof 40-50 percent will occur in Stockholm (today 480 000 working places). This growth is mainly expected to take place in the service sector. The challenge for planning in Stockholm is to establish new business locations, mainly to achieve Stockholm's goal to have mixed urban areas, thus providing high-quality business locations that can be combined with housing and good public transport and logistic offers. Here also the question of creating urban density comes in. How can higher densities of housing and business be established when at the same time e.g. traffic disturbances, access to high-quality green areas and health have to be considered?

A third overarching challenge, as in most European cities, is the growing road traffic due to enhanced economic activities, higher incomes and changes in leisure attitudes. Despite the fact that 60 percent of the City's inhabitants use public transport in order to go to/from the inner city parts and nearly 70 percent walk or bike when moving within the inner city parts of Stockholm,[10] road traffic causes severe problems regar¬ding bad air quality, congestion, noise and accidents. Especially the strong and enduring increase of goods transports is important to tackle. Moreover, public transport and walking/bicycling have to be given even more priority in order to be able to solve the massive road traffic problems of a growing city region. This is the case in Stockholm's new Accessibility Plan[11] which gives clear priority to public transport,

[11] City of Stockholm: Accessibility strategy (draft), Stockholm, 2011

walking and biking. Other efforts to reduce road traffic are high parking fees, low parking norms in new projects (0.7 parking lots/housing unit), new city logistic concepts, more exclusive bus lanes, many new bicycle lanes and new pedestrian friendly infrastructure. This will help to reduce car dominance within the city, to give space to public transport, to connect the cities' various districts and to create a more functionally mixed, human friendly city with high quality of public spaces.

2.2 The City Plan's main intentions

The City Plan of 2010 is both a "traditional" comprehensive land use plan and at the same time a strategic navigation instrument that guides the city's various administrations and companies. The City Plan and the Regional Development for the Stockholm Region 2030[12] were elaborated simultaneously (2007-2010) which guarantees the continuity of principal development strategies and principles for both the region and the city: polycentricity, density and functional mix, priority to public transport, sustainable land use (brown field development) and a careful interplay between green and built-up areas. Social and economic aspects are well integrated parts of both plans. The City Plan also points out 21 major urban development areas and the 30 most important transport infrastructure projects in the coming 20 years. The City Plan is well in line with current urban planning theory, European standards and important guiding documents such as ESDP and the Leipzig Charter on sustainable European cities. Sustainable thinking is well established in the City Plan.

The City Plan has been worked out by broad dialogue and stakeholder processes with a particular focus on the involvement of academia, the private sector, schools and associations. The exchange with property developers and construction firms has been quite important to make realistic sugges¬tions for the city's future. Another initiative towards citizens was "Phone and we will be there" which resulted in over 200 meetings throughout the city. The work was even accompanied by an EIA, an analysis of social effects and a report showing the most important conflicts between goals in the implementation of the plan's strategies. The City Plan also specifies principles and guiding development orientation for underlying programme work, detailed planning and building permits. NB that the City Plan is a guiding plan and not a legally binding document.

The City Plan presents four strategies for sustainable growth: strengthening of the central parts of Stockholm, a particular focus on nine strategic nodes, the connection of city areas which until now have been separated and the creation of a vibrant urban environment in all of Stockholm. This is illustrated in the figure below. Together with nine overarching focus areas/goals of the plan the strategies are intended to make Stockholm denser, cleaner, safer, better integrated and more functionally mixed. Generally, Stockholm's major landholdings increase the opportunities to achieve the goals of Vision 2030 and the City Plan.

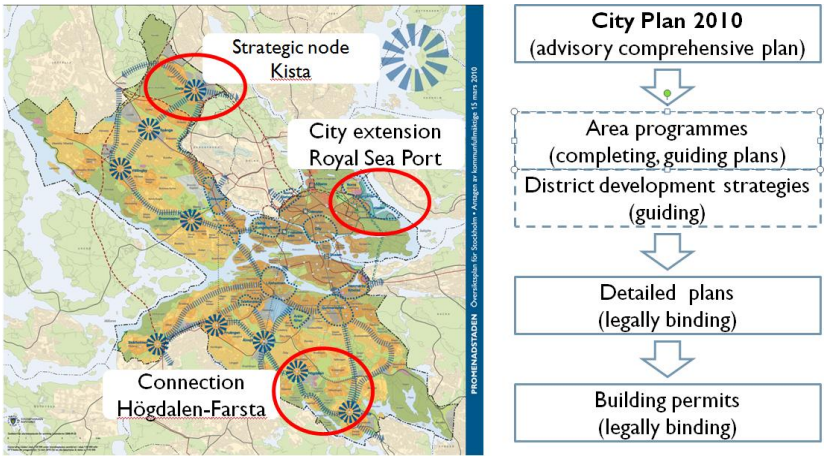

Fig. 1: Stockholm City Plan, chosen examples of strategic planning areas and hierarchy of plans in the Swedish system.

The central area of Stockholm will be extended along several strategic development areas which are all brown field areas or former industrial zones/harbors e.g. the Royal Seaport. This will provide new diverse city areas that support Stockholm's competitiveness, sustainable mobility i.e. walking/cycling and connect

[12] Regional Planning Office Stockholm: Regional Development for the Stockholm Region - RUFS 2030, Stockholm, 2010

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

hitherto isolated areas. In practice, this means expanding the inner city beyond its historic borders which is a big change in Stockholm's planning philosophy. The current distinct morphology is disappearing.

Structurally the efforts to strengthen nine strategic nodes and to create new connecting corridors, containing housing, improved green areas and infrastructure, between to date non-integrated city areas shall contribute to restrengthen the city's suburban context e.g. planning programme for the connection "Högdalen-Farsta". Even this is a planning effort that leaves behind the former concepts of clearly defined areas and form new mixed and better interrelated areas. Examples of strategic nodes such as e.g. "Kista Science City" provide evidence for the need of working together over sector borders, public-private partnerships and involving academia in order to create new vital, well-functioning and resilient city areas.

Another new approach in Stockholm is to work with "continuous comprehensive planning" i.e. to leave behind the former idea of creating a completely new city plan every now and then. This concept creates flexibility and clear planning intentions, but it does not restrict innovations and necessary new arrangements. It includes to producing guiding planning documents which deepen the City Plan i.e. a new energy plan, a new green plan and a new concept of what good quality architecture should stand for in Stockholm (called "Architecture Stockholm"). It also means to work out various area programmes and district development strategies. It even comprises intensified collaboration processes, especially in the early planning stages.

3 THREE EXAMPLES OF STRATEGIC PLANNING APPROACHES

Three cases will show how the City Plan is implemented. For more detailed information on these development areas a visit to the City of Stockholm's website[13] is recommended.

3.1 Royal Seaport project - an environmentally "world class" extension of central Stockholm

One example of the city's extension is the Stockholm Royal Seaport project[14] on a harbour brown field area (236 ha) which will comprise 10,000 dwellings and 30,000 working places i.e. mixed urban functions. It will offer a new entry point from the Baltic Sea. Transport options are subway, tram (to be built), biogas bus and boat. The new district shall be fossil-free in 2030 and adapted to climate change effects. Another goal is to achieve 1.5 ton CO_2 emissions/district inhabitant in 2020. The area is a test bed for new urban technologies, business models and commercial concepts: ICT solutions i.e. substituting and optimizing transportation, smart grid systems, combined energy systems, resilient green planning, eco-cycle solutions and climate-neutral lifestyle concepts. This is to be done in close cooperation between the City, the port, academic institutions and private stakeholders as well as the Clinton Climate Initiative.[15]

The work is guided by a general vision for the entire district which bill be built up in 2030. Three development programmes for the three different district parts are successively worked out in order to clarify the vision's targets. In order to achieve the high environmental ambitions each developer and company involved has signed a particular contract with the City to guarantee that best (new) techniques and very high standards are applied. Detailed plans and exploitation contracts combined with action programmes then set severe and differentiated sustainability goals (building standards, transport solutions, green areas, urban technical solutions such as energy, water, sewage, streets/public spaces) for every real estate. These goals and standards require much more than demanded by current laws and rules. The increased expenditures of these efforts will result in costs of 7,000-7,500 Euros per square meter of a new owner occupied flat which excludes many people from buying a flat and live there. A measure of the City to dampen this negative cost effect is to guarantee a high number of rental flats.

The Royal Seaport extends the borders of the inner city. Dense mixed use is a major criterion to achieve a lively urban environment.[16] High urban density in this area means mid-rise blocks (4-10 storeys) integrated with small parks, green facades and roofs. Also the street network is crucial to succeed in connecting the new dense area to the existing inner city parts. It links the city's public spaces and is a basic prerequisite for integration and exchange. Barrier free mobility for pedestrians and cyclists is an important planning aim, too.

[13] City development issues: http://international.stockholm.se/. Look for: Future Stockholm

[16] Regionplanekontoret: Tätare Stockholm, rapport 8:2009, Stockholm, 2009

How all this will work out will depend on the success of the chosen integrated planning approach and on how rather restricting EU-norms (air quality, noise) can be handled.

3.2 Kista – a role model for other strategic nodes in Stockholm

Since the year 2000 the strategic node Kista Science City[17] has been developed (115,000 inhabitants) from a merely industrial area into a mixed urban district. The area is part of a new regional city core and borders on four municipalities, all of which have agreed on a shared vision for Kista. It involves joint initiatives as housing, transport networks, public transit, economic development and higher education. Totally 65,000 people work in Kista's 8,500 companies. Kista is by now a world leader in ICT providing 23,000 high quality work places in 1,100 ICT companies which is an extreme concentration of expertise and innovation potential. A science city (currently 7,000 students, 1,000 researchers) is being created where many different sectors interact: academia, real estate and housing, culture, recreation, services and high tech businesses. Thus the specialty of Kista is its progress in working together. "Cooperating, networking, influencing!" this is the device of Kista's business and research communities. Different networking platforms are established where individuals from different companies can meet in the area. In terms of the implementation of the City Plan's intentions this is a sort of role model of processing for other strategic nodes in Stockholm.

In Kista land prices are generally high which makes it possible to construct a dense and mixed district.[18] Spatially, Kista's development is supported by heavy investments in infrastructure, increased accessibility and improved links to the surrounding municipalities and districts. Work is done to join street networks, focus on central corridors and develop new buildings in order to strengthen the area's cohesion and attractivity. Even the values of the nearby situated Järva nature reserve are integrated in Kista's development.

3.3 Connection programme Högdalen – Farsta: a trial to use a new planning tool

As a means to fill the gap between the City Plan and detailed planning a new tool is tested: a planning programme for connecting the nodes Högdalen and Farsta.[19] The City Council's commission to work on this started in 2009, which means that the programme was elaborated parallel to the City Plan. The programme follows the planning law's steps and rules. It shall render possible to smoothen detailed planning and to improve the understanding of local communities for the overall development needs. The intention is to establish a new thinking what a connection between two so far isolated areas can contain. Of course it comprises new transport infrastructure, but foremost the ambition to establish new green passageways of walking/cycling, better public transport links, new housing and urban corridors as well as new functions for recreation and improved ecological values of these the "in-between-areas". At the same even this trial to connect two so far distinct areas will change the urban morphology, in this case in a suburban area.

The consultation phase in 2011 however showed that people in these areas are not so keen on being spatially more connected. NIMBY effects aroused, too. There were critical voices concerning the suggested intrusion into green areas, exploitation too close to shore areas and housing forms (e.g. semi-detached houses) that are regarded as impropriate. Another problem is to find ways of financing the suggested new corridors and improved green areas.

4 CONCLUSION

Urban planning is a complex issue. Coming up with new spatial development concepts as in the City Plan means that planners have to be prepared to convince many different stakeholder groups. This requires diffe¬rent and partly new communication forms and processes in order to reach people and create necessary insights. New forms of planning (e.g. connecting urban areas) is a way to implement sustainable ideas. However urban planning cannot continue to be investment driven only. It must deliver suggestions which open up for a dynamic, creative and attractive city development based on user driven solutions. The form of conti¬nuous comprehensive planning unlocks for that. It is flexible and can react on new global requirements.

Stockholm's political goals of a sustainable, dense, healthy city with resilient ecosystems and high living qualities are transfered into spatial planning concepts. The chosen examples above are pilote projects. They

1 ABSTRACT

In Japan, there are several major "building types" according to the purposes of building, such as apartment building, commercial building or office building. However, actual activities inside buildings are sometimes different from original purposes of the buildings and different activities are often mixed in a single building. Japanese urban cities are consisted of mixtures of different building types and activities, which eventually complicate street images and also attract people visiting the cities. Though such mixtures of activities characterize Japanese cities, there are a few researches which figure the mixtures. In this paper, we clarify the characteristics of three-dimensional mixtures, as research activities in buildings nearby three railway stations in Tokyo, and visualize the activities from past to present in the following method: 1) count up activities in each building, 2) draw figures of urban section, 3) color-code each unit according to the activity.

Information of usage in each property is collected by surveying present activities of 370 buildings from the nameplates of mailbox at the entrance of the buildings. Information of past activities of 130 buildings is also collected from the map data 10 and 20 years ago. These survey were done in three areas in Tokyo were selected. The first area is Shibuya, which has developed since Meiji era as one of the most bustling places in Tokyo. The second area is Azabu-juban located in south-central district of Tokyo, developed as a local midtown. The third area is Kasai, a relatively new residential area around 15 minutes away from the center of Tokyo.

