PREFACE

Manfred SCHRENK,

Chairman CORP,
Managing Director of CEIT – Central European Institute of Technology &
CEIT ALANOVA – Institute of Urbanism, Transport, Environment and the Information Society, Schwechat, Austria
Vice President ISOCARP – International Society of City and Regional Planners

WELCOME to REAL CORP 2012, the 17th International Conference on Urban & Regional Development and Spatial Planning in the Information Society!

Cities worldwide are facing rapid social, economic, environmental, technological and cultural changes such as rapid urbanisation, aging of society, security issues, housing emergency, new solutions on mobility, integration of immigrants, food and water shortage, etc.

Especially in times of economic crisis and demographic changes in cities, it is necessary to think about how to best handle the available resources, therefore this year's conference motto is **"RE-MIXING THE CITY"**.

How can planners deal with mixed city structures? Isn't the major aim of spatial planning to define usage structures by sorting different types of land use in space. Can mixed use or a mixed city be planned anyway? Or can planners only set up a framework of basic conditions so that the mixed use of the city can grow on its own? How can planners influence existing city structures, for example turn a former monofunctional industrial area into new town quarter a full of prospering city life?

Well, of course we must be aware that "re-mixing" – as all other approaches – can not be the one and only solution for any kind of urban tasks. But in the core areas, in the hearts of our cities, there is a need for multi-functional, mixed structures allowing life to take place without the need to cover long distances.

Some of the topics that we will be dealing with during the next 3 days are

- Can "mixed cities" be more sustainable and resilient?
- Living, working, learning, relaxing, enjoying, shopping, ... – anything anywhere & anytime?
- Is it the purpose of spatial planning to "sort land uses in space"?
- Do the urban patterns and structure of our cities still meet the needs of the people in their everyday life?
- How do urban, transport and environmental technologies and solutions shape our cities?
- New faces, new approaches, new ideas – does and can migration re-mix the city?
- Time-space patterns of the 24/7 city

Additional special topics of REAL CORP 2012

- Urban, Transport & Environmental Technologies and Solutions
- Urban Ambient Assisted Living (AAL)/intelligent urban environments
- Resilience, Safety & Security

The **conference venue Multiversum Schwechat** is an outstanding key project for an urban intermix. The versatile sports, event, fair, concert… hall with its perfect transport connection – directly opposite the railway station and only 10 minutes from the airport – makes it an ideal location for any kind of urban event.

Schwechat is and outstanding example of a "(Re-)Mixed City": it is Vienna's "airport city", directly neighbouring Vienna, situated between Vienna and Bratislava, the motorways A4 and S1 are crossing here, it hosts Austria's largest rail shunting yard and the Danube harbour and the oil and gas pipelines to the industrial complexes in the city complete the unique"5-modal Central European transportation hub".

Schwechat is not only an industrial city with a long tradition (there are more people working than living here), but Schwechat is also a small town which offers excellent quality of life with a good variety of shops and business opportunities, high quality social and educational infrastructure, an extensive green system and leisure facilities – and last, but not least, Schwechat is Austria's top sports city. The Werner Schlager Academy – part of the Multiversum – is one of the world's leading table tennis training institutions.

Last but not least the city of Schwechat has energetic and innovative city leaders who are willing to take up the challenges of the future and make the best for the city and its people – not only in the current situation, but also to prepare the ground for long-term successful development of the city.

REAL CORP 2012 in Schwechat offers the possibility to discuss a wide range of topics in different panel groups and workshops. It is a great pleasure and honour that **the world's four most reputated planners' organisations** are represented by their leading representatives at REAL CORP 2012 and take an active role in the conference:

- International Society of City and Regional Planners (ISOCARP, www.isocarp.org),
- International Federation for Housing and Planning (IFHP, www.ifhp.org),
- International Urban Development Association (INTA, www.inta-aivn.org), and
- Association of European Schools of Planning (AESOP, www.aesop-planning.eu)

For the first time, REAL CORP is accompanied by an independent exhibition and trade fair: "CORP EXPO 2012" on the topic "Livable City" collects the key enterprises for urban development, mobility, environment, energy and the field of Urban Ambient Assisted Living (U-AAL).

REAL CORP 2012 brings together almost 500 experts from different fields and from all over the world and provides the stage for meeting and learning from each other how to deal with city structures and prepare them for a sustainable future enhancing their resilience.

REAL CORP 2012 covers many different topics in about 200 presentations. The proceedings comprise about 1,500 pages of hand-picked knowledge for planners and for cities.

Since our first conference in 1996, REAL CORP has turned into a real interdisciplinary and international event. This year again we bring together people from 5 continents, from around the globe. During the upcoming three days, Schwechat will be the host of an incredible exchange of planning knowledge, face to face networking and development of new thoughts, ideas and projects.

Welcome to Schwechat, Austria, and the outstanding conference site Multiversum!

Have a great conference!

1 ABSTRACT

Focal point of this conference is to examine urban patterns and city structures regarding the changing needs of people in their everyday life. In order to do so, involved stakeholders such as planners and decision makers need to have precise information about citizens' needs and feelings concerning actual difficulties or tasks. Thus, approaches are needed to identify such topics, and to evaluate urban processes. One potential for this can be seen in new developments like Ubiquitous Computing and pervasive sensing with mobile devices which can act as small and connected sensors in the spatial environment. Due to the increasing prevalence of such mobile devices, more and more geospatial data is being produced, and some of it allows for inferring information about people's behaviour in specific areas. The main problems in these tasks are on one side that the processing of such data is a difficult task, due to the heterogeneity of interfaces and used data formats, but also because of the absence of a target-oriented question and the overlook of the potential for spatial and urban planning. We consider mobile crowdsourcing approaches to gather data in combination with the potentials of ubiquitous computing via new generation smartphones with the RADAR SENSING app as a promising approach. This app is a target-oriented software application that allows non-experts and citizens of a city to easily provide location based data just by using their mobile device and to attach urban spaces with specific planning relevant information. The presented test study was conducted in Kaiserslautern and aimed at validating methods to process and analyse localised tags in an urban area with the RADAR infrastructure. Hence, this study is an elaboration of the potential of new sensing and monitoring methods for urban areas.

2 INTRODUCTION

As mentioned in the conference title, the changes in cities and urban areas are inevitable phenomena with a high relevance for urban planning. It is thus important to create a sense of understanding for monitoring the various spatial patterns of a city, and there is a need to develop tools and methods for this purpose. From a planning perspective, the RADAR SENSING app and the associated RADAR infrastructure can be seen as a real-time monitoring tool. With these technologies, it is possible to install a monitoring system for the observation of a phenomenon in a chronological sequence. With the help of sensor technology, it is possible to install so called deductive monitoring systems. Main characteristic of these monitoring systems is that a public or private authority in a top-down process with a specific task initiates them. The opposite of deductive monitoring is "inductive monitoring", where no fixed top-down oriented infrastructure is given. The main idea behind inductive monitoring is that expressions and statements regarding a special topic are collected, but without being initiated by in a traditional, organisationally driven top-down process. So people aren't instructed to observe preselected phenomena that shall be examined. Examples are .g., postings and other traces that people leave when interacting with digital media and respective devices can be important information sources for planners. Some promising approaches for such bottom-up driven, mobile apps are "next hamburg mobile"[1] and "leerstandsmelder"[2] in the city of Hamburg. These apps were designed for only one specific task in one specific area, and they are top down initiated. However, for our solution, it was important to have a tool which is able to detect new urban spatial patterns. So a mobile application was developed that allows citizens to easily contribute information about the quality of arbitrary places in a city. Therefore, a number of predefined "urban categories" was provided. Each of these predefined categories can be rated as "positive" or "negative" for the selected location. Additionally, users can add own categories. The information is stored in a generic geodata infrastructure with various means for data analysis and visualisation. Hence, it can be used by planners for an analysis of spatial-temporal interactions and be embedded in the planning process. First results of these approaches were gathered within a sound

[1] See "next hamburg mobile" for iPhone (Source: http://www.nexthamburg.de/mobile.php)
[2] See "Leerstandsmelder online" (Source: http://www.leerstandsmelder.de/)

propagation project (compare Paper "Sensing the City", Bergner et al. 2012) where a group of test persons tried to identify noise hotspots, and also provided related "city parameters" using the newly developed smartphone app in the city of Kaiserslautern.

The paper is into three major parts. Whereas the state of research presented in Section 3 will give insights about developments like ubiquitous computing, monitoring, and humans as sensors, the Section 4 will explain the RADAR infrastructure and the RADAR Sensing app. The study set-up described in Section 5 will provide information about the field study including results and further research approaches. We conclude with a a summary and an outlook on future work.

3 STATE OF RESEARCH

3.1 Ubiquitous computing and pervasive sensing

New technologies like smartphones and sensors as well as the prevalence of wireless access to the Internet and will induce lots of changes for urban planners. With the rapid development of mobile communication devices, the postulated vision of ubiquitous computing as already predicted by Mark Weiser in 1991 seems to come true. This means that all devices are mutually connected and able to share data in order to create an additional value for its users. Smartphones in this context have to be considered as pioneers of a new era of computers that allow the user to share data and to participate, simply by using their Internet connection (Zeile, 2010). These small, connected, flexible sensors build the basis for pervasive sensing approaches of urban areas (Martino et al., 2010). Mobile communication devices are small, smart, and flexible, and the functionalities they offer will be constantly enhanced in the future. GPS-tagged pictures or sound files are just some simple examples. In contrast to ordinary sensor networks, where all measurement devices are constituted in a top-down-approach, lots of new potentials will emerge around crowdsourcing approaches as predicted by O'Reilly (2005). If those bottom-up-approaches are producing geospatial content, they are described with the term "Volunteered Geographical Information" (VGI) (Goodchild, 2007). Hence, it will be possible for citizens to interact with their electronic devices as a sensing unit together with their urban environment.

Smartphones equipped with various kinds of sensors could be considered as perfect sensors for spatial planning issues. These sensors can be subdivided in sensors for self-location (for example a GPS-Tracker) or position detecting, (Streich, 2011). Other available technologies are data collecting methods with the assistance of visual sensors (like digital cameras), audio sensors or with the help of newly developed and additional sensors, the measurement of the degree of pollution. A general classification in sensor types can be stated as follows: sensors for state variables and material properties, sensors for geometrical and mechanical parameters, electromagnetic and optical sensors and other possibilities for image processing (Schanz, 2007) or especially for psychophysiological monitoring purposes in spatial planning like it is done by the skin conductance and the skin temperature (Bergner et al., 2012). The sensors produce mostly quantifiable data and could be used in different planning related issues. Hence, the crucial point is to organise these complex and heterogeneous data sets together with new technologies and to develop new planning methods for their administration, organisation, and management. In order to show the potential of combined data flows, the SENSEable City Lab at the MIT in Boston followed a promising approach with the "Copenhagen Wheel" project. In In this project, bikes were used as mobile sensors in which environmental conditions like carbon monoxide or nitrogen concentration, temperature, noise, and humidity were directly measured by built-in sensors during the biker's city tours. With the help of these data, a thematic map of different ecological values (Outram et al., 2010) can be produced. Foci in these cases were particularly citywide sensory data, data management and the integrated real time visualisation, which embeds the bikers as dynamic and connected urban sensors. This example shows the huge potential of involving humans in a sensing process for urban planning purposes.

Generally, sensing units in sensing systems for urban planning issues with mobile devices can be divided into two main subcategories:

1. Mobile devices as (location based) communication units

One approach is the use of smartphones primarily as communication devices in order provide and share information. Predominant function is the use of various kinds of channels in order to provide an explicit statement for a specific location. The localised statements are called location-based tags. Besides the GPS-

sensor of the smartphone and the timestamp, the use of other sensor technologies is not necessary. The RADAR system could be considered as such an approach to collect and provide people's explicit statements regarding specific locations in the urban area. Features to share and provide data are often provided via common social media apps like Facebook or Twitter. Other good examples of apps, which are collecting people's explicit comments on the environment, are the previously mentioned app "NextHamburgMobile" or "trendsmap"[3], which maps the twitter-activity of users. With "NextHamburgMobile", it is possible to set up localised addendums in the urban area related to urban planning topics. Due to the use of interfaces, the gained data could also be used by third-party-developers for own specific research questions. E.g., Fabian Neuhaus from UC London created Twitter density maps, which allow detecting locations with a high concentration of Twitter posts (Neuhaus, 2012). As an example, the map of San Francisco shows that geolocated Twitter messages are also reflecting the urban area of the Bay Area in California.

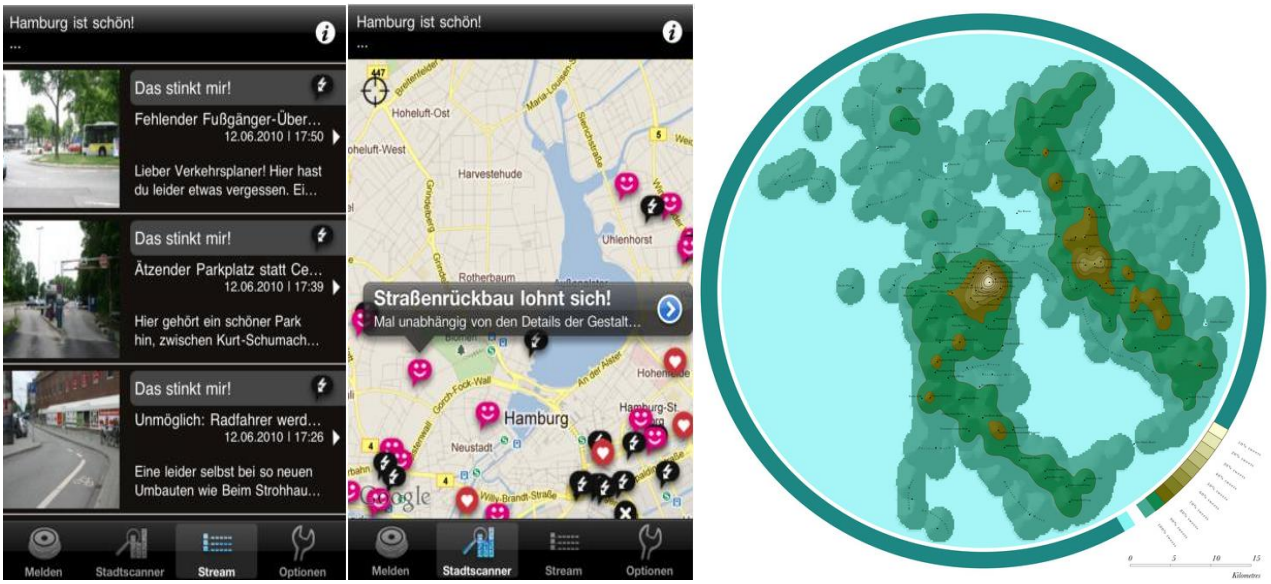

Fig. 1: iPhone App "NextHamburg Mobile" & Twitter heatmap San Francisco

2. Mobile devices as sensor units

As stated before, smartphones are multisensory devices and could be used as mobile urban sensors. The variety of embedded sensors like GPS or noise level recorder, and the possibility to dock on additional sensors open a wide range of opportunities for creating additional geospatial data.

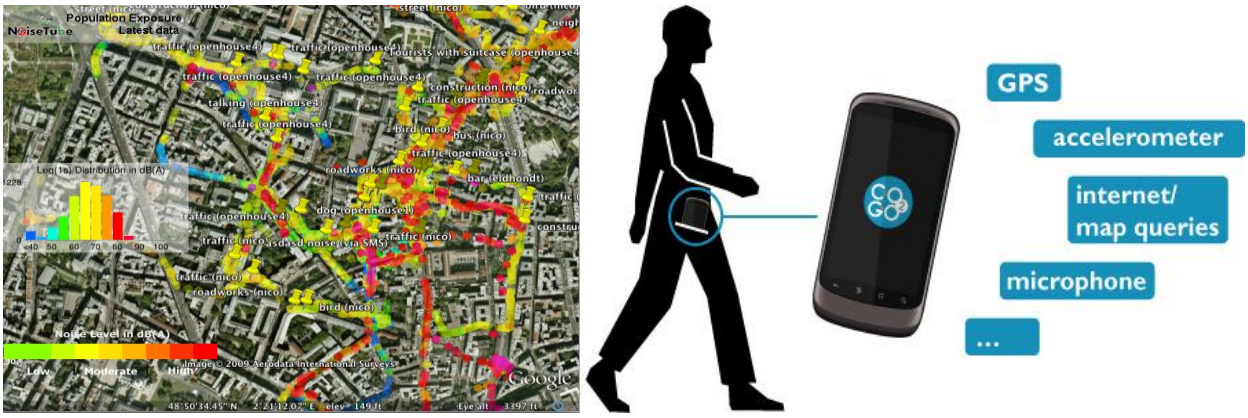

Fig. 2: App "Noisetube" & App "CO2GO"

Another value of this concept lies in the ability to aggregate those different data streams to gain new insights. E.g., the app "Noisetube"[4] is able to create a noise load level map just with a smartphone. The app "CO2GO"[5] from the SENSEable City Lab at MIT uses a combination of the GPS tracks and the

[3] See Trendsmaps online (Source: http://trendsmap.com/)
[4] See App "Noisetube" (Source: http://noisetube.net/)
[5] See App "CO2GO" (Source: http://senseable.mit.edu/co2go/)

smartphone's acceleration sensor to calculate a carbon footprint. The already mentioned project "Copenhagen Wheel" pursues a similar approach. In this project, local bikes are equipped with a wide range of sensing devices. With a smartphone app, all the integrated sensors could be observed and maintained to see the actual concentration of pollution or the prevailing weather conditions. All equipped sensor bikes also send these data to a server which is calculating the conditions in the whole city.

3. Sensing systems

With these devices and applications, it is necessary to develop holistic methods to create systems, which will function as a city wide sensing network. The development towards Smart Cities is an approach where such networks are top-down-oriented and planned by an authority, organisation or enterprise. If a deeper collaboration with citizens is intended, it should easily be possible for people to embed their device and data into the system and as well to share and access already existing data. Besides the technological hurdles, there also has to be an intuitive, easily understandable and attractive system for users to encourage them to participate and contribute with own data. This is crucial in order to create an additional value for users and a city. The RADAR[6] infrastructure is such an approach, because it allows integrating geocontents from a variety of different sources, and it also provides means to organise, aggregate and visualise this data via a web based user interface as well as a smartphone app. In addition to that, RADAR enables the user to also go deeper into analysing the data, which, e.g., is possible by using heatmap visualisations for tags. Another comprehensive approach is SMART-Singapore which is a project that could be classified as a Smart City initiative. The setup of this project is an opportunistic monitoring approach including various deployed sensors in the city with an inductive approach. Various data streams are provided on a platform which makes it possible for citizens and developers, to create their own apps to use this data in order to create data with an additional value for city and community (Ratti, 2011).

3.2 Monitoring

Monitoring comes from the Latin word "monitor", which means some kind of surveillance or observation. Hence, essential point is the observation of a phenomenon over a longer period, with the result of using the gained forecasts for a reactive or constructive control. This also embraces data collection, analysis and interpretation in a systematic way in order to have data as a basis for decisions and further observations. Thus, a monitoring system consists of two elements: One part is the approach to gather and process data, the other is the infrastructure needed collect and manage the considered data. Monitoring systems are the basis for forecasts, which makes them important especially in the working field of spatial planning (Streich, 2011).

Web 2.0 and associated technological opportunities already had an influence on monitoring approaches, and they will continue to do so in the future. Monitoring approaches were historically initiated in top-down approaches by mostly public authorities and organisations. With the development of pervasive sensing, the fertile ground for bottom-up approaches was set. Hence, with the empowerment of non-experts to create, analyse, visualise and publish geospatial information, there will be a new mode for monitoring issues in spatial planning. Due to the mentioned elaborations, monitoring has to be distinguished between deductive monitoring (top-down) and inductive monitoring (bottom-up) approaches. Deductive monitoring is an approach, which is mainly top-down oriented and composed of data generated by time series analysis: People collect data sets, with or without the awareness that they wear a sensor device and collect data. Or data were collected unconsciously, e.g., by cell phone carriers or hardware developers with the help of the cell phones internet connection and ability to access and store data. The use of the data gained by sensor networks like climatologic measurements is such an approach. The gained data could be used for various purposes and it has a large potential, not only for spatial planning. Opportunistic sensing could also be part of a deductive monitoring system. Regardless of the way these monitoring technologies deal with personal data and data security, the continuous recording of this kind of data has a large potential, not only for spatial planning.

Mobile devices give users the possibility to create this data in an explicit way related to a specific situation. So it is an active use of a smart device as "communication unit" and as "sensor unit". If this bottom-up approach is making use of mobile devices to collect and share data, it is considered as participatory sensing.

[6] See RADAR Project (Source http://radar-project.de)

However, if such systems are aiming to involve citizens into participatory monitoring projects, there has to be some kind of incentive mechanism to encourage them to participate in the project.

3.3 Humans as sensors

As previously mentioned, the consideration of new sensor technologies for urban planning purposes will be more important in the future. In 2010, "The Economist" stated that "Everything will become a sensor, and humans may be the best of all" (The Economist 2010). It thus has to be elaborated how a person senses its environment, and how these impressions and emotions could be measured in an objective way. This ensures that citizens, who should be the focal point of any planning consideration, could act as active sensors for the urban environment. The synchronised multi-sensor „human" thus should be considered as the most important sensor for urban planning issues (Exner et al., 2011). Due to the technological development in mobile device technologies, the combination of smartphones and human interaction will provide huge potential in planners' everyday work because the generated data could be used for monitoring purposes in urban planning. Hence, crowdsourcing and inductive monitoring integrates an entirely new mode of participation in processes of urban discussion for geospatial data gathering (Exner et al. 2011). The study project „Sensing the City" at TU Kaiserslautern shows the potential of this approach, because it combines the mentioned sensor technologies with both implicitly and explicitly generated crowdsourcing data of the test persons. Whereas the implicit emotions of the test persons were recorded via psychophysiological monitoring with a SMART-Band for measuring skin arousal and stress, the test persons were equipped with mobile phones and a tagging app that allowed them to tag their surrounding area making use of several predefined criteria. Exploiting the above mentioned potentials given by smartphones and monitoring approaches, and using the new RADAR technology that will now be introduced, it is possible to gain new insights for defining the quality of an urban place in order to show the potentials of psychophysiological monitoring and prospects for their use in urban planning like it has been done in the project "Sensing the city" (Bergner et al., 2012).

4 THE RADAR INFRASTRUCTURE AND THE RADAR SENSING APP

RADAR[7] (Resource Annotation and Delivery for Mobile Augmented Reality Services) was a one-year project initiated in 2010 at the Knowledge Management department of the German Research Center for Artificial Intelligence in Kaiserslautern. The aim was to realize an open and flexible infrastructure that allows users to contribute and manage arbitrary types of geocontents. On the one hand, the RADAR infrastructure is able to process very simple representations of geocontents; on the other hand, it is also be possible to use more complex and multidimensional objects.

The RADAR infrastructure consists of two main components:

- The RADAR Web Interface is an intuitive, web based GUI for comfortable contribution, sharing, and management of arbitrary geocontents. It is based on DFKI's ALOE[8] infrastructure and offers a plenitude of social media features.
- The RADAR Web Service realises a rich Web Service API and thus allows integrating RADAR contents and functionalities in different contexts and applications, such as the RADAR SENSING App.

For different scenarios, specific RADAR instances can be set up, thus allowing the realisation of controlled and closed as well as open and collaborative scenarios. Figure 1 provides a coarse overview of the RADAR main components. For a detailed description of the system architecture as well as system features please refer to (Memmel 2012).

To address the needs of inductive monitoring approaches, a specific instance of the RADAR infrastructure (RADAR-SENSING) was set up. In addition to the usual RADAR functionalities, means to analyse user contributions by means of heatmaps are offered on this instance. The RADAR SENSING app was developed for Android-based devices and connects to the RADAR-SENSING backend where all information such as user data, user contributions, etc is stored in a respective database. As exchange format, JSON was chosen because it allows for efficient processing of information while still providing means to exchange arbitrary data types.

[7] See http://radar-project.de
[8] See http://aloe-project.de

To take part in experiments on this platform, users first have to register using the RADAR-SENSING Web frontend. After installing the RADAR SENSING app, they have to provide the respective credentials and can then provide positive and negative votes for a set of predefined categories. Optionally, a free category can also be entered. After submitting these votes, the app tries to estimate the user's position by means of several sensors (preferably GPS) and shows this position on a map. The users then have the possibility to change this position in case the sensors were not able to retrieve the precise location.

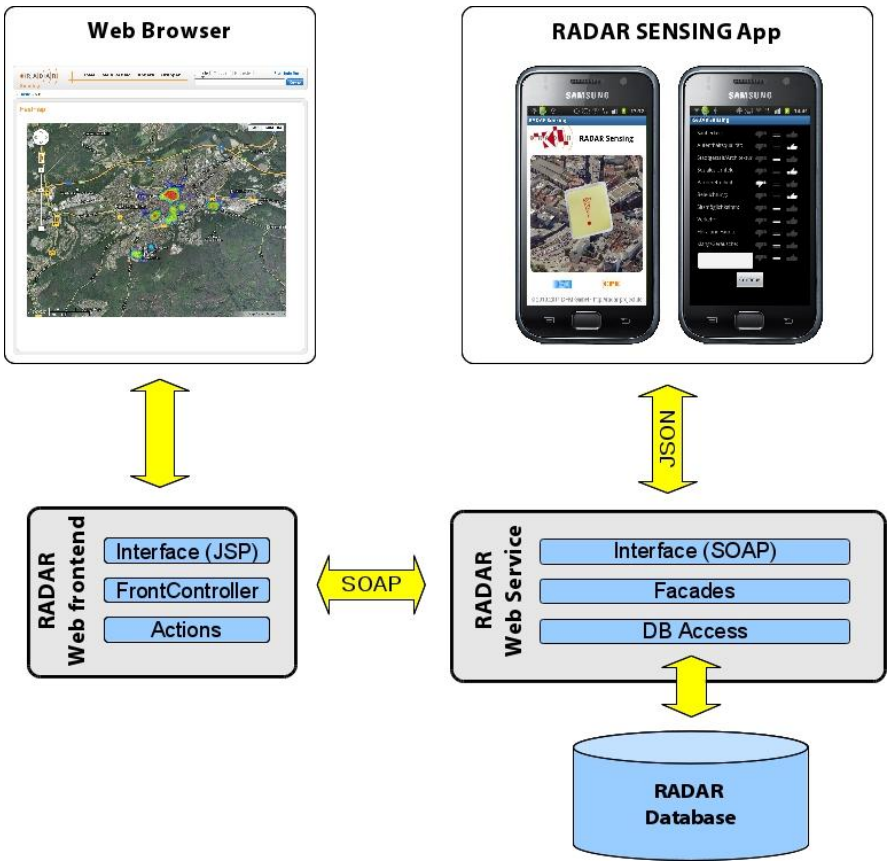

Fig. 3: Simplified architecture of the RADAR infrastructure

Furthermore, it is possible to get first impressions about the tagged attributes by means of a tag cloud accessible through the RADAR Web Interface. However, the most helpful tool for spatial planning is the interactive heatmap of the tagged points. Here, users can select which attributes to take into account for the generation of the heatmap, and whether only positive, negative or both votes are used. The heatmap is then displayed on an interactive map where users can drag and zoom. Furthermore, it is possible to provide further parameters to filter the used data (e.g., time restrictions), and the heatmap can optionally be refreshed automatically in case new relevant data for the heatmap shall be displayed on-the-fly.

5 STUDY SET-UP

Accompanying to the project „Sensing the City – How to identify Recreational Benefits of Urban Green Areas with the Help of Sensor Technology", the "tagging the city" –project (attribute tagging) should consolidate the findings of the above mentioned study (compare Bergner et al., 2012): In this study, the topic was to identify urban retreat areas against the background of the EU environmental noise directive with the help of psychophysiological measurements. Parameters like the subjective perception were measured by using SMART-Bands. The SMART-Bands record through Skin Conductance Level and Skin Temperature, which allow doing a statement about people's arousal in the city. , The study was in addition supported by traditional, 5 level ICBEN-questionnaire (International commission on biological effects of noise), which described the perception of noise pollution.

In support of this set-up, it was possible to record volunteers' impressions in the city with the help of RADAR SENSING App. The collected data support the plausibility check of planning and it can be seen as a combination of implicit human emotions (stress measured vie SMART-Bands) and explicit emotions (Tags and questionnaires). During the measurement period, the test persons were able to tag points with noise, or

points where is silent in the city. Additionally it is possible to give ratings about other urban properties, like cleanliness, attractiveness of urban areas, urban design, accessibility, lighting, seating, traffic and flora/fauna. These tagged points can deliver hints for planners, where it is a pressure to act.

5.1 Findings

Within the test period of two weeks, the test persons collected almost 1900 tagged places, spread over 20 micro places at the city of Kaiserslautern. A distinction was made by the following categories, because these values are highly relevant for urban planners.