Main findings of this research are as follows; In Shibuya case, there are many mixtures near the station, and the rate of office units in an apartment building goes down gradually with the distance. At Azabu-Juban, usages as office in an apartment exist at random, and this tendency doesn't change over the years. At Kasai, there were many units which have had user's name on nameplates until 2000. However, in 2010, number of anonymous units without user's name has increased rapidly.

2 INTRODUCTION

In Japan, rules and regulations on landscapes or building types are loose compared with many Western countries. As a result, variety of shapes and usages of buildings exist. Then, diriment kind of buildings mix in neighborhood. For instance, at classical areas with many wooden low-rise houses, some modern high-rise buildings stand. Mixtures of many kind of buildings means mixtures of many types of usages of land and buildings in the area. Such diversity gives image of complexity and sometimes attracts people visiting Japanese urban cities. As part of this trend, not only mixture of many shapes and usages of buildings, mixtures of different activities inside buildings, which didn't designed at planning phase of architecture, are found. We know many offices, shops and service activities are in dwelling units of apartment building. By the contraries, some people dwell in office buildings. Control of users' activities tend not to be done and mixtures of activities inside buildings tend to be ignored. However, for the residents in apartment buildings, mixture of different activities is not welcomed state from viewpoint of security, privacy and comfort because unspecified people enter the common space for residents.

These mixed activities inside buildings cannot be distinguished from its façade. Even from nameplates on the mail boxes or doors because many people living in apartment buildings don't show their names for outsiders. It is difficult to grasp ratio of residents and non-residents. Relations between mixture of different activities and trend of anonymities of resident in apartment buildings are not focused and clarified, but it is supposed that people living in commercial purposed buildings or apartment buildings highly used in non residential uses tend not to show their information even it is small information like "names". It may show loss of the community at area societies.

There are several research on mixture of activities. Hatori analyzes mixture in buildings locate on Tokyo 23 wards by using NRR (Non resident-ratio) that is ratio of non resident units inside of the building and is calculated from "The Zenrin Zmap town2" and "the GIS data of the Tokyo metropolitan government". This

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

study clarifies that over 20 % buildings have different usage from the original. And also clarifies that mixtures of activities are prone to occur low floor in the buildings. Hibata focuses on mixture of non residential uses in the residential zone around Yamanote Railway Line in sub-center of Tokyo. Ant it analyzes mixture of non residential uses by area characteristics, traffic convenience, zone district, and temporal-spatial change. Yamaga researches 13 business zones in Tokyo by defining "Usage Section" which color-codes cross-section diagrams of buildings with 53 patterns of categorized usages. Yamaga finds peculiar characters in each district from Usage section. It demonstrates diversity of those business zones.

These previous researches show that mixtures of activities have three-dimensional characters and characters of mixtures of activities are different by area. Therefore this study analysis mixtures of activities three-dimensionally in three local areas. by collecting past-to-present data of names of buildings dwellers. Units without information of dwellers names are also recorded. Also, characteristics of dwellers inside buildings are not found data. Mixtures and distributions of activities inside buildings are horizontally and vertically visualized.

3 DEFINITION AND METHOD

3.1 Definitions

Mixed rate

Mixed rate is a ratio of different usage from the original usage in the building. When define number of whole units in each building that can contract as "W", and number of units that don't conform to original usage as "a". Mixed rate is presented "a / W".

Non – named rate

Non-named rate is a ratio of non-named mailboxes that locate on building entrance. And such non-named mailbox can categorize two types. One is the case that there are no people who use those units. And other is the case that there are used by the contractants but they don't named on their nameplate because of security. But, it is already fully-clarified that latter case is the large part from questionnaire to the managers of the buildings. So, in this paper, assume all case is the latter. When define number of whole units as "W", and number of units that don't exist name on the nameplate of the mailboxes as "b". Non-named rate is presented "b / W".

3.2 Investigation method of usage in the building

Survey

In this research, authors collect activity data of the units from the name on the mailboxes in the building. And collect such data from three areas in Tokyo – Shibuya, Azabu-juban and Kasa. These areas have different histories, size of city block. The fields of survey is nearby the railway station of these areas, and list up other characteristics (distribution character of the building type, use district etc.) on the Table 1. Also, do this survey to apartment buildings and buildings that can't recognize its original usage from façade. And this survey conducted between August, 2010 and July, 2011.

- Shibuya

Shibuya is the one of most bustling area in Tokyo. But Shibuya has also residential area. There are commerce buildings very near of the station, and high-rise buildings also exist. And number of detached houses and low-rise buildings is increase with increasing distance from Shibuya station. And this area has developed from Meiji period (1880's). So old and new buildings are mixing. 104 buildings that locate on between Shibuya station and Kyu-yamate dori Avenue are chosen.

- Azabu-juban

Azabu-juban locates on Minato ward where is the center of Tokyo metropolitan area. This area has developed as city for merchants from Edo period (16th century). And Roppongi or Ebisu where are famous area to the foreigners are near from this area. As consequence of this history, blocks of this area are divide smaller than other area and various ages and usages of buildings are mixing. 272 building that locate on

south-west side of Azabu-juban station where gathers many residential buildings or office buildings are chosen.

- Kasai

Kasai locates on 15 minutes away from Tokyo station and there is new commuter twon. There are many commercial buildings near the station, but there are almost residential buildings with increasing distance. This area's characteristics is there has been farmland since urbanize plan started about 40 years ago. So blocks are larger than other area. And because of this, building area is also large and there are many building has over 100 units. 318 building that locate on between Kasai station and Nishi-kasai station and along the main streets are chosen.

Counting past activities from ZENRIN bekki data

In this research, it is very important to analyze usages inside of the buildings of the past. So authors collect such past data. By using ZENRIN bekki data that is on the appendix of the ZENRIN map, we can collect decennial data from units' name, and that data is almost same to our survey's data because that data also has gathered from mailboxes in the buildings or questionnaire to the people who live. But this data exist only specific buildings. So there are some buildings that can't collect usages of the buildings. We use 1990 and 2000 data.

	Shibuya	Azabu-Juban	Kasai
number of surveyed buildings	104	272	318
main building type	commercial building apartment building	commercial building apartment building	large apartment building commercial only building
use district	commercial district, category 2 residential district, category 2 low-rise exclusive residential district	commercial district, neighborhood commercial district	commercial district, neighborhood commercial district, quasi industrial district, category 1 residential district
history	from Meiji period	from Edo period	from past 40 years
land price[2)]	4.88 million yen / tsubo[(3)]	4.11 million yen / tsubo	1.26millon yen / tsubo

Table 1: characteristics of areas and other profile

4 TWO DIMENSIONAL ANALYSIS OF MIXTURE OF ACTIVITIES

We draw Mixed rate and Non-named rate of each areas by using GIS (Geographic Information System) and analyze these distribution tendency. The maps of result show on the Table 2.

4.1 Shibuya

Character of Shibuya is that Mixed rate is gradually decrease with distance from the station. And by contrast, Non-named rate gradually increase. Use district gives great effect to this trend. There is commercial district nearby the station and use district changes to category 2 low-rise exclusive residential district around 300m away from the station. And these districts affect to Mixed rate and Non-named rate.

4.2 Azabu-Juban

Character of Azabu-juban is that two indicators spread widely in the area. This is also strong effect of use district. Commercial district is the use district. However this area has developed also for merchant, so there are many demands for living and for business. By consequence of this, Azabu-juban has this characteristic.

4.3 Kasai

Character of Kasai is that there are a lot of high Non-named rate buildings. In addition, a lot of buildings have over 80 % Non-named rate. However, from aspect of Mixed rate, Kasai's buildings indicate low value and this result shows that activities are distribute correctly in this area.

	Shibuya	Azabu-Juban	Kasai
Mixed rate			
Non-named rate			
0.000 - 0.200 0.201 - 0.400 0.401 - 0.600 0.601 - 0.800 0.801 - 1.000

Table 2: result of each indicator in 2010 of each area

5 THREE DIMENSIONAL ANALYSIS OF MIXTURE OF ACTIVITIES

The distribution characteristics of each area are written in section 3. And in this section, we choice one street from each area which has characters of distribution and connects to station directly, and then, draw urban section of these streets. Then, by using data from survey and ZENRIN bekki data, we color-code each unit of 1990, 2000 and 2010. The chosen streets are the red lines on the Table 2. And urban sections of these streets are shown figure 1, 2 and 3. As a result of color-code from type of business, almost retailing stores or restaurants, those colored red or orange, locate on the lower floor. And other industries don't have relation with number of floor.

5.1 Shibuya

Character of this area is that, same to two dimensional analysis, commercial of office activities inside of the building is decrease. And this character has not changed 20 years. In building No. B - 13 in 2010 case (in 2000: No. B – 12, in 1990: No. B - 12), there are almost used for residence in 20 years ago but different activities from the original usage gradually increase and there is most units are used for office now. And farther than 500m from station, there are mostly low-rise detached houses.

5.2 Azabu-Juban

Case of Azabu-juban, distance from station doesn't have relation with mixture of activities. During this 20 years, mode of mixture has not changed in this area and activities has mixed at random in almost all buildings.

5.3 Kasai

Case of Kasai, number of non-named units increases sharply 2000 to 2010. Look at building No. B – 7 (in 2000: No. B – 7, in 1990: No. B - 7) , some units had changed to non-named 1990 to 2000, but during 2000 to 2010 almost all units have changed to non-named.

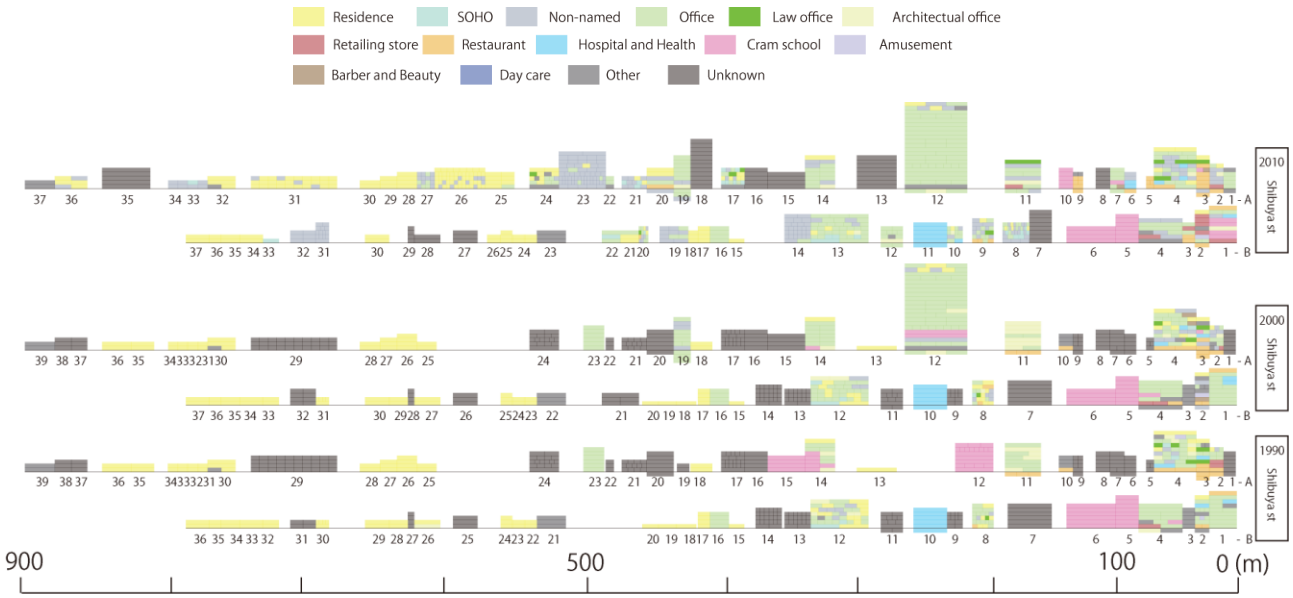

Figure 1: Urban section of Shibuya

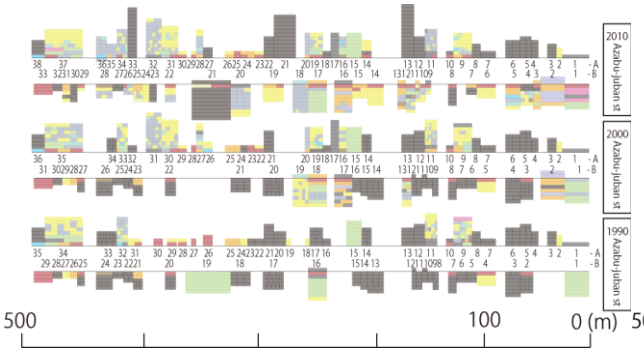

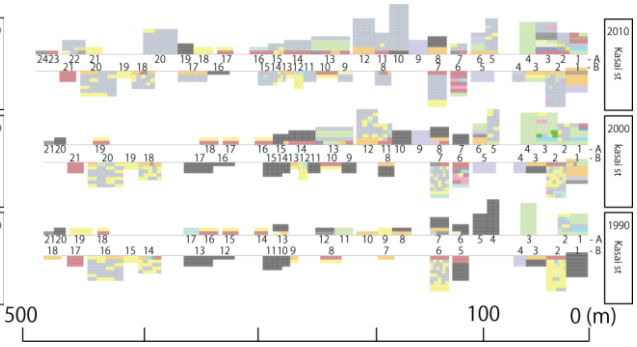

Figure 2:Urban section of Azabu-juban. Figure 3: Urban section of Kasai.