	Sojourn quality (+)	Sojourn quality (-)	Accessibility (+)	Accessibility (-)	Lighting (+)	Lighting (-)	Flora & Fauna (+)	Flora & Fauna (-)	Sound / Noise (+)	Sound / Noise (-)	Cleanliness (+)	Cleanliness (-)	Seating (+)	Seating (-)	Social Environment (+)	Social Environment (-)	Urban Design (+)	Urban Design (-)	Traffic (+)	Traffic (-)
Tags	149	63	187	35	98	28	120	85	128	79	176	35	158	77	100	55	120	47	86	129

Fig. 4: Totalised values of the "tagging the city" project

The upcoming figure shows this for the attribute "noise" (Fig. 5).

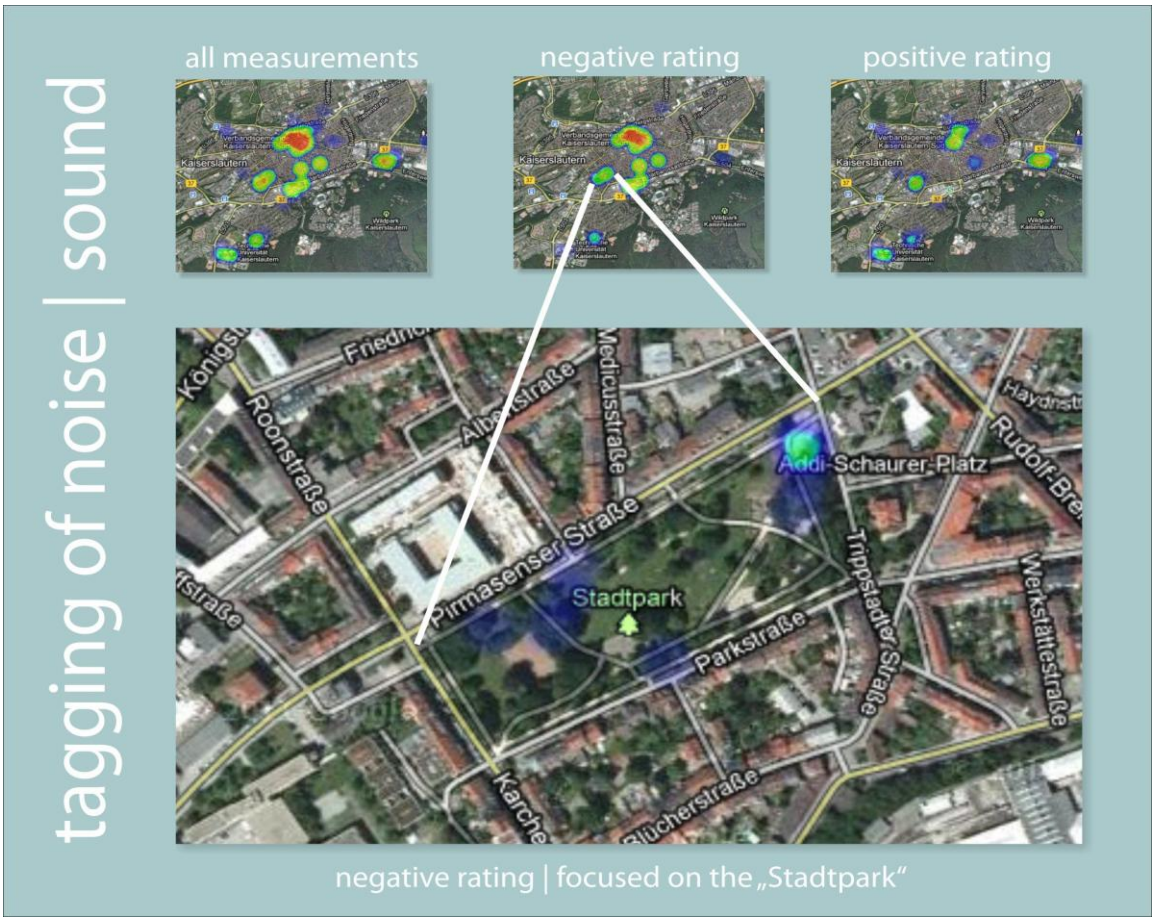

Fig. 5: Real-time heatmaps of the collected tag "noise" (own figure, based on Google Maps)

A full validation of the results for the location "Stadtpark" within the "Sensing the City"- project (compare Bergner et al., 2012), is not possible in the moment in fact of to less tagged points in the test area. But it can be observed, that the negative comments about the noise level were mostly done on the street sides of the park and not in the calmer centre.

Besides for the tagged attributes, it is now possible to produce specific heatmaps, even for the newly developed attributes. The system will also display this data in real-time. Another important value for urban planners is the accessibility of public open areas, especially for those ones with retreat function. If accessibility has to be considered (in German: Barrierefreiheit), it is possible just by choosing the parameter

accessibility. After closing the first study period, it was remarkable, that a place called “Stadtplatane” was identified by the heatmap visualisation which has an insufficient accessibility level compared to other places. This small inner-city recreational area with its six park benches is just accessible via stairs which would be a big hurdle for wheelchair users. With the help of the respective heatmap, this important point could be identified.

Fig. 6: Bad accessibility at location “Stadtplatane” (own figure, based on Google Maps)

5.2 Problems and Questions

One problem of the present study is the homogeneity of the group. It is necessary to have a heterogeneous volunteer group that represents the cross-section of the public. Furthermore, tagging and also questionnaires are explicit expression. Hence, it could be interesting to combine those data with implicitly gained data, for example via emotional mapping with SMART-Bands in order to make a cross-validation. Methods and approaches to merge these two types of data have to be developed and get maturity in order to have resilient data for the planning process. Another important point will be the detection of “wrong” data. This could be on the one hand a bad GPS-signal but also manipulative entries of users. Methods for additional validation have to be developed in order to get the guarantee that the gained data is reliable in terms of technology and content-relation. Questions about how to delete “wrong” data and when to delete older data which isn’t needed anymore (e.g. because of a repaired trashcan which was tagged as broken). Furthermore, especially when it comes to the point of visualizing data with heatmaps, it has to considered, that the chosen way complies with the set standards and the has to be an awareness of the manipulative elements of maps with for example simple elements like positive or negative colour schemes.

6 CONCLUSION

From a technical perspective, there are several potentials which could be exploited for improved and enhanced analysis means in the future. E.g., it will be interesting to compare the different tagging timestamps to analyse how grievances and complaints appear in the urban space. With this approach, static phenomena at the specific location (e.g., accessibility for wheelchair users) and more dynamic phenomena (e.g., a broken trashcan) could be distinguished. Further options in displaying the datasets will help planners to derive demands for multi-layer analysis to gain better planning insights. E.g., there could be an overlay of the negative content of “noise“and “sojourn quality” which might lead to better results. In addition, it would be interesting to integrate information from other social media applications (e.g., Twitter or Facebook) and process this information for further analysis. And, at least, there will be the question about how to deal with this data and to interact with population and government. The question of the resilience of this kind of data will emerge and it has to fit demands of the various planning processes, like the integration in formal or informal processes. Hence urban planners have to be aware not only of potentials, but also of challenges and difficulties when using these new methods for the planning purpose. Without a basic understanding of the complex interactions, they won’t be able to use these new tools in the most promising way.

7 ACKNOWLEDGMENTS

The authors are grateful to the support of the University of Kaiserslautern, which enabled these research studies by support this department and the faculty of spatial and environmental planning with financing the “Laboratory for Monitoring and Spatial Sensing”. Furthermore, thank goes to the German Research Centre for Artificial Intelligence (DFKI) for extensive knowledge transfer and for cooperating in informal projects.

The authors would like to express their gratitude to German Research Foundation (DFG – Deutsche Forschungsgemeinschaft) for supporting the project "Development of methods for spatial planning with GeoWeb and Mobile Computing (Städtebauliche Methodenentwicklung mit GeoWeb und Mobile Computing)". In addition, this study contains some data of seminar works of students in the summer 2011. The RADAR project was funded by the Stiftung Rheinland-Pfalz für Innovation.

A Preliminary Study of the Impact of Urban Energy Consumption with Urban Form in Taiwan

Chin-Ying Chen, Hsueh-Sheng Chang

(Master Degree, Institution of Author 1, 1, University Road, Tainan City, 701, Taiwan, chadjun@hotmail.com)
(Assistant Professor, Institution of Author 2, 1, University Road, Tainan City, 701, Taiwan, changhs@mail.ncku.edu.tw)

1 ABSTRACT

In recent years, because of the energy demanding increment, it will perhaps make energy dried up in the future. To view the status of the Taiwan's energy development, dependence on imported energy has reached up to 99.3% in 2007.It is limited in self-produced energy in Taiwan. Therefore, the energy subject became one of quite important topics. Many experts are beginning to look for renewable or alternative energy to solve the energy shortage. In the urban planning field, planners try to achieve the minimum energy consumption from the urban planning and management. In each kind of urban planning strategy, many scholars said that the compact city may save the energy under the high density centralism. But recently there is the research to point out that if excessively crowded, it will create more congestion costs, parking costs and energy consumption. There are the different characteristics between the different cities. There might be the different variables about energy consumption. The purpose of this study is attempt by the different urban form variables to find the affecting factors of the urban energy consumption. Final result is expected to provide preliminary conclusion to make a plan use urban energy more efficiently and achieve sustainable development.

2 DEVELOPMENT OF COMPACT CITY

Rickaby discusses the relatedness among the urban form, the energy use and the efficiency of the energy use. He discovered that no matter what kind of the urban development can save more energy consumption which compared to the original plan.(Rickaby,1987)The development of compact city started from the two schools dispute about the development of the urban form between the decentralized person (Decembrist) and the centralized person (Centrist). The centralized person advocated that the high-density urban development, and opposed the urban sprawl. It was most early in 1935, Le Corbusier proposed that enhanced the urban density to solve the congestion.Afterward in 1960, Jane Jacobs positioned to maintain the urban vigor and the urban multiplicity by the high density development.

The compact city appears clearly most early by George Dantzig and Thomas L. the Saaty.These two mathematicians proposed about the spatial form ,spatial characteristic and the function indicators of the compact city in 1973.But it still was fuzzy like sustainable development, it also belonged to the descriptive stage, In 1990, the urban environment green book , British policy guiding plan and so on research induced the concept of the compact city gradually. The compact city was one of the urban regulatory policy which proposed at that time.The original intention was that preserved the village land outside of the urban area. Thus the urban spatial development was limited, and there were more and more population.The compact city advocated that the city should raise the density toward the centralism development. At the same time, there were also many researchs pointed out that policy of the compact city, was helpful to reduce the transportation energy consumption because of the centralism. And they promoted to improve the utilization ratio of the public transportation.It reduced petrochemical energy consumption.Therefore they advocated the development of the compact city.

However the later period scholars pointed out that the excessively compact city possibly created the crowded phenomenon, the bad neighborhood effect , the healthy question and so on, instead caused more impacts ,energy consumption, air pollution and so on. Therefore recently the scholars starts to ponder the balance point of pro and con of the compact city.

The scholars pointed that urban stucture would impact the transportation energy consumption. Because of different attributes

The different cities has the different form and the scale, must have the different cities management

The impact of the trasportation enrgy consumption would be different with different compactnesss.And the impact would be different because the city has different the public transportation ,landuse zoning,infrustruction and so on.(Yeh kuang-yi, Huang kan-chung, Lee yung-lung,2003)

However it has not yet the research to point out that the “compact city” would consume transportation energy least under what kind of urban form.

3 STUDY AREA AND METHODOLOGY

This research reorganizes the different urban form variables, and discusses them to development influence of the compact city. Then it carries on the statistical examination, and it attempts to understand that what kind of city can cause the urban transportation energy disbursement to be least.

The covering scope includes the principal element like dense degree and the mix use that most scholars discusses from the compact city.Then it inducts the degree of the public transportation, information degree, knowledge degree,economy development as well as resources use. The expectation could find the urban variables affects urban energy use.

This research collects the data of Taiwan 22 cities to carry on the series scoring to analyze. Then it uses multiple regression analysis, carries on the examination in view of the urban form to influence of the energy use. First it calculates various cities energy use, then introduces the different urban form variable to analyze what kind of the urban form variable would affect the urban energy use. Next it divided to two groups according to the different urban density and the mix use degree, and then establish in each crowd of groups its model, gives to analyzes the comparison.

3.1 Study Area

Tainan County is located in the Southwest part of the island, an average density of 547.79 persons/km, and total area is approximately 2016 km2.The study areas are 22 cities in Taiwan. (See Figure 1)

Fig. 1. Study Area

3.2 Variables and Indicators

Compactness

There are a lot of ways to meature the compactness.The most complete way is the research from Burton in 2002.Burton measured the compactness in UK towns and cities.He said the better measures of compactness are needed for three reasons(Burton,2002) :

1. To assist research on the impacts of compactness, and thus to guide policy;

2. To enable measurement of progress towards sustainability;

3. For use as planning tools.

And he pointed out the compact city was usually described as one or other or all of three types of city, two that are related to `product':

1. the high-density city,

2. the mixed-use city,

and one that is related to `process':

3. the intensified city.

However,this research only discuss single year.It means that this research needs to ignore the `process' and only discuss the `product': the high-density and the mixed-use .

Energy

Peter W. G. Newman & Jeffrey R. Kenworthy (2007)used Gasoline use to measure the energy consumption.

Therefor,this research take the statistic of every gasoline station in Taiwan 22 cities to be the data measuring the energy consumption.

Urban Form

Urban form includes spatial elements and non-spatial elements.Except for compactness to describe the spatial attributes, this reseach still bring non-spatial elements into mearsuring the urban form.The variables are urban service function, development degree of transportation, information circulation,and knowledge education level.Th indicator of urban service function is industry and commerce factory number.It can describe the activity of the city.The indicator of the development degree of transportation is the utilization ratio of transportation. Because there were more people use publice transportation, and there were less energy consumed.The indicator of the information circulation is the rate of internet surfer.It was reseach pointed out that the rate of internet surfer was higher, the city was more advanced. It has the possibility to express to reduce more energy consumption. Table1 is all variables and the indicators.

Dimension	Variable	Indicator
Compactness	Density	Population per hectare
		Develop household of number the land per hectare
	Mix Use	The proportion of Housing and non-housing
		Entropy
		Retail trade number per hectare
Energy	Energy Consumption	Average each gasoline and diesel oil consumption
Urban Form	Urban Service Function	Industry and commerce factory number
	Development Degree of Transportation	The utilization ratio of Transportation
	Information circulation	The Rate of Internet Surfer
	Knowledge education level	Above 15 years old of education level structure - technical college population and above

Table 1: Variables and Indicators of this research

4 ANALYSIS AND RESULT

According to the indicators in table1,and collecting Taiwan 22 datas.It mainly divides into two parts, the first part surveys the Taiwan different compactness to realize the attributes in different cities, and analyze the energy consumption impact belong to urban compactness and urban form.The second part according to the compactness height classification.The purpose is to realize the difference of the impact of the energy consumption and urban form under the different compactness height classification.

4.1 Compactness of Taiwan Cities Development

There are twenty-two cities in Taiwan. The urban compactness and the average energy per person consumption, as we can see in Figure.2 and Figure.3.

By Figure.2, the higher compactness cities mainly distributes in the north and south two main cities.

By Figure.3, the higher energy consumption cities mainly distributes in the north and south two main cities.But it is not the same cities with the higher compactness cities in Figure.2.To compare these two figures,it appears that the higher compactness cities in Figure.2 instead is the average each person of energy use is lowest in Figure.3.

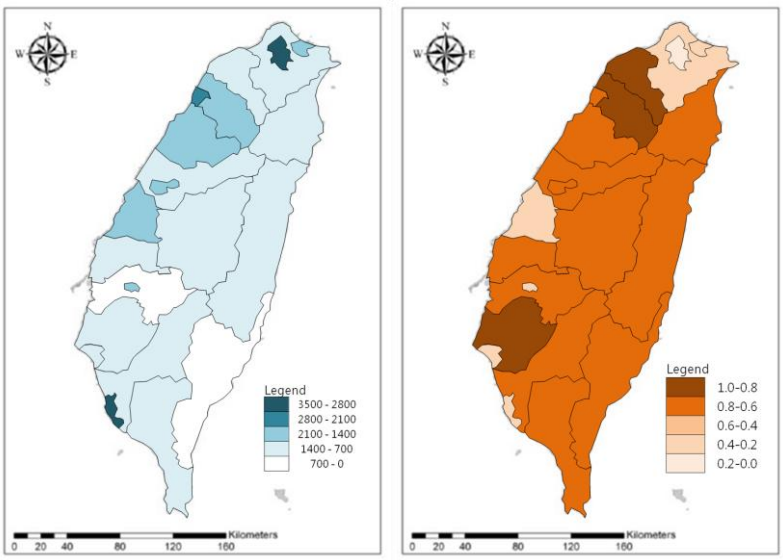

Fig.2 (left): Urban Compactness in Taiwan. Fig.3 (right): Average Energy per person Consumption in Taiwan

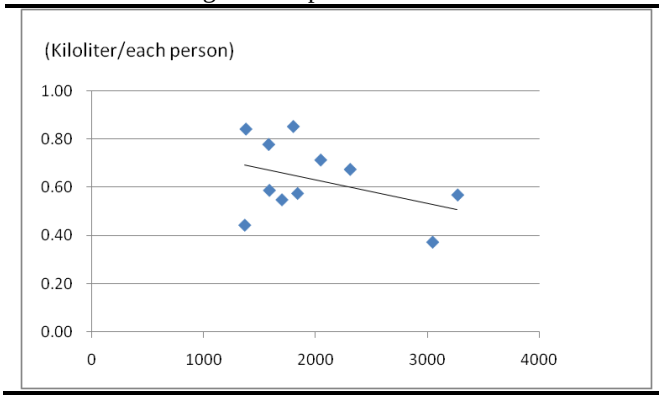
The compactness of various cities will divide into two groups, a group for the high compactness city, and a group for the low compactness city. In order to understand different compactness and the energy consume relations. (See Table2)By different compactness, in the high compactness, the many urban energy use is low.Therefore, whatever the compactness is higher or lower,the compactness and the energy consumption is negative correlation.

Higher Compactness of Cities	Lower Compactness of Cities
	


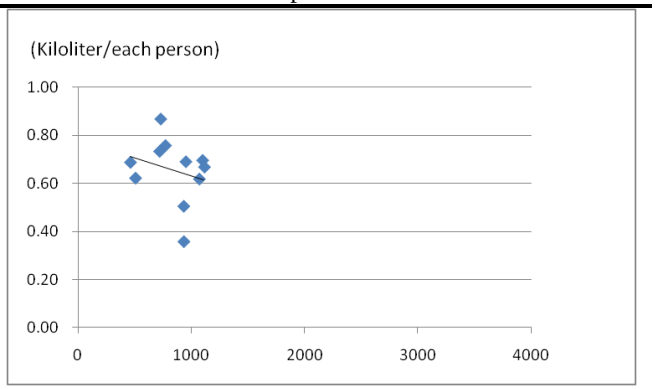


Table 2: The relation of Compact City energy consumption and the Compactness

4.2 Identification of Factors Affecting the Urban Energy Consumption of Urban form

Urban service function

By Table 3, its energy use is high. Extrapolated that the reason is the industry and commerce number are few, causes the trip times to increase. The trip times increase, the trip length to increase, causes the energy consumption to increase. They are negative correlation.

Dimension	Higher Compactness of Cities	Lower Compactness of Cities
Urban Service Function		
Table 3: Identification of Factors Affecting the Urban Energy Consumption of Urban form

Development degree of transportation

By Table 4, regardless of compact highly or low, the utilization ratio of public transportation is high, the energy use would be quite few.

Dimension	Higher Compactness of Cities	Lower Compactness of Cities
Development Degree of Transportation		
Table 4: Identification of Factors Affecting the Urban Energy Consumption of Urban form

Information circulation

By Table 5, under different compactness, different information circulation has the different energy consumption. In the high compactness cities, information circulation is higher, the energy use are more. In the low compactness cities, information circulation is higher, and then the energy use is less.

Dimension	Higher Compactness of Cities	Lower Compactness of Cities
Information circulation		
Table 5: Identification of Factors Affecting the Urban Energy Consumption of Urban form

Knowledge Education Level.

By Table 6, regardless of compact highly or low, knowledge education level is higher, the energy use will be few. The cities of high compactness are quite obvious.They are negative correlation.

Dimension	Higher Compactness of Cities	Lower Compactness of Cities
Knowledge education level		
Table 6: Identification of Factors Affecting the Urban Energy Consumption of Urban form

5 CONCLUSION

According to the above result and the analysis, it may understand that the different urban form truly would affect the energy use. But in different compactness situation, it also will have the different influence energy consumption. In order to achieve sustainable development, it should probably consider the more urban

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

variable in the future. Although this research is a preliminary study. For sustainable development,reducing more energy consumption is saving more energy.

Transportation is one of the major energy consumption department.Many experts advocate to use alternative energy.However,this research prove that various urban form and compactness would consume different energy.Therefore,when urban planner will make the urban planning, they should consider the energy consumption impact of the urban form and compactness.Then the city can achieve the sustainable development.

1 ABSTRACT

This study presents a spatial approach with a methodology for re-mixing current rural buildings into landscape which will support stakeholders to make decisions within a unique environment. A spatial methodology described in this paper is coupling with geographic information systems (GIS), fuzzy logic and multi-criteria evaluation (MCE). The aim of this methodology which applies an overlay and index method involving several parameters is to evaluate the suitability of the study region, Hervás (Spain), in order to optimally plan a building integration with rural landscape. The analytical hierarchy process (AHP) is used to generate the alternative decisions using the multi-criteria evaluation techniques used, enhanced with fuzzy factor standardization. The parameters are categorized into five criterion groups: criterion group 1 includes parameters relevant to the physical environments; criterion group 2 comprises visual conditions which are divided into two states, external and internal state; criterion group 3 depicts economical situations; criterion group 4 incorporates social activities; criterion group 5 consists of environmental circumstances. Besides assigning weights to factors through the AHP, the simple additive weighting (SAW) method is applied to the calculation of final grading values in multiple criteria problem for the suitability re-mixing of the study area. The methodology will result in five intermediate suitability maps, physical, visual, economical, social, and environmental criterion. Combination of the five intermediate maps will result in the final composite suitability map for rural building integration with landscape.

2 INTRODUCTION

The appropriate integration of man-made rural buildings into their landscapes is a challenging task, as most of the times various controversial parameters should be considered. The integration of the building with rural landscape usually depends more on the right choice of location than on any other weighted factors. Geographic information systems (GIS) offers useful tools to study the location in depth when considering spatial planning limitations, opportunities, visual characteristics and the overall landscape scene (Hernández et al., 2004). The potential advantage of a GIS-based approach for siting arises from the fact that it not only reduces the time and cost of site selection but also provides a digital data bank for long-term monitoring of the site (Moeinaddini et al., 2010). The appropriate integration of rural constructions into their surroundings, however, is not a common consideration in general practices yet (Tassinari et al., 2007).

The siting of rural buildings into their landscape is a particular multi-criteria decision-making process. Multi-criteria evaluation (MCE) is one particular type of spatial planning to help decision makers explore and solve multiple and complicating problems (Malczewski, 1999). In general, this kind of process consists of three phases (Forman and Selly, 2001): identifying the problem, designing or identifying the alternative solutions to the problem, choosing the best alternative. Choosing the best alternative is the third phase of the decision making process. Decision-making includes choosing from various criteria and alternatives. The criteria usually have different importance and the alternatives in turn differ on users' preference for them on each criterion. We need a way to measure to make such tradeoffs and choices. Measuring needs a good understanding of the measurement methods as well as the different scales of measurement (Saaty, 1996; 2005). The analytic hierarchy process (AHP) is a widely accepted decision-making method (Gemitzi et al., 2006).

The present paper describes a method of determining site suitability for re-mixing buildings on the rural fringe, Hervás (Spain), using the AHP for multi-criteria evaluation (MCE) combined with fuzzy standardization and the simple additive weighting (SAW) (Eastman, 2003) in a GIS environment. The methodology presented herein evaluates the entire study area using a common grading scale, i.e., 0 to 100 byte grading value, where 0 values a site fully unsuitable for rural building integration while 100 values a site optimum for its integration. Evaluation criteria identify a spatial data treatment with a grading system

based on physical, visual, economical, social, and environmental aspects. In addition, the utilization of sophisticated spatial statistics methods is an innovation in the rural building siting process, giving some efforts in the analysis of the results, showing the tools provided by GIS and spatial statistics are very important. Finally, it ends indicating how the study is based on and developed from existing knowledge as well as presents the specific aims of the study.

3 SITING METHODOLOGY

A substantial multi-disciplinary evaluation process with multiple sets of criteria is required to identify the best available location or locations for a new rural building siting, the final goal of the present work. The research procedures are as follows:

- A digital geographical information system (GIS) database development which incorporates all spatial information;
- The evaluation criteria determination and hierarchical multi criteria structure formation;
- Determination of the relative importance weights of the criteria and sub-criteria by applying the analytic hierarchy process (AHP) method. By comparing pairs of criteria, decision makers can quantify their opinions about the criteria's magnitude;
- Aggregation of the criteria weights and attribute values to yield suitability scores of the areas; and
- A spatial clustering process implementation to represent the suitable areas.

The methodology presented here did not perform a primary screening, initially excluding unsuitable areas, and the whole region was evaluated for rural building siting. The methodology presented here did not exclude unsuitable areas called as a primary screening. The entire study region was evaluated for integration of rural buildings and their landscapes. The methodology, therefore, resulted as the land evaluation based on the suitability indexes. In a certain attribute map, the suitability grade assignment for every class is carried out in the ArcGIS software. In the study case area of Hervás (Spain), the suitability index is assessed as to use the simple additive weighting (SAW). This method is a widely utilized one to calculate the final grading values in multiple-criteria problems; Eq. (1) describes the mathematic formulation (Yoon and Hwang, 1995):

$$V_i = \sum_{j=1}^{n} w_j v_{ij} \quad (1)$$

where V_i is the suitability index for area i, w_j is the relative importance weight of criterion j, v_{ij} is the grading value of area i under criterion j, n is the total number of criteria.

3.1 Background information

Hervás, the proposed study area, has an area of 60 km2 located in the Ambroz Valley region of the northern Cáceres province (Extremadura) on the border of the Salamanca province (Castilla y León) and in the foothills of the Béjar and Gredos Sierra as shown in Fig. 1. Hervás is one of 8 municipalities in the Ambroz Valley region: Abadía, Aldeanueva del Camino, Baños de Montemayor, Casas del Monte, La Garganta, Gargantilla, Hervás, and Segura de Toro. In this region, deciduous forests, the outstanding species, with the chestnut tree is predominated. It gives an important nucleus of chestnut product companies. Also, water sources are very essential resources for both agrarian and leisure activities which attract touristic visitors (Jeong et al., 2011).

During 18th and 19th century, the traditional wood working and crafts was the most significant income source of this area. From the fifties to eighties, the abandonment, an enormous emigration to the cities, happened in this study area. In the early nineties, the introduction of several European initiatives in Extremadura occurred to change this region for the sustainable rural development (LEADER and PRODER projects). During the last decades, rural buildings' developments due to the holiday residences' growths and its natural environments has increased for tourist activities. These do, however, cause their consequent impacts. As some researchers have already described, the continuing development in urban and rural environments has caused substantial changes to land use which are reflected in the loss of traditional landscapes (Tassinari et al., 2008). In a very short period, it has resulted in the destabilization of the nature due to the accelerated land use changes associated with tourism and urbanisation. The recent response for the

current situation (LESOTEX, Law 15/2001 of land and landscape planning of Extremadura) cannot give the proper answer for this situation yet.

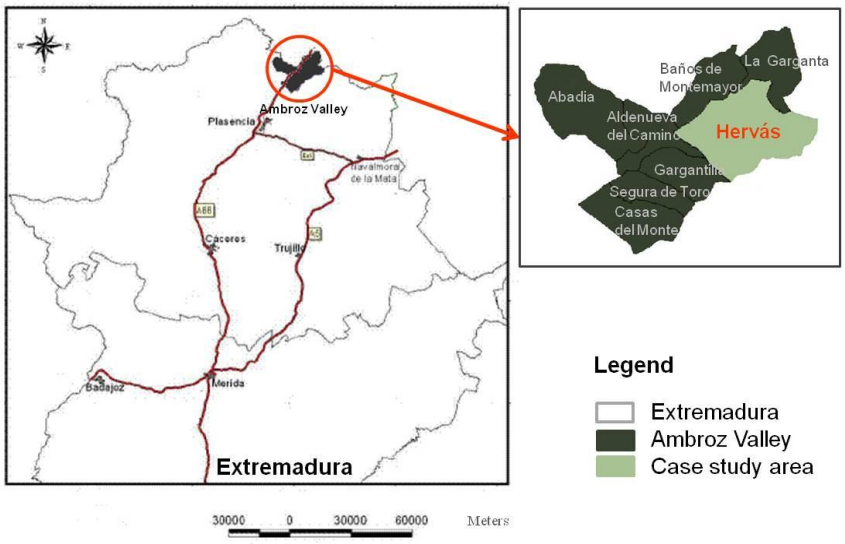

Fig. 1: The study area across Hervás (Extremadura province), Spain.

3.2 Identification of the decision-making criteria

The evaluation criteria used in this paper are classified into five main groups, as depicted in Fig. 2, namely physical, visual, environmental, social and economic criteria. The hierarchical structure of decision process consists of four levels: first level shows the main goal, rural building suitability; second level represents criteria which support the main goal; third level is subcriteria of each criterion; fourth level demonstrates the spatial attributes of each subcriterion. Fourteen factors are involved in the computation process, distinguished in five main groups according to the way they influence rural building integration to their landscapes. All criteria in the 5 groups are quantified in a common scale, i.e., 0 to 100 byte grading value. Each of these grid cells reveals a single site-sized land parcel for the purposes of further analysis. The grading value 0 is assigned to the least suitable areas and 100 to the most suitable ones, transforming the different measurement units of the factor images into comparable suitability values.

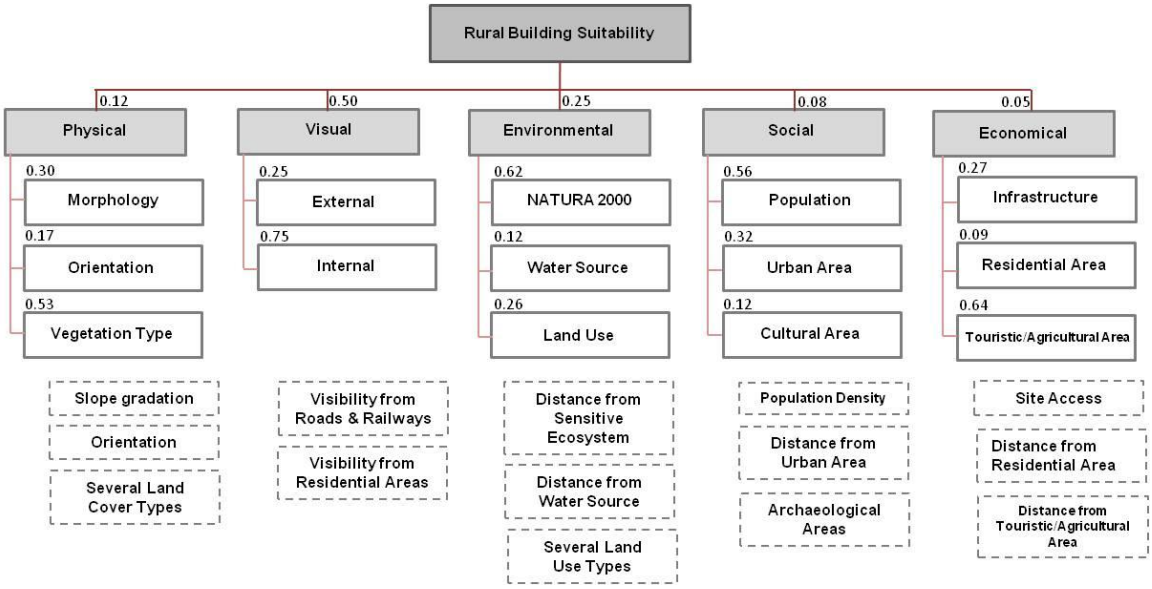

Fig. 2: Hierarchical structure of decision evaluation problem.

The following five criteria involved the computation process and selected on the relevant literatures, regional polices and European Union (EU) directives and described each issue are analyzed:

- Physical criteria: this category has three subcriteira, morphology; orientation; vegetation type.
- Visual criteria: this category has two subcriteria, external visibility; internal visibility.

- Environmental criteria: this category has three subcriteria, presence of sensitive ecosystem following European commission regulation for nature & biodiversity policy (NATURA 2000); presence of water source; land type.
- Social criteria: this category has three subcriteria, population density; proximity to urban area; proximity to cultural area.
- Economical criteria: this category has three subcriteria, site access; proximity to residential area; proximity to touristic and agricultural area.

3.3 Standardizing map layers

With a number of different approaches, the multi-criteria evaluation (MCE) has the need of the values included the criterion and subcriterion map layers and can be transformed to comparable units. Criterion and subcritieron maps can be classified on the basis of the types of available information for map construction. This classification is related to the distinction between deterministic decisions and uncertain decisions (Malczewski, 1999). Fuzzy functions can standardize map layers in GIS and evaluate the possibility of each pixel belonging to a fuzzy set by evaluating any of a series of fuzzy set membership functions. To apply fuzzy functions in the GIS environment in this case study, all the map layers are digitized or imported and converted to a raster format with 10m pixel size.

In this process, sigmoidal, also called as s-shaped, fuzzy membership functions are used and specified for each factor. The sigmoidal membership function is the most commonly used function in fuzzy set theory (Eastman 2003), offering a gradual variation from non-membership, i.e., 0, to complete membership, i.e., 1. The sigmoidal membership function can be specified by four parameters (a, membership rises above 0; b, membership becomes 1; c, membership falls below 1; d, membership becomes 0) as shown in Fig. 3.

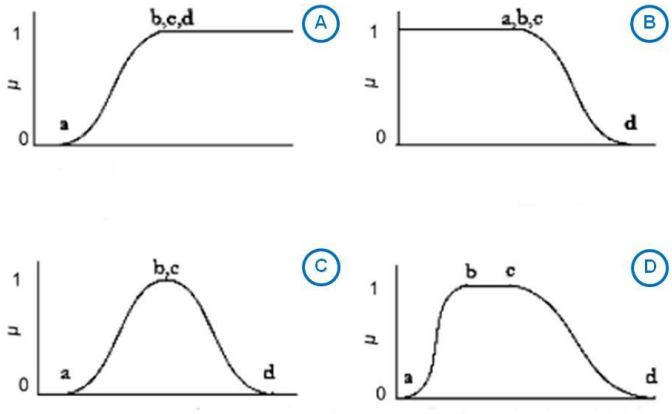

Fig. 3: The Sigmoidal fuzzy membership functions (A-monotonically increasing, B-monotonically decreasing, C and D-symmetric curves).

3.4 Evaluation of land suitability

The AHP method proposed by Saaty (1996) is an effective approach to extract the relative importance weights of the criteria in a specified decision making problem. One of the most important steps in any multiple criteria problem is the accurate estimation of the pertinent data. Although qualitative information about the criterion importance can be found, it is difficult to quantify it correctly. The AHP has steps including specifying the hierarchical structure, determining the relative importance weights of the criteria and sub-criteria, assigning preferred weights of each alternative and determining the final score (Fig.2).

The next stage is to specify the relative importance weights of the criteria and sub-criteria through pair-wise comparison. The AHP is based on pair-wise comparisons, which are used to determine the relative importance of each criterion as shown in Table 1. By comparing pairs of criteria at a time and using a verbal scale, decision makers can quantify their opinions about the criteria's magnitude.

Intensity of importance	Definition
1	Equal importance or preference
2	Equal to moderate importance or preference

3	Moderate importance or preference
4	Moderate to strong importance or preference
5	Strong importance or preference
6	Strong to very strong importance or preference
7	Very strong importance or preference
8	Very to extremely strong importance or preference
9	Extreme importance or preference

Table 1: Various states for pair-wise comparison and their numerical rates.

The pair-wise comparison matrix (PCM) formed by the decision makers in the previous step must obey the following attributes, $a_{ii} = 1$ and $a_{ij} = 1/a_{ji}$. The next step is the calculation of the criteria's relative importance weights implied by the previous comparisons. Saaty (1996) proposes the estimation of the right principal eigenvector of the PCM which can be approximated using the geometric mean of each row of the PCM. This mode is known as multiplicative AHP (Saaty and Millet, 2000) and was used in the present work. The calculated geometric means are then normalized and the relative importance weights are extracted as shown in Fig. 4. The AHP method allows slightly non-consistent pair-wise comparisons. If the PCM is perfectly consistent, then $a_{ij} = a_{ik} * a_{kj}$ for all possible combinations of comparisons in the PCM. It is rare to have a perfectly consistent PCM. The AHP method includes an index called consistency ratio (CR) that indicates the overall consistency of the PCM. According to Saaty (1996), the CR should have a value of less than 10%, indicating consistency of the matrix.

Fig. 4: Sample calculation of preference weights in relation to the criteria (1 (Physical), 2 (Visual), 3 (Environmental), 4 (Social), and 5 (Economical)).

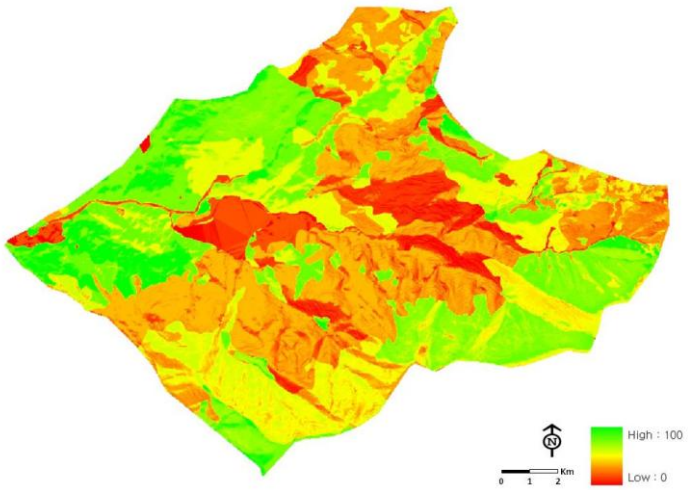

Fig. 5: Standardized suitability map of physical criteria combined with morphology, orientation and vegetation type factor.

The next step in the presented methodology is the application of the SAW method, shown in Eq. (1). Evaluation criteria were combined in a grid that contains all grades calculated from each of the separate grids (Fig. 5). The grading values for each evaluation criterion are included in the complex grid at the appropriate attribute field. The relative importance weights of the evaluation criteria are calculated by using the PCM matrix. The suitability index is computed by using the SAW method.

4 CONCLUSIONS

The methodology described in the present paper is an efficient approach in a rural building siting process considering its landscape. The methodology combines the evaluation abilities of multi-critera evaluation (MCE) methods and analytical tools of geographical information system (GIS). The MCE was utilized to form the siting problem into a decision structure of three hierarchical levels, namely, the goal (suitability), evaluation criteria/subcriteria and spatial attributes. The evaluation criteria were developed according to the relevant literatures, regional polices and EU directives. The AHP method was utilized to extract the relative importance weights of the evaluation criteria and the SAW method is utilized to calculate the suitability indexes, in order to solve the rural building integration problem with its landscape.

Future studies will be conducted in order to analyze the five intermediate suitability maps and then to combine these maps in the final composite suitability map for the rural building siting with its landscape. Thus, several updates could be performed in the methodology, the scene in which the rural building will be set needs to be investigated and analyzed so as to consider the visual elements of the scene that characterize the landscape in terms of number of stakeholder interests represented after selected a proposed location using this methodology (García et al., 2006) and various multiple criteria analysis methods such as compromise programming (Zeleny, 1982). The final decision regarding optimal sites will be based on social and political will. However, an integrated spatial decision support system, based on the methodology described in the present work, can be very useful in the final decision. It must be noted that the presented methodology is only a tool to help decision- makers but is not the decision itself.

5 ACKNOWLEDGEMENTS

This research has been carried and carrying out with the financial support from Ministerio de Ciencia e Innovación (BIA 2007-61166) and Captación y Formación de Recursos Humanos de Excelencia en Investigación, Desarrollo e Innovación (Universidad de Extremadura); the support of both institutions is gratefully acknowledged.

Addressing Environmental Problems in the Coastal Urban Area of Attica

Agisilaos Economou

(Agisilaos Economou, Phd, Laboratory of Geographic Information Systems in Urban and Regional Planning, National Technical University of Athens, Nikaias 18, 17122, Athens, Greece, aghs@mail.ntua.gr)

1 ABSTRACT

Nowadays a large proportion of the population lives in coastal urban areas. These areas face different environmental problems that degrade the natural and cultural resources. This leads to degradation of the quality of life of residents and threatens the viability of these areas.

This paper refers to the coastal urban area of Attica from the Bay of Faliro to the area of Vouliagmeni, which has witnessed great development in recent decades. The research focuses on how areas have developed, on local problems, as well as on the policies and measures that have been implemented until now for their protection of and upgrading.

The results show that the region faces a great number of environmental problems. Moreover, the public works that have been carried out in recent years have improved the overall situation and to some extent the quality of life of residents as well. However, further measures concerning land uses, exploitation of existing infrastructure and protection of the natural resources of the area, are necessary.

2 INTRODUCTION

Nowadays, it is a reality that there is an absolute relationship between the quality of life and the environment and the way that cities are shaped as well as the way they work (European Commission, 2007).

Changes in lifestyle, increasing dependence on cars, increasing per capita resource use, demographic changes, the increase in the number of households, the need for greater consumption of products, and others, are the main causes of environmental problems cities are facing today.

Some of the basic problems that cities are facing, are the poor quality of the built environment, derelict land, greenhouse gas emissions, urban sprawl, traffic congestion, noise pollution, degradation of air quality, creation of solid and wastewater.

However, the quality of life in urban areas depends additionally on the natural and cultural heritage, public spaces and the existing architectural heritage (buildings, traditional areas and other.) (Commission of the European Communities, 1997).

These environmental problems occur in most urban areas, but with different intensity. For example, the green spaces offered in the cities of Hanover, at Evora, and Brussels are more than 20% of their respective surfaces, while in the cities of Rotterdam and Madrid the percentage of green areas is 5% or less. At the same time, urban areas are more vulnerable to floods, heat and lack of water.

Nowadays the European Commission is promoting a set of indicators that could be used to collect data necessary for monitoring and evaluating the strategy for the urban environment. Thus, reports on the situation of the urban environment must cover the main environmental sectors (air, water, waste, noise, biodiversity), the priority areas of the thematic strategy (management, transport, design, construction) and finally issues related with the life and health standards.

3 METHODOLOGY

In order to carry out this research, in the coastal urban area of Faliro Bay, up to the Municipal District of Vouliagmeni, an evaluation of the status quo initially took place. At first we researched the mode of development of the coastal zone and its significance. Afterwards, the research focused on the urban environment and an attempt to evaluate the situation through indicators took place. Furthermore, a research in situ and interviews with relevant staff of the municipalities to identify problems, followed. Finally, an evaluation of the results took place and guidance on the sustainable development of the area and the addressing of environmental problems was provided.

4 CASE STUDY

As a search area the coastal urban area of Athens from the Faliro Bay until the area of Vouliagmeni is selected. The southern and western part includes the sandy beaches while the eastern area is limited by the Mount of Hymettus, which is crossed by small streams. The Northern area is bordering with the urban area of Athens. Kifissos and Ilissos rivers flow to the coastal marine zone. At the estuary of these rivers dunes and marshlands have formed. The climate of the area is temperate and Mediterranean.

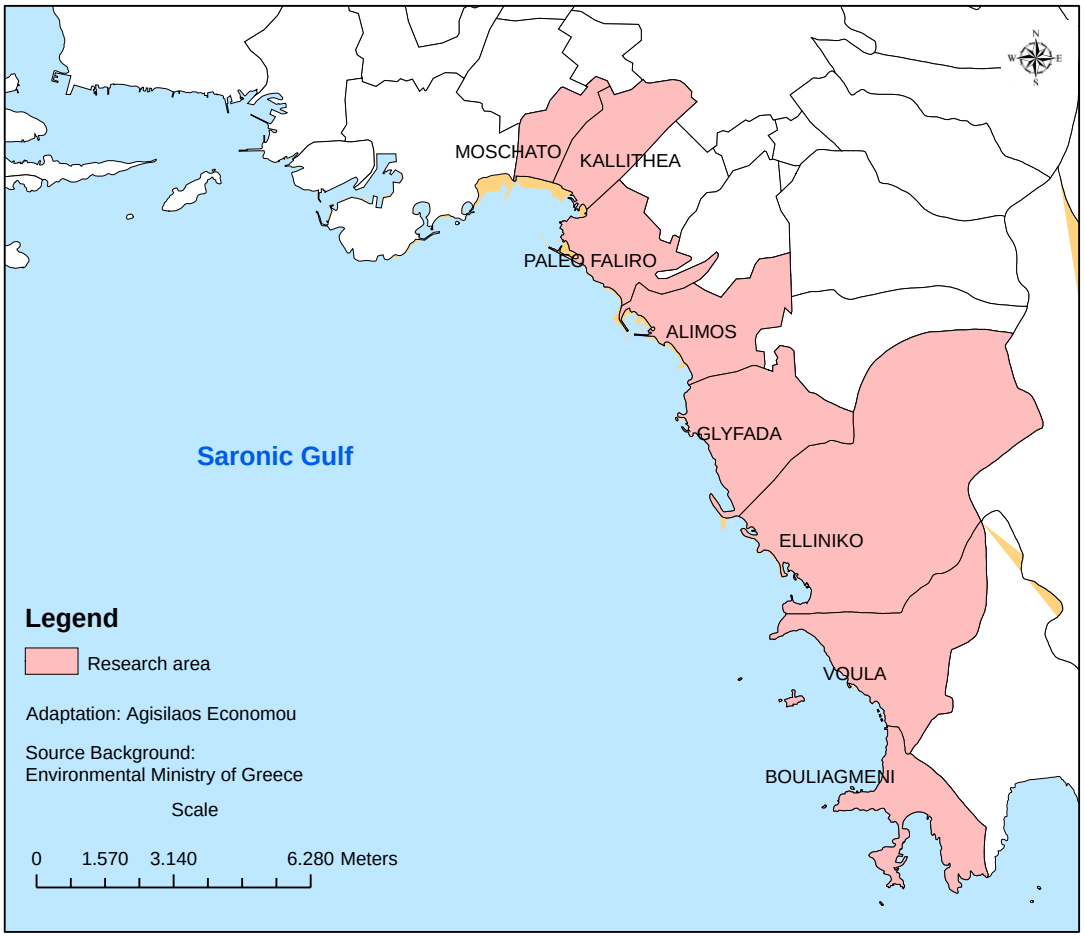

Fig.1:Map. Study area in the coastal urban area

The importance of the area

The region has important natural environment

- A significant variety of avifauna and fauna in the areas of the Delta of Ilisos and Kifissos
- The Delta of Ilissos river belongs to the list of important habitats in the Greek CORINE. While the avifauna is included in Annex I to Directive 79/409 EEC.
- In the area there are plant species that belong to the Natura list . For example, in the area of St. Kosmas the most important species are the Populus alba, eucalyptus, Tamarix sp., Pinus pinea, Cupressus seprervirens, palanus x hybrida), Olea europea, acacia (Albizia julbrissin), oleander (Neriym oleander), angelica (Pittosporum tobira), rosemary (Rosmarinuw officinalis). There are also shrubs (Viburnum, Ligustrum) (http://www.filotis.itia.ntua.gr).
- The coastal area of the Saronic Gulf presents a remarkable benthic ecosystem. Specifically, in the area of Agios Kosmas, there are Reefs (Natura code 11.70, CORINE code 11.2). Fotofilon algal biocoenosis. Species of green algae, brown algae and red algae. Underwater meadows of Posidonia (Natura code 11.20, Corine code 11.34) (Hellenic Centre for Marina Research, 1999)
- In addition to that , the study area has historical and cultural value. The specific coastal area was inhabited from the Bronze Age. In the point of St. Cosmas remarkable ruins of the Early Helladic and the late Helladic settlement, the Artemis Temple and necropolis of the Early Helladic years have

been found. There was also a monastery, dedicated to the namesake saint. In the area of Vouliagmeni there is the temple of Apollo Zoster.

- At the same time there are remarkable monuments of nature such as the Lake of Vouliagmeni.
- The coastal area has sandy beaches used for swimming.

Development physiognomy

The coastal region from the Faliro Bay to Vouliagmeni, over the last few decades has shown large populations and residential development. The good weather condintions of the coastal area, the short distance from the center of Athens, the existence of a waterfront offering recreational opportunities, the search of the people of Athens for a higher quality of life in suburban areas, favored the development of this coastal area.

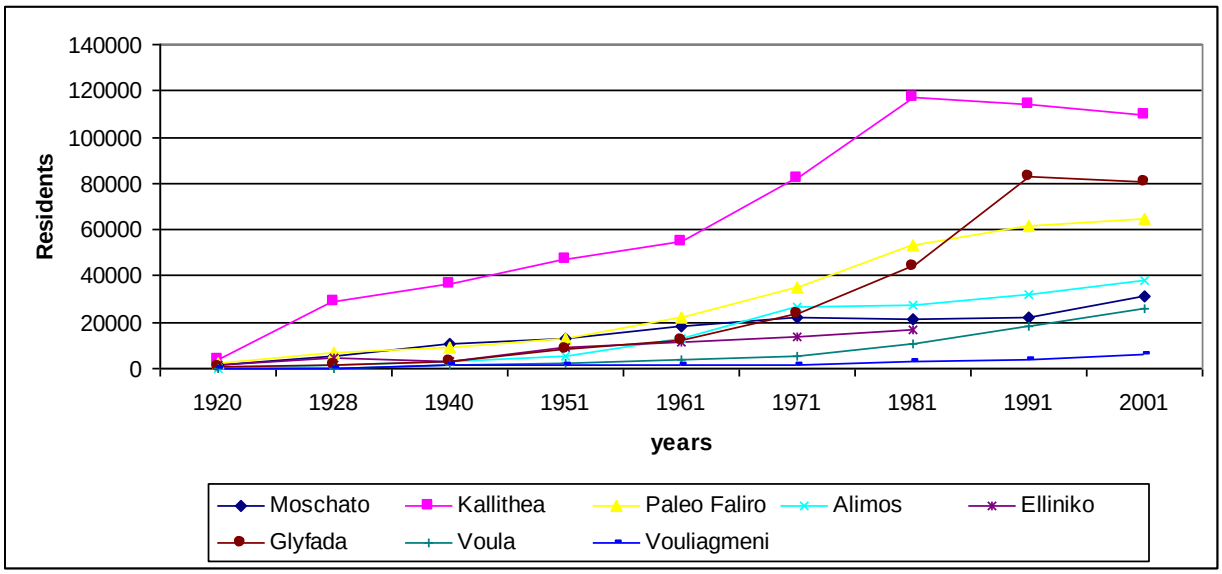

Fig. 2: Population in the coastal area of Attica at time interval 1920 - 2001 (Source: National Statitistical Service of Greece, 2002)

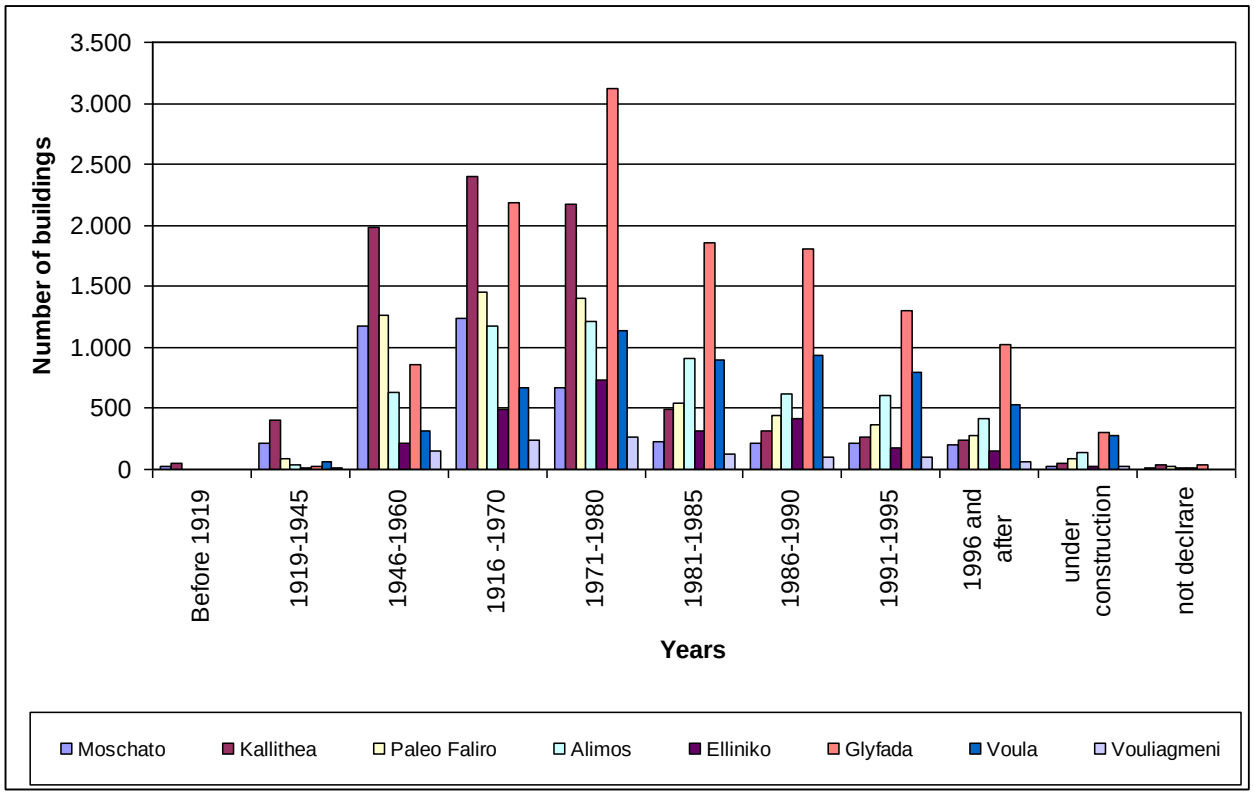

Fig. 3: Residential development in the coastal urban area of Attica at time interval 1919 - 1996 (Source: National Statitistical Service of Greece, 2002a)

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

This large population and residential growth (Fig. 1 & Fig.2) has been accompanied by the need for more services resulting in the further development of the area. Also, the area was upgraded by the Olympic projects that were constructed in recent years in order to facilitate the Olympic Games.

Thus, on the one hand they enhance the sporting infrastructure and on the other hand they have lead to the construction of road works for their service. For example, the construction of the interchange in Kifissia and the elevated highway of Kifisos, are projects that have facilitated the traffic in that direction.

At the same time, there have been many redevelopment projects to improve the natural environment. However, today the area is facing many problems that have degraded the natural resources and the quality of life.

Coastal area land use regulations

During the development of coastal areas, legislative regulations have been issued to determine land use and to constrain construction in order to protect these areas. Thus, land use and building conditions are set by the Presidential Decree 28.9.1993 (Official journal of the Helenic Republic, 1993), which is part of the wider legislative framework that is set by the Master Plan of Athens (Law 1515/1985) (Official journal of the Helenic Republic, 1985) and subsequent amendments of the law 2052/1992 (Official journal of the Helenic Republic, 1992).

Within the framework set by the directions and objectives of the Master Plan, the General Urban Planning Designs for the symmetric development of urban municipalities , in their entire surface, were created.

Despite the land use planning, coastal areas have faced many problems, which resulted in new laws to regulate land use (Presidential Degree 254). As we will analyze below, despite the above mentioned land use regulations, there are many prombles.

Urban environment and quality of life

Taking into account the area of the municipalities, the population and land uses, it is clear that that the municipalities of the study area present varying degrees of quality of life.

To assess the quality of life of residents some factors such as the proportion of green, open spaces and sports facilities per capita were taken into account.

Coastal area	Vegetation (green area) %	Sp.m./inhabitant	Open spaces -parking places %	Sp.m./inhabitant
Moschato	3.16	1.57	9.18	6.51
Kallithea	4.24	0.75	12.39	1.85
Paleo Faliro	8.08	4.09	5.14	3.25
Alimos	10.51	2.79	5.10	0.0
Elliniko	13.89	18.06	62.28	22.22
Glyfada	8.30	2.69	3.40	2.65
Voula	12.55	10.837	2.62	0.0
Vouliagmeni	21.61+5.79	138.68	3.10	27.66

Table 1: The proportion of green, open spaces in the coastal area.

The search shows that the area of Vouliagmeni occupies the largest green areas 21.61%, followed by Voula with 12.55%, Elliniko (13.89%), Glyfada (8.30%), Faliro (8.08%), Kalithea (4.24%) and Moschato (3.16%). Taking into account the ratio of green space per inhabitant it is found that the areas of Vouliagmeni, Ellhniko and Voula have rates > 10 sq.m. / Inhabitan, in contrast to other areas with smaller ratios.

Regarding the ratio of open space / resident, it is noted that the areas of Vouliagmeni and Elliniko due to the former airport, are showing high rates of approximately27.66 sq.m. / inhabitant and 22.22 sq.m. / inhabitant respectively.

With regard to sports facilities, the areas showing significant sporting infrastructure are, the area of Paleo Faliro, Elliniko and Alimos due to Olympic construction projects in the area. Thus, the proportion of sports facilities is 0.52 sq.m. / Inhabitant (Faliro), 5.68 sq.m. / Inhabitant (Alimos), 4.30 sq.m. / Inhabitant (Helliniko) and 4.82 sq.m. / Inhabitant (Voula) and 1.16 sq.m. / inhabitant (Vouliagmeni).

Taking into account the waterfront, the areas with beaches for swimming are Faliro, Alimos, Elliniko, Glyfada, Voula and Vouliagmeni. Specifically:

Coastal area	Area of beaches	Sq.m / inhabitant
Moschato	-	
Kallithea	-	
Paleo Faliro	30199.65	0.47
Alimos	30245.78	0.79
Elliniko	27222.33	1.63
Glyfada	33199.6	0.41
Voula	39802.87	1.56
Vouliagmeni	42528.26	6.60

Table 2: Area of beaches in the coasta area

The areas which have a waterfront but do not have beaches for swimming are the areas of Moschato and Kallithea. In contrast, other areas have sandy beaches, which attract not only local residents for recreation and swimming, but bathers from the entire basin of Athens.