6 CONCLUSION

Through two and three dimensional analysis of mixtures of activities inside of the buildings, authors clarify some characters.

6.1 Two dimensional mixture

- Use district is affecting to the distribution tendencies every areas. Mixed rate is high in commercial district and Non-named rate is large value in residential district.

- In Shibuya, Non-named rate goes up with increasing distance from station.

- In Azabu-juban each indicators distributes at random regardless position or building type of the buildings.

- In Kasai, activities of units are separated depending on the building types or the original usages of the units and Mixed rate is indicated small value. But Non-named rate is very high and many residential buildings are over 80 %.

6.2 Three dimensional mixture

- In this investigation, we clarify that distribution or its change tendency is not depending on floor number excluding retailing stores or restaurant.

- In Shibuya case, there are many office units that have changed from residential usage. And the majority of building type becomes low-rise detached house more than 500m from the station.

- In Azabu-juban, it is same that mixture distribution is at random through three years, but usages change intensely in the building.

- In Kasai, during 2000 and 2010, Non-named units slightly increase no relation to floor number.

Note

(1) Survey term covers to 2011, however, relating to analysis is do every 10 years in this paper, so standardize all data "2010" for descriptive purpose.

(2) This land price is average price of land that away from the each station between 5 and 10 minutes.

(3) Tsubo is a Japanese traditional unit that is used when measure area. 1 tsubo is equal to around 3.3 m2.

TURaS: Transitioning to Urban Resilience and Sustainability

Marcus Collier, Louise Dunne and Zorica Nedović-Budić

(Dr. Marcus Collier, School of Geography, Planning and Environmental Policy, University College Dublin, Ireland, marcuscollier@ucd.ie)
(Dr Louise Dunne, School of Geography, Planning and Environmental Policy, University College Dublin, Ireland, louise.dunne@ucd.ie)
(Professor Zorica Nedović-Budić, School of Geography, Planning and Environmental Policy, University College Dublin, Ireland, zorica.nedovic-budic@ucd.ie)

1 ABSTRACT

The TURaS Project brings together neighbourhood communities, researchers, local authority and urban councils as well as small or medium enterprises (SMEs), in order to research, develop, demonstrate and disseminate transition strategies and scenarios to enable European cities and their rural interfaces to build vitally-needed resilience in the face of significant sustainability challenges. This paper is an illustration of how the TURaS Project will carry out research in collaboration with communities, agencies and institutions within selected cities, with the target of moving towards a reduction of their ecological footprint through proposing new visions, feasible strategies, spatial scenarios and guidance tools to help cities address these challenges. This paper illustrates how the impact of these new approaches will be measured across participating cities and a final set of strategies and tools will be developed for demonstration, dissemination and exploitation in other European cities. Community representatives and SMEs are integral to all aspects of the project, and specific measures have been put in place to ensure the optimal economic impact of the project is achieved. While there are numerous studies into resilience and urbanisation, little is known of the impact that participation by different kinds of urban stakeholders may have on communities and environments, or the effects that greener environments may have on communities and human health. This paper will conclude by showing how TURaS will explore these themes, leading to a stronger understanding of how to mainstream sustainability in urban areas.

2 INTRODUCTION

The extent and financial cost of global biodiversity loss related to unprecedented urban growth is only just being realised. From pollinator declines to the loss of coastal protection services, anthropogenic-driven loss of ecosystem services have impacted communities, governments and industry worldwide. Built upon old models of high density living and economic development, Europe's cities are beginning to encounter detrimental environmental impacts. Responding to these complex challenges requires a long-term and integrated approach to city planning and development, involving significant participation by all stakeholders towards a common goal. The TURaS Project has a design methodology that partners different institutions in research couplets (figure 1) within a resilience focused paradigm.

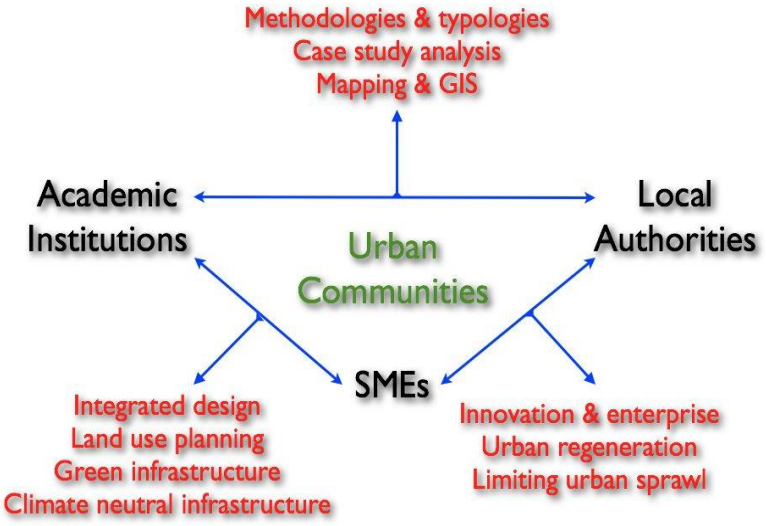

Fig. 1: Research typology of the TURaS twinning concept illustrating three expertise couplets and their respective areas of speciality (red). Central to the concept are urban communities in the form of local neighbourhoods or districts.

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

2.1 Resilience

Resilience thinking derives from studies of ecosystem dynamics and conservation practice. It is an explanation of how complex ecological systems change and persist over time particularly with their interaction with human interference especially in relation to how systems recover from human-oriented environmental change. Resilience can have different meanings. It can be used to describe a response to environmental disturbance or how habitats and ecosystems can re-organise spontaneously after a disturbance. It can mean the capacity for adaptation within a system and, in relation to human systems, the ability to learn and adapt. Thus, resilience theory is at the root of what are known as social-ecological systems. These are the complex interactions between humans and ecosystems and have particular poignancy in urban settings. The notion of urban resilience is a relatively new concept and is still hotly debated. However, the TURaS Project has taken the ideas of resilience and aims to see how these ideas can be practically adopted.

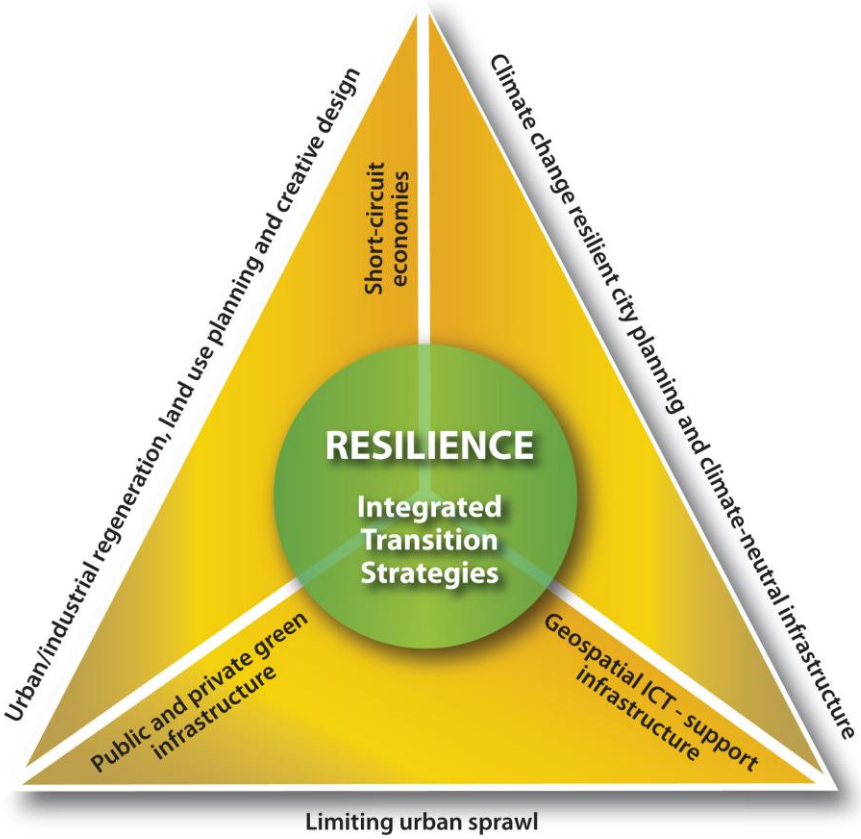

Fig. 2. Typology illustrating the six principal RTD work packages of the TURaS Project. All six are interconnected and inter-reliant with each other, and the ultimate focus is to establish mechanisms for building resilience into urban planning and design through integrated transition strategies.

2.2 Methodology

The cities represented in TURaS are representative of typical European regions in terms of size, geographical location and sustainability challenges. They include 6 European capital cities: Brussels, Dublin, London, Rome, Sofia, Ljubljana as well as other cities representing regional capitals and smaller cities including Nottingham, Seville, Rotterdam, Stuttgart, and Aalborg (Denmark). The TURaS Project will begin by developing a new infrastructure (currently under way) that will enable inventory, visualisation and analysis of a variety of aspects of urban resilience and sustainability. Provision of information infrastructures to support sustainable development and planning is still in its infancy. In the first phase of TURaS a new framework and process will be demonstrated for developing and using a geospatial information and communication technology (ICT) infrastructure at sub-city / neighbourhood scale, featuring relevant contextual as well as project-specific data. The most important and innovative element of the infrastructure will be its availability to local organisations and communities as a communication and project management tool. Using this infrastructure developed in the initial phase of the project, data will be collected and presented in a common format for a selected case study neighbourhood in each of the participating cities. In the next phase of the project, this case study data will be used to develop and test new approaches to build

increased urban resilience and reduce the urban ecological footprint of each participating city. Figure 2 illustrates the connectivity of the different approaches to building urban resilience, which will be developed in the TURaS Project and how these interact together to build urban resilience and reduce ecological footprints. The final phase of the TURaS Project involves the demonstration, dissemination and exploitation of results in other European cities with the ultimate target of motivating policy-makers, planners and managers at local, regional, national and international levels. Over the five year duration of the project, the feasibility of these new approaches will be tested in selected case study neighbourhoods and new measures to enable adaptive governance, collaborative decision-making, and behavioural change towards resilient and sustainable European cities will be tested.

3 DISCUSSION

Resilience is a contested and debated issue. For some it can mean a 'bouncing back' or recovery from disaster or serious impact to a status quo situation, where little has changed in planning and designing in the urban arena and a business-as-usual stance is taken. For others, resilience can mean a 'bouncing forward' to an awareness and acceptance of dangers and threats, and a thus there is a desire to change or modify the attitudes of urban communities and learn from past mistakes. This idea of resilience sees change as gradual and inevitable. Still others see resilience as a transformation act; a transition to a new urban development ideology and a mainstreaming of the original sustainabile development ideals. This sees resilience as a motivator for societal change. The TURaS project seeks to explore the latter, by developing strategies using differing disciplinary approaches. By using this synergistic approach, the TURaS Project may yield practical information that communities, designers, planners and policy-makers all seek in the cities of a modern Europe.

Urban Nomads: How to Remix the Demography of the City

Ehsan Bazafkan

(Ehsan Bazafkan, No 16, Eslami alley, Sohrevardi st., Tehran, Iran, Zip: 1587653834, e.bazafkan@gmail.com)

1 ABSTRACT

Cities, nowadays, are scene of a fierce competition among citizens for resources. And as usual the rich and powerful have better access to jobs, amenities and facilities, even to natural features like climate zones. This sort of inequality has been accompanied with urbanism for such a long time that even it has been manifested in settlement patterns of the city. Rich are usually living in the north, while south us home to poor and center is occupied with business and industry and agriculture roam the perimeter.

It seems that we are bounded to these fixed patterns, and so does the efficiency of our cities. But for thousand years, human race had a more flexible way of living: Nomadism. The nomads travelled in order to have better access to resources, be it jobs, food or better climate. They invented kinds of mobile shelter and adapted a very flexible life style. They also developed a system of prediction and planning, upon the result of which they each time chose the destination, the trail and the how-to of their seasonal immigrations.

Nowadays, metropolitan areas has become so vast that they contain several distinctive zones of settlement, work and even various micro-climates. This variety offers a lot of dynamics yet we are stuck to our fixed homes, workplaces and lifestyles. And in this manner we impose a lot of costs to our cities and to ourselves. What if we could live like an urban nomad, a wanderer inside the city walls?

In this paper I propose inner city migration and Nomadism as way to cope with serious lack of resources in our urban areas. I'll try to study both Bedouins and modern urban nomads, and assessing the advantages and obstacles of moving toward nomadic lifestyle, whether remixing the demography of our cities, and not their physical features, could improve our living conditions? And also I'll try to propose an experimental framework for accommodating this lifestyle in Tehran, a megalopolis with around 9 millions population.

Urbane Zentren für alle Menschen nutzbar machen

Dagmar Everding

(Dr. Dagmar Everding, Architektin und Planerin, Kempten, Deutschland, dagmar.everding@t-online.de)

1 ABSTRACT

Zur Urbanität gehört die Teilhabe aller Bevölkerungsgruppen an den Aktivitäten im öffentlichen Raum der Städte und Gemeinden. Noch finden sich in den Zentren für Versorgung und Freizeit und auf den Wegen zu ihnen zahlreiche Barrieren, die alten und behinderten Menschen den Zugang erschweren bzw. unmöglich machen.

Der Umbau zu barrierefreien Stadträumen hat begonnen. Er kann in Deutschland und in vielen anderen Staaten auf ein fast komplettes Paket von Gesetzen und Normen zum barrierefreien Bauen zurückgreifen. Allerdings wird es nicht möglich sein, diesen Umbau innerhalb weniger Jahre zu vollenden.

Es werden räumliche und zeitliche Strategien benötigt, die Bau- und Verkehrsmaßnahmen mit dem Einsatz von Informationstechnologien verknüpfen. Aus ersten Ansätzen in Städten lassen sich Anforderungen an das Instrumentarium für solche kommunalen Strategien ableiten.

2 URBANE ZENTREN FÜR ALLE MENSCHEN NUTZBAR MACHEN

2.1 Erklärung von Barzelona "Die Stadt und die Behinderten" von 1995

Nachdem 1995 im Rahmen der Europäischen Konferenz „Die Stadt und die Behinderten" teilnehmende Kommunen sich auf Ziele zur Teilhabe behinderter Menschen am urbanen Leben verständigten, traten in Europa viele Städte der „Erklärung von Barzelona" bei. In Deutschland sind es mittlerweile rund 50 Kommunen, die zur Umsetzung der „Erklärung von Barzelona" in Abstimmung mit ihren Behindertenbeiräten bzw. Behindertenbeauftragten Handlungskonzepte für eine barrierefreie Stadt aufstellen und fortschreiben.

Aufgrund der ausgeprägten wechselseitigen Abhängigkeiten der verschiedenen Maßnahmen der Handlungskonzepte, erweist es sich als notwendig, das kommunale Handeln stärker strategisch auszurichten. Dabei nehmen die urbanen Zentren eine Schlüsselstellung ein.

2.2 Zur Urbanität gehört die Teilhabe aller Bevölkerungsgruppen

Stadträume, in denen urbanes Leben stattfindet, sind Plätze, Boulevards und innerstädtische Parks. Platz meint eine Freifläche, um die sich öffentliche Einrichtungen, Geschäfte und Wohnquartiere gruppieren. Diese Freifläche eignet sich für Pausen, für das Zusammensitzen, zum Miteinander Spielen. Der Boulevard ist mehr als eine Straße. Er verfügt zusätzlich über Freiflächen in Anlehnung an Plätze, oft mit schattenspendenden Bäumen ausgestattet. Die Geschäfte und Gastronomie entlang des Boulevards zeichnen sich durch ein besonders attraktives Angebot aus. Städte, in denen es keinen Boulevard gibt, haben vielleicht eine Fußgängerzone mit vergleichbaren Attributen. Innerstädtische Parks zeichnen sich besonders dann durch urbanen Charakter aus, wenn die räumliche Beziehung zwischen öffentlichem Stadtraum und Grünanlage eng ist und in dem Park Räume bestehen, in denen ein Aufenthalt mit Kommunikation und öffentlichen Aktivitäten gepflegt wird: schachspielende ältere Menschen, kletternde Kinder, skatende Jugendliche, Gruppen, die Boule spielen und Menschen, die diese Aktivitäten von Sitzbänken aus betrachten.

Wenn man sich in diesen Stadträumen bewegt, fühlt man sich dem gesellschaftlichen Leben zugehörig. Wie wichtig diese immer wiederkehrende Erfahrung der Zugehörigkeit ist, wird einem oft erst bewusst, wenn man z. B. aus Krankheitsgründen über längere Zeit den öffentlichen Stadtraum nicht aufsuchen kann.

In den urbanen Stadträumen trifft man die Stadtgesellschaft in ihrer ganzen Breite an. Als Besucher einer fremden Stadt erkennt man hier zum Beispiel, ob es sich eher um eine junge oder ältere Stadtbevölkerung handelt. In einer sehr großen Stadt unterscheidet sich der Eindruck nach den Quartieren mit ihrer jeweiligen soziokulturellen Bevölkerungszusammensetzung.

Die Vielfalt und Gemischtheit der sich im öffentlichen Raum aufhaltenden Menschen macht einen großen Teil von dem aus, was wir in der europäischen Stadt unter dem Begriff Urbanität verstehen. Voraussetzung für diese Vielfalt ist auch Toleranz aber mehr noch Akzeptanz von Andersartigen sowie die gegenseitige Rücksichtnahme.

Für die Gestaltung des öffentlichen Raumes gab es von Anbeginn der Stadtentwicklung Bauvorschriften zur Gebrauchstauglichkeit dieses Raumes für verschiedene Nutzergruppen. Als Beispiel sei die Stadt Potsdam in der Nähe von Berlin genannt. Schon im 19. Jahrhundert war geregelt, dass zwischen dem stabilen tragfähigen Pflaster für Pferdewagen in den Straßen für Fußgänger glatt gepflasterte Laufspuren anzulegen sind.

2.3 Zahlreiche Barrieren erschweren den Zugang

Behinderte Menschen waren bis zu den 70er Jahren des 20. Jahrhunderts vom öffentlichen Leben stark ausgeschlossen. Alte Menschen machten nur einen geringen Anteil an der Bevölkerung aus und lebten relativ isoliert in den Familien bzw. in Heimen. Dies bildet den Hintergrund, dass die gebaute Umwelt noch bis heute in weiten Bereichen so gestaltet ist, dass alten und behinderten Menschen der Zugang erschwert bzw. unmöglich ist.

Noch in den 80er und 90er Jahren des 20. Jahrhunderts wurden im Rahmen von Wohnumfeldverbesserungs- und Stadterneuerungsmaßnahmen viele Straßen und Plätze relativ uneben gepflastert und mit abgestuften Ebenen versehen. Dadurch sind sie heute für Menschen im Rollstuhl oder mit Rollator schwer zu meistern.

Vorhandene Strukturen in den Städten wurden durchbrochen, so dass die Orientierung schwieriger wurde. Der Autoverkehr dominiert in den Stadträumen und fordert von den Fußgängern höchste Aufmerksamkeit. Er stellt für blinde und stark sehbehinderte sowie für alte Menschen ein besonders hohes Risiko dar, weil die Gefahr besteht, dass sie unbemerkt in den Fahrbahnbereich geraten. Zur Abgrenzung zwischen Fahrbahn und Gehweg bestehen hohe Borde, die von Menschen im Rollstuhl und von gehbehinderten Menschen nur mit Erschwernis überwunden werden.

Auch wenn ein modernes Einkaufszentrum oder eine neue Fußgängerzone barrierefrei gestaltet sind, fehlen häufig noch barrierefreie Wegeketten und ÖPNV-Reiseketten, um von allen Wohnquartieren diese zentralen Anlagen ohne Barrieren zu erreichen.

2.4 Der Umbau zu barrierefreien Stadträumen hat begonnen

Die Barrierefreiheit als Planungsprinzip stellt eine entscheidende Innovation dar, da es ihr gelingt, die Bedürfnisse von Menschen mit ganz unterschiedlichen Einschränkungen in ihren Bewegungsmöglichkeiten (Motorik) bzw. in ihrer Wahrnehmung (Sensorik) in eine gemeinsame technische und gestalterische Leitlinie zusammenzuführen. Dieses Planungsprinzip wurde bzw. wird für alle wesentlichen baulich gestalteten Lebensräume in Normen konkretisiert, also für

- öffentlich zugängliche Gebäude,
- öffentliche Verkehrs- und Freiräume,
- Wohnungen und Wohngebäude,
- Arbeitsstätten.

Hier einige sinngemäße Auszüge aus der aktuellen Normung barrierefreier Gebäude, baulicher Anlagen sowie Straßen, Wege, Plätze und Grünanlagen in Deutschland (DIN-Normen des Deutschen Instituts für Normung, Berlin). Vergleichbare Normen gibt es auch in Österreich, in der Schweiz und vielen anderen europäischen Staaten:

<u>Gehwege/Flächen für Fußgänger</u>

Die Fläche von barrierefreien Gehwegen muss nach dem Zwei-Sinne-Prinzip eindeutig erkennbar sein, d. h. visuell durch optischen Kontrast als auch taktil durch das Ertasten entweder entlang einer Kante oder einer gut unterscheidbaren Bodenstruktur. Je nach Funktion des Gehweges sind Mindestbreiten zu beachten, z. B. eine Mindestbreite von 150 cm bei einem Gehweg neben einer Straße. Der Bodenbelag muss erschütterungsarm, rutschfest und bei jeder Witterung sicher begehbar und mit dem Rollstuhl befahrbar sein. An Hindernissen soll ein optisch und taktil im Bodenbelag erkennbarer Leistreifen rechtzeitig mit ausreichendem Abstand herumführen. Ein zur Fahrbahn vorhandener Bord ist an Querungsstellen sowie neben barrierefreien PKW-Parkplätzen auf genau 3 cm abzusenken, damit er mit dem Rollstuhl überfahren und von einem blinden Menschen ertastet werden kann. Auch an die Längs- bzw. Querneigung der Wegefläche werden Anforderungen gestellt.

Eingangsbereiche von öffentlich zugänglichen Gebäuden

Öffentlich zugängliche Gebäude sind nicht nur Schulen und Rathäuser, also öffentliche Gebäude, sondern auch Gebäude, in denen sich Nutzungen mit öffentlichem Charakter befinden, z. B. Geschäfte, Gastronomie und Gesundheitseinrichtungen wie Arzt- und Therapiepraxen. Die Eingänge zu diesen Gebäuden bzw. Einrichtungen sollen gut auffindbar sein, visuell durch optischen Kontrast sowie taktil durch einen zum Eingang führenden Streifen im Bodenbelag. Eingangsbereiche zu öffentlich zugänglichen Gebäuden müssen stufenfrei und schwellenlos sein. Rampen und Aufzüge machen eventuell vorhandene Höhenunterschiede barrierefrei überwindbar. In einem solchen Eingangsbereich soll man sich sicher und geschützt aufhalten, sich orientieren und sich anmelden können. Dafür benötigt man Witterungsschutz, Beleuchtung sowie gut erkennbare Informationstafeln bzw. Klingel- und Sprechanlagen auf einer mittleren Bedienhöhe von 85 cm über Oberkante Fußboden. Vor und hinter den Türen wird eine ausreichende Bewegungs- und Rangierfläche (150 x 150 cm) benötigt. Die Türen müssen ohne großen Kraftaufwand betätigt werden können. Großflächige Glastüren bedürfen einer Sicherheitsmarkierung, ebenso eventuell vorhandene Stufen im Eingangsbereich.

2.5 Strategien für den barrierefreien Stadtumbau mit Nutzung von Geoinformationssystemen

Gesetze und Normen greifen bei „sowieso“ stattfindenden Baumaßnahmen und führen häufig nur zu isolierten baulichen Veränderungen. So kann z. B. der Umbau eines öffentlichen Gebäudes die Normen des barrierefreien Bauens beachten, wenn aber die Bushaltestelle in der Nähe des Gebäudes nicht barrierefrei ist, stellt sich die Erreichbarkeit für behinderte Menschen noch als eingeschränkt dar.

Immer mehr Städte verfolgen Konzepte einer kontinuierlichen Umsetzung von Barrierefreiheit:

Für kommunale Liegenschaftsbereiche werden – häufig angeregt von den Behindertenbeiräten bzw. Behindertenbeauftragten – Programme und Richtlinien aufgestellt. Manche Städte legen z. B. in einer Gebäuderichtlinie Anforderungen an die Barrierefreiheit bei Sanierungs- und Neubaumaßnahmen in ihrem eigenen Gebäudebestand fest. Andere beschließen Programme zur barrierefreien Umgestaltung von städtischen Grünanlagen und Parks. Programme enthalten Entscheidungen über Orte und Maßnahmen und damit auch das Setzen von sachlich begründeten Prioritäten.

Neben den Kommunen stellen auch die Unternehmen des öffentlichen Nahverkehrs sowie Straßenbauverwaltungen und -betriebe Leitlinien und Programme zur Barrierefreiheit auf. In vielen Städten fahren Niederflurstraßenbahnen und Niederflurbusse, die den Fahrgästen ein fast ebenes Ein- und Aussteigen ermöglichen.

Das seit 2002 in Deutschland geltende Bundesbehindertengleichstellungsgesetz sieht als weiteres Instrument Zielvereinbarungen von Mitgliedsorganisationen des Deutschen Behindertenrates mit Unternehmen, Vereinen oder öffentlichen Körperschaften vor, die in einem Zielvereinbarungsregister eingetragen werden. Eine besonders erfolgreiche Zielvereinbarung stellt das Programm der Deutschen Bahn dar. Barrierefrei umgebaut werden Bahnhöfe ab 1.000 Reisenden pro Tag. Die neu bestellten Fahrzeuge müssen barrierefrei gestaltet sein, die Reiseketten werden optimiert, eine Mobilitätszentrale bietet behinderten Fahrgästen eine Vielzahl von Dienstleistungen. Mittels Zielvereinbarungen lassen sich komplexere Verbesserungen ganzer Lebensräume erreichen, indem bauliche, technische und organisatorische Maßnahmen kombiniert werden.

Eine vollständige barrierefreie Umgestaltung der Städte ist auf absehbare Zeit nicht realisierbar. Die Stadt Zürich hat in ihrer Mobilitätsstrategie, Teilstrategie Behinderte, Betagte und Kinder (2003) ermittelt, dass die Kosten allein für eine konsequente Bordsteinabsenkung bei allen Fussgängerquerungen etwa 10 bis 20 Millionen Franken kosten würde.