The marine area is protected from pollution due to its connection with the tertiary treatment sewerage system sewage treatment plants, at Psitalia. At the same time, the implementation of recycling programs (Paleo Faliro, Kallithea, Alimos) and the use of natural gas, reduce the environmental impact of pollutants and protect natural resources.

Generally, in the coastal urban area there are no abandoned sites. On the contrary, open spaces for commercial use and new green areas are sought.

5 ENVIRONMENTS PROBLEMS

The survey showed that coastal municipalities face many environmental problems that degrade the standard level of life. Mainly, the problems are related to land use, intensity, and to the policies followed by local authorities to develop and protect the area.

Many of them are common to two or more municipalities and can be addressed via commons actions and policies. Based on interviews with relevant staff of the municipalities, it was found that the most common problems faced by coastal municipalities are:

- Cutting the coastal zone of the urban fabric due to the coastal road and parallel construction along the beach.
- Noise pollution from heavy traffic on the coastal road . Measures that should have been taken to levels of noise have not been implemented at all or have been only partially implemented. This has as a result, an increase in the level of noise levels above the allowable limits, making life unbearable for people as well as an increase of health hazards.
- Noise from the operation of nightclubs in the coastal zone. (Alimos, Glyfada, Elliniko)
- Problems of accessibility to the beach for the residents
- Increased traffic on the coastal avenue, due to the link between urban areas in the urban area of Athens and the southern suburbs.
- Lack of parking.
- Air pollution by NO_2 due to heavy traffic.
- Degradation of the urban environment due to increased construction. To the ncreased construction, the law of compensation which took place in 1970 has contributed to a large extent.
- Not all the projects mentioned in development studies are realized due to time constraints and inadequate funding.
- Non-implementation of Presidential Decree 254 (Official journal of the Helenic Republic, 2004) on land uses outside the areas of Alimos and Paleo Faliro.

- Lack of green space in areas presenting low rates compared compared to the total area of the municipality.
- Rainwater management problems in Glyfada, Alimos, Faliro and Muschato.
- Problems with parking on commercial streets and the central squares of the municipalities of Paleo Faliro and Glyfada.
- The region of Elliniko faces many problems of land uses. There are incompatible land uses on the beach and the center of the municipality. Generally, in the area there is a fragmentation of space. Today there is a concern for the management of the area of the former airport of Ellhniko. Its management involves many agencies whith large parts of the airport belonging to Alimos and Glyfada.
- In the area of Voula there are strong pressures to develop commercial uses along the Athens - Poseidon Avenue.
- The coastal area is faced with problems of pollution in the estuaries of the Kifissos and Ilissos rivers, because of illegal household waste dumping.

6 MEASURES TO ADDRESS ENVIRONMENTAL PROBLEMS

The problems of coastal areas mentioned above are related to the intensity of land uses.

The plans of the municipalities are to conduct studies to link the seafront with the rest of the urban fabric. These studies refer mainly to subways for the areas of Paleo Faliro, Kallithea and Alimos.

Also in the plans of the municipalities are to conduct studies to address the problems faced by some areas

Many of the problems require common actions. For example, facing the pollution of the streams marine area, requires coordination on behalf of the Municipalities that these streams across.

Many strains of land use in coastal areas, may be addressed by imposing more stringent conditions to limit the urbanization of coastal areas and to remove activities from the already burdened areas.

In areas with future development plans such as the area of the old airport in Elliniko, the new land uses will play a key role in upgrading the area. Here, we need proper planning so that new activities do not cause land use intensification and degradation of neighboring areas.

Many problems such as the reduction of green areas, the non-application of the Presidential Degree to regulate land uses, should be addressed directly by the municipalities. The implementation of the Presidential Decree which regulates land uses in the coastal front, as well as a review of the general urban plans in areas with acute problems are necessary. The design should follow the principles of sustainable development and the respect the characteristics of this sensitive coastal area.

Regarding the protection of natural resources, it is found that recycling programs are not implement by all municipalities. Even those who apply recycling, only do so at a percentage of 20%, for the municipalities of Paleo Faliro Kallithea and Alimos.

7 CONCLUSION

The research showed that the coastal area faces many problems caused not only by the intensity of land uses but also by the policies which have been implemented for the organization and function of the area.

The projects which have taken place in the coastal area have upgraded the area to an extent and on the other hand, have caused environmental problems due to non implementation of existing studies for the protection of the environment . The area has a need for new interventions and new infrastructure projects that will face the environmental problems which are mentioned above.Natural resources should be preserved and protected, because further deterioration will have as a result the reduction of the residents' quality of life.

The efforts should focus on increasing the green areas, regulating traffic problems, adjusting land use, implementing legal provisions for the regulation of land use as well as on the expansion of protected areas.

Also it is clear that the coastal area of the bay from Phaleron to Vouliagmeni, has a potential for further development and utilization of open spaces. The good cooperation between municipalities and the active participation of local residents is necessary.

An Exploration of Efficiency and Influencing Factors of Low Carbon City

Wei-Han Cheng, Hsueh-Sheng Chang

(Wei-Han Cheng, Master Degree, 1, University Road, Tainan City, 701, Taiwan, curisy@hotmail.com)
(Hsueh-Sheng Chang, Associate Professor, 1, University Road, Tainan City, 701, Taiwan, changhs@mail.ncku.edu.tw)

1 ABSTRACT

Recent years due to global environmental change, environmental protection and carbon dioxide reduction have become urgent issues. At the same time, it is also required to ensure the maintenance of urban economic activities and human life. The priority of economic development and environmental protection has caused much controversy. The tradeoff between economy and environment implies the concept of urban efficiency. And this corresponds to the viewpoint of low carbon economy:"the least carbon emission in exchange for the largest urban benefits".

Therefore, this paper takes the concept of eco-efficiency to simulate the process that a city consumes natural resources in exchange for social and economic development, and adopts Data Envelopment Analysis as a tool to analyze the urban efficiency performance and the factors of urban efficiency. First, this paper assesses urban development efficiency of Taiwan cities and counties, and analyzes the room for improvement of inputs and outputs. Second, this paper explores the influential factors of urban efficiency and the effects of these factors. Final result is expected to provide a reference to low carbon strategies of Taiwan cities and counties, and it will be helpful to future urban management, so that cities will develop towards low carbon economy and achieve the goal of sustainable development.

2 INTRODUCTION

In the face of global environmental change, carbon dioxide reduction is an urgent issue. However, a city can't sustain the basic needs of urban development by only considering for the environment. It is also required to ensure the maintenance of urban economic activities and human life.

Therefore, how to consume the least environmental resources while improving the effectiveness of urban development, so that the use of environmental resources will be more efficient under the condition of limited resources is an important issue. And this issue corresponds to the viewpoint of low carbon economy: "the least carbon emission in exchange for the largest urban benefits".

In view of this, this paper explores the impacts on the environment during the period of urban development from the viewpoint of low carbon economy, and measures the status of urban development by the evaluation of urban efficiency. Furthermore, this paper tries to construct an evaluation method of sustainable urban development in order to providing the reference of the future urban management.

3 RELATED THEORIES

3.1 Low Carbon Economy

British Government announced "Energy White Paper" in which the "low carbon economy" was first proposed in 2003. It points out that low carbon economy is to obtain more economic outputs through less consumption of natural resources and environmental pollution to create the opportunities of better quality of life.

Low carbon economy contains "low carbon" and "economy". "Low carbon" means that we must minimize or stop the dependence on carbon-based fuels in economic development; "economy" means that we should maintain the stability and sustainability of economic growth while achieving the transformation of the energy.

Low carbon economy suits the main points of sustainable development, and it could essentially show that economic growth is towards the direction of sustainable development or not. Furthermore, low carbon economy is easier to monitor and to measure the progress of sustainable development than "clean production", "green economy" and "ecological economy".

3.2 Low Carbon City

Cities are the major sources of carbon dioxide emissions, and the critical locations where emissions can be effectively managed. Adopting low carbon urban development model is the pathway towards reducing the emissions(Stanley C.T.YIP, 2010).

The core of low carbon city is low carbon economy, which intends to get more economic outputs through less consumption of natural resources and environmental pollution, and achieves better quality of life. Low carbon city development is aimed at achieving an ecological economic mode of low consumption, low pollution, high performance and high efficiency, so that we would get more economic and social benefits relatively through consuming fewer natural resources.

In the face of the trade-off between environmental protection and socio-economic development, low carbon city is the response to climate change issues with its emphasis on protecting the environment while ensuring the social and economic development. The concept of low carbon economy and low carbon city is put forward under the background that all people over the world is taking action to deal with climate change. Low carbon economy is the trend and the construction of low carbon city is necessary for future development.

3.3 Urban Development Efficiency

In the beginning, urban development efficiency was mainly used to assess the administrative efficiency of organizational performance and planning policy. And then, urban development efficiency was used to evaluate the urban efficiency by labor, income or expenditure. Later it gradually transferred to the study of the environmental and economic aspects.

Schaltegger and Sturm proposed the concept of eco-efficiency in 1990 (Schaltegger, S. and Sturm, A., 1990), and defined it as the ratio of the environmental impact and the value. "Eco-" is the prefix of economical and ecological. The original intent of eco-efficiency includes both economic and ecological benefits. World Business Council for Sustainable Development (WBCSD) has developed the following equation, which merges value and ecological aspects into an efficiency ratio:

$$\text{Eco} - \text{efficiency} = \frac{\text{Product or service value}}{\text{Environmental influence}}$$

Whitford et al (Whitford, V., Ennos, A. R. and Handley, J. F., 2001) and De Koeijer et al (De Koeijer et al., 2003) applied the concept of eco-efficiency in the urban development efficiency. They thought that we should reduce the environmental damage in the urban development process, and improve the efficiency of urban development.

4 METHODOLOGY

This study takes cities and counties in Taiwan as the spatial units, and the research year is 2009. The input of urban efficiency is carbon emissions in a city, including carbon dioxide emissions of residential sector, industrial sector and commercial sector. And the outputs are disposable income and public facilities area, which represent economic and social benefits of a city.

4.1 Calculation of Carbon Emissions

The calculation method of carbon emissions is according to the "sectoral approach" in 2006 IPCC Guidelines for National Greenhouse Gas Inventories. And the energy emission information of Taiwan is from Energy Balance Sheet.

This study calculates the carbon dioxide emissions of industrial sector and commercial sector in every counties and cities by the proportion of number of establishments, and calculates the carbon dioxide emissions of residential sector by the proportion of number of households.

4.2 Data Envelopment Analysis

This study takes cities and counties in Taiwan as the decision making units (DMUs).The inputs of urban development efficiency are: 1.carbon dioxide emissions of the residential sector 2.carbon dioxide emissions of the industrial sector 3.carbon dioxide emissions of the commercial sector. The outputs of urban development efficiency are: 1.disposable income per capita of economic aspect 2.public facilities area per

capita of social aspect. And then this paper conducts data envelopment analysis through DEA-solver software.

Overall Efficiency

It represents the efficiency that carbon dioxide emissions convert to urban development benefits. The value is between 0 and 1. The higher the value, the more efficient the urban development is.

Technical Efficiency

It represents the relative efficiency that compares the urban development benefits of DMUs which have similar degree of environmental loss (inputs of environmental resources). The value is between 0 and 1. And it implies that the inputs are used effectively to get the maxima of outputs or not.

Scale Efficiency

It represents the relative efficiency that compares the status of environmental loss and urban development benefits of one DMU with another DMU which is in optimal scale.

5 ANALYSIS RESULT

5.1 Urban Development Efficiency Analysis

The evaluation results of urban development efficiency could be an initial view of urban status in different counties and cities. According to the performances of the overall efficiency, technical efficiency and scale efficiency of DMUs, we could figure out where the efficiency problem is in different cities.

Figure 1 shows the result of the overall efficiency, technical efficiency and scale efficiency value of Taiwan counties and cities. Because the efficiency of Penghu County and Taitung County is much greater than the other 21 counties and cities, we remove Penghu County and Taitung County from this analysis, so that we will be easier to tell the differences in the remaining DMUs.

Table 1 and Figure 2 shows the result of overall efficiency, technical efficiency and scale efficiency in 21 counties and cities. And Figure 3 shows the result of overall efficiency in Taiwan map. Hsinchu County, Chiayi County, Hualien County, Keelung City, Hsinchu City and Chiayi City whose overall efficiency are 1.0 are efficient cities and counties; Other cities and counties are inefficient.

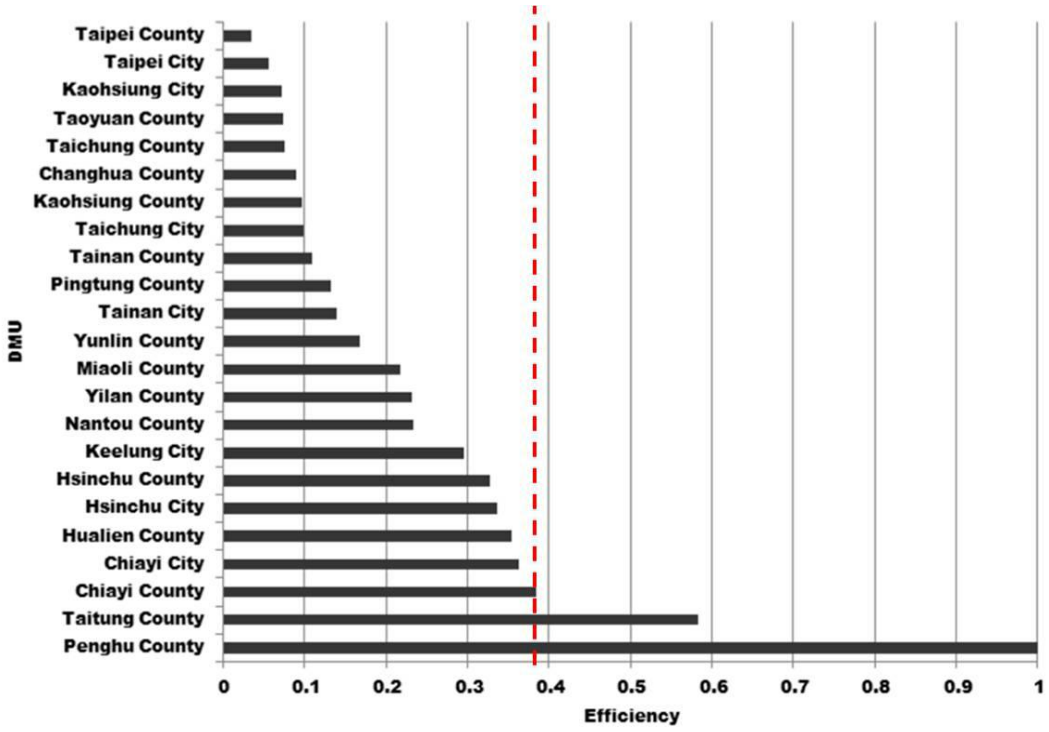

Fig. 1: The results of overall efficiency, technical efficiency and scale efficiency in Taiwan.

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

In non-efficient cities and counties, the technical efficiency of Taipei City is 1.0, which shows that the inefficiency is due to "scale inefficiency". Taipei City should change its amount of resources use to improve the efficiency performance. And the reason of other non-efficient cities and counties is mainly from "technical inefficiency", which implies the inputs are not used effectively to reach the output maximization. These cities and counties should maintain the consumption of natural resources, and make further improvements for economic and social policies.

DMU	Overall Efficiency	Technical Efficiency	Scale Efficiency	Reference times
Taipei City	0.2098	1.0000	0.2098	0
Kaohsiung City	0.2337	0.3081	0.7586	0
Taipei County	0.1060	0.1113	0.9519	0
Yilan County	0.7327	0.7909	0.9264	0
Taoyuan County	0.2203	0.2293	0.9605	0
Hsinchu County	1.0000	1.0000	1.0000	8
Miaoli County	0.6801	0.7958	0.8546	0
Taichung County	0.2324	0.2669	0.8707	0
Changhua County	0.2785	0.3364	0.8281	0
Nantou County	0.7742	0.7905	0.9794	0
Yunlin County	0.5543	0.6386	0.8680	0
Chiayi County	1.0000	1.0000	1.0000	1

Hsinchu City	1.0000	1.0000	1.0000	11
Taichung City	0.2742	0.2812	0.9754	0
Chiayi City	1.0000	1.0000	1.0000	6
Tainan City	0.4098	0.4258	0.9624	0

Table 1: The result of overall efficiency, technical efficiency scale efficiency and reference times.

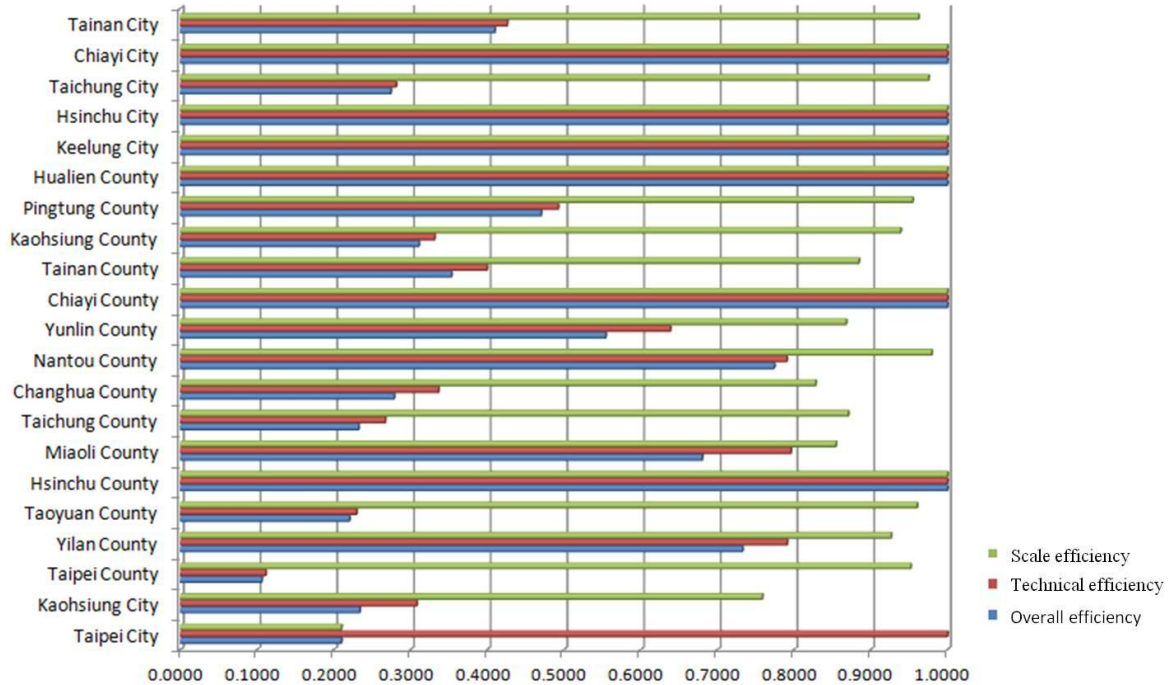

Fig. 2: The result of overall efficiency, technical efficiency and scale efficiency in 21 counties and cities.

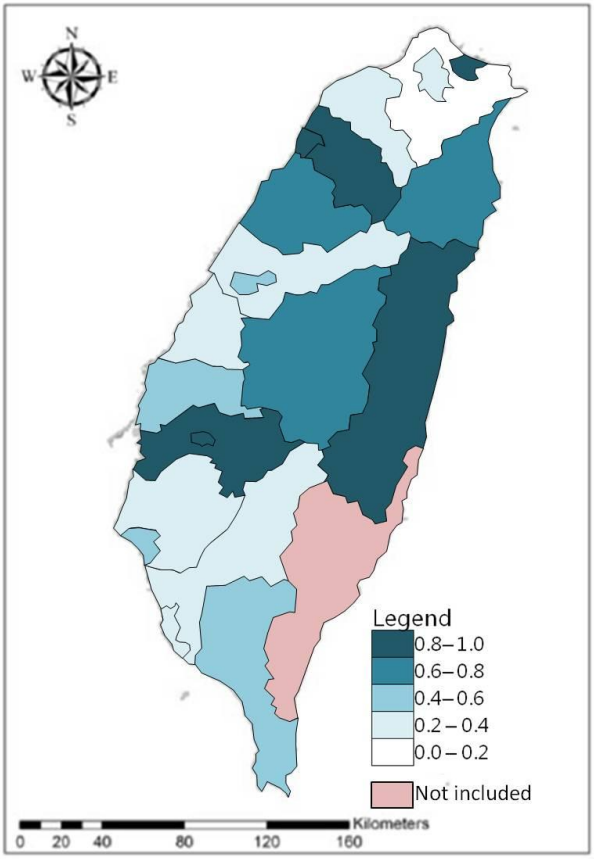

Fig. 3: The result of overall efficiency in Taiwan map.

Norman and Barry (Norman, M., Barry, S., 1991) distinguish four types of efficiency performance: "Robustly Efficient units", "Marginal Efficient Units", "Marginal Inefficient Units" and "Distinctly Inefficient Units". Taiwan counties and cities are classified by these four types as shown in Table 2.

Efficiency type	Description	DMUs
Robustly Efficient Units	The value of overall efficiency, technical efficiency and scale efficiency of the DMUs is 1.0. And the DMUs appear in many reference sets.	Hsinchu County, Hualien County, Keelung City, Hsinchu City, Chiayi City
Marginal Efficient Units	The value of overall efficiency of the DMUs is 1.0. And the reference times of the DMUs is only one or two.	Chiayi County
Marginal Inefficient Units	The value of overall efficiency of the DMUs is between 0.9-1.0. And the DMUs will be relative efficiency by adjusting the inputs and outputs.	-
Distinctly Inefficient Units	The value of overall efficiency of the DMUs is less than 0.9. And the DMUs with overall efficiency less than 0.75 will maintain the inefficient status if there are no big changes in those DMUs.	Nantou County, Yilan County, Miaoli County, Yunlin County, Pingtung County, Tainan City, Tainan County, Kaohsiung County, Changhua County, Taichung City, Kaohsiung City, Taichung County, Taoyuan County, Taipei City, Taipei County

Table 2: Efficiency types of Taiwan counties and cities.

5.2 Slack Variable Analysis

In slack variable analysis, the input variables represent the input volume should be reduced, and the output variables represent the volume should be increased. DMUs will obtain the best efficiency by reducing inputs and increasing outputs. In other words, we could analyze improvement direction and potential improvement

space of urban inputs and outputs in different cities. The result of slack variable analysis are given in Table 3.

Taipei County, Taoyuan County, Taichung County, Nantou County, Yunlin County, Tainan County, Kaohsiung County and Pingtung County could improve their urban development efficiency by reducing carbon dioxide emissions of residential sector. And there are more required improvements in Taipei County, Taoyuan County and Yunlin County. Taipei City and Pingtung County could improve their urban development efficiency by reducing carbon dioxide emissions of commercial sector. And there are ten couties and cities that could improve their urban development efficiency by reducing carbon dioxide emissions of industrial sector. It shows that the carbon dioxide emissions of industrial sector is the main factor to affect the efficiency of urban development in Taiwan.

In addition, there are no couties and cities could improve their urban development efficiency by increasing disposable income. And Taipei City, Kaohsiung City, Taipei County and Taichung City could improve their urban development efficiency by increasing public facilities area per capita.

DMU	Inputs			Outputs	
	CO_2 emissions of residential sector	CO_2 emissions of industrial sector	CO_2 emissions of commercial sector	Disposable income per capita	Public facilities area per capita
Taipei City	0	0	55503.4048	0	46.1747
Kaohsiung City	0	0	0	0	8.2798
Taipei County	21843.5571	482014.1919	0	0	2.0741
Yilan County	0	0	0	0	0

Number of DMUs	8	10	2	0	4
Mean	8722.6219	515199.0784	28665.1000	0	16.4557

Table 3: The result of slack variable analysis.

6 CONCLUSION

The tradeoff between economy and environment implies the concept of urban efficiency. This paper tries to explore the environmental impacts of urban development from the viewpoint of low carbon economy, and evaluates the status of urban development by measuring the urban efficiency. And then this paper assesses urban development efficiency of Taiwan cities and counties through data envelopment analysis.

The evaluation results of urban development efficiency could be an initial view of urban status. And then we could analyze potential improvement of urban inputs and outputs by slack variable analysis, so that we could provide suggestions of improvement direction to those cities with poor urban efficiency and set up the different development goals to cities with different urban efficiency.

This paper constructs an evaluation method of sustainable urban development through the evaluation of urban development efficiency from the perspective of carbon efficiency. We could examine that the urban development is towards sustainable development or not by this method. And it will be helpful to future urban management, so that it will achieve the goal of low carbon economy and develop towards sustainable development.

1 ABSTRACT

The paper presents the first results of the project ways2gether which focuses on the reduction of barriers in terms of communication and accessibility in participative planning processes through a specifically adapted tool set. This tool set is based on visualisation techniques through augmented-reality applications (AR) and interactive Web 2.0 tools. This also enables the 3-dimensional presentation and easy modification of planning areas – both online and on site. The paper gives an overview on the state of the art of AR and Web 2.0-tools with regard to (traffic-) planning. The requirements of future user groups of the ways2gether tools are summarised. The use of the ways2gether tools in different phases of a planning process as well as the technical requirements and implementation possibilities are described.

2 EINLEITUNG

Das Paper stellt erste Ergebnisse aus dem im Frühjahr 2011 gestarteten Projekt „ways2gether – Zielgruppenspezifischer Einsatz von Augmented Reality (dt. Erweiterte Realität/Wahrnehmung) und Web 2.0 in partizipativen Verkehrsplanungsprozessen“[1] vor. Das Ziel des Projekts ways2gether ist die Verringerung von Kommunikations- und Zugangsbarrieren in partizipativen Planungsprozessen durch ein spezifisch angepasstes Tool-Set, basierend auf Visualisierungstechniken durch Augmented-Reality-Anwendungen und interaktive Web-2.0-Tools. Das Projekt fokussiert den Bereich der mobilen Augmented-Reality-Anwendungen.

Die Darstellung der AR-Information kann auf unterschiedlichen mobilen Geräten erfolgen (z. B. Head-Mounted-Displays, See-Through-Displays etc.) (vgl. u. a. Wietzel 2007:164ff). Da eine Unterstützung von Beteiligungsprozessen im Vordergrund des Projektes steht und die Nutzerinnen und Nutzer auch selbstständig die AR-Informationen nutzen können sollen, wird die Entwicklung auf Hand-Held Geräte wie Tablet-PCs und Smartphones fokussiert. Diese haben die für mobile AR Anwendungen notwendigen Kameras, GPS sowie Lagesensoren in den meisten Fällen bereits eingebaut. Eine weiter Anforderungen an das AR System ist, dass die AR Anwendungen auf mobilen Endgeräten laufen müssen.

In diesem Beitrag wird ein Überblick über die einzelnen Web-2.0- und AR-Instrumente gegeben, die durch eine inter- und transdisziplinäre Zusammenarbeit von Verkehrsplanerinnen und Verkehrsplanern, Landschaftsplanerinnen und Landschaftsplanern, Sozialwissenschaftlerinnen und Sozialwissenschaftlern sowie Technikerinnen und Technikern ausgearbeitet wurden.

3 WEB 2.0 UND AUGMENTED REALITY IN DER PLANUNG

Viele, bereits gut etablierte Web-Anwendungen wie Online-GIS-Systeme und Social Networks finden bereits zahlreich Verwendung und unterstützen (Verkehrs-)Planungs und Beteiligungsprozesse (vgl. u. a. Körnig-Pich et al. 2010). Diese Instrumente werden in Beteiligungsprozessen hauptsächlich im Bereich der Informationsgewinnung,[2] der Informationsverbreitung,[3] für den Austausch[4] oder die Konsultation[5] verwendet.

[4] z. B. Seestadt Aspern, zur Organisation von Baugruppen, also der Koordination der Mitglieder untereinander (http://www.brot-aspern.at/)

Augmented Reality ist eine neue Art des Sehens und erweitert die Möglichkeiten der Inhaltsvermittlung. In die reale Situation werden zusätzliche digitale Informationen eingespielt. Diese neue Technik, die zum Beispiel im Marketing, der Navigation, bei Spielen, in der Medizin, im Servicebereich, aber auch dem Tourismus erfolgreich zur Anwendung kommt (vgl. u. a. Höhl, 2007, Heldal 2007), kann auch in Verkehrsplanungsprozessen einen entscheidenden Beitrag zur Qualitätssicherung und -verbesserung leisten (vgl. Nash 2010).

Erste Versuche mit virtueller Realität wurden bereits in den 50er-Jahren des letzten Jahrhunderts durchgeführt, aber erst bis 1997 wurden die Begriffe definiert (vgl. Carmigniani et al. 2011). Obwohl Augmented Reality seit den 1990er-Jahren stark diskutiert wird (vgl. u. a. Azuma 1997), sind außerhalb von Forschungsprojekten wenig greifbare Projekte umgesetzt worden. Die Analyse der aktuellen Praxis-Beispiele im Bereich der Augmented Reality hat gezeigt, dass es ein breites Spektrum an Anwendungen von AR-Instrumenten gibt, aber sehr wenige Beispiele im Bereich von mobilen AR-Anwendungen. Insbesondere mit planerischem Bezug und im Bereich der dreidimensionalen Visualieirung sind sehr wenige Beispiele vorhanden.