Deshalb gilt es, nach Wegen zu suchen, die mit vertretbarem Aufwand eine barrierefreie Nutzbarkeit prioritärer Stadträume ermöglichen.

- Herstellen von Erreichbarkeiten wichtiger Zielpunkte wie öffentlichen Einrichtungen durch barrierefreie Wegeketten. Es muss sich nicht um den kürzesten und schnellsten Weg handeln, aber die barrierefreie Wegekette muss planbar und erkennbar sein.
- Eine Kategorie von Zielpunkten barrierefreier Wegeketten sollten Quartierszentren/Quartiersplätze darstellen, um die sich Wohnquartiere und Altenwohnprojekte gruppieren.
- Ausrichtung der Wegeketten am Hauptstraßennetz und an einer verständlichen Stadtstruktur.

Bei dieser Aufgabe werden Geoinformationssysteme einen wesentlichen Beitrag leisten.

Im Geografie-Fachbereich der Universität Augsburg wird ein Stadtplan für barrierefreie Mobilität entwickelt. Es handelt sich um einen wachsenden Plan, der seine Informationen von Bewohnern und Nutzern des Stadtraums erhält. Die Informationen werden in einem Geoinformationssystem festgehalten und sind über das Internet abrufbar. Die Erfassung der Daten ist in der Aufbauphase sehr aufwändig. Deshalb liegt der Plan erst für einen Teilbereich der Stadt Augsburg vor. Auf jeden Fall steckt in diesem Projekt ein großes Potential für eine verbesserte Mobilität behinderter Menschen. Mit Hilfe der Stadtplaninformationen können behinderte Menschen im Vorfeld ihre Wege planen, Arztpraxen, Geschäfte, Restaurants, Kultureinrichtungen nach deren barrierefreier Zugänglichkeit und Nutzbarkeit aussuchen.

Eine zusätzliche ebenfalls weitreichende Funktion eines solchen Stadtplans ist sein Informationsgehalt für die Planung. Der Stadtplan lässt eine Visualisierung von barrierefreien Wegeketten ebenso zu wie das Erkennen von Lücken. Auch der Grad der Versorgung mit barrierefrei gestalteten Infrastruktur- und Dienstleistungseinrichtungen könnte bei entsprechender Informationsdichte des Plans evaluierbar werden. Geplante Maßnahmen können hinsichtlich ihres Beitrages zu einem barrierefreien Stadtumbau bewertet und verglichen werden.

Eine weitere Chance bietet der Einsatz von Geoinformationssystemen für die vergleichende Bewertung von Städten und Stadtquartieren. Barrierefreiheit stellt ein Kriterium für den Grad der Nachhaltigkeit dieser Lebensräume dar. Darin, dass es in Zukunft möglich sein wird, die barrierefreie Qualität von städtischen Gebieten zu messen, liegt eine große Chance, dass behinderte Menschen durch systematischen und strategischen Stadtumbau am urbanen Leben gleichberechtigt teilhaben.

1 ABSTRACT

Utility tunnels have been elements of urban supply systems for almost two centuries now. However, their use and implementation is still less determined by urban planning and urban needs – and more by the qualities, preconceptions and determination of the urban managers in question. During the 1990s in the course of the German reunification process the fluidity of the urban management situation created opportunities for new approaches to this old technology.

In conjunction with landmark urban development projects on the path to urben sustainability, utility tunnels were used as one of the many instruments and approaches to achieve sustainable developments. Now – almost 20 years later we can look at these developments and the utility tunnels and have a first discussion on their sustainability success.

At present a new relevance developes in regard of this technology. The current urban development schemes in China, India and many other places of the world are of such scale, that questions of doing it right while doing it timely are of prime significance. At the same time, we are facing a situation, in which – within the coming 40 years – the whole energy supply and distribution system of the world – including China and India – will need to be 100% restructured and reworked. We need a whole new quality of system flexibility and reaction capacity in urban engineering to achieve the path to urban sustainability.

Taking proven experience in sustainable urban development and engineering, what are and will be the taskings and quality expectations to urban design and development in the coming years and decades? System changes will require mental, philosophical and educational changes in human minds – also those of the developers, planners, architects, and engineers. So what do we need to learn, and how do we teach it fast and to many of us in a short time?

2 HOW DID WE COME BY THE IDEA TO BUILD UTILITY TUNNELS?

In the 1980s, when considering the known damages, especially in the community pipeline networks transporting water and sewage, in a context of soil & aquifer protection, the technical and engineer community in Germany began to think about how to design better controlable systems. Ideas developed, like absolutely straight line house connections, or double pipes with leak detection systems.

Hermann Laistner injected into this discussion a rectangular infrastructure culvert (utility tunnel), large enough to be easily walked in. From this utility tunnel property and building connections could be constructed in a controllable way, while the main pipes and cables would be inside mounted and accessible. In the early and mid 1980s, these were rather theoretical thought constructs.

2.1 Research Focus "Ecological Development Concepts"

Working within the experimental research on urban development, such ideas however, could be injected for further consideration and detailing of concept. In the state capital of rhineland-palatia, the City of Mainz , the city planning authority – thematically lead by Dipl.-Ing. Jürgen Hoffmann – had applied for, and had been awarded, a federal research demonstration project on the development of an ecological business and industrial park. Hermann Laistner and his company IfEU, having worked succesfully in this research field before, and bringing both an understanding of the research process and the practical every day experience of urban development and supply system engineering into such projects, were selected to be the lead expert researchers for and together with the various offices of the City of Mainz.

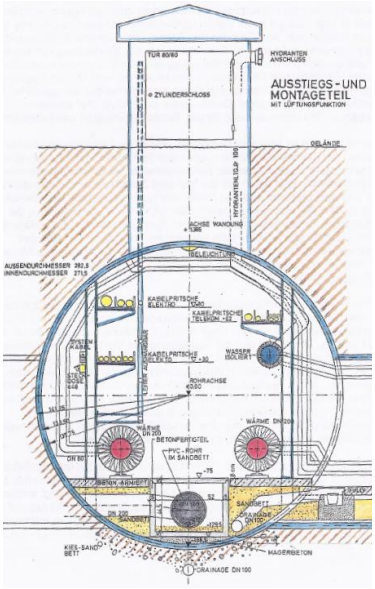

Fig. 1: Sustainable underground system development for urban development area = the utility tunnel picture excerpt from research final report[1] Abb. 17

The urban development tasking was started by an encompassing ecological evaluation study. It was intended to develop a purposfully structured occupation mixed area. A tram-way was to be a high quality public transport connection for the area. State roads were to be the vehicle access routes. In developing the key idea of orienting the developments along wide green corridors, with an explicite focus on empowering pedestrian traffic and their easy connection between public transport and work place. In this context the idea of an utility tunnel was first incorporated by us into a development project and injected into its discussion process.

2.2 The German Reunification

It was 1989 when we had these discussions and did the concept development of a utility tunnel for the City of Mainz. And then the German reunification came and all of a sudden totally new urban development taskings were to be tackled. Through our research we had, after the opening of East Germany, developed contacts to the "Bauakademie Leipzig", because they had written for the GDR (East Germany) the standards on utility tunnels – and nothing comparable was available within the West German standards.

At the time the main development tasking was to create business areas fast, to begin to satisfy the expectations of a better economic and supply situation after the long time of "managing dearth" during the final two decades of the socialist regime. Among the available development areas, in discussion and under review, were the huge refill areas of the lean-coal strip mines. After visiting such an area "Espenhain" next to Borna, we considered the special problems of the large differential ground settlements, that were to be expected in such an uneven industrial refill situation. The idea was to implement utility tunnels with a certain hull flexibility. So we came to look at the long proven corrugated steel culverts instead of the originally envisioned (traditional) concrete culverts. Requests on information regarding as yet undeveloped or unusual production elements of such steel culverts (e.g. bends, manholes, side-penetrations, e.g.) produced an intensive interest within one of the producers – the Austrian Voest-Alpine Krems Finaltechnik corporation.

In the meantime we were contracted to be the development planners and engineers for one specific such new business development in the small village of Wachau directly bordering on the City of Leipzig to the south. The situation there was driven by the need to inject at least a minimum of mandated urban planning into a situation already dominated by a large shopping center construction investor in the north-east corner of the area. Time was of the essence. All over the larger area and many parts of the eastern states of Germany, communities used their new found freedom of communal decission making and planning. Whereever one looked there were growing large billboards advertising business developments in the green fields next to the

[1] For more information and the literature references to this research project: "Modellvorhaben Mainz – Ökologischer Wirtschaftspark Mainz-Süd" please see the paper "Sustainable Urban Development in Germany in the 1990s – a situation report after 20 years" in these proceedings by the same authors

settlements. It was clear, that for the just developing small business and industrial structure in the changing society, there would be very shortly an over-availability of zoned business areas.

We used the many experiences gained in the 1970s and 1980s in urban development projects, development research, and a practised unterstanding of the community political process involved, to help Wachau to a speedy process and solution for the community development. We especially used all the readily developed ideas from the Mainz project. The overall situations were comparable. Close proximity to a city, just outside the city development, with tram-way access to the area, and outside but bounding state road connections.

When coming to the design and then the tendering process of the development construction works for the area, we had presented to the by then just founded PPP business park development company, the concept of using utility tunnels. As this was a known technology, used in most large urban developments of the GDR, this was a readily understood and agreed to concept. However, we did open up the tender to enable bidder proposals for the use of other tunnel materials then the well known concrete culverts. We defined the necessary cross sections and the intended inside installations, but left the material choice to the bidders. At the time, the steel culvert came in with the lowest price – and was selected. In the perpetual see-saw of cement and steel prices worldwide – steel was cheaper at the time.

2.3 The Learning Curve – Execution Problems

Even though the idea of the utility tunnel was nothing unusual in eastern Germany, there was significant concern, that the transition staff of West-German public servants (Wessies), which had been transfered into the East German civil authorities, would project their own rather limited expereince in this field, and reinstate all the problems that had limited the use of utility tunnels to universities, airports and private industry in the West. Individualized and legally protected compentences for supply and utility companies, public suppliers, and a resulting highly differentiated authority structure – with a seperate office for everything – had in the West effectively stifled most atempts to create combined public systems. And the utility tunnel very definitely is a combined services system.

So one of our first steps was to ask the TÜV Rheinland – Divission for Nuclear and Chemical Plants for a safety analysis of the utility tunnel we were designing. The result came in as expected – very positive, and disqualifying all the fake arguments against utility tunnels – while at the same time enhancing our understanding on the special considerations that needed to be given to this technology.

The easy part of engineering and planning work was to incorporate the utility tunnel into the community area zoning plan (Bebauungsplan) and have it politically decided upon by the council. It was a bit more difficult, and a learning process, to design and construct our first utility tunnel. For example – putting the utility tunnel system on a sloped grading to accomodate the function of the integrated gravity sewer and its connection to the Leipzig sewage system – was easy. Then however, coordinating the utility tunnel slopes with the surface profiling of the development area, so that the open surface drainage ditches and their road crossing culverts could be kept consistently safely above the utility tunnels, already became more difficult. Being under time pressure to achieve early marketability of the area was very helpful in the decission making process on this and other issues. Solutions had to be found and compromises could be reached easier.

2.4 Government Subsidies & Initial Discoveries on Utility Tunnel Economics

The decisison to build the utility tunnel system was made easier by the situation of a special canon of federal subsedies and special conditions for the development of business areas in East Germany at the time. Normally e.g. sewers would not be subsedised, the utility tunnel however, as a combined system, could be subsidised with 30% of construction costs including systems at the time. This subsidy more than balanced the expected higher investment costs.

Then we discovered an unplaned economic effect. Steel culverts can be built with a progress of up to 25 m per day completed tunnel hull. And immediatly after – later with – the backfill the internal systems installation started. Due to the fast backfill and closing of the surface, the road construction could progress with only a few days delay behind the hull construction. A fundamental difference in development process exists to the buried pipe and cable system. There road construction usually is delayed by weeks or months to commence only after completion of most or all pipes and cables underground.

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

Property in the development area was consequently almost immediatly markteable. And buildings were already going up while we were still equipping the utility tunnel with the systems. This created an immediate and unexpected market advantage. Hleped by the fast approval process of the urban zoning process, by the state authorities (Regierungspräsidium Leipzig), and the decoupling of above and underground construction development, this area was the only one in the larger area of souther East Germany, that was able to sell accessible plots already during the summer of 1991. By enabling the investors and enterpreneurs to enact their own developments earlier, their acceptance of some accompanying unusual conditions of the business park, such as mandatory permanent green areas on their business property, and membership in an operations cooperative for the upkeep of the business park area, were a much easier sell than expected.

2.5 So What?

Why have such "anecdotal" story telling in a reviewed paper? Isn't that what you're asking yourself right now as reader? Because it illustrates and highlights an important and very dissatisfying state of affaires in urban supply and engineering of utility systems as a whole – not only regarding utility tunnels.

We're worldwide hide bound and turf cracy when it comes to the fictional independence of our supply systems owners and operators, and our authority and decission perogatives.

Why? Very often for reasons driven by the legal system and its developmen history in our countries. Among other reasons however not for a small part also, because academic education is dropping the ball! We all learn or teach intensively the ins and outs of our technical systems, don't we. Yes we do – the electrical engineer for the cables, the mechanical engineer for pipes and plant installations and their operation, the civil engineer about how to construct these under and above ground, and the architect and urban planner how to shape cities, environments and buildings to human needs and functionalities.

- And that's the point – WE'RE STOVE-PIPING OURSELVES ! -

And we're happily projecting this mental self-limitation onto generation after generation of young academics. We've so much dropped the ball on academic interdisciplinary training and team functionality, that it needed the totally destabilized administrative situation of the first few years of German reunification, to re-inject a combined services system into the public sphere again. And when the administrative system stabilized again – that came to an early end again.

AND THAT'S THE STARTING POINT FOR UTILITY TUNNELS IN OUR REALITY!

3 UTILITY TUNNELS – WHERE THEY COME FROM – WHERE THEY'RE GOING

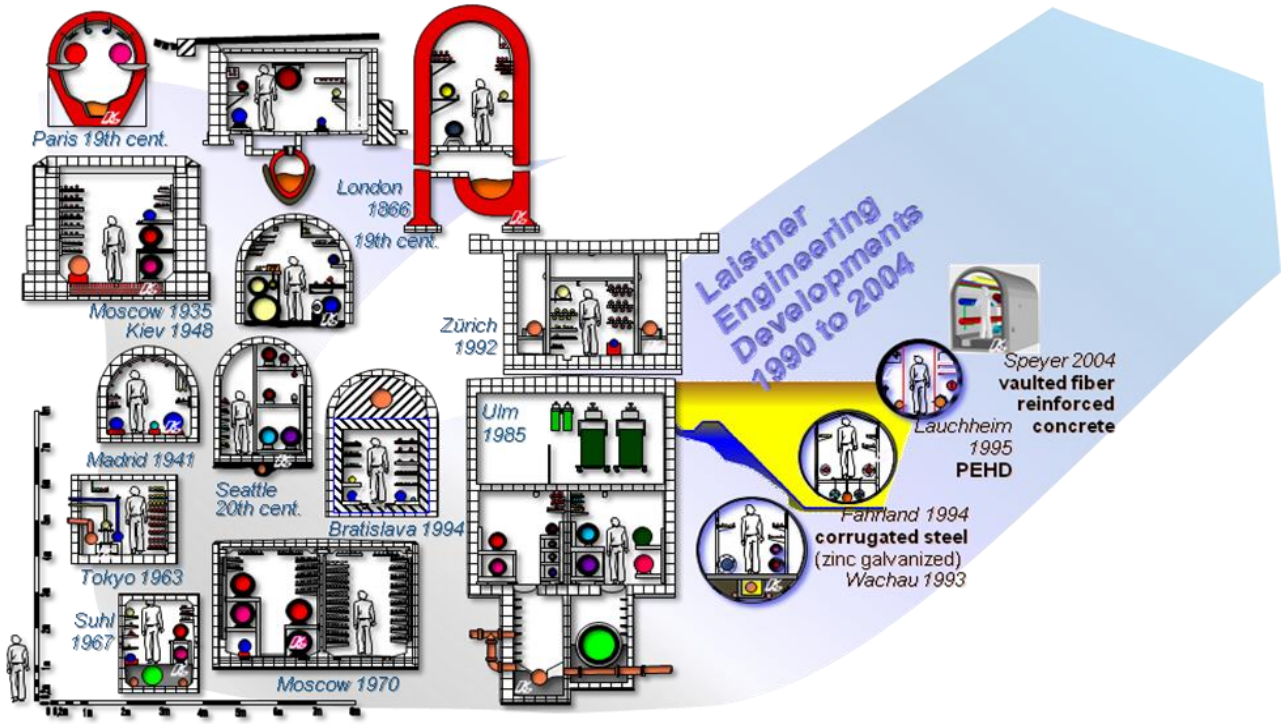

Fig. 2: Utility Tunnels since 1866 – worldwide and developing – pictures Axel Laistner 1994 to 2012 – use of fibre concrete was developed together with and first implemented by Carl Dupré GmbH & Co KG

As you can see above, there are many more utility tunnels than you probably thought. These depicted here are with the exception of Seattle and Ulm all public space utility tunnels. The latter two are university system utility tunnels. When we started into this field as described above – we teamed with the Prof. Knoflacher, at the Institute for Transport Planning and Transport Technology (IVV) of the TU Wien and the VOEST ALPINE KREMS FINALTECHNIK and jointly financed and conducted a privately funded research project into the technology. This produced 1 doctoral thesis and 5 diploma dissertations and a variety of publications from 1992 to 1997. From 1995 until 1997 and thanks to Prof. Jodl we even had a targeted graduate level course on the subject of utility tunnels offered at the Institute for Construction Operations and Construction Economics (IBB) of the TU Wien for civil engineering, architecture and mechanical engineering students. Together with Prof. Stein of the IKB of the Ruhr-Uni Bochum and the GSTT, working groups on the subject of utility tunnels were established in Germany and internationally within the ISTT.

Our intention was to produce a large enough critical education and knowledge base to enable this technology to finally become the accepted state of the art in urban engineering. Now 15 years on – we're again entering a phase of renewed interest in utility tunnels.[2] A little earlier than the historic cycle of 20 to 25 years hiatus and dormancy until the next engineering generation discovers this technology, which we had discovered in our research back all the way to the late 1800s. So we were at best only partially successful in our efforts.

Between 1991 and 2008 we were ourselves involved in designing, or instigating, and supporting the development of 10 utility tunnel systems or system modifications, 7 of which were built, and 4 of which pioniered new forms of hull materials or enlarged their field of suitable implementation. We've been responsiblly involved for the design of ~31 km of utility tunnels and constructed ~ 13.5 km to date. We've gathered experience with utility tunnels in ground water and in earthquakes – and not just as design parameters – but having to deal with the real thing happening. We'd in each situation designed for such known hazards, and the tunnels performed well. And we encountered unknown, or at least unexpected hazards, mostly originating from human thoughfulness and thoughlessness both. We've seen utility tunnels float in their construction ditches, and suffer from water incursion because the outside drainage protection system had been forgotten and needed to be rediscovered. With all this experience through 20 years we can unequivocally state:

There is no more effective, efficient, economic, safe, supply secure, environmental and sustainable urban supply and support systems technology than the Utility Tunnel !

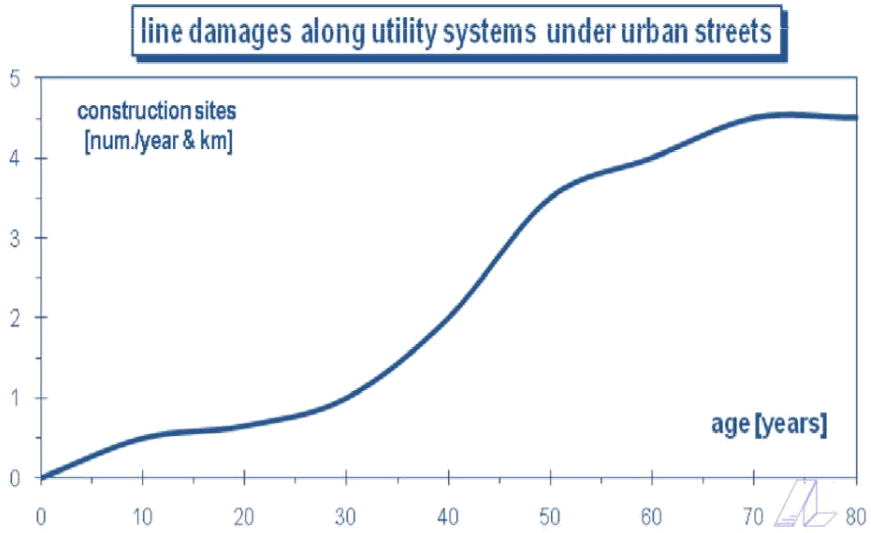

Fig. 3: Utility Faults per m Public Road – Age Dependency Axel Laistner 1995/2012

[2] in 2011/2012 we conducted visits to our utility tunnels for delegations from China, Sweden, Finland, Austria and were invited to present on the system in India

3.1 Utility Tunnel Economics

Let's talk Reality about the Urban Underground

Our urban supply systems leak like sieves! Even a quick look into the literature makes this clear, and the constant sight of urban undergound construction is known to all of us. In 1994/95 we analyzed, with the help of the City of Wien, Austria their construction site database in the public road spaces. We present these results here again – as their impact is so grave, that it needs to be restated again and again.

Our societies spend immense sums of public money (a scarce commodity when lately we listened to the news) on pipes and cables under ground – and doesn't even know it. It's so well hidden in the scattered budgets and responsibilities, that on the whole not even the supply company itself has any idea what their reality of system maintenance by daily construction costs them per running meter of system line.

The reality check of this rare data[3] sends a clear message. Any private industry manager would call them crazy – not knowing the costs of operation of what in fact is their main method of product delivery to their paying clients – but such is the way we've structured our western urban engineering economy. Well as long as the client = the end-user of water, power, IT, etc. is willing to pay – it's an easy job, isn't it? It could be funny – if it wasn't so sad, and so bad for our urban societies.

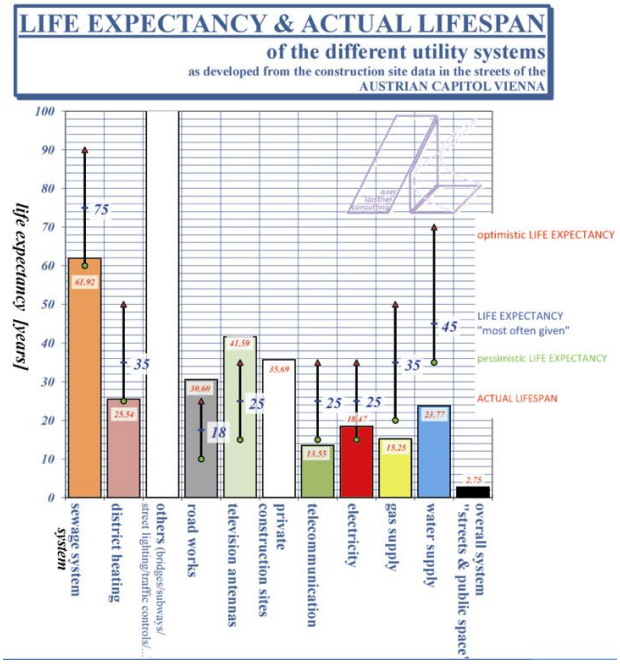

Fig. 4: Utility Systems real LIFETIME EXPECTANCY per m Pipe/Cableway Axel Laistner 1995/2012

We compiled the data and projected onto it assumed maintenance construction costs (fault repair, system enhancement etc.) and combined them with the real statistical life expectancies of the underground buried pipes and cables. Result was a system comparison between conventional construction and the utility tunnels for 7 Reference Projects using real construction costs from 5 projects (3 Utility Tunnels and 2 Conventional Constructions). In the end, we came up with a realistic economic picture of the comparative operational running maintenance cost per year and technical system and "m" Utility Tunnel as homogenizing unit.

The Utility Tunnel beats conventional construction hands down on operating costs. In many cases, even if the responsible utility tunnel owner would put aside a reconstruction and rehabilitation fund for the future. At present we're in the process of verifying the UT numbers for the three constructed systems as best as possible. Early indications of the returning information is, that the UT operational costs are even lower than estimated in 1995.

[3] most cities and towns – and most utility companies and supply system operators, have no clue about their real line costs – as the operate by strictly segregating larger construction sites as investment into their development divisions with a project based system monitored site by site, and their smaller maintenance by construction into their operational divisions, usually equipped to execute all measures with fixed rate contractors.

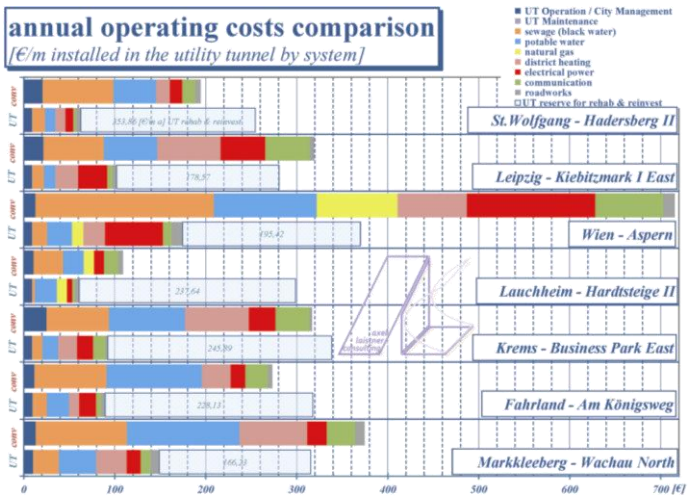

Fig. 5: Utility Systems with/without UT. Real Operational Cost Comparison, projected onto the base unit of 1 m Utility Tunnel – Axel Laistner 1995/2012

This comparison, by the way, is totally without economic costs of the normal conventional product losses (e.g. water leaks, sewage spills, cable-way resistance heat, etc.) all of which are much lower or non existent in a utility tunnel, as well as any discounting of the significantly longer road and surface stability over utility tunnels.

UTs beat buried pipes and cables operationally any day

Let's talk Cost of Urban Development

That might be so, you're maybe thinking at this time, but THE INVESTMENT COSTS of the utility tunnel will take care of that. So lets look at these investment costs, but in total, and with proper consideration of timelines of credit and repayment by the public investor, developing an urban area.