4 AUGMENTED-REALITY-TECHNOLOGIEN FÜR MOBILE ENDGERÄTE

Erst durch die aktuelle Verbreitung von geeigneten mobilen Geräten, die über Kamera, Datenverbindung und ausreichende Rechenleistung verfügen, wurden (mobile) Augmented-Reality-Anwendungen auch für den Endnutzer interessant. In der Werbung wurde bereits früher mit AR experimentiert, hierzu wurden aber Webcams verwendet, die an PCs gebunden sind. Durch die Verbreitung von Smartphones und die Möglichkeit, Anwendungen von Drittanbietern für die mobilen Geräte zu nutzen, hat sich in den letzten Jahren ein Trend zur Augmentierung entwickelt, der allerdings erst noch Einzug in das tägliche Leben halten muss.

	Wikitude[6]	Layar[7]	Junaio[8]

Points of Interest	Ja	Ja	Ja
3D-POI	Ja	Ja	Ja
Animation 3D-Objekt	Nein	mit Hoppala: nein (l3d statisch); eigenes Web-service: ja; mit buildAR: ja	Ja
Speicherung auf Server	Server: eigener (Webservi-ce) oder Anbieterserver (z. B.: Hoppala, Wikitude)	Server: eigener (Webservice) oder Anbieterserver (z. B.: Hoppala)	Server: eigener (Webservice) oder Anbieterserver (z. B.: Hoppala)
LLA-Marker	Nein	Nein (Übergabe von Koordinaten mit QR-Code möglich)	Ja
In eigene Applikation einbetten	Ja (iOS und Android)	Ja (iOS Q4/2011 Android)	Ja (iOS Q4/2011 Android)

Tabelle 1: Vergleich der verbreitetesten AR-Applikationen

Bisher ist die alltägliche Relevanz der angebotenen Anwendungen noch als gering einzustufen, jedoch werden laufend neue Entwicklungen auf den Markt gebracht und durch den einfachen Zugang und die Verbreitung der Endgeräte können große Teile der Bevölkerung erreicht werden. Nun geht es darum, interessante und sinnvolle Anwendungen die Augmented Reality nutzen, anzubieten. Das Projekt ways2gether will hier im Bereich der Stadt- bzw. Verkehrsplanung und vor allem der Partizipation einen Beitrag leisten.

[5] z. B. Stadt-Wien-App, um Mängel und Missstände zu melden (http://data.wien.gv.at/apps/machmit.html)
[6] http://www.wikitude.com/en/
[7] http://www.layar.com/
[8] http://www.junaio.com/

Im Projekt wurden dafür bereits bestehende AR-Frameworks untersucht und ausgewählt, um sowohl deren Verbreitung zu fördern, als auch bestehende Ressourcen zu nutzen. Tabelle 1 zeigt einen Ausschnitt der erfolgten Recherchearbeit mit den relevantesten Anbietern von AR-Applikationen auf mobilen Endgeräten. Es wurden abgesehen von den genannten noch Tripwolf,[9] Peak.AR,[10] RADAR,[11] Popcode[12] und Aurasma[13] auf ihre Eignung für das Projekt untersucht.

Die untersuchten Kriterien ergeben sich aus den Anforderungen, die das Projekt ways2gether für die Anwendung von AR in Planungsszenarien und der Partizipation definiert hat. Dabei sind vor allem die Unterstützung von dreidimensionalen Objekten sowie die Verbesserung der GPS-Positionierung durch sogenannte LLA-Marker (LLA = Latitude, Longitude, Altitude) von Bedeutung.

LLA-Marker können als QR-(Quick-Response-)Codes zum Einsatz kommen; dabei wird ein gut sichtbares Symbol (Fig. 1) am relevanten Ort angebracht und im Falle der Nutzung im Rahmen eines Partizipationsvorhabens mit weiterführenden Informationen versehen. An einer Baustelle können Interessierte und betroffene Bürgerinnen und Bürger beispielsweise direkt über ein Plakat die wesentlichen Fakten erhalten und zusätzlich durch das Scannen des angebrachten QR-Codes weitere Informationen abrufen oder sich das Modell des Bauvorhabens mit ihrem Smartphone vor Ort ansehen.

Fig. 1: LLA-Marker, aktiviert einen Junaio-Channel.

5 ANFORDERUNGEN AN DAS WAYS2GETHER TOOL-SET AUS SICHT DER PLANER UND AR-EXPERTEN

Befragungen im Rahmen der Projekte HOLODECK[14] und TechnoVeP[15] brachten das Ergebnis, dass der Einsatz von technologischen Planungsinstrumenten nur dann erfolgt, wenn damit die Effizienz und die Effektivität gesteigert werden können sowie die Vermittlung der Planungsergebnisse leichter erfolgt (Berger et al. 2011:1344).

Im Rahmen von Expertengesprächen[16] im Projekt ways2gether wurden die Anforderungen an die AR- und Web-2.0-Instrumente aus Sicht der Planerinnen und Planer sowie AR-Expertinnen und AR-Experten erhoben. Themen der Gespräche waren die Abläufe der Planungs- und Beteiligungsprozesse, die Zielgruppen, die sich an Planungsprozessen, beteiligen, Hindernisse in der Beteiligung sowie die bisherigen Erfahrungen mit AR- und Web-2.0-Instrumenten. Im Folgenden werden die wichtigsten Anforderungen an den Einsatz von AR- und Web-2.0-Instrumenten abgeleitet aus den Expertengesprächen zusammengefasst.

Vor- und Nachteile des Einsatzes von AR Instrumenten in Planungsprozessen

Eine Verbesserung der Kommunikation, vor allem in Hinblick auf die Auswirkungen der Planungen kann durch den Einsatz von AR-Instrumenten nach Einschätzung der Expertinnen und Experten erreicht werden. Der Vorteil von AR-Visualisierungen im Vergleich zu den derzeit eingesetzten 3D-Visualisierungen in Form

[16] Die ein- bis eineinhalbstündigen Interviews wurden im Zeitraum von Mai bis Juli 2011 von Florian Reinwald und Christoph Stoik durchgeführt. Interviewpartner waren: Christoph Schwarz (FGM), Thomas Pilz (FGM), Ulrich Bergmann (verkehr+), Peter Zeile (TU Kaiserslautern), Martin Forstner (GB 20), Roman Koselsky (Aspern – Wien 3420), Annemarie Hietler (Aspern – Wien 3420); Martina Jauschneg führte ein Gespräch mit Christine Chaloupka-Risser, (Verkehrspsychologin).

von Renderings ist, dass sie weniger manipulativ durch eine freie Wahl des Augpunktes sind. AR-Visualisierungen bieten eine weit größere Flexibilität in der räumlichen Ansicht. Die Auseinandersetzung mit den AR-Modellen in Kombination mit der realen Umgebung schafft und verbessert eine Identifikation mit dem Projekt.

Als Nachteile des Einsatzes von AR-Instrumenten wurden hauptsächlich Einschränkungen aufgrund der technischen Möglichkeiten der derzeitigen Geräte und der Software genannt. Eine Anschaulichkeit und Genauigkeit muss gegeben sein, sonst „schreckt es eher ab". Auch ein zusätzlicher Aufwand, der sowohl durch den Einsatz der Instrumente als auch durch die damit verbundene Steigerung der Informationen und Beiträge der Bewohnerinnen und Bewohner entsteht, wird befürchtet.

5.1 Anforderungen aus den unterschiedlichen Planungs- und Beteiligungsprozessen

Die einzelnen Expertinnen und Experten wurden auch nach den unterschiedlichen Abläufen ihrer üblichen Planungs- und Beteiligungsprozesse befragt. Die unterschiedlichen Ziele und Anlässe der Planungs- und Beteiligungsprozesse führen zu unterschiedlichen Prozessgestaltungen und Arbeitsschritten und verlangen daher einen differenzierten und anpassbaren Einsatz von Web-2.0- und AR-Instrumenten. Innerhalb des ways2gether-Projekts werden daher anhand von unterschiedlichen Planungs- und Beteiligungsprozessen[17] die Einsatzmöglichkeiten geprüft.

Auf fast allen Ebenen und Phasen des Planungsprozesses wurden Anknüpfungspunkte und Einsatzmöglichkeiten für Web-2.0- und AR-Instrumente identifiziert, die in unterschiedlichen Phasen sowie in Abstimmung auf die Ziele der Betetiligung eingesetzt werden können. Als zentrale Instrumente in Beteiligungsprozessen in der Verkehrsplanung wurden (1) die (Online-)Information und Konsultation, (2) die Vor-Ort-Information, (3) die Analyse des Planungsraumes (4) Begehungen und Vor-Ort-Besprechungen (5) die Beteiligung am Entwurf (6) die Visualisierung der Entwürfe sowie (7) die Ergebnisvisualisierung identifiziert.

5.2 Anforderungen aus Sicht der Planer und Nutzer

Der Einsatz der einzelnen Instrumente des ways2gether-Tool-Sets muss auf die unterschiedlichen Planungsprozesse abgestimmt werden können, da nicht alle Instrumente in jedem Anwendungsfall eingesetzt werden. Die Planerinnen und Planer und die Prozessbegleiterinnen und –begleiter müssen die Möglichkeit haben, rasch die notwendigen Instrumente auswählen und die Plattform einzurichten zu können. Zur Einbindung des ways2gether-Tool-Sets in den üblichen Arbeitsablauf muss dieser bei der Entwicklung der einzelnen Instrumente von Anfang an berücksichtigt werden (Datenschnittstellen, Visualisierungsprogramme etc.).

Die AR-Visualisierungen sollten mit bestehenden, im üblichen Planungsalltag verwendeten Softwareprodukten erarbeitet werden und dann in die AR-Umgebung migriert werden können. Bei der Implementierung in die Planungs- und Beteiligungspraxis muss auch gewährleistet sein, dass die Prozessbegleiter in das Tool eingeschult werden und damit vertraut gemacht werden können. Eine Einschulungsphase ist zu konzipieren und von Anfang an zu kommunizieren. Weiterführende Inputs dazu sind aus den zukünftigen Testfällen im Projekt ways2gether zu erwarten.

Die Nutzerinnen und Nutzer müssen die einzelnen Instrumente des ways2gether-Tool-Sets relativ einfach bedienen können. Der Lernaufwand für soll gering sein. Vorausgesetzt werden kann der Umgang mit Smartphones und Applikationen, ebenso jener mit Onlineplänen wie Google Maps. Für die Benutzung der einzelnen Instrumente sollten Leitfäden und Anleitungen vorbereitet werden. Im Rahmen von begleiteten Veranstaltungen wie Begehungen und Treffen können die Nutzer eingeschult werden.

Eine Transparenz bei Kosten und Downloadvolumen muss geschaffen werden. Auch der Datenschutz und die Datensicherheit sind wichtige Anforderungen der Nutzerinnen und Nutzer, sowohl von den Planern als auch den Bewohnern.

[17] Anhand folgender Planungsprozesse wurden die Einsatzmöglichkeiten geprüft: (1) Verbesserung von bestehenden Straßenfreiräumen durch Umbauten und Adaptionen. In diesem Beispiel werden die Lösungsvorschläge und Empfehlungen durch Arbeitsgruppen von Bewohnerinnen und Bewohnern eingebracht (Gebietsbetreuung 20, Wien); (2) AR-Visualisierung von Straßenfreiräumen in Stadtentwicklungsgebieten (Seestadt Aspern, Wien); (3) Innerörtliches Verkehrsplanungsprojekt mit Bürgerbeteiligung (Verkehr+/Forschungsgesellschaft Mobilität, Steiermark).

6 DAS WAYS2GETHER-TOOL-SET ALS BAUKASTEN FÜR PLANUNGSPROZESSE

Die ways2gether-Toolbox soll in unterschiedlichen Verkehrsplanungs- und Beteiligungsprozessen zur Anwendung kommen. Die Instrumente müssen also vielfältig einsetzbar und auf die spezifischen Anforderungen in den unterschiedlichen Verkehrsplanungsprozessen anpassbar sein. In einem intensiven Diskussionsprozess wurden durch die im Projekt ways2gether beteiligten Fachdisziplinen (Planer, Sozialwissenschaftler und Techniker) zuerst Anforderungen für die unterschiedlichen Zielgruppen und für die vielfältigen Arbeitsschritte in den Planungsprozessen definiert und darauf aufbauend die (technischen) Möglichkeiten einer Umsetzung ausgearbeitet.

Das ways2gether-Tool-Set

Basis für das ways2gether-Tool-Set ist eine Online-Plattform. Auf diese setzen Tools (Web 2.0 und AR) auf, die abgestimmt auf die Ziele des Planungs- und Beteiligungsprozesses eingesetzt werden können. Als zentrale Onlinetools werden die „digitale Nadelmethode“ als Erhebungsinstrumente, „Foren“ als Austauschplattformen sowie ein „Online-Baukasten“ zur Mitgestaltung eingesetzt. Als mobile AR-Tools kommen „AR-Post-Its“ als Erhebungs- und Austauschinstrumente, „AR-Informations-Tools“ zur Bereitstellung von georeferenzierten Informationen sowie „AR-Visualisierungs-Tools“ für die Darstellung der Entwürfe zum Einsatz.

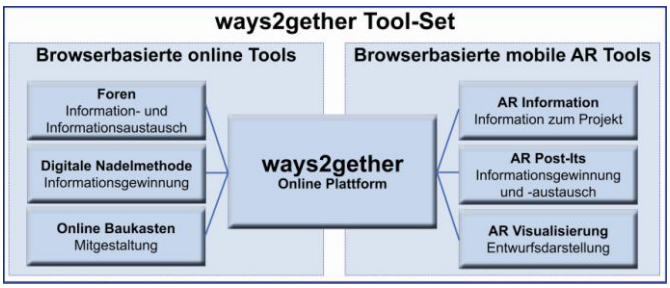

Fig. 2: Bestandteile des ways2gether-Tool-Sets (Draft).

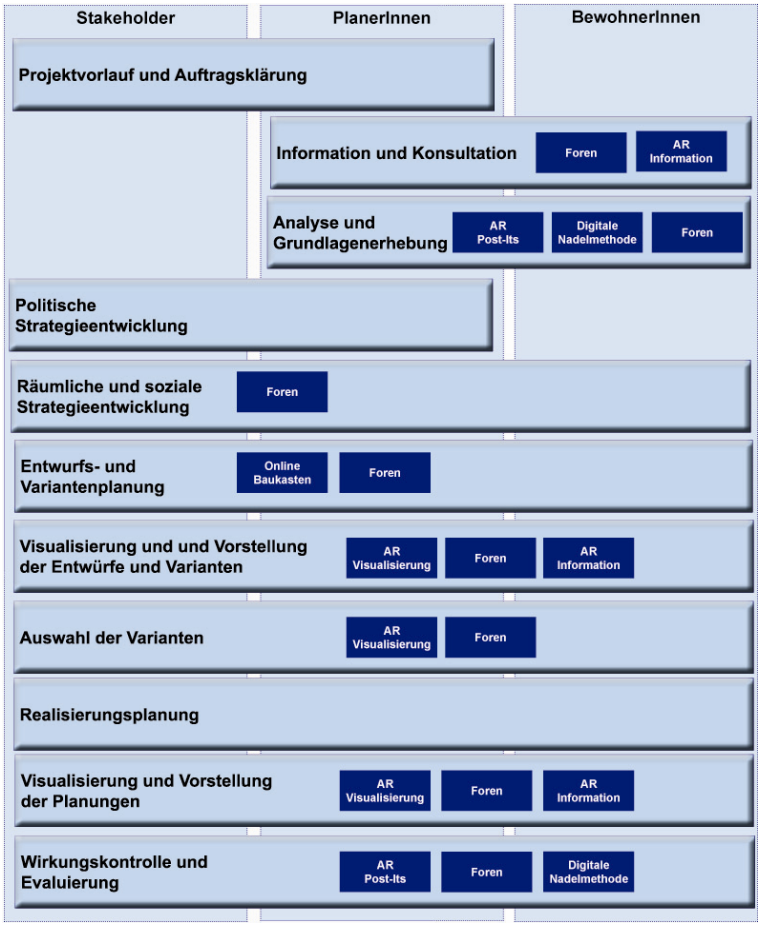

Fig. 3: Einsatzmöglichkeiten des ways2gether-Tool-Sets (Draft)

6.1 Einsatz der Instrumente im Prozess

Die einzelnen Instrumente können in unterschiedlichen Phasen des Planungsprozesses zur Informationsgewinnung und dem Informationsaustausch eingesetzt werden (Siehe Fig.3).

Informationsgewinnung und Informationsaustausch über Web-2.0-Instrumente

Zur Konsultation der Bewohnerinnen und Bewohner und zum Austausch untereinander, werden „Foren" in das ways2gether-Tool-Set mit einbezogen. Mit Hilfe der „digitalen Nadelmethode" soll die Analyse des Untersuchungsraumes unterstützt werden. Die Nutzer sollen die Möglichkeit haben, Orte, Wege und Räume zu markieren sowie Kommentare und Bewertungen dazu abgeben können. Ein (browserbasierter) „Online-Baukasten" soll eine Beteiligung am Entwurf ermöglichen. Dazu wird ein Baukasten mit einfachen Gestaltungselementen benötigt, die die Nutzer im Raum bewegen und positionieren können. Die Ergebnisse der Entwürfe sollen in das AR-System einspielbar sein um auch anderen Prozessbeteiligten zugänglich zu sein.

Informationsgewinnung und Informationsaustausch über AR-Instrumente

Durch „virtuelle Bautafeln" kann vor Ort über die Planungsabsichten und zum aktuellen Planungs- und Arbeitsablauf informiert werden. Dazu werden QR-Codes verwendet, die über die Handys und Tablets eingelesen werden können und zu aktuellen und verorteten Informationen auf der Projektseite führen. Damit können ortsbezogene Informationen mit einer hohen Aktualität den Nutzerinnen und Nutzern zur Verfügung gestellt werden. Als zweite Möglichkeit werden georeferenzierte Informationen über AR-Browser angeboten. Kommentarfunktionen sollen bei beiden Instrumenten ein Feed-Back der Nutzerinnen und Nutzer und Rückfragen der Planerinnen, Planer, Prozessbegleiterinnen oder Prozessbegleiter ermöglichen.

Durch „digitale Post-Its" (POI) können georeferenzierte Beiträge der Bewohnerinnen und Bewohner zu räumlichen Situationen gesammelt werden (z. B. da muss was getan werden, gefährliche Situation etc.). Sie unterstützen die Analyse des Raumes durch die Beiträge der Nutzer. Zusätzlich soll die Möglichkeit geboten werden, Bilder georeferenziert zu posten um die Analyse aus Nutzersicht zu unterstützen. Die „digitalen Post-Its" sollen auch für andere Nutzer sichtbar sein, um die bereits vorgenommenen Anmerkungen und Beiträge einzusehen, kommentieren oder erweitern zu können.

Zentraler Fokus im Projekt ways2gether wird auf die AR-Instrumente zur Visualisierung von Entwürfen und Planungen gelegt. Zentral dabei ist eine Unterscheidung zwischen der Visualisierung der Entwürfe und in der Ergebnisvisualisierung (Bestand und Neuplanung). Für die AR-Visualisierung der Entwürfe ist eine „skizzenhafte" Darstellung notwendig. Auch müssen die Visualisierungen aus dem „Online-Baukasten" in diese Umgebung migriert werden können. Für die Ergebnisvisualisierung ist eine möglichst hohe Darstellungsgenauigkeit notwendig.

7 TECHNISCHE ANFORDERUNGEN UND UMSETZUNG

Die Umsetzung der AR-Instrumente erfolgte nach gründlicher Recherche der zur Verfügung stehenden AR-Frameworks für mobile Endgeräte mit dem freien metaio Mobile SDK.[18] In der ersten Phase der Entwicklung wird ein Demonstrator für iOS-Geräte entwickelt. Dabei handelt es sich um eine eigene App, die auf dem Endgerät installiert wird. Das ermöglicht es, in Zukunft ein eigenes Branding einzusetzen, im Gegensatz zu AR-Entwicklungen, die sich darauf beschränken, einen sogenannten Channel zur Ansicht mit dem juniao-Client (beziehungsweise Layer für die layar-App) zur Verfügung zu stellen. Es bietet sich dadurch die Möglichkeit, die App mit der Onlinepräsenz des Projekts zu verknüpfen und weitere Informationen anzubieten.

Die Grundvoraussetzungen für die Entwicklung einer iOS-Applikation ist ein Computer mit dem Betriebssystem Mac OS mit einer installierten XCode-Entwicklungsumgebung und dem metaio Mobile SDK, das als Modul in XCode eingebunden wird und Zugriff auf diverse AR-Funktionen bietet.

Um den geschriebenen Code als Applikation zu verpacken und zu Testzwecken auf ein Endgerät bringen zu können, ist außerdem ein Zugang zum Developer-Programm von Apple vonnöten. Damit kann die entstandene Applikation dann auch in den App Store eingereicht werden.

Mögliche Endgeräte für diese Applikation sind:

[18] http://www.metaio.com/software/mobile-sdk/

- iPhone 3GS
- iPhone 4/4S
- iPad 2

jeweils mit dem Betriebssystem iOS ab Version 4.3.

In einer späteren Phase des Projekts folgt die Implementierung für Android-Geräte. Dazu wird ebenfalls das metaio Mobile SDK verwendet, allerdings im Zusammenspiel mit Eclipse und dem Android SDK. Die in Frage kommenden Endgeräte für Augmented Reality müssen zumindest folgende technische Anforderungen erfüllen: Kamera, Positionsbestimmung mit GPS, Internetverbindung. Eine gute Datenverbindung ist nötig, da die Modelle für die Visualisierung erst bei Abruf aus dem Internet von einem Server geladen werden.

Für die internen Tests der 3D-Modelle, die mit SketchUp Pro in ein geeignetes Format gebracht werden, wurden einige zusätzliche Funktionen in die Applikation eingebaut, die den späteren Endbenutzern nicht zugänglich sein werden. „Administratoren" der Software haben Zugang zu Funktionen um die 3D-Modelle in der Visualisierung nach den drei Achsen auszurichten sowie zu skalieren. Damit können die Modelle im Vorfeld den Gegebenheiten vor Ort optimal angepasst werden, bevor sie im Rahmen der Beteiligungsprozesse der Bevölkerung zur Verfügung gestellt werden.

8 DISKUSSION UND AUSBLICK

Erst seit wenigen Jahren zeigt sich bei den AR-Anwendungen eine verstärkte Präsenz und die Nutzung von AR-Browsern (z. B. Wikitude seit 2008, Layar und Junaio seit 2009) nimmt stetig zu. Die Anwendungen haben sich bereits weit verbreitet und zeigen eine dynamische Entwicklung. Auch die Etablierung in verschiedenen Anwendungs- und Forschungsfeldern gibt Hinweise auf die möglichen Verbesserungen, die durch den Einsatz von AR-Informationen erreicht werden können und die zukünftige Wichtigkeit von AR-Instrumenten.

Insbesondere die Verkehrsplanung kann neben der Architektur, der Stadt-, Raum- und Landschaftsplanung, von dem Einsatz von AR-Instrumenten profitieren. In all diesen Disziplinen muss (meist) mit einem Bestand umgegangen werden und es gibt keine Möglichkeiten für „Laborversuche" (vgl. u. a. Vollweiler, Jung 2011:86). Die Realität ist der Maßstab, innerhalb dessen sich Planungen und Gestaltungen bewähren müssen. Der Einsatz von augmentierten Realitäten kann hier einen entscheidenden Beitrag leisten, die Auswirkungen im Vorfeld zu prüfen.

Die derzeit vorhandenen Einschränkungen für den Einsatz von mobilen AR-Instrumenten wie die Prozessorgeschwindigkeit, die Bildschirmgrößen und Auflösung oder die geringe Akkulaufzeit fallen immer weiter weg. Zentrale Herausforderungen bleiben die Geschwindigkeit und Genauigkeit von GPS-Systemen, die Fähigkeiten der AR-Browser sowie insbesondere die Akzeptanz der Nutzer.

Hier setzt das ways2gether-Projekt an. Eine zentrale These des ways2gether-Projekts ist, dass durch den Einsatz von AR-Instrumenten neue Gruppen angesprochen werden können und durch eine Vermittlung mit AR-Instrumenten Inhalte besser transportiert und das Verständnis über die Folgen und Möglichkeiten von Planungsprojekten verbessert wird.

Das Standards der Öffentlichkeitsbeteiligung wie, dass „Inhalte und Rahmenbedingungen klar und verständlich kommuniziert und zugänglich gemacht" oder die „Chancengleichheit der beteiligten Gruppen und gleichwertige Einflussmöglichkeiten" (BKA 2008) verbessert werden, kann durch den Einsatz von AR-Instrumenten erreicht werden. Neue Präsentations-, Vermittlungs- und Visualisierungsmethoden, die von allen Akteurinnen und Akteuren in den Planungsprozessen verstanden, selbständig angewandt werden und damit nachhaltig die Standards der Öffentlichkeitsbeteiligung verbessern, sind dazu notwendig (vgl. Siegler, Wietzel 2009). Augmented-Reality- und Web-2.0-Lösungen haben das Potenzial, Verkehrsplanungen und Verkehrsplanungsprozesse in dieser Richtung weiter zu verbessern und effizienter zu gestalten (vgl. Nash 2010).

Die Analyse der Nutzeranforderungen – Planungsexperten sowie Laien – haben aber gezeigt, dass der Einsatz auch mit Vorsicht gewählt werden muss, um nicht bestimmte Gruppen durch den Technikeinsatz auszuschließen. Im Projekt ways2gether steht daher der Test des Tool-Sets in unterschiedlichen Einsatzumgebungen und mit unterschiedlichen Zielgruppen im Vordergrund.

Ähnlich wie bei der Einführung von hochauflösenden Renderings als Visualisierungsinstrumente in der Planung stellt sich hier die Frage: Wie ist die Resonanz der Nutzerinnen und Nutzer auf den Einsatz von AR-Visualisierungen und welchen Vorteil haben sie gegenüber herkömmlichen Visualisierungen?

Die Interpretation dessen, was in Plänen und Visualisierungen der Planungen enthalten ist, variiert sehr stark zwischen einzelnen Personen. Zur Einführung von Computervisualisierungen in der Planung wurden unter anderem Vergleiche vorgenommen, wie sich die Wahrnehmungen von Personen unterscheiden, in Abhängigkeit davon, ob sie die reale Umgebung, Pläne oder Visualisierungen betrachten. Die Ergebnisse waren unter anderem, dass die Qualität der Bilder bewertet wird, nicht die Qualität der Planung, dass Visualisierungen durch den Bildausschnitt und die Augpunktwahl manipulieren können oder dass Unterschiede in der Wahrnehmung der Virtualität und der Realität vor allem durch Außeneinflüsse wie die Umgebung, Lärm, Bewegungen etc. beeinflusst wurden (vgl. u. a. Wergles, Muhar 2009:177ff). Die Erwartung war aber auch, dass Animationen oder virtuelle Umgebungen zu Visualisierungen helfen können, die Wahrnehmung wesentlich zu verbessern (ebd. S. 181).

Genau hier setzen die AR-Instrumente und die Tests in realen Einsatzumgebungen innerhalb des Projekts ways2gether an. Als nächster Schritt werden die AR-Instrumente im Einsatz getestet und sowohl die Auswirkungen von AR-Instrumenten auf die Wahrnehmung und die Interpretation von Planungen als auch auf die Beteiligung und die Eignung für unterschiedliche Zielgruppen, aufgezeigt. Praxisnah sollen daher die ways2gether-Instrumente in den zukünftigen Einsatzumgebungen und -feldern getestet und die Auswirkungen differenzierter betrachtet werden.

1 ABSTRACT

Disaster management and metropolitan planning both involve making decisions and taking actions which has wide-ranging and diverse spatial information requirements. One major challenge in existing disaster management and metropolitan planning – on both fields of knowledge and practice – is the lack of relevant, accurate and available information or in other words an appropriate decision support system (DSS) along with a knowledge management framework (KMF) which not only establishes a DSS but also converts information to knowledge and considers the knowledge of past experiences.

In the context of disaster management worldwide, the crucial problem is that there are apparent gaps in terms of information coordination and knowledge management at different stages of disaster management. The post-disaster stages too require appropriate information as there are little common terminology and definition amongst relief agencies and assistant groups worldwide. Considering the fact that varied and multiple agencies are involved in different stages of disaster management and metropolitan planning, this makes sharing and integration of information between such agencies very intricate. A key problem is that such information is fragmented and is not efficiently organised.

Knowledge management that aims at facilitating the processes of collecting, maintaining, sharing and utilising information and knowledge in disaster management can provide a framework that integrates multiple information in order to subsequently analyse and manage information. Knowledge management initiative has been envisaged as a tool to integrate, store, retrieve, disseminate and manage information and knowledge related to disaster management. The main functions of knowledge management in any disaster management process are to enhance and develop the knowledge of disaster management and to support decision making in an emergency situation. Using comprehensive, Integrated, accurate and reliable information and knowledge may enhance the process of disaster management, and reduce the negative impacts of disaster in the communities at risk.