The first glance already shows, that the utility tunnel actually is only a small part of the developement costs. Even First-Prototype projects like Wachau have a fighting chance with the utility tunnel investment being recovered by the faster pay back of financing costs through the earlier marketing start of the property sales. Other considerations also come to the fore. Where it is difficult to built a utility tunnel (e.g.in a river flood plain like in Krems), this is equally so for the normal burried systems, and their extra protection and function requirements.

Where the utility system demand however is too low (e.g. in Lauchheim or St. Wolfgang, rural housing with only 25/65 individual buildings only) utility tunnels do significantly raise the property development costs to such an extent, that this cannot be compensated. So there is a lower limit of supply volumen and urban density that is needed or should be there in future projection, for a utility tunnel to be the implementation method of choice. Or to say it in another way. Because it needs to be large enough to be walked in, it is too large if only 25 to 65 single family homes in a spacious rural development are to be supplied and connected.

In our successful public utility tunnel projects (Wachau, Fahrland, Lauchheim,[4] Speyer), even including the utility tunnel investment costs, the development cost on the sales price of the developed property was identical to a conventional construction development. This was validated by other nearby conventional developments at the time.

Again, these costs depict single point in time development investment only. The do not consider that while the pipes and cables within a utility tunnel might last with a little maintenance for a verified 100+ years in some cases (e.g. London), while the pipes and cables in the ground will face major and/or point rehabilitation much, much earlier than that. The more congested the area the shorter the buried system lifetime.

[4] At Lauchheim – the worldwide first "High Density Polyethylene Hull" Utility Tunnel – the producer of the hull pipe sponsored the project as a demonstration prototype – accepting as payment the avoided conventional pipe construction costs of the city as calculated and expected from the original design conventional development design.

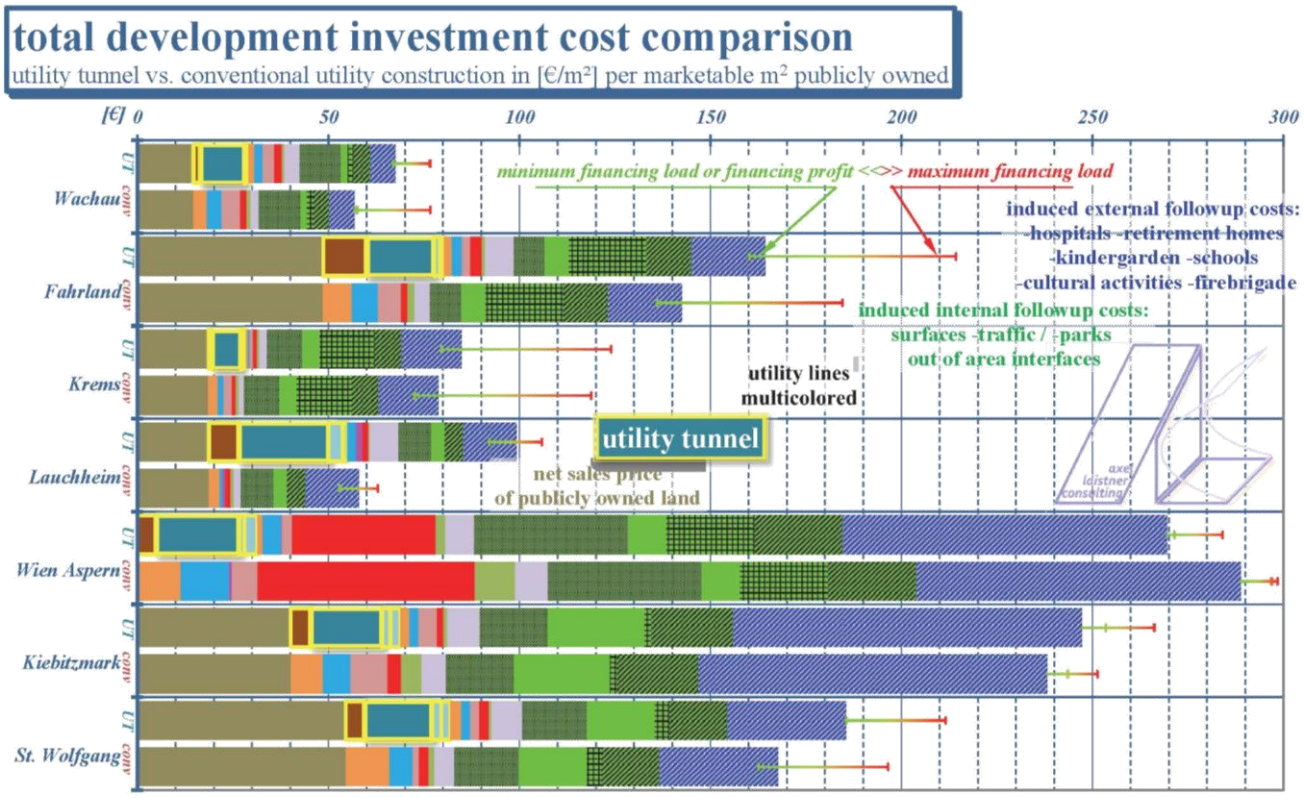

Fig. 6: Total Urban Development Costs: Comparison: Utility Systems with/without UT per m² marketable developed property Axel Laistner 1995/2012

Therefore also the effect on longevity of road surfaces is again NOT included in this depiction. With a utility tunnel road and surface conditions are truly only traffic and climate dependent, and can be extended by up to a factor of 2 in low load cases and 1.5 in high load cases. As the bearing layers of the surface are never interrupted, the total surface structure endurance and life expectancy is finally that, which is always calculated in the pavement design methods, as the surface is once built and then remains intact on an uninterrupted homogenous base.

Site inspections in Wachau, Fahrland and Lauchheim conducted in February 2012 have consistently shown, that even after 20 years most surfaces still look pristine, even like newly built. In Wachau due to an implementation of salt for snow clearing during the first years, the asphalt top-layer shows some degradation. However, even with the heavy loads of truck traffic in a business park – the road structure is still ok. No developing depressions as indication of bas instability, below frost damage, or developing water pipe leaks and breaks, or the like anywhere.

Taking these lifetime and system quality effects also into account, the utility tunnel beats conventional construction everywhere except in the budget sheets of one year only public budget calculations. These procedurally discount any future cost saving or producing effect of any technology, and therefore depict a significantly if not wholly wrong, but very prevalent, picture of the costs of urban development and the associated systems.

As currently in Germany communities are so cash strapped that a federal change of law is under consideration, allowing a community to bill property owners also for any future road and system rehabilitation works – this easy but shortsighted perception of cost might come under political pressure fast.

Let's talk Cooperation

Utility tunnels are unifying, combining systems. They therefore require poeple and institutions to cooperate, which they usually do in some form anyway, but not, maybe, so focused and in such an all encompassing group, of all technical supply system operators and engineers in an area.

A utility tunnel also is a plant facility – however, it is NOT a working place, and it classifies as an equivalent of a large storm drainage culvert in the German administrative system (only in Brandenburg is a building permit needed). But it needs – a little – but continuous maintenance (meaning – a well operated and upkept

utility tunnel needs a technical inspection walk through -every 3 to 6 months – and after all pipe and cable modification works). So foresight and consideration should be given who in the urban supply company structure takes on this operations job and why.

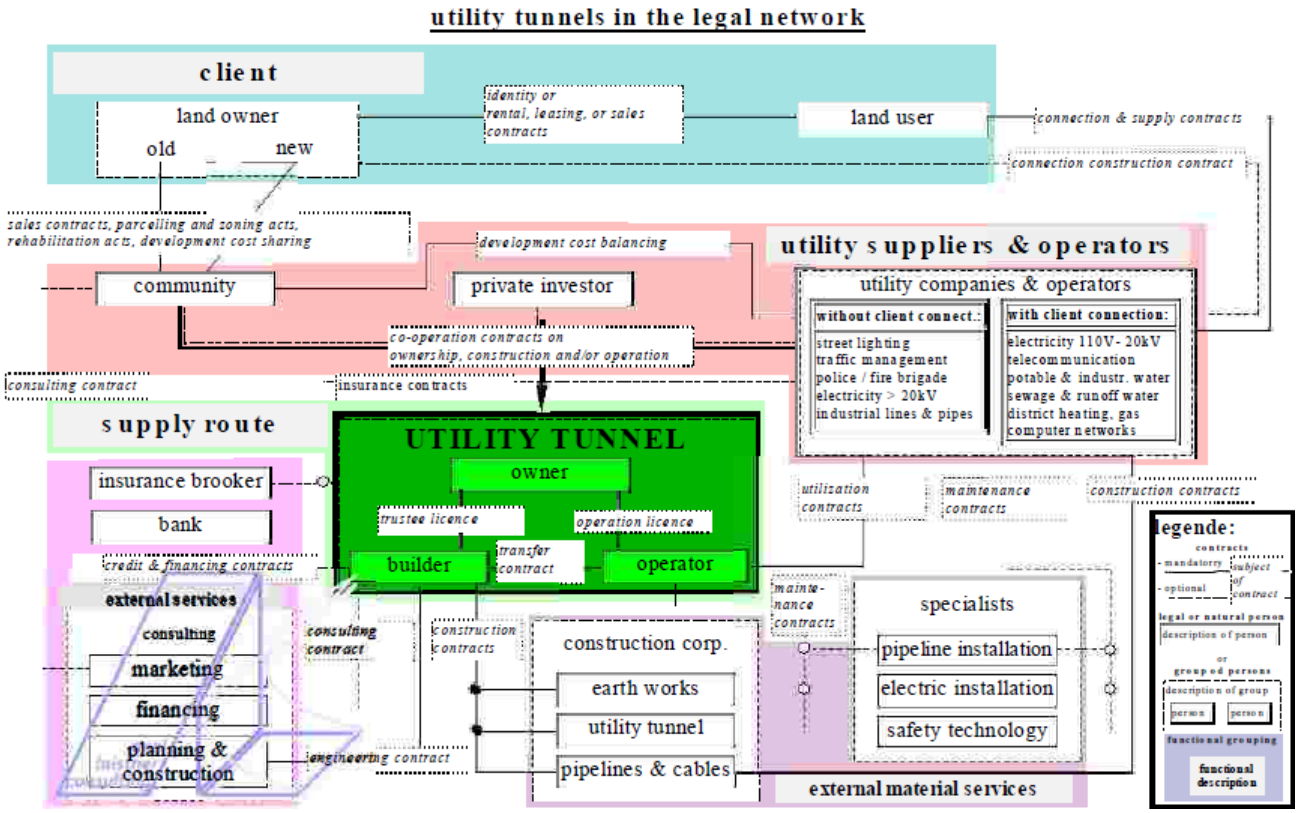

Fig. 7: Utility Tunnel in the network of Urban Legality – Axel Laistner 1995/2012

The Wachau solution – while it is a splendid example how PPP should work to enable and empower the public sector in the long term – is not necessarily the prefered one. Where there are other entities around, like city works corporations, power and transportation companies, why not have them do the job. They operate power plants and other equipment, and very well understand what needs maintenance and how much.

What a utility tunnel in a development fosters, is a sustained joint cooperation of all parties, also later during operation. A significant benefit in a future that requires all of us to find more cost effective, and longer lasting solutions. In our experience of between us almost 65 years as engineers – we believe from our own experience, that more often than not, the synergy is discovered in the cross trade cooperation.

4 CONCLUSION

Utility tunnels, those designed and build with our help and those discovered in our research, all have proven an unexpected longevity. Many even survived the city bombing of the second world are. If a single urban supply system technology can lay any claim at all to sustainability on a long-term time perspective – it's the utility tunnel.

Utility tunnels are the second hull around the transported media, they can have very benefitial side effects. One is absolute and easy leak and fault detection – another can be electro-magnetic-shock-shielding of cables against lightning or weapons impact – or the better power transmission due to lower cable temperatures.

After working in this field for 20 years, we know of 2 cable joint explosion, 2 water main breaks and 1 fire, in all the many utility tunnels around the world we know of (~ 35 UT systems). For sure, there must have been more faults, but this short list of faults is, what one city engineer of conventional systems, has in every small village on a half-yearly basis continuously! So again – no comparison here! Not even close.

However, utility tunnels are almost completely absent from our academic curricula and training, and from our technical standardization structure. The latter might be a boone – as it allows engineering knowledge, and sensibility to risks, to dominate utility tunnel design and operations. Simply following a cook-book recipy is out. The academic situation however is a shame. If at all this subject is touched within in the

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)

education of a young civil engineer or architect or planner, in maybe one lecture, of one course on principle technical systems for urban supply, at some universities.

This technology is not rocket science, but requires the understanding and cooperation of almost all engineering and architectural professions, and the inclusion of public and private administrators and managment. This is exactly what is meant when we all call for more team skills. That the teams by and large don't form by themselves in public development, is an indictment of the education of our city planners and engineers, as well as the administration structure of cities and their public works divisions overall.

Wherever – even in the public sector – there is a coherence of responsibilty (e.g. at universities, hospitals, or airports, or within private factory grounds) the utility tunnel is the technology of choice. It doesn't even need to be talked about – naturally it's expected to be part of any large development or modification project of such facilities.

We wonder why, or shouldn't we ?

Wir schützen uns zu Tode. Schallschutz ohne Ende oder akustische Raumplanung?