Tehran, as the case study of this paper, lies on a seismic zone with a high risk of earthquake which can have severe impact upon the life of its residents. This has been one of the most important challenges of the country in general and also in decision-making and planning for this city. One important aspect of planning and managing change in this city is to have due regards to disaster management. This requires not only an integrated method of planning and management but also an appropriate information and knowledge base. Information required for operating disaster management in Tehran currently is fragmented (i.e., owned by different organizations) and not capable to be converted to an appropriate DSS and KMF.

The dual aim of this paper is first to delineate the situation of Tehran in terms of its disaster management related information and knowledge base and second to propose an appropriate and integrated knowledge management framework. The proposed framework is intended to facilitate integrating, sharing and reusing knowledge in order to support decision making in both disaster management and metropolitan planning. The proposed knowledge management framework can help achieving an efficient and effective disaster management process which can be integrated in a metropolitan planning process, reducing the future risks and improving the resilience of vulnerable communities in case of a crisis in Tehran. The proposed framework – as a comprehensive, consistent and dependable knowledge base which will facilitate knowledge sharing – will help identify the information needs, will present an awareness of a disaster situation for the society at large and for decision-makers and can provide practical recommendations based on past experiences. This framework can also be applied to other parallel decision-making environments, such as crisis management.

2 INTRODUCTION: PROBLEM UNDER STUDY, PURPOSE AND AIM

Urban planning that makes and implements spatial decisions and policies about different aspects of urban structure and urban life, including decisions and policies relevant to disaster management, has wide-ranging, diverse and all-embracing spatial information requirements. Not only the availability, continuity and quality of data are essential components of an information system, as part of a knowledge base, it must also be considered that the dependency of such systems upon many sources of production is a key impediment to the establishment of such systems.

It is common that in different societies a specific planning approach is practiced (either traditional, rational comprehensive or some form of a mixed approach). Each approach requires its specific information or knowledge base. Important point about the adoption of any planning approach in any society is not only the planning process with its different stages and the information requirements of each stage, but what is vital is the adaptation of the process to local circumstances and also the type and the availability of information at the local level of planning and decision-making. While there are many information sources in any metropolitan area, there are many information gaps. Thus it must be considered that the official procedures do not usually enable and facilitate the sharing and integrating process of the available information to support decisions when planning and managing an urban environment.

It is important to note that an effective disaster management process is an important component of a successful spatial urban planning. Within the disaster management framework and the different stages of its process, the crucial and worldwide problem is that there are apparent gaps in terms of information, information coordination and knowledge management. Such information is fragmented and is not efficiently organised. The post-disaster stages as well as pre-disaster stages of such a process too require an appropriate information system (especially that there are little common terminology and definition amongst relief agencies and assistant groups worldwide). Considering the fact that there is varied and multiple agencies involved in different stages of either metropolitan planning or disaster management, the sharing and integration of information between such agencies turns out to be very intricate. Information required for operating either disaster management or any sort of metropolitan planning in Tehran is currently fragmented (i. e., owned by different organisations) and not capable to be converted to an appropriate decision support system (DSS) or a knowledge management framework (KMF). These information systems can help improving the efficiency of urban planning management activities including disaster management in general and in the case studied in this paper.

This paper has a dual aim of first to delineate the situation of Tehran in terms of its disaster management related information and knowledge base and second to propose an appropriate and integrated knowledge management framework that is intended eventually to improve urban resilience in Tehran. To achieve this aim, this paper – both in general and in Tehran – examines the the role of urban planning in disaster management and also the current links and gaps between urban planning and disaster management and also between the information and knowledge base of the two distinct, though highly connected, realms. In addition, this paper explores possible and appropriate courses and approaches to manage and plan urban systems in order to reduce risk in urban communities: advocating that a new way of thinking and a more collaborative and interdisciplinary approach is required. The development of knowledge management framework as a decision-support system for disaster management has possible consequences for all levels and forms of decision-making, including urban planning and disaster management in general and in the case studied in this paper.

3 CONCEPTUAL FRAMEWORK

Information plays a central role in urban spatial planning as well as in disaster management. Information requirements of urban spatial planning include the collection, manipulation and analysis of spatial structure.

Disaster management and urban planning both involve making decisions and taking actions which has wide-ranging and diverse spatial information requirements. One major challenge in existing disaster management and urban planning – on both fields of knowledge and practice – is the lack of relevant, accurate and available information or in other words an appropriate decision support system (DSS) along with a knowledge management framework (KMF) which not only establishes a DSS but also converts information to knowledge and considers the knowledge of past experiences.

3.1 Disaster management

Occurance of natural disasters is inevident in many cases worldwide. Disasters increasingly threaten human beings and bring tremendous social, economic, and environmental impacts.

Within the field of Disaster Management, disaster has been defined as a progressive or sudden, widespread or localised, natural or human-caused occurrences which can cause death, injury or disease, damage to properties, infrastructure or the overall environment that exceeds the ability of those affected by the disaster to cope with its effects using only their own resources (Disaster Management Policy 2002).

Disaster management refers to a continuous and integrated multi-sectoral and multi-disciplinary process of planning and implementation of specific measures aimed at reducing or avoiding the potential losses from disaster, promoting appropriate assistance to victims of disaster and seeking to achieve rapid and effective recovery(Seneviratne, Baldry, and Pathirage 2010).

Disaster management process includes the two main phases of (a) pre-disaster risk reduction and (b) post-disaster recovery.

The pre-disaster risk reduction phase involves three stages as follows(Seneviratne, Baldry, and Pathirage 2010):

- Stage one: Risk and vulnerability assessment, this stage involves identifying the nature and magnitude of risks (current and future) from diasters to people, infrastructure and buildings.
- Stage two: Mitigation or risk reduction activities, this stage include structural and non-structural measures undertaken to limit the adverse impact or consequences of diasters.
- Stage Three: Preparedness, this stage deals with the activities and measures taken to ensure effective response to the impact of diasters.
- Post-disaster recovery phase involves three stages as follows (Seneviratne, Baldry, and Pathirage 2010):
- Stage one: Relief, this stage refers to the provision of assistance – or intervention by the relevant authorities – during or after a disaster to meet the life preservation and basic subsistence needs of the people affected by disaster.
- Stage two: Transition, this stage involves the relevant transitional related activities, including community surveys, needs assessment, land survey and acquisition and provision of transitional shelter.
- Stage Three: Reconstruction, this stage refers to the rebuilding of damaged living conditions with considering the aim of long term sustainability.

3.2 Knowledge management

For holistic understanding of knowledge management, it is necessary to identify knowledge. There are wide-ranging definitions of knowledge. A comprehensive definition has defined knowledge as “a fluid mix of framed experience, contextual information, values and expert insight that provides a framework for evaluating and incorporating new experiences and information” (Otim 2006). In addition, knowledge is defind from a dual perspective of practical and general, as follows(Dongsong et al. 2002):

- Specific and practical definition of knowledge defines knowledge as applied information that actively guides task execution, problem-solving, and decision making.
- General definition of knowledge, defines knowledge as any fact, event, rule, hypothesis, or model that increases understanding or performance in a domain or discipline.

In the applied perspective “knowledge is to know when, why and which information is needed, how information could be obtained and processed, and where information can be found to achieve a desired objective” (Dongsong et al. 2002).

There is no general agreement on the definition of knowledge management, though some of its relevant definitions are listed below:

- knowledge management is "a discipline that promotes an integrated approach to identifying, managing, sharing, and reusing all of information assets by using advanced technology" (Dongsong et al. 2002).
- Knowledge management is the creation and subsequent management of an environment which encourages knowledge to be created, shared, learnt, enhanced, organised and utilised (Sujit et al. 2011).
- Knowledge management is "the practice of selectively applying knowledge from previous experiences of decision making to current and future decision making activities with the express purpose of improving the organisation's effectiveness"(Otim 2006).
- Knowledge management is "the creation, organisation, sharing and use of knowledge for development results"(UNDP 2007).
- Knowledge management is "about facilitating the process by which knowledge is created, shared and utilised"(Seneviratne, Baldry, and Pathirage 2010).
- The process of knowledge management or what is known as the Knowledge Management Cycle (KMC) has three main essentials as follows (Sujit et al. 2011):
- Management: This focuses on capturing, organising and facilitating knowledge.
- Application: This focuses on effective retrieval of relevant content through advanced searches and mining headed for (a) conducting knowledge-related work and tasks and (b) using the results for discovery.
- Organizations: This focus on learning, sharing and collaborating: the education component of the cycle.
- Main processes of knowledge management are (Otim 2006):
- The process of knowledge creation: This can be done by (a) acquiring external knowledge, or (b) by means of creating knowledge in the process of learning.
- The process of retention of knowledge: To keep knowledge available, some kind of memory is needed. Retention of knowledge refers to the process of storing knowledge and making its retrieval possible.
- The process of knowledge sharing: Its aim is to make sure that (existing) knowledge is obtained and shared – or in other words knowledge disseminates or transferred – at the right place.
- The process of application or use of knowledge: The other three knowledge processes (mentioned above) are supplementary to this process, i.e., the application of knowledge.

4 URBAN PLANNING, INFORMATION AND KNOWLEDGE

During the post Second World War period, in many European countries, urban planning was essentially an exercise dealing with "the physical planning and design of land-use and built form". The "general and fundamental criticisms" of the prevailed approach to urban planning led to radical changes and the introduction of adapted concepts of planning. Primarily it was the rational process view of planning. Considering the debate about the necessity and implication of this view of planning, an alternative approach which claimed to be more relevant to the real world of planning and policy-making, i.e. the incremental or piecemeal approach, was later introduced. The mixed-scanning approach as was also introduced, involved distinguishing more fundamental or strategic decisions from more detailed decisions. In fact it is the mixed-scanning approach – as a hybrid model of both the rationalist and incrementalist approaches – which involves imposing patterns on information received, formulating a program within this framework and going back to changing that framework (Daneshpour 2007). The major point about the adoption of any of these approaches, in any country or urban/metropolitan area, is that of their process, the different stages of the adopted process and the alteration of the process to the local circumstances as well as the information requirements of each of the stages. Almost all of these stages not only require spatial information but also require considerable information processing and analysis. Part of the information requirements of the planning process, especially problem formulation and evaluation of the existing conditions, require the

collection, manipulation and analysis of spatial features with the aim of being able in the subsequent stages of the planning process to produce plans, whether with strategic or operational nature. Not only problem definition but also problem formulation and the evaluation of circumstances require the collection; manipulation and analysis of spatial information (Daneshpour 2007).

The act of management too requires agencies to use more detailed information for routine operations. These different requirements concerning information can "explain the existence of various specialised ad hoc systems in urban planning, such as management information system (MIS), land information system (LIS), and urban GIS". One important point about using the methods devised in the more developed countries of the world is that general principles and analytical tools that have been developed there is not feasible in the less developed countries of the world without considerable modifications and adaptations. So there is a need to develop new approaches to launch an appropriate decision support system (DSS) along with a knowledge management framework (KMF), appropriate to the varying conditions (Daneshpour 2007).

While there are many formal and informal sources of information in any urban/metropolitan area, the official procedures are usually incapable of sharing and integrating necessary information to support decisions when planning and managing an urban/metropolitan area. Besides information deficiency in cities, there are many concealed and unused information potentialities that not included in or part of an established and effective Dss and KMF system. Decision-making activity involves merging a variety of information in order to analyse the different elements of the applicable spatial structure and their interaction. Integration of incoherent, incomplete and dispersed information that have diverse information sources can reduce information gaps and strengthen the decisions to solve problems in an urban area.

5 DISASTER MANAGEMENT AND INFORMATION AND KNOWLEDGE

Information plays a central role in disaster management, while the input of all stages of disaster management process is considered to be information and knowledge. Uusing integrated, accurate, reliable and timely information has an important role in achieving the aims and objectives of any attempt related to not only disaster management but also towards improving pertinent attempts of decisions-making. Two major challenges in existing disaster management procedure worldwide – on both fields of knowledge and practice – are (a) the lack of relevant, accurate and available information and (b) ineffective management of information despite the importance of management of information in reducing the impacts of disasters.

5.1 Information and knowledge requirements of disaster management

Information in disaster management is an essential resource that is translated into decisions and actions in the two main phases of disaster management process.

The information needs of disaster management can be categorised in two distinct, but closely related, categories as follows (Dongsong et al. 2002):

- Pre-disaster risk reduction: including information about risk assessment, mitigation and preparedness to improve the existing knowledge about disaster.
- Post-disaster recovery: including information about the impact of the disaster and the resources available to combat it to support decision-making.

5.2 Challenges related to information and knowledge in disaster management process

One main barrier of effective disaster management in urban/metropolitan areas worldwide is related to their information system and knowledge base. These barriers can be listed as the following:

- Information and knowledge on disaster management are fragmented (Seneviratne, Baldry, and Pathirage 2010), widely distributed and owned by a great number of organizations/agents (Dongsong et al. 2002).
- Information, experiences, approaches, adopted modalities and generated/created knowledge of disaster management remain in individual or institutional domains and are not usually translated to and transformed into applied knowledge for future experiences for the communities at risk (Seneviratne, Baldry, and Pathirage 2010) & (Sujit et al. 2011).

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

- Information and knowledge coordination, sharing and creation on any process of disaster management is usually inadequate and ineffective(Seneviratne, Baldry, and Pathirage 2010).
- The linkages among all agencies working on disaster management is usually weak and inefficient and this fact inhibits an efficient management approach and an integrated and an appropriate coping mechanism (Sujit et al. 2011).

5.3 The role and importance of information and knowledge to support decision-making in disaster management as an emergency situation decision-making

Decision-making is a process of analysing information and using knowledge to resolve problems. During the decision-making process, the problems should be detected, relevant information should be gathered and the right judgment should be made so as to make appropriate decisions (Dongsong et al. 2002). Accordingly, information is the main input of this process, while the main element of a relevant decision-making is accurate, reliable and integrated information. Decision-making during a disaster management process – especially its post-disaster phase – is different from decision-making processes in general. Decision-making in disaster management is by and large faced with a variety of challenge such as (Dongsong et al. 2002):

- Gathering relevant information in a timely and accurate manner;
- Synchronized acquisition and analysis of distributed information;
- Reusing knowledge (or consider past experiences) to facilitate current decision making;
- Organising, sharing and managing the information efficiently; and
- Dynamically changing the situation under study.

6 INFORMATION AND KNOWLEDGE MANAGEMENT IN URBAN PLANNING AND DISASTER MANAGEMENT

Knowledge management that aims at facilitating the processes of collecting, maintaining, sharing and utilising information and knowledge in disaster management can provide a framework that integrates multiple information in order to subsequently analyse and manage information. Knowledge management is envisaged as a tool to integrate, store, retrieve, disseminate and manage information and knowledge related to disaster management in an urban/metropolitan area. As one main function of knowledge management in any disaster management process is to enhance and develop the knowledge of disaster management and to support decision making in an emergency situation, thus using comprehensive, integrated, accurate and reliable information and knowledge may enhance the process of disaster management, and reduce the negative impacts of disaster in the communities at risk in an urban/metropolitan area.

6.1 The functions of knowledge management frameworks in urban planning and disaster management

Though there is no way of neutralising all negative impacts of disasters, efforts can be made to reduce their resource costs and consequences (Seneviratne, Baldry, and Pathirage 2010). Knowledge management can undoubtedly maintain a decision-support system for disaster management in urban/metropolitan areas. This will have possible consequences for all levels, forms and aspects of decision-making, including urban planning and disaster management. In this respect, some functions of knowledge management frameworks can be listed as below:

- Knowledge management frameworks can act as a tool to store, retrieve, disseminate and manage information related to urban planning and disaster management (Sujit et al. 2011).
- Knowledge management frameworks can facilitate the entire process of acquisition, sharing, management, and utilisation of information and knowledge for the support of urban planning and disaster management processes (Dongsong et al. 2002) &(Otim 2006).
- Knowledge management frameworks can avoid repeating past errors of practice, highlight good practice to be replicated and make lesson-learning (UNDP 2007).
- Knowledge management frameworks make it possible to learn from and leverage past experience in the management of current problems (Otim 2006) and to build a culture of learning from previous lessons and the adoption of best practices (Seneviratne, Baldry, and Pathirage 2010).

7 CHALLENGES OF PLANNING AND DISASTER MANAGEMENT RELATED INFORMATION AND KNOWLEDGE IN TEHRAN

Tehran, as the case study of this paper, lies on a seismic zone with a high risk of earthquake which can have severe impact upon the life of its residents. This has been one of the most important challenges of the country generally as well as in planning, decision-making and managing this city, one main aspect of which is to have due regards to disaster management. This requires not only an integrated method of planning and management but also an appropriate information system and knowledge base for the two areas of knowledge and practice. Information required for operating disaster management in Tehran is fragmented and is in the possession of diverse agencies/organisations. This is while this information system and knowledge base is not capable to be converted to an appropriate DSS and KMF.

The lack of reliability, consistency and coordination of urban planning and disaster management related information and knowledge in Tehran has stemmed from factors such as (a) administrative inefficiencies, (b) resource limitations, (c) the shortage of skilled personnel and technical expertise and (d) the lack of funding or political will to support the construction of the an appropriate and integrated DSS and KMF system. These factors, in addition, reflect a disapproval of the policy makers; urban planners and managers for the different aspects of application and importance of information systems and knowledge basis in any urban planning and disaster managing activity especially when continuance and sustainability reveal themselves as important agendas, locally and internationally (Daneshpour 2007).

The main challenges of urban planning and disaster managent related information and knowledge in the case of Tehran can be listed as below:

There is a large gap between the two areas of activity, i.e., urban planning and disaster management. In other words, disaster managemnt – as a category of planning activity – has been done without due consideration to urban planning and urban plans as the product of it. Thus the result of risk assessment – as one important stage of a disaster management process – has not been considerd in the process of generating urban plans.

- There is varied and multiple agencies/organisations involved in different stages of disaster management which perform the tasks such as research and action. This is relevant to the both fields of urban plannig and disaster managent. Accordingly it can be deduced that the information and knowledge required for operating disaster management within the broad context of urban planning in Tehran is fragmented.
- There is the lack of information and knowledge coordination at the different stages of urban planning and disaster management in Tehran.
- Agencies involved in urban planning and disaster management in Tehran have their own information sources, while others are not aware of the available information of the other agencies that might aid them and provide a support system for their task of decision-making.
- There is not relevant, accurate and available information system and knowledge base concerning urban planning in general and disaster management in particular in Tehran.

8 EXPLANATIONOF THE PROPOSED KNOWLEDGE MANAGEMENT FRAMEWORK FOR TEHRAN

Knowledge management framework in this paper has been envisaged as a tool to share, integrate, store, retrieve, disseminate and manage information and knowledge related to disaster management in Tehran. The main functions of knowledge management framework in disaster management process of Tehran are to enhance and develop the knowledge of disaster management and to support decision making in an emergency situation, while keeping this within the urban/metropolitan planning context of Tehran. Using comprehensive, integrated, accurate and reliable information and knowledge in this city may enhance the process of disaster management, and reduce the negative impacts of disaster in Tehran.

Two essential principles for establishing an appropriate information and knowledge management framework for managing disaster in Tehran are first defining the purpose of the framework, and second investigating the existing information system in Tehran i order to integrate the two (UNDP 2007). In Tehran the main proposes of the proposed knowledge management frameworks are:

- Integrating multiple information and knowledge related to disaster management in order to subsequently analyse, manage information and creat knowledge.
- Integrating disaster management with urban planning activity altogether.

Relating to the second base of establishing knowledge management framework for managing disaster in Tehran, there is no complete and integrated pool of information for urban planning and disaster management.

9 APPLICATION OF KNOWLEDGE MANAGEMENT FRAMEWORK AS A DECISION-SUPPORT SYSTEM FOR DISASTER MANAGEMENT IN TEHRAN

A comprehensive knowledge management framework is presented here in support of disaster management in metropolitan area of Tehran. The core of the proposed framework is the knowledge base with a set of involved knowledge management processes for knowledge acquisition, organisation, creation, and sharing. This knowledge base must evolve incrementally over the time (figure 1).

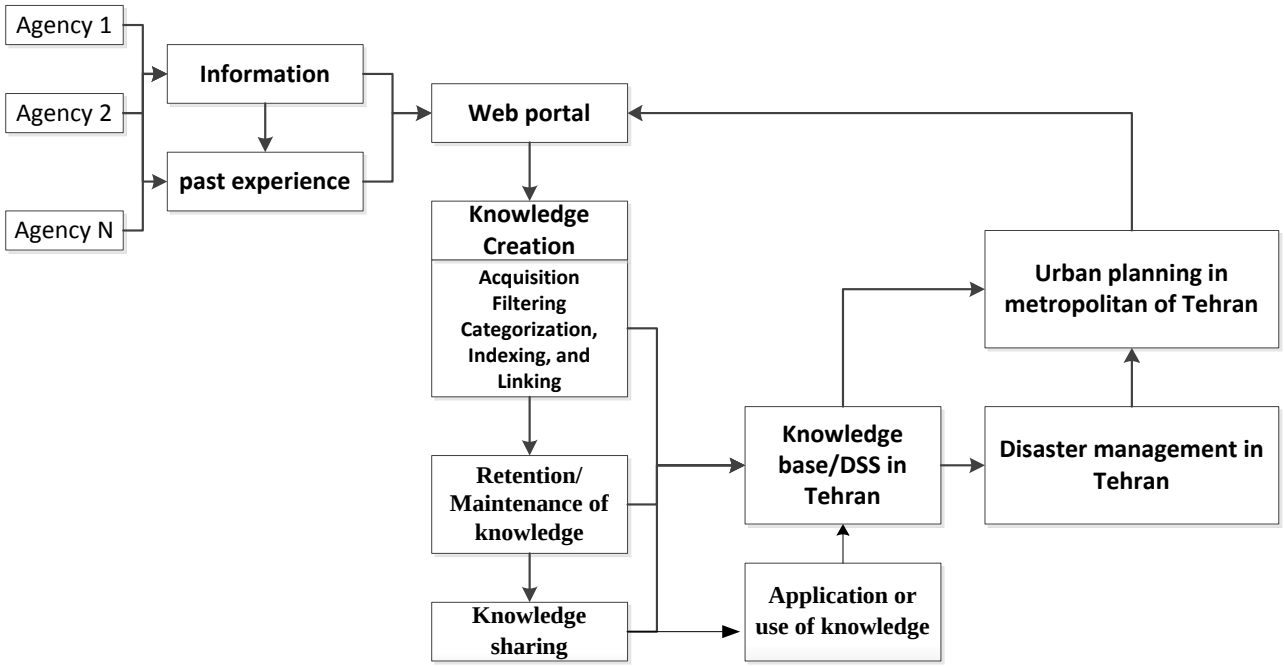

Fig. 1: The proposed knowledge management framework of disaster management within an appropriate metropolitan DSS for Tehran

The proposed framework is intended to facilitate integrating, sharing and reusing knowledge in order to support decision making in both disaster management and metropolitan planning in Tehran. The proposed framework can help achieving an efficient and effective disaster management process which can be integrated in a metropolitan planning process in order to reducing the future risks and improving the resilience of vulnerable communities in case of a disaster in Tehran. The proposed framework – as a comprehensive, consistent and dependable knowledge base which will facilitate knowledge sharing – will also help identify the information needs, an awareness of a disaster situation for the society in general and for decision-makers can provide practical recommendations based on past experiences.

10 CONCLUSION

Disaster management requires comprehensive information and knowledge as well as extensive assistance from many relief agencies. The demand for efficient knowledge management to help the agencies make decisions widely recognised. This paper made an attempt to present a comprehensive knowledge management framework in support of decision-making in disaster management process within a broader context of metropolitan planning. It advocates multiple knowledge management processes that create, maintain and share the knowledge, provide consistent support to decision-makers in disaster management operations, and recommend possible solutions based on the knowledge base which includes the past experiences. The proposed knowledge management framework is intended to evolve incrementally while the framework must allow the disaster management agencies/organisations to transcend the existing limitations

and redundancies created by fragmented information and knowledge. This framework can also be applied to other similar decision-making environments, such as crisis management.

1 ABSTRACT

Angesichts sich verändernder klimatischer und gesellschaftlicher Rahmenbedingungen ist es wichtig die Menschen für die Fragen der Stadtplanung zu interessieren und darüberhinaus zu ermutigen sich in Planungsprozessen aktiv einzubringen. Es zeigt sich, dass immer mehr Menschen die Dienste des Web 2.0 nutzen und sich webbasierten Gemeinschaften, den so genannten Communities anschließen (vgl. ARD/ZDF Onlienstudie 2011). Blogs, Foren und Soziale Netzwerke dienen als Plattformen, um sich zu informieren und zu diskutieren. Mit Blick auf ein gesteigertes Bedürfnis nach Partizipation kann die Berücksichtigung des bürgerschaftlichen Engagements der Web-2.0-Bewegung einen möglichen Lösungsansatz für die Bürgerbeteiligung in der Stadtplanung darstellen. Mit einer partizipativen Planungscomunnity soll den an Planungsfragen interessierten Menschen eine Plattform geboten werden, auf der sie miteinander kommunizieren und interagieren können. Das Hamburger Projekt Nexthamburg kann als ein Beispiel für eine partizipative Planungscommunity gesehen werden. In dem unabhängigen Ideenlabor können Bürger ihre Vorstellungen über die zukünftige Entwicklung der Stadt äußern und gemeinsam mit anderen Nutzern darüber diskutieren. Gegenstand des vorliegenden Beitrags ist der Aufbau und die Zusammensetzung einer partizipativen Planungscommunity am Beispiel von Nexthamburg. Als Forschungspartner des Projktes hat die HafenCity Universität im Sommer 2011 eine Befragung in der Nexthamburg Community durchgeführt. Die daraus resultierenden Ergebnisse biden die Datanbasis für die Betrachtung.

2 EINLEITUNG

Nach über 50 Jahren Erfahrung mit der Beteiligung des Bürgers in Deutschland zeigen die Ereignisse rund um das Bahnhofsumbau- und Stadtentwicklungsprojekt Stuttgart 21, dass eine umfassende und zufriedenstellende Form der Partizipation nach wie vor eine große Herausforderung darstellt. Trotz Schlichtungsverfahren und Volksentscheid wurde gegen das Projekt bis zuletzt protestiert (weltonline 2012).

Die künftigen Handlungsfelder der Stadtplanung werden unter anderem durch die Themen Klimaschutz, Klimaanpassung und demographischem Wandel geprägt sein. Mit Blick auf die beschriebenen Tendenzen steht zu erwarten, dass die neue Protestbewegung auch künftig die Umsetzung von Maßnahmen erheblich erschweren wird. Somit stellt sich die Frage, welche Formen der Beteiligung langfristig geeignet sind.

Auch in Hamburg regt sich seit einigen Jahren vermehrt Widerstand in der Planungslandschaft. Gängeviertel, Stadtbahn, Fernwärmetrasse Moorburg oder die Planungen rund um die Neue Mitte in Hamburg Altona haben viele Menschen aufgeschreckt, zum Protest ermutigt oder einfach nur für Planungsthemen sensibilisiert. Dementsprechend bildet Hamburg einen geeigneten Nährboden, um neue Beteiligungsansätze zu erproben. Ein Beispiel dafür, wie eine solche zukunftsweisende Beteiligungsform aussehen kann, zeigt das Projekt Nexthamburg. Dort konnten die Hamburger/-innen in den zurückliegenden zwei Jahren aktiv ihre Überlegungen und Wünsche über die zukünftige Gestalt Hamburgs vorstellen und mit anderen Interessierten darüber diskutieren. In Online- und Offlineverfahren sind von den Nexthamburg Nutzern Zukunftsideen eingebracht und durch ein Fachgremium zu umsatzfähigen Konzepten weiterentwickelt worden. Über das Zusammenwirken und den Austausch der Nexthamburg Nutzer ist aus dem Kreis interessierter Personen eine Nexthamburg Community entstanden.

Sollen Fragen zur Stadtentwicklung von einer breiten Öffentlichkeit diskutiert werden, stellen Planungscommunities einen interessanten Löungsansatz dar. Ein Grundgedanke der Partizipation ist es, dass Vertreter aus allen gesellschaftlichen Millieus angesprochen werden. Für den Aufbau solcher Communities besteht dabei Forschungsinteresse an der Zusammensetzung des Nutzerkreises. Darüberhinaus ist es wichtig zu erfahren, welche von den angebotenen Kommunikationskanälen die Nutzer am besten erreichen, sowie welche Beteiligungswerkzeuge von der Community wie häufig und zu welchem Zweck genutzt werden.

Am Beispiel von Nexthamburg soll eine Nutzergruppenanalyse zeigen, wie sich der Nutzerkreis einer solchen partizipativen Community zusammensetzt. Grundlage dieser Betrachtung bilden Ergebnisse einer

Nutzerbefragung zu den auf Nexthamburg eingesetzten Informations- und Kommunikationsangeboten. Die hier präsentierten Ergebnisse sind als weiterer Baustein in der Analyse der Nutzer von Partizipationsangeboten zu sehen. Nachdem von Weninger, Poplin, Petrin (2010) eine Typologie für Public Participation 2.0 User am Beispiel von Nexthamburg vorgestellt wurde, liegt der Fokus in diesem Forschungsbeitrag auf der Zusammensetzung und der Entwicklung von partizipativen Gemeinschaften.

Dieser Artikel ist wie folgt gegliedert. Im zweiten Teil der Arbeit wird ein allgemeiner Überblick zum Thema Beteiligung in Planungsverfahren gegeben. Daraufhin folgt im dritten Kapitel die Auseinandersetzung mit der Partizipation im Web 2.0. Unter anderem werden Eigenschaften und wichtige Onlinedienste des Web 2.0 benannt sowie ein Einstieg in das Thema partizipative Planungscommunity gegeben. Im vierten Abschnitt wird die Informations-, Ideen- und Diskussionsplattform Nexthamburg näher vorgestellt. Dabei wird auf den Beteiligungsprozess, die Beteiligungsangebote und den Aufbau der Befragung näher eingegangen. Im fünften Kapitel der Arbeit werden die Ergebnisse der Befragung präsentiert. Im sechsten und letzten Teil werden die für den Aufbau der Planungscommunity Nexthamburg wichtigen Erkenntnisse dargelegt.

3 PARTIZIPATION IN DER PLANUNG HEUTE

Dass die Beteiligung der Bürger bei Planungsfragen auch künftig eine Herausforderung darstellen wird, hat mehrere Ursachen. Pfenning (2011) sieht drei klassische Probleme in der Bürgerbeteiligung. Demnach ist der Personenkreis der am Planungsverfahren aktiv Teilnehmenden oft homogen. In der Regel sind am Beteiligungsprozess weder alle Bevölkerungs- noch Altersschichten verteten. Die sich im Beteiligungsverfahren einbringenden Teilnehmer, die eher gut gebildet sind, nehmen nur ihre partikularen Interessen war. Dies kann dazu führen, dass sich soziale Ungleichheiten verstärken.

Ferner ergibt sich ein Legitimationsproblem. Die Entscheidungsträger sehen in den partizipativ erarbeiteten Ergebnissen Empfehlungen, denen sie nicht Folge leisten müssen. Die Teilnehmer ihrerseits hegen demgegenüber die Erwartung, dass die von ihnen erarbeiteten Empfehlungen auch umgesetzt werden. Geschieht dies nicht, können Vertrauensverlust und Resignation der Bürger die Folge sein.

Letzlich wird von Seiten der Planungsverantwortlichen argumentiert, dass es den Bürgern an Fach- und Sachwissen fehlt, um sich qualifiziert in die Plannungsdiskussion einzubringen. Jedoch suchen auch Politik und Verwaltung nach neuen Beteiligungsformen. Zum einen sind die Themen der Stadtentwicklung oft eher abstrakt, so dass sie sich dem Bürger schwer vermitteln lassen (Maly 2010). Zum anderen sind mit der Stadtentwicklung lange Planungshorizonte verbunden. Von der ersten Idee über die rechtliche Festsetzung bis hin zur tatsächlichen Umsetzung können mitunter Jahrzehnte vergehen. Durch fehlende Kommunikation, die idealerweise den Prozess begleiten sollte, fühlen sich die Bürger am Ende übergangen. Langfristig kann dies zu Akzteptanzverlusten bei den Menschen führen. Im schlimmsten Fall droht der „Wutbürger“ (Kurbjuweit 2010), der durch seine Blockadehaltung die Stadtentwicklung folgenreich behindert. Gegen diese Form der Ablehnungsbeteiligung wünschen sich die kommunalen Planungsverantwortlichen die Etablierung neuer Dialogformen im Sinne einer Gestaltungsbeteiligung (vhw 2010).

Aus heutiger Sicht bieten sich den Planungsverantwortlichen zahlreiche Verfahren, um den Bürger zu beteiligen. Neben den klassischen gesetzlichen Verfahren sind Dialogformen wie Beratungsgremien, runde Tische oder Fokusgruppen bereits weit verbreitet. Weitere Lösungen stellen Dialogverfahren auf Basis von modernen Governancestrukturen oder open-source Verfahren dar Verfahren dar, in denen sich die Menschen zu bestimmten Fragen oder Problemen der Stadtentwicklung äußern können (Thalgott 2011). Daneben kann auch das Bürgerbegehren als Verfahrensmittel angesehen werden. Gezielt eingesetzt kann es als Notausstieg dabei helfen, Planungen, die nicht dem Gemeinwohl dienen, abzuwenden (Thalgott 2011).

Es zeigt sich, dass eine zukunftsweisende Stadtplanung auf die Einbeziehung und Mitwirkung der Menschen setzt (Pahl Weber 2011). Dabei geht es nicht mehr nur um die Informationsbereitstellung oder darum den Bürger „mitzunehmen“, sondern den Stadtbewohner als aktiven und gestaltenden Akteur in die lokale Planungsdiskussionen mit einzubeziehen (Thalgott 2011). Um über die Fragen der Stadtplanung mit einer breiten Öffentlichkeit diskutieren zu können, ist die Einbindung von webbasierten Diensten und Anwendungen hilfreich. Welche dies sind und wie sie eingesetzt werden können, wird im nächsten Abschnitt behandelt.

4 PARTIZIPATION IM WEB 2.0

Mit dem Web 2.0, dem sogenannten Mitmachnetz, haben die Kommunikationsgewohnheiten der Menschen umfangreiche Wandlungen erfahren. Im Internet der zweiten Generation steht das Produzieren, Sammeln, Teilen und Verbreiten von Inhalten im Vordergrund. Die Menschen geben Informationen über sich preis, arbeiten auf Plattformen kollaborativ an Projekten zusammen und benutzen soziale Netzwerke zur Kommunikation miteinander. Die Funktionen der Onlinedienste sind intuitiv erfassbar und erfordern keine großen Fachkenntisse. Daher haben die Dienste des Web 2.0 inzwischen in weiten Teilen der Gesellschaft Eingang gefunden. An Beispielen, wie Frankfurt gestalten (www.frankfurt-gestalten.de), das Unortekataster der Stadt Köln (www.unortekataster.de) oder der Seite www.moorburgtrasse-stoppen.de, wird zudem ersichtlich das Onlinedienste des Web 2.0 auch für Partizipationszwecke bei Stadtplanungs- und Stadtentwicklungsthemen eingesetzt werden..

Als Beweggründe, warum sich Menschen im Web 2.0 engagieren, nennt Goodchild (2007) drei Ursachen. Zum einen ist es die öffentliche Selbstdarstellung und der Glaube daran, dass andere Nutzer an den bereitgestellten Inhalten interessiert sein könnten. Ferner spielen altruistische Gründe eine Rolle. Der Wunsch Daten mit Freunden über das Internet teilen zu können vernachlässigt die Tatsache, dass auch andere Nutzer auf diese zugreifen und verwenden können. Den Entstehungsprozess zu begleiten und zu sehen, wie aus dem geleisteten Beitrag in Gemeinschaftsarbeit ein fertiges Produkt entsteht, kann ebenfalls als Motivation angesehen werden sich aktiv im Web 2.0 zu beteiligen (Goodchild 2007).Im Folgenden werden ausgewählte Anwendungen des Web 2.0 erläutert sowie der Begriff der partitipativen Planungscommunity vorgestellt.

4.1 Anwendungen und Dienste des Web 2.0

Für die zwischenmenschliche Interaktion hält das Web 2.0 unterschiedliche Dienste und Technologien bereit. Nachfolgend soll auf Einige näher eingegangen werden.

Weblogs

Ein wichtiges Element des Web 2.0 sind Weblogs. Als eine Art Onlinetagebuch werden vom „Betreiber in regelmäßigen Abständen und in chronologischer Ordnung neue Inhalte“ (Behrend, Zeppenfeld 2008:26) erstellt, welche von Besuchern der Seite kommentiert werden können. Durch Verlinkung einzelner Blogs lässt sich ein Netzwerk, die sogenannte Bloggosphäre aufbauen. Auf diese Weise vergrößert sich der Teil der erreichten Menschen.

Soziale Netzwerke/Online Communities

Online Communities sind offene, webbasierte Gemeinschaften (Rölver, Alpar 2008), die sich zumeist aus einer unbestimmten Anzahl von Menschen zusammensetzen, die auf einer Plattform miteinander interagieren (Behrend, Zeppenfeld 2008). Für den Austausch und das kollaborative Arbeiten werden den Nutzern verschiedene Onlinedienste wie Mailing, Instant Messaging, Blogs, Chat, Foren oder Videoportale bereitgestellt. Durch die Vielfalt der zusammengeführten Angebote werden Communities für ihre Mitglieder zu netzbasierten Kommunikationszentralen (Busemann, Gscheidle 2011:360). Eines der erfolgreichsten sozialen Netzwerke ist Facebook. Um auf Facebook aktiv sein zu können müssen sich Nutzer registrieren und für die eigene Präsentation innerhalb der Community eine Profilseite anlegen. Neben den bereits genannten, in Facebook eingebeteten Onlinediensten, ist dass Posten von Informationen eine wichtige Funktion. Es dient im wesentlichen dem schnellen, öffentlich nachvollziehbaren Hinterlassen von Nachrichten. Nach Zahlen der ARD/ZDF Onlinestuide 2011 nutzen besonders junge Menschen im Alter zwischen 14 bis 29 Jahren, die Onlinenetzwerke regelmäßig, mindestens einmal die Woche. Die Studie belegt jedoch auch, dass ab einem Alter von 30 Jahren, die Aktivität in Communities (bisher) deutlich abnimmt (Busemann, Gescheidle 2011).

RSS-Feeds

Really Simple Syndication ist ein Dienst, der für die schnelle und gezielte Informationsbereitstellung genutzt wird. Der Benutzer aboniert die ihn interessierenden Inhalte einer Webseite als RSS-Feed. Durch einen Klick auf das Icon werden sämtliche Neuigkeiten der abonierten Webseiten angezeigt.

Mobile Dienste

Durch sogenannte Location based Services lassen sich Informationen in der Stadt direkt vor Ort erfassen und abrufen. In einem mobilen Endgerät, bspw. einem Mobiltelefon, lassen sich die Informationen dann selektiv anzeigen. Um die Standortdaten zu bestimmen können Techniken wie GPS, GSM, Bluetooth oder RFID eingesetzt werden (Althoff et. al. 2010; Wagner 2011). Mit Hilfe spezifischer Dienste können räumliche Informationen bspw. durch Fotografieren dokumentiert und durch Verlinkung mit einer Online Community direkt einem größeren Publikum mitgeteilt werden.

4.2 Partizipative Planungscommunity

Eine partizipative Planungscommunity ist eine Gemeinschaft, die unterschiedliche Formate der Informations- und Kommunikationsbereitstellung aktiv oder passiv nutzt, um sich über planungsrelevante Themen zu informieren und auszutauschen. Der dazugehörende Kerngedanke ist es, dass die eingebrachten Ideen unter Verwendung unterschiedlicher Partizipationsangebote Online und Offline und unter Mitwirkung anderer Nutzer weiterentwickelt werden. Über den kontinuierlichen Prozess des Diskurses formiert sich eine Community. Die Themen der Stadtplanung und Stadtentwicklung sind integratives Element der Community.

Durch das Zusammenwirken einzelner Mitglieder können die aus Sicht der Bürger planungsrelevanten Sachverhalte gezielt angesprochen, Lösungvorschläge erarbeitet und einem größeren Publikum zugänglich gemacht werden. Die Interessen werden gebündelt, wodurch einzelne Meinungen in einem Planungsverfahren mehr Gewicht erhalten. Auf diese Weise kann eine solche webbasierte Gemeinschaft als wichtiger Interessenvertreter in der lokalen Planungslandschaft auftreten und im Sinne der Gestaltungsbeteiligung den Verantwortungsträgern Feedback und Denkanstöße geben.

In einer partizipativen Planungscommunity befassen sich die Mitglieder durch kontinuierliche Diskussionen langfristig mit Planungsthemen. Dadurch angeeignetes spezifisches Fachwissen ermöglicht es dem Nutzer sich auch an anderen Beteiligungsverfahren qualifiziert einzubringen. Desweiteren übernehmen die Mitglieder die Funktion von Mulitplikatoren, da sie das innerhalb der Gemeinschaft generierte Wissen durch Kontakte im persönlichen Umfeld weitergeben. So besteht die Chance, dass der Kreis der Planungsinteressierten und letztlich auch die Community selbst kontinuierlich wächst. Durch den partizipativen Ansatz leistet die Community darüberhinaus einen wichtigen Beitrag zur Verbesserung der Beteiligungkultur.

Für die Entwicklung neuer Beteiligungsansätze ist es wichtig zu Wissen, wer durch die Partizipationsangebote erreicht wird und wie intensiv diese genutzt werden. Damit sich die Menschen einbringen können, ist es zudem von Interesse, welche Partizipationsangebote Online und Offline bevorzugt werden. In der wissenschaftlichen Diskussion liegen darüber bisher nicht genügend Ergebnisse vor. Anhand des Beispiels von Nexthamburg soll im Folgenden der Aufbau und die Zusammensetzung einer partizipativen Planungscommunity nachgezeichnet werden. Als Pilotprojekt der nationalen Stadtentwicklungspolitik wurde Nexthamburg von April 2009 bis Dezember 2011 vom Bundesministerium für Verkehr-, Bau- und Stadtentwiklung gefördert. Im Sommer 2011 ist in dieser partizipativen Planungscommunity eine Befragung zur Zufriedenheit der Nutzung der bei Nexthamburg eingesetzten Beteiligungsangebote durchgeführt worden. Als Kooperationspartner war die HafenCity Universität Hamburg mit der wissenschaftlichen Begleitforschung beauftragt. Ihre Aufgabe bestand in der Konzeption, Durchführung und Auswertung der Befragungsergebnisse,

5 ÜBER NEXTHAMBURG

Nexthamburg ist eine unabhängige Plattform, auf der Bürger/innen ihre Vorstellungen über die künftige Gestalt Hamburgs äußern und gemeinsam mit anderen Interessierten diskutieren können. „Nexthamburg gibt Bürgern eine Plattform, die eine Vorstellung davon haben, welche Themen drängend sind, und ermutigt bisher planungsferne Menschen, mit spielerischen und untypischen Werkzeugen ihre eigenen Vorstellungen von der Zukunft der Stadt zu formulieren“ (Petrin 2011:25). Ein Redaktionsteam begleitet und koordiniert den Beteiligungsprozess und arbeitet daran die Ideen, Meinungen und Wünsche der Menschen zu einem Zukunftsbild zusammenzufügen. „Das Ergebnis ist eine dauerhaft fortgeschriebene Bürgervision, die Ziele und Prioritäten deutlich macht, die in die Politik und Verwaltung zurückgespeist werden und dabei gezielte Impulse auf die Stadtentwicklung geben sollen (Petrin 2011:25). Die Nexthamburg Community zählt inzwischen über 5.000 Personen (Stand Februar 2012). Zum Zeitpunkt der Befragung (Juni 2011) waren es

ca. 3.000 Personen. Die Nexthamburg Community setzt sich aus aktiven und passiven Nutzern zusammen. Damit sind sowohl die Menschen gemeint die Nexthamburg für den Informationszweck nutzen als auch jenen, die sich aktiv in Diskussionen einbringen oder Beiträge erstellen und Kommentieren. Auch die Freunde von Nexthamburg auf Facebook zählen zur Community.

5.1 Gestaltung des Beteilgungsprozesses

Der Beteiligungsprozess bei Nexthamburg gestaltet sich durch vier aufeinander aufbauende Arbeitsschritte. Auf der Webseite nexthamburg.de können zunächst von jedem Interessierten Ideen gepostet werden. Die eingebrachten Beiträge können lokal begrenzt sein und sich auf die Untertunnelung einer Straße beschränken. Sie können aber auch ein größeres Stadtgebiet umfassen wie im Fall der Umweltkarte (nexthamburg.de 2012). Andere Nutzer erhalten die Gelegenheit ihre Kommentare und Meinungen dazu abzugeben. Die so angestoßene öffentliche Diskussion trägt sowohl zur Verfeinerung als auch umfassenden Reflexion der Idee bei. Im zweiten Schritt wird von der Community via Voting über die beste Idee abgestimmt. Im nächsten Bearbeitungsstadium werden die gewählten Ideen unter Mitwirkung von Fachleuten weiterentwickelt und münden schließlich in einer Zukunftsstudie. Langfristig ist auch die Umsetzung der ausgearbeiteten Ideen angedacht.

5.2 Beteiligungsangebote

Für die Kommunikation werden unterschiedliche Kommunikationskanäle angeboten. Die Webseite nexthamburg.de dient als zentrale Plattform für den dauerhaften Online Dialog. Hier können Informationen zum Hamburger Planungsgeschehen aufgerufen, Ideen für die Stadt von Morgen eingestellt oder Beiträge anderer Nutzer nachvollzogen und kommentiert werden. Über die Webseite lässt sich auch der Onlinekartendienst Hamburg Navigator erreichen. Die Flash-Karte vermittelt dem Betrachter einen schnellen Eindruck über Ideen, Planungvorhaben und was die Hamburger gut („das find ich toll“) bzw. weniger gut („das stinkt mir“) finden. Die Onlinekarte wird zudem für das Gebäudevoting genutzt. Dort können von der Community Gebäude als Lieblingsgebäude und Abrisskandidat verortet werden. Nexthamburg verfügt auch über eine mobile Applikation. Mit der iPhone-App, Nexthamburg mobil, lassen sich Informationen unterwegs aufnehmen, kommentieren und über die Onlinekarte mit anderen Communitymitgliedern teilen.

Der Nachrichtendienst Twitter und der E-Mail Newsletter dienen wiederum der Informationsverbreitung. Mit der Nexthamburg Facebook Seite ist die Initiative auch in einem sozialen Netzwerk präsent. Facebook dient dabei dem Aggregieren von aktuellen Themen und Meldungen aus Stadtentwicklungsdebatten (Petrin 2011).

Neben den angeführten Onlinediensten finden auch Offline-Veranstaltungen statt. Sie dienen der Rückkopplung des Online Dialoges an einen konkreten Ort. Bisher wurden drei Formate erprobt:

- Sessions, in denen Ideen und Themen gesammelt und anschließend weiter bearbeitet werden.
- Zukunftscafés, die eher ein mobiles Veranstaltungsformat darstellen und die Menschen in Alltagssituationen an den Nexthamburg Prozess heranführen (Petrin 2011).
- Nexthamburg-Salon, in dem mit einem Fachpublikum Hintergrunddebatten geführt werden (Petrin 2011).

Bis zum Februar 2012 wurden insgesamt vier Sessions- Bürgerworkshops, vier Zukunftscafes und ein Salon Veranstaltung abgehalten.

5.3 Aufbau der Befragung

Um zu ermitteln, wie zufrieden die Nutzer mit den bereitgestellten Angeboten waren, ob gegebenenfalls Verbesserungen erforderlich oder Alternativen erwünscht waren, wurde eine Befragung in der Nexthamburg Community durchgeführt. In dieser sind die von Nexthamburg angebotenen Instrumente zur Beteiligung Webseite nexthamburg.de, Nexthamburg Facebookseite, Nachrichtendienst Twitter, E-Mail Newsletter, Nexthamburg mobil und Nexthamburg Sessions näher betrachtet worden. Da diese Formate wesentlicher Bestandteil der Konzeptidee von Nexthamburg sind, sollten insbesondere die Anwender an der Verbesserung und Weiterentwicklung des bestehenden Angebotes mitwirken. Im Mittelpunkt stand dabei die Frage, welche der von Nexthamburg angebotenen Onlinedienste bisher am häufigsten verwendet wurden. Basierend auf den Erkenntnissen der Befragung sollte dann das bestehende Angebot angepasst werden. Um Restriktionen

und Probleme, die von Seiten der Nutzer im Zusammenhang mit dem Internetauftritt bestanden, leichter identifizieren und eventuelle Verbesserungsmaßnahmen einleiten zu können, war auch die Benutzerfreundlichkeit der Webseite Gegenstand der Untersuchung. Fragen zum Nexthamburg-Verfahren und zur Person rundeten die Befragung ab.

Die Befragung wurde sowohl Online als auch Offline durchgeführt. Die Onlinebefragung startete am 12.05.2011 und endete am 23.06.2011. Der Link zum Fragebogen wurde zunächst via E-Mail verschickt. Ab dem 23.05.2011 stand dieser auch auf der Internetseite www.nexthamburg.de zur Verfügung. Zudem wurde über den Facebookauftritt von Nexthamburg via Postings mehrfach auf die Befragung aufmerksam gemacht. Die Offlinebefragung fand im Rahmen des Nexthamburg-Salons zum Thema „Ist die Zukunft der Bürgerbeteiligung digital?“ am 24.05.2011 statt. Der Befragungsbogen konnte von jedem Interessierten ausgefüllt werden, richtete sich aber grundsätzlich an die Nexthamburg Community. Während des sechs wöchigen Befragungszeitraums wurde der Fragebogen insgesamt 114-mal ausgefüllt. Je nach Fragestellung und Antwortmöglichkeit waren Ein-, Zwei- oder Mehrfachnennungen möglich. Die technische Umsetzung des Fragebogens erfolgte mithilfe des Onlinetools Survey Gizmo (Version 3.0). Der generierte Link, unter welchem der Fragebogen erreichbar war, wurde entsprechend in die Website nexthamburg.de, die Postings über die Befragung auf der Nexthamburg Facebook Seite und in E-Mails eingebettet.

6 ERGEBNISSE DER BEFRAGUNG

Um die Zusammensetzung und das Nutzerverhalten innerhalb der partizipativen Planungscommunity analysieren zu können, sollen an dieser Stelle sechs von insgesamt 20 Fragen näher vorgestellt werden. Der Blick richtet sich dabei neben soziodemographischen Angaben auch auf die von den Nutzern verwendeten Onlinedienste.

Die Frage nach der Geschlechtszugehörigkeit (Abb. 1) brachte hervor, dass in der Nexthamburg Community mehr Männer als Frauen vertreten waren. Von insgesamt 78 teilnehmenden Personen waren 49 Nutzer männlich und 29 weiblich.

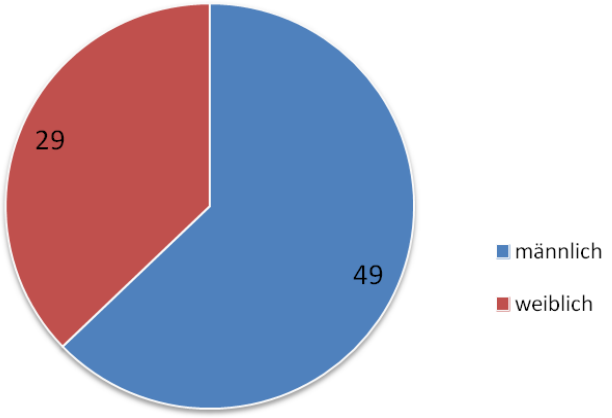

Abb. 1: Geschlechterzugehörigkeit. Frage: Ich bin männlich/weiblich.

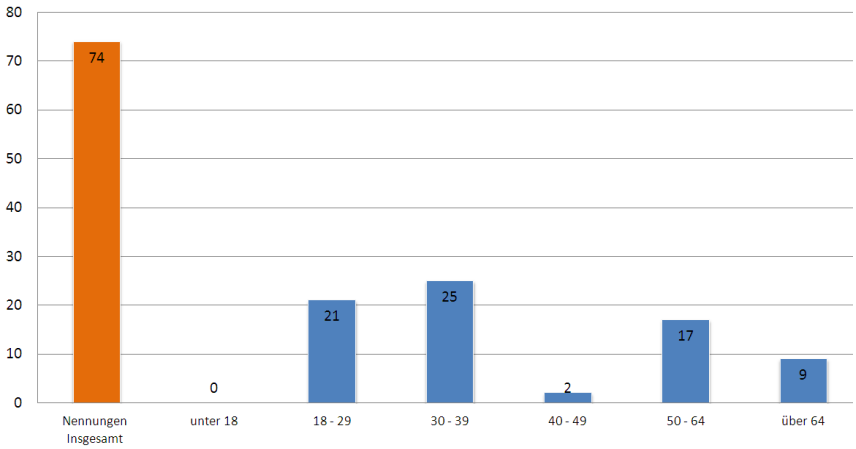

Abb. 2: Altersklassenzugehörigkeit. Frage: Welcher Altersklasse gehörst du an?

Folgende Ergebnisse lieferte die Frage zur Altersklassenzugehörigkeit (Abb.2), an der sich insgesamt 74 Personen beteiligten. Die größte Klasse der Communitymitglieder war mit 25 Angaben die Altersgruppe der zwischen 30- und 39-Jährigen. An zweiter Stelle befanden sich die 18- bis 29-Jährigen mit 21 Stimmen. Die Altersklasse der 40- bis 49-Jährigen war mit lediglich zwei Mitgliedern vertreten. Auch die Klasse der 50- bis 64-Jährigen mit einer Größe von 17 Nutzern sowie die Altersklasse der Über-64-Jährigen, welche insgesamt sieben Nutzer angegegeben haben, waren in der Nexthamburg Community zu finden. Auffällig war, dass es bei der Altersklasse der Unter-18-Jährigen keine Nennungen gab.

Ein wichtige Rolle für das Gelingen einer partizipativen Planungscommunity spielt die Motivation der einzelnen Nutzer sich am Planungsprozess zu beteiligen. Innerhalb einer Community gibt es unterschiedliche Beweggründe das bereitgestellte Angebot zu nutzen. Entscheidend dabei sind sowohl die Haltung, das Thema als auch die Frage, wie aktiv oder passiv das Angebot genutzt wird. Unter aktiver Nutzung wird das Diskutieren, Ideeneinbringung sowie Mobilisieren von Unterstützern verstanden. Währenddessen versteht die passive Nutzung die reine Informationsaufnahme.

Das Interesse sich am Thema Planung einzubringen kann in der Regel auf die persönliche Motivation zurückgeführt werden. Diese kann dabei sowohl privater Natur sein als auch aus beruflicher Verbundenheit resultieren. Um dies klären zu können, wurde in der Nexthamburg Community erfragt, wie die Haltung zum Themengebiet Stadtentwicklung gewesen ist. Insgesamt wurden 87 Nennungen erfasst. Es bestand die Möglichkeit der Mehrfachnennungen, wovon allerdings nur vier Personen Gebrauch machten. Das Ergebnis, dargestellt in Abb. 3, zeigt, dass die Nexthamburg Nutzer dem Thema Stadtentwicklung sowohl aus privatem als auch beruflichem Interesse verbunden waren. Auf beide Antwortmöglichkeiten entfielen jeweils 34 Nennungen. Mit 19 Nennungen gab eine geringere Anzahl der Befragten an, sich persönlich in der Stadtentwicklung zu engagieren.

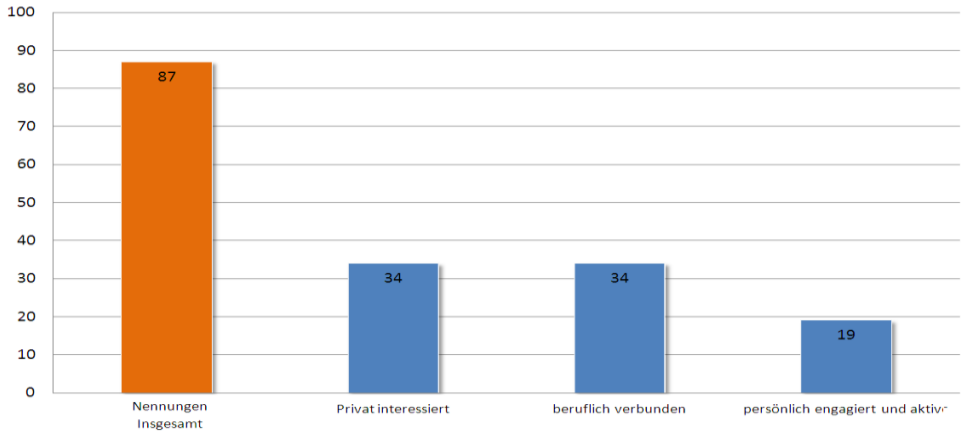

Abb. 3: Motivation. Frage: Wie ist deine Haltung zum Themengebiet Stadtentwicklung?

Auf die Frage zum Nutzungszweck der Nexthamburg Community entfielen insgesamt 162 Nennungen. Auch hier waren Mehrfachnennungen möglich. Mit Blick auf Abb. 4 wird deutlich, dass die Mehrheit der Befragten mit insgesamt 91 Nennungen Nexthamburg für die Informationsaufnahme nutzte. 28 Personen sahen in Nexthamburg darüber hinaus einen Ort, um Ideen und Verbesserungsvorschläge einbringen und diskutieren zu können. 22 Befragte nutzten Nexthamburg eher, um sich mit anderen auszutauschen. Nur acht Personen gaben an, mithilfe der durch Nexthamburg bestehenden Angebote Unterstützer für ihre eigenen Ideen mobilisieren zu wollen. Von diesen acht Personen gaben fünf Teilnehmer an, dass sie Nexthamburg auch nutzen, um eigene Ideen und Verbesserungsvorschläge einbringen und diskutieren zu können.