Peter Androsch

(Peter Androsch, Leiter von Hörstadt (Acoustic City), Linz, Austria, peter.androsch@hoerstadt.at)

1 VORBEMERKUNG

Beschallungstechnologien, Verkehrslärm, neue Baumaterialien und -techniken, das Verschwinden von Ruhezeiten und -orten und andere vergleichbare Phänomene kennzeichnen die radikale Veränderung der akustischen Umwelt. Schwere gesundheitliche, wirtschaftliche und soziale Probleme sind im Gefolge zu konstatieren, wie die massive Zunahme von Erkrankungen auf Grund akustischer Einwirkungen beweist (Herzkreislauf, Tinnitus, Hörsturz, Morbus Menière, Konzentrationsstörungen u.a.).[1] Dies ist vor dem Hintergrund zu sehen, dass der Mensch den weitaus überwiegenden Teil von Schallwellen indirekt, also über Reflexion, und damit hauptsächlich über die gebaute Umgebung wahrnimmt. Herkömmliche Raumplanung integriert akustische Kriterien nur mangelhaft und durchgehend aus der Sicht von Lärmvermeidung, Lärmbekämpfung und Lärmschutz. Die Überwindung der Konzentration auf Lärm ist wohl Bedingung, um von Vermeidungs- zu Gestaltungsstrategien zu kommen.[2] Zu einer qualitativen Betrachtung des Akustischen eben, die als Grundlage einer akustischen Raumplanung diente. Die Erfassung des akustischen Raums als elementaren Lebens- und Planungsraum und die Entwicklung von Kriterien für die Beurteilung und Gestaltung dieses Raumes sind dabei Wegmarken.[3]

2 ANTHROPOLOGISCHE GRUNDLAGEN

Eine akustische Raumplanung muss naturgemäß auf den grundlegenden Funktionen und Charakteristika des auralen Apparates aufbauen. Er gewährleistet die Sinnesapparaturen Gleichgewicht, Orientierung und Hören. Diese drei werden zu einem Raumeindruck "verrechnet" und mit den anderen Sinnen abgeglichen. Diesen Vorgang nennt man Sinnesintegration. Räume, die einer dauernden sinnvollen Sinnesintegration abträglich sind, machen unglücklich und krank.[4]

Das Gleichgewicht wertet Informationen aus dem Flüssigkeitsstand im Gleichgewichtsorgan aus, die Orientierung die Laufzeiten der eintreffenden vielfach reflektierten Schallwellen im dreidimensionalen Raum, das Hören die Aufnahme und Interpretation von Schallwellen, auch die Veränderung der Frequenzen durch Reflexion.

Dieses komplexe Zusammenspiel gewährleistet folgende Leistungen: Warnfunktion, Kommunikation mittels Sprache, Orientierung und Positionierung im Raum, Gleichgewicht, Sinnesintegration, auraler Rückkopplungsmechanismus (efferente und afferente Verarbeitungstrategien).[5]

3 UMWELTGRUNDLAGEN

Die Frage, wie sich Gebäude und Gebäudegruppen verhalten, indem sie reflektieren, ist in jeder Hinsicht relevant. Denn dadurch ergibt sich Raum respektive Raumwahrnehmung. Besonders erkenntnisreich ist diese Analyse in ungewöhnlichen Bauzusammenhängen z.B. am oder gar im Wasser. Jede bauliche Tätigkeit in einem solchen Umfeld bedarf besonders intensiver akustischer Vorbereitung, um nicht ungewollte und unerwartete akustische Effekte zu erzielen: Verstärkungen, Schallleitung über weite Distanzen, Lärmverteilung über große Gebiete, reflektorische Frequenzungleichgewichte besonders im tiefen Hörbereich (Stressfaktorenanalyse) u. ä..[6]

Die Rolle der gebauten Umgebung hat sich im akustischen Sinne noch nie so schnell und nachhaltig verändert wie in den letzten 25 Jahren. Gebautes erfüllt gänzlich neue Funktionen, - und dies nahezu ohne Kenntnisnahme durch Architektur und Stadtplanung.[7] Einerseits "werfen" Verkehr und Beschallungstechniken Schall in ungekannter Fülle und Dauer gegen Fassaden, andererseits verhalten sich Fassaden neuen Typs durch industrielle Bautechniken unerwartet. Schallharte Materialien wie Glas, Metall und Beton "reflektieren" einen Großteil des auftreffenden Schalls und wirken damit wie Schall-Verstärker, was durchaus bis zur Verdoppelung von Lautstärken und damit zu gesundheitsrelevanten Belastungen führen kann. Genauso sind die Absorptions- versus Reflexionsverhältnisse bzgl. Frequenz und Struktur von Schallereignissen von Relevanz, besonders in Hinblick auf akustischen Stress mit allen bekannten und unbekannten Folgen. Schon diese akustische Rolle der gebauten Umgebung im Raumzusammenhang ist weitgehend unbeleuchtet, erst recht in Bezug auf die neuen Entwicklungen im Bereich der energetischen Nutzung von Fassadenflächen durch Photovoltaik, Solartechnik u.ä.[8]

Erforschung und technische Weiterentwicklung der Lärmverursacher im Verkehrsraum, baulicher Schutz vor Lärmbelastungen sind etabliert und stellen durchaus verankerte Bereiche in Stadt- und Verkehrsplanung bis zur Umweltpolitik dar. Die aktive Rolle der Verkehrsflussbetten findet dagegen wenig Widerhall in der theoretischen und praktischen akustischen Analyse. Die "Instrumentalität" von Straßen, Plätzen, Tunnels, Unterführungen, Brücken u.ä. braucht eine angemessene Berücksichtigung. Das "Flussbett" des Verkehrs beeinflusst die akustische Faktizität des Alltags grundlegend, denn über Schallreflexion erzielt Verkehrslärm größere Wirkung als über Direktschall, besonders in urbanen Gebieten.[9] Die Instrumentalität, konstituiert durch die Parameter Volumen, Form, Material und Oberfläche der gebauten oder natürlichen Gegebenheiten, die Schallformung also bedarf besonderer Aufmerksamkeit, weil durch und in ihr gesundheitliche und soziale Folgen generiert werden. Die Instrumentalität und die vertikale und horizontale Proportionalität von Schallreflexionen sind in Relation zu phylo- und ontogenetischen Dispositionen zu setzen, um Indizien einer adaptierten Raumplanung entwickeln zu können.[10]

4 AKUSTIK UND RAUMPLANUNG

Eine akustische Raumplanung muss mit einer konventionellen Raumplanung kompatibel sein. Und das in allen Abstufungen, die zwischen einer Mikro- und einer Makroperspektive liegen können. Eine akustische ist also einzubetten in die Funktion einer gesamthaften Raumplanung.[11]

Da dabei wohl in den meisten europäischen Raumkonzepten eine nachhaltige Raumentwicklung angestrebt wird, die die sozialen, wirtschaftlichen, rechtlichen und ökologischen Ansprüche an den Raum miteinander in Einklang bringt, unterstreicht die Notwendigkeit eines erhöhten akustischen Bewusstseinsstandes.[12]

Was ist der akustische Raum? Der akustische Raum ist alles, was wir hören. Also der Raum an sich. Unter raumplanerischen Kriterien handelt es sich also nicht um einen Teilraum, sondern eine Raumschicht. Vielleicht eine Raum-Wahrnehmungs-schicht. Die Schallwahrnehmung ist die Bedingung für Raumwahrnehmung.[13] Deshalb ist in raumplanerischer Hinsicht das Wort "Schallschutz" irrelevant. ("Luftschutz" wäre ein vergleichbares Wort aus der Welt des Atmens.)

5 ZIELE AKUSTISCHER RAUMPLANUNG

Die Ziele einer akustischen Raumplanung leiten sich ab aus dem Status quo der Umweltbedingungen, respektive deren fundamentaler Veränderung, und den Modi des auralen Apparates. Seine Funktionstüchtigkeit ist Bedingung nicht nur menschengerechter und menschenrechtskonformer

Umgebungs- und Raumgestaltung, sondern möglichst hoher Lebensqualität und damit Arbeits-, Wohn- und Aufenthaltsqualität.

Die essentiellen Ziele zur Erreichung hoher akustischer Lebensqualität sind:

- Gewährleistung der Warnfunktion des Gehörs
- Optimierung der Kommunikationsbedingungen durch möglichst hohe Sprachverständlichkeit (innen wie außen)
- Gewährleistung der Orientierungsfunktion des auralen Apparates
- Gewährleistung der Gleichgewichtsfunktion des auralen Apparates
- Gewährleistung optimaler Sinnesintegration
- Gewährleistung auraler Rückkopplungsmechanismen, also einer ausgeglichenen efferenten und afferenten Schallinformationsverarbeitung
- Vermeidung gesundheitsschädlicher akustischer Ambientes und unerwünschter akustischer Phänomene
- Integration möglichst vieler Menschen mit Hörbeeinträchtigung in die Gesellschaft als Teilhabe am Leben
- Integration möglichst vieler Menschen mit Sehbeeinträchtigung durch reichhaltige akustische Orientierungsmöglichkeiten

6 METHODEN EINER AKUSTISCHEN RAUMPLANUNG

Als Teil einer gesamthaften Raumplanung müssen gleichwohl neue Methoden entwickelt werden. Nachdem die quantitative Erfassung akustischer Situationen im Bereich von Lärmschutz und Lärmbekämpfung durchaus zu Lautstärkesenkungen geführt hat, selten aber zur akustischer Lebensqualität, erfordert es neue, auch experimentelle Zugänge. Eine akustische Morphologie könnte dafür Richtschnur sein. Die Differenzierung der Ziele und die Methodenentwicklung wird die nächste Zeit der Forschung bestimmen.[14]

Instrumentalität und Zonierung sind korrespondierende Begriffe im Gefolge einer akustischen Morphologie. Das Wie-Sein akustischer Ereignisse ist erst durch die Instrumentalität des Raumes erfassbar. Der offene Raum, der Straßenzug, die Kreuzung, der Hof, die Eisenbahntrasse - das alles sind Instrumente, die Schall durch die vier Parameter Volumen, Form, Material und Oberfläche formen. Ihre Instrumentalität korrespondiert mit akustischer Zonierung.[15]

Der Anspruch, akustische Ambientes zu schaffen, in welchen das Warnorgan Ohr möglichst gut funktioniere oder möglichst hohe Sprachverständlichkeit herrsche, braucht das Begreifen der Instrumentalität. Dann könnte ein flexibler Lautstärkenabgleich durch divergierende Reflexions- und Absorptionsmuster und Verteilung in der Zeit gelingen. Orientierung erleichtern und Gleichgewicht geben durch akustische Referenzverläufe (innen und von innen nach außen und vice versa) ist eine weitere Aufgabe. (Übrigens eines der Grundprobleme des sogenannten Passivhauses.) Und die Gewährleistung optimaler Sinnesintegration und auraler Rückkopplungsmechanismen erfordern komplexe akustische Reflexionsmustern. Akustische Vielfalt ermöglicht die Entwicklung einer differenzierten Wahrnehmung. Das hieße, daß monotone und dominante Faktoren, die die Klangvielfalt beherrschen oder einebnen, zu vermeiden sind. Die Integration möglichst vieler Hörbeeinträchtigter in die Gesellschaft setzt voraus, daß die Anliegen eines Viertels der euroäischen Bevölkerung verstanden werden. Vermeidung dauerhafter Hintergrundbelastung, starken Nachhalls und großer Dynamikunterschiede ergäben sich aus dieser Perspektive.

Bauen und Architektur ist Schaffung von Raumqualität. Und Raumqualität ist per se eine akustische Qualität. Akustische Gestaltung ist daher eo ipso Architektur und Raumplanung und -gestaltung.[16] Damit könnten als erste Felder definiert werden: Integration der Ziele akustischer Raumplanung in alle Planungsprozesse so früh wie möglich, Entwicklung einer Methodik der Instrumentalität und Entwicklung

[14] vgl. Androsch, Peter: Wie wollen wir akustisch leben? In: Raum, Wien 2009
[15] vgl. Lampugnani, Vittorio Magnago: Die Stadt im 20. Jahrhundert. Visionen, Entwürfe, Gebautes. 2 Bd. Berlin: Verlag Klaus Wagenbach. 2010
[16] vgl. Androsch, Peter: Bauen ist Hören. In: Modulor Magazin 1/2008. Boll Verlag. Urdorf, 2008.

einer Methodik der qualitativen akustischen Zonierung. Weitere Felder - wie Klanggestaltung - müssen folgen.[17]

Der Titel von Neil Postmans Bestseller "Wir amüsieren und zu Tode" ist eigentlich ein Widerspruch in sich. Der Tod steht für etwas Negatives und Amüsieren für etwas Positives. Wie kann man sich zu Tode amüsieren? Postman beantwortet diese Frage aufsehenerregend in dieser doch sachlichen Abhandlung über die Unterhaltungsindustrie.[18]

So ähnlich stellt sich auch die Lage im Bereich Lärmschutz dar. Der positive Impetus des Schutzes hat sich über weite Strecken als Hemmschuh für eine konzeptuelle Weiterentwicklung erwiesen. Im Bestreben nach Schutz behindern wir uns selbst einerseits durch Vernachlässigung eines gesamthaften Zugangs zur akustischen Umwelt und andererseits durch eine mangelhafte Analyse der auralen physiologischen Bedürfnisse des Menschen abseits von Schutz vor und Vermeidung und Bekämpfung von Lärm.