13 Befragte nutzten die Antwortmöglichkeit sonstige. Die Teilnehmer gaben dabei völlig unterschiedliche Beweggründe an. Für einige diente das Angebot als Inspirationsquelle und Ideengeber für den Beruf. Andere gaben an, dass sie auf diesem Wege ihre Ideen austauschen konnten. Ein Befragter nutzte Nexthamburg, um sich über die Funktionsweise und den Ablauf von Onlinebeteiligungen zu informieren.

Auf die vorhergehende Frage nach der Motivation zurückblickend waren die Antworten zur regelmäßigen Nutzung der angebotenen Onlinedienste interessant. Es wurden insgesamt 184 Nennungen abgegeben, wobei Mehrfachnennungen möglich waren (Abb. 5). So nutzten, mit 73 Nennungen, ein Großteil der Befragten die Website nexthamburg.de regelmäßig. Die herausgehobene Bedeutung sozialer Netzwerke und die daraus

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

resultierende Erfordernisse, diese auch in einer partizipativen Planungscommunity zu berücksichtigen, verdeutlichten die 40 Nennungen zur regelmäßigen Nutzung der Facebookseite. Auch Angebote wie E-Mail Newsletter und Sessions wurden von den Community Mitgliedern genutzt, wenn auch mit 27 und 22 Nennungen etwas seltener. Ebenfalls wurde ersichtlich, dass Onlinedienste wie Twitter (11 Nennungen), mobile Applikationen (Nexthamburg mobil - 8 Nennungen) oder RSS Feed (3 Nennungen) noch eher selten genutzt wurden.

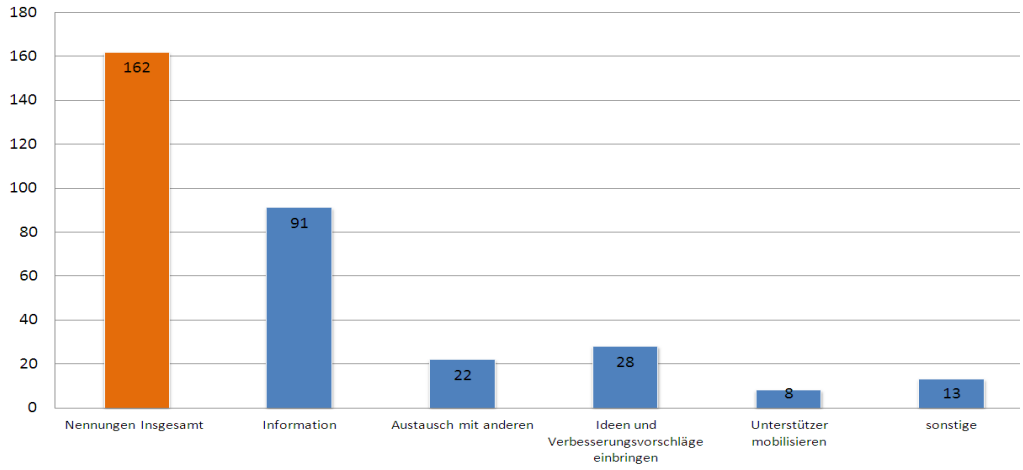

Abb. 4: Nutzungszweck. Frage: Zu welchem Zweck nutzt du Nexthamburg?

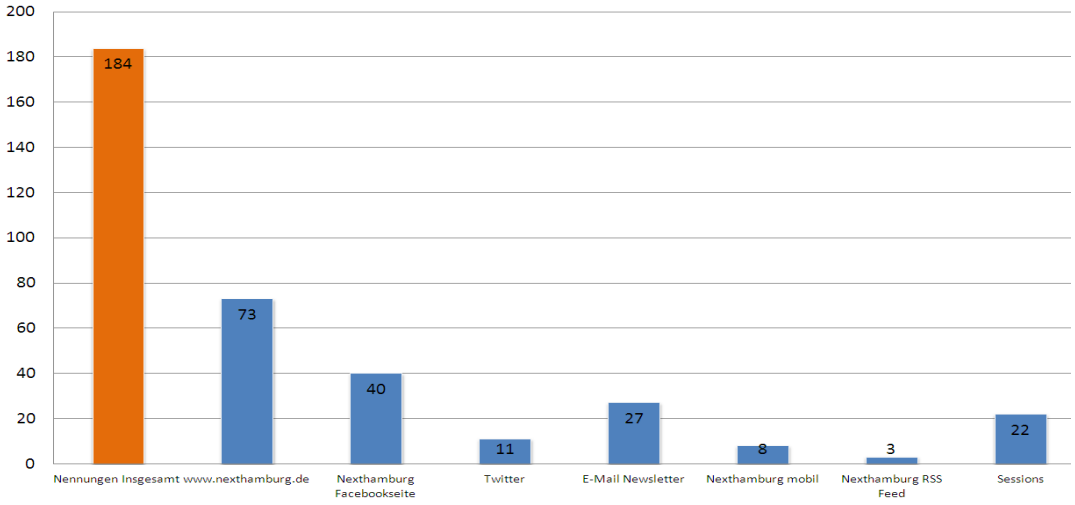

Abb. 5: genutzte Angebote. Frage:Welche Angebote von Nexthamburg nutzt du bereits regelmäßig?

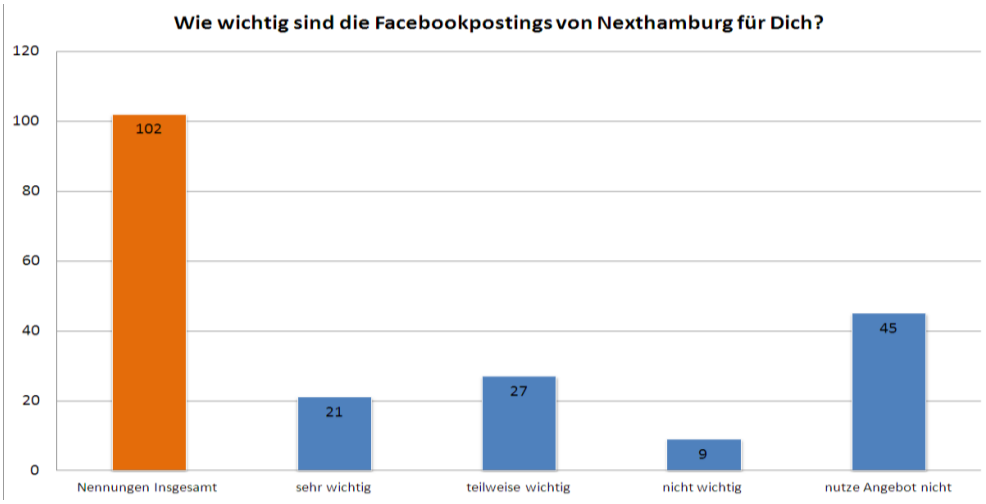

Abb. 6: Facebookpostings. Frage: Wie wichtig sind die Facebookpostings von Nexthamburg für Dich?

Zum Zeitpunkt der Befragung konnten auf der Facebookseite insgesamt 1.100 Freunde (Stand Juni 2011) gezählt werden. Aufgrund der Vielzahl an Nutzern war es daher spannend zu erfahren, wie wichtig den Community Mitgliedern die Facebook Postings sind. Diese Frage wurde von insgesamt 102 Personen beantwortet. Es konnte nur eine Antwort abgegeben werden. Von 45 Teilnehmern wurde angegeben, dass sie das Angebot nicht nutzen. Für 27 Personen waren die Postings teilweise wichtig. Für 21 Befragte waren die Facebookpostings sogar sehr wichtig und für neun Personen war das Angebot nicht wichtig. Abb. 6 verschaulicht das Ergebnis.

Fasst man die Nennungen der Befragten zusammen, denen die Postings sehr oder zumindest teilweise wichtig waren, wird deutlich, dass dieses Format für mindestens 48 Personen von Bedeutung war. Stellt man dem nun die 45 Nennungen der Befragten gegenüber die das Angebot nicht nutzten, wird sichtbar, dass die Facebookpostings gemessen an den von Nexthamburg angebotenen Kommunikationskanälen von gut der Hälfte der Befragten mindestens als wichtig angesehen wurden.

Als Gründe, warum die Facebookpostings nicht wichtig waren, wurde in vier Fällen angegeben, dass Facebook entweder nicht genutzt wurde oder grundsätzlich Vorbehalte bei der Nutzung dieses Kommunikationskanals bestanden („oberflächlich, niveaulos, Unübersichtlichkeit von Facebook, nervt!“).

7 ZUSAMMENFASSUNG UND DISKUSSION DER ERGEBNISSE

In diesem Beitrag ist die Zusammensetzung und der Aufbau von partizipativen Planungscommunities gezeigt worden. Es wurde dargelegt welche Probleme im Zusammenhang mit der Bürgerbeteiligung bestehen und welche Partizipationsmöglichkeiten durch die Nutzung von Web 2.0 Diensten existieren, Anhand des Beispiels von Nexthamburg und der diesbezüglich zur Verfügung stehenden Daten, wurde dargestellt, wie eine partizipative Planungscommunity zusammengesetzt sein kann.

Zunächst ist festzuhalten, dass trotz der breitangelegten Befragung, der Nutzung unterschiedlicher Medien und einer Communitygröße von ca. 3.000 Personen (Stand Juni 2011) die Teilnehmerzahl mit 114 verwertbaren ausgefüllten Fragebögen sehr gering ausfällt. Aus diesem Grund sind die hier dargestellten Ergebnisse eingeschränkt repräsentativ.

Bei der Betrachtung der Befragungsergebnisse wird erkennbar, dass sich die Menschen in einer Planungscommunity einbringen wollen und dies, wie im Fall der Nexthamburg Community, auch altersunabhängig tun. Den Hintergrund das Partizipationsangebot zu nutzen bildet in den meisten Fällen das private oder berufliche Interesse am Themengebiet der Stadtentwicklung. Allerdings zeigt sich mit Blick auf den Nutzungszweck der Community, dass der Anteil derer, die Inhalte erzeugen, also Ideen einbringen, vergleichsweise gering ist. Dieses Phänomen deckt sich mit den Erkenntnissen der ARD/ZDF-Onlinestudie 2011, in der ebenfalls herausgestellt wurde, dass der Großteil der Onliner nicht an der aktiven Generierung von Inhalten interessiert ist (Busemann, Gscheidle 2011). Auch spielt der Austausch mit anderen Nexthamburg Nutzern eine eher untergeordnete Rolle. Die überwiegende Mehrheit der Nutzer sieht in der Community im Wesentlichen einen Ort, um sich Informationen zu beschaffen.

Wird die Zusammensetzung der Community hinsichtlich des Alters der Mitglieder betrachtet, fällt auf, dass besonders die Altersklassen 18 bis 29 und 30 bis 39 am stärksten vertreten sind. Erfreulich ist, dass sich ältere Menschen (50+) in der Nexthamburg Community beteiligen. Die unter 18-Jähiren sowie die Gruppe der 40- bis 49-Jährigen beteiligen sich dagegen nur sehr wenig an der Nexthamburg Community. Es gilt zu überprüfen, inwiefern eine Erweiterung der Zielgruppenansprachen notwendig ist. Sollen partizipative Planungscommunities künftig als eine wichtige Beteiligungsform wahrgenommen werden, ist darauf zu achten, dass alle Altersklassen angemessen vertreten sind. Dies betrifft in erster Linie die in Nexthamburg unterdurchschnittlich bzw. gar nicht vertretenen Altersklassen der 40 bis 49- Jährigen und der unter 18-Jährigen. Sollen sich diese künftig stärker einbringen, müssen hier entsprechende Maßnahmen ergriffen werden. Gegebenenfalls ist es erforderlich für diese Zielgruppen spezielle, neue Konzepte und Angebote zu schaffen.

Die Internetpräsenz www.nexthamburg.de bildet die zentrale Plattform des Onlinedialogs und hat als solche den Anspruch einen möglichst großen Personenkreis anzusprechen. Die Resultate bezüglich der regelmäßigen Nutzung der Formate haben gezeigt, dass die Webseite bereits von vielen Befragten regelmäßig genutzt wird. Die Webseite kann daher als zentraler Ort für die Informationsvermittlung, Ideenentwicklung und den Austausch über Selbige angesehen werden. Die Präsenz in Sozialen Netzwerken

wie Facebook stellt für einen Teil der Community einen wichtigen Kommunikationskanal dar. So sind Postings für die Überwiegende Mehrzahl der Facebooknutzer teilweise oder sogar sehr wichtig. Die 1.100 Nexthamburg Facebook Freunde zum Zeitpunkt der Befragung machen deutlich, dass auf diesem Wege viele Menschen erreicht werden können. Ebenso muss jedoch herausgestellt werden, dass durch dieses Onlineangebot nicht jeder Nexthamburg Nutzer angesprochen wird. Neben einigen wenigen Befragten, die angeben, dass für sie die Facebookpostings nicht wichtig seien, gibt nahezu die Hälfte der befragten Personen an, dass sie das Angebot von Nexthamburg auf Facebook nicht nutzen. Um die Bedeutung Sozialer Netzwerke wie Facebook in einer partizipativen Planungscommunity besser einordnen zu können, besteht hier weiterer Forschungsbedarf. So ist es von Interesse zu erfahren, welche Nutzergruppen dieses Angebot am häufigsten nutzen und wofür. Von Interesse ist dabei auch, welche Rolle die Facebooknutzer innerhalb der Community einnehmen.

Mit Ausnahme des E-Mail Newsletters werden Dienste wie Twitter, RSS Feeds von den Nexthamburg Communitymitgliedern zwar genutzt, spielen im Vergleich zur Webseite und der Facebookseite eine untergeordnete Rolle. Auch mobile Applikationen werden bisher wenig genutzt. Die Gründe hierfür können nur durch weitere Forschungsarbeit geklärt werden.

Gemäß der Befragungsergebnisse haben Sessions für die Nutzer nicht den selben Stellenwert wie die Webseite oder der Facebook Auftritt. Doch unter der Berücksichtigung der Besucherzahlen aus den bisher abgehaltenen Offline-Veranstaltungen, müssen diese Angaben relativiert werden. An den Bürgerworkshops, den Nexthamburg Sessions, haben nach Angaben der Veranstalter jeweils bis zu 100 Personen teilgenommen. Selbiges kann für die Zukunftscafes gesagt werden. Diese relativ hohen Teilnehmerzahlen können als Beleg für die Wichtigkeit von Offlineveranstaltungen im Beteiligungsprozess angesehen werden.

Aus der Betrachtung geht hervor, dass Communities ein geeignetes Mittel sind, um mit einer großen Öffentlichkeit über die Themen der Stadtentwicklung ins Gespräch zu kommen. Es zeigt sich, dass der Aufbau einer aktiven Community Zeit benötigt und dass dafür sowohl Online- als auch Offlineangebote wichtig sind. Um die Entwicklung zu fördern, ist der Beteiligungsprozess fortwährend fachlich zu begleiten. Die Web-Anwendungen, ebenso wie die Offline Beteiligungsangebote können dabei helfen, aus einzelnen Ideen und Meinungen partizipativ Konzepte für die Stadt von morgen zu erarbeiten. Allerdings sind daran auch gewisse Erwartungshaltungen geknüpft. So erhoffen sich die Menschen, dass die erarbeiteten Egebnisse auch umgesetzt werden. Ist dies nicht der Fall, stellt sich über kurz oder lang Frust ein, der die Bereitschaft mitzuwirken schmälert. Somit ist in der Umsetzung von partizipativ erstellten Ideen ein wichtiger Bestandteil im Erhalt und dem Auf- bzw. Ausbau der Community zu sehen.

BIBBIDI-BOBBIDI-BOO: The Reinvented Magic of Urban Shopping?

Mira Milakovic, Aleksandra Stupar

(Mira Milakovic, Teaching Assistant, University of Belgrade, Faculty of Architecture, Bul. Kralja Aleksandra 73/II, mira.milakovic@gmail.com)
(Dr Aleksandra Stupar, Associate Professor, University of Belgrade, Faculty of Architecture, Bul. Kralja Aleksandra 73/II, stupar@afrodita.rcub.bg.ac.rs)

1 ABSTRACT1

Built on the principles of the Athens charter and Modern movement, New Belgrade was a spatial representative of a new state and the post-war Yugoslav society. However, at the turn of the 21st century the processes of transition, globalization and EU-integration started, shaping New Belgrade into a polygon of another experiment, initiated by a number of local and foreign greenfield investments. The intensification of commercial, business and administrative activities has created a new identity of this urban entity, imposing new rules and elements into the rigid modernist concept. The shifts of consumption patterns and contemporary life style have imposed new shopping demands which reflected in a new typology of shopping nodes/centers dispersed throughout the territory.

The paper will focus on the period of the 1990s and 2000s analyzing the application of 'global rules' to shopping nodes and their network. The new layer of consumerism will be related to large/small scale spatial and social changes of New Belgrade, which have generated new urban energy while boosting further development and increasing the value of existing structures. The emphasis of the analysis will be on large shopping malls which announced another phase of New Belgrade's development offering elements of traditional 'inner city' atmosphere implanted into the modernist grid.

2 INTRODUCTION: THE JOY OF CONSUMERISM

The contemporary way of life has generated a number of problems which are directly or indirectly caused by our patterns of consumption and their effects on environment. Saturated by increasing consumerism, modern cities face difficulties related to production technologies, distribution, transportation and – consequently - pollution, while the gap between low-income and high-income social groups becomes more visible then ever. However, it is difficult to step out of the vicious circle of shopping addiction and to return to a simple fulfillment of basic needs.

The 'art of shopping' has become a well-elaborated subject for architects, urban planers, psychologist and sociologists, while its importance for urban development has been frequently underlined. Sometimes, shopping represents a necessity, everyday routine or even a nuisance. On another level, it could be glorified as an activator of total urban regeneration or it could be labeled as an instrument of personal catharsis for over-stressed consumers. Therefore, it is not surprising that the relation between shopping and urban morphing becomes very strong, which reflects in a number of types that evolved during the last few decades. Hugh Pearman (2002) identifies seven main categories/types of shopping centers – open mall, 'black box' enclosed mall, daylit covered mall, mega-mall, 'speciality center', village-like 'factory shopping center' and 'intersection city'. Most of these types could be considered as the latest development/transformation phase of a traditional shopping street, while the seventh type represents a mega-manifestation of commerce and its globalized character and performance. Pearman also emphasizes the revival of big department stores, which actually represent a social and architectural innovation of the 19th century (although the first one appeared even earlier in the UK, during the 18th century).

The position of new shopping nodes indicates recent changes and trends in urban development, demonstrating all the turbulence which occurred in the city of the 20th and early 21st century. The decline of the inner city, the expansion of town edges, urban growth and regional re-grouping, each one of these phases has affected different modes of shopping - their scale, architectural appearance, theme and attractions, favored atmosphere and relations to the city. However, the selected type of shopping could also define a preferred urban image, channeling its future nature and form (Sudjic, 1993).

[1] The paper was realized as a part of the research project "Spatial, Environmental, Energy and Social Aspects of Developing Settlements and Climate Change – Mutual Impacts" (project number TP36035), PP1: "Climate change as a factor of spatial development of settlements, natural areas and landscapes", financed within the program Technological Development by the Ministry of Education and Science of the Republic of Serbia (from 2011to 2014).

Consumerism usually overlaps with ideology, enabling a bifocal view to a society and its spatial manifestations. Therefore, this paper will give an insight into the urban transformations of New Belgrade analyzing the changes which occurred in shopping patterns during the last two decades. Representing a unique testimony of an epoch, New Belgrade has become the best example of recent social changes, revealing a striking image of transition - from socialism to capitalism (Fig. 1).

Figure 1: The image(s) of New Belgrade – snapshots of history and urban transformations (1950s and 2000s).

3 SETTING THE STAGE: MORPHOLOGY VS. IDEOLOGY

Conceived as a new administrative economic and cultural node of the post-war Yugoslavia and its society, New Belgrade played an important representative and symbolical role, which essentially distinguished its character, appearance and quality from other modern(ist) settlements and satellite towns with similar design pattern. As such, a new node of the Yugoslav capital had a necessary economic and ideological backup to implement a number of modernist ideals. Conceived as a functional city, it was composed according to an orthogonal grid of mega-blocks and mono-functional zoning. Consequently, it should have provided a variety of activities adjusted to the accepted concept and recognizable image of residential blocks with free standing buildings, greenery and large open spaces for social interactions. However, the changes of socio-political and economic conditions reduced the original idea transforming New Belgrade into a predominantly residential city. Nowadays, global trends and continuous debates about city development have underlined the importance of this area, bringing the question of its functional (re)structuring and activation into the limelight.

Figure 2: The local center in residential block no. 1 intended to serve the community cultural and daily needs.

3.1 The image of progress

New Belgrade, planned and designed as a modern, functional city, materialized some of the ideas launched by CIAM and Le Corbusier's Athens Charter. Beside its foreseen important position of a new administrative, economic and cultural hub of the capital, it also had the crucial impact on the integration of historical centers of Zemun and Belgrade into a greater metropolitan region. Thus, it does not represent a peripheral satellite settlement, but a unique central territory planned for further growth and concentration. Although conceived as a complex spatial structure with a number of functions, it was only partially realized. For many years, it has been dominated by residential modernist blocks. The mix of activities existed only on a community level, as a local center in each orthogonal mega-block, and it represented a state property (Fig. 2). The main role of every local center was to act as a meeting point, local supplier and a focus of cultural activities for the residents.

3.2 The critic of Modern

The critic of the applied modern concept marked the 1980's architectural scene, together with the impacts arising from the changed socio-political context. The concept was re-questioned, a number of problems was detected and some ideas about a renewal of this area appeared. This situation caused a shift of the original paradigm, transforming the open plan of New Belgrade and adjusting it to new users and needs. These changes could be decoded through two interesting events related to two different spatial levels. The first was The international competition for the future of New Belgrade, where majority of authors proposed fragmentation of over-scaled urban elements/blocks and suggested a return to traditional urban values. The second one was visible through the reinvention of residential scenery i.e. the construction of semi-open shopping centers which represented extensions of existing local centers.

The concept of these shopping centers was more traditional than modern, since their form and function resembled features and the atmosphere of old urban cores. Mostly composed of one or two longitudinal buildings, these nodes of shopping usually occupied only ground floor level. The space was divided into separate functional units – small shops which could only be accessed from outside. The variety of mixed contents included fashion stores, bakeries, cafes, bookstores, home appliances, etc. The land was state-owned, but each store was in private ownership. However, having in mind their small spatial capacity and structure and the fact that they were constructed only in a few mega-blocks, their role was mainly identified on a local level (Fig. 3).

Figure 3: First shopping centers built in New Belgrade - a/ the position in the block; b/ and c/ the built structure.

3.3 The period of transition

After 1989 and the beginning of European integration, Yugoslavia disintegrated. During the 1990s, the political, economic and social situation in Serbia was additionally complicated by the influence of international embargo, civil wars in ex-Yugoslavia and a continuous flow of refuges from ex-Yugoslav republics. Belgrade, as a capital, again became a stage for social turbulence, while New Belgrade, once conceived as an administrative and residential paradise of a socialist society, lost its prominent label. Reflecting a gloomy reality and limitations imposed by the economic isolation of the country, its urban tissue became a setting for new social transformation and architectural experiments.

The new postmodern streams that already emerged in the profession set off an imperative of 'thickening' the urban structure of New Belgrade. The guidelines were clear – to recreate a human scale of streets, to provide better accessibility for pedestrians, to reconsider scale of mega-blocks, superpose traditional urban patterns and, finally, to stimulate mixed-use by introducing new activities - culture, commerce, business, etc. (Milakovic and Vukmirovic, 2011). Consequently, the changed socio-economic circumstances and preferred spatial concepts reflected in the typology of shopping centers/nodes and this period generated three new types.

The first one – the flea/open market, represented a direct consequence of social stratification. In order to support socially vulnerable groups and meet their needs limited by low-income, this type was generated from informal sales near official markets and along streets. In time, this mode of shopping was relocated to a new, legal(ized) site, utilizing a large wired plot in which metal counters were set in rows. The market is totally open-air, with some characteristics of oriental bazaars (Fig. 4). The plot is still city-owned but each counter is private. Although its main role is to sell a wide range of products, there are some complementary activities, such as cafes and restaurants. The gravitation area of the largest New Belgrade open-market has also changed along with the change of its informal character. Nowadays, its importance on a city level is additionally supported by the proximity of a metro/tram station and a large parking lot.

Figure 4: The flea/open market - a/ the position in the block; b/ the entrance to the market, and c/ the daily atmosphere.

The second type appeared in a form of semi-closed malls along the main boulevards in just one area of New Belgrade and there are two examples of this concept. The spatial organization is based on a longitudinal building parallel to the main street, with two levels – ground floor and first floor. There are two types of galleries – closed, oriented toward the inner space, and opened, oriented toward the street. Both galleries actually represent a special kind of pedestrian 'street', providing access to all stores (Fig. 5). The longitudinal form is divided into three sections and two central atria are designed to be meeting points. Activities range from simple fashion stores to kindergartens and private medical offices. The buildings are still owned by the city, while individual stores are private. Parking lots exist, but their capacity in both cases is limited and inadequate – for ex. for more than 500 stores in one of the malls there are only 96 available parking places.

Although with similar spatial and functional structure, two representatives of this type have generated different importance and impact. The one which was built first remained locally oriented, attracting mostly residents of the nearby blocks. The structure of users has been changed in the second mall, becoming the biggest Chinese shopping center in the city and evolving into a shopping node of regional importance. This trend also influenced some changes in social diversity, replacing the inherited consistent structure of residents (originally mostly middle-income state officials) with a more multicultural (and globalized) milieu, composed of newcomers attracted by specific economic circumstances.

Figure 5: The semi-closed mall in Block 70: a/ the position in the block; b/ the system of open and closed galleries; c/ the daily atmosphere.

Figure 6: The transition type: from the semi-closed mall to the enclosed mall.

The third type actually represents a transition mode of the enclosed mall. Its semi-closed scheme consists of satellite standalone buildings located on the same lot/block. Visually, the central facility (the shopping center) and the surrounding satellite buildings are perceived as a single 'unit', although the outlying buildings are not physically connected (Fig. 6). At first, its importance was recognized on a city level, but nowadays its activities are mostly limited to the local area. Since it is not a typical representative of its kind, this paper will not consider further details.

4 MIRRORING THE GLOBAL FASHION

4.1 Shopping (in) the City

At the turn of centuries, the political and economical conditions in the country became more or less stable and a transition towards democracy influenced significant changes in planning practice. Stimulated by international trends, the area of New Belgrade has commenced its new life cycle and its disadvantages turned out to be potentials: the low index of built areas has indicated a number of possibilities for large development projects, while infrastructure and connectivity have provided a good backup. Open public spaces in this area have embraced some elements of traditional design and the process of reorganization and upgrading has started – responding both to an internal pressure (to transform the spatial structure) and respecting the global trends. The privatization of some public spaces has become a reality, imposing a business interest over the public one. The commercial facilities have been considered as positive markers of neighborhoods, while the penetration of private sector and the increased commercialization of public spaces have been accepted and promoted as an appropriate answer to the problems of mono-functional zoning and an opportunity to intensify activities, their quality and diversity (Fig. 7).

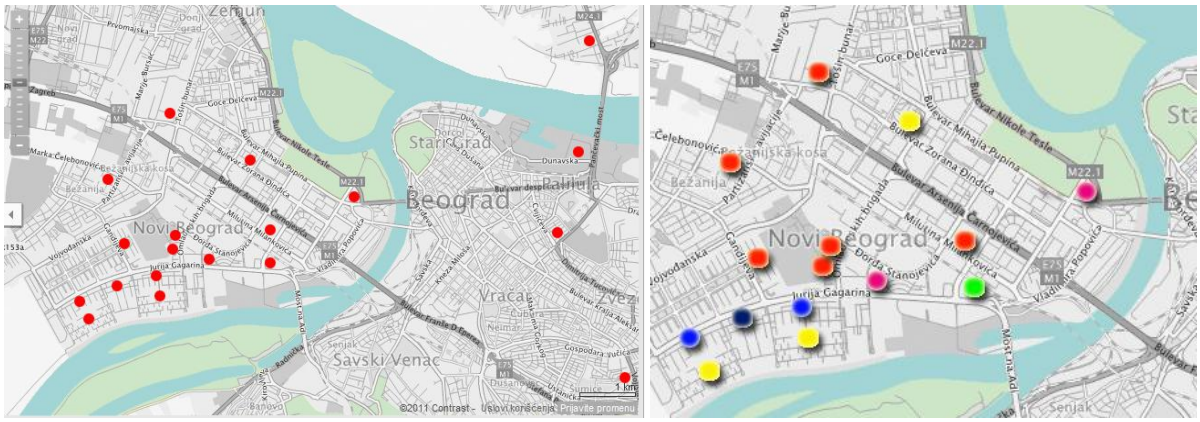

Figure 7: a/ Concentration of shopping malls in Belgrade; b/ Distribution of shopping mall types in New Belgrade (yellow – semi-open; blue – semi-closed; red – ‚big-box‘ mall; pink – enclosed mall; green – open shopping center).

The first enclosed malls in New Belgrade were positioned at strategic locations, attached to important traffic arteries. Occupying large plots they represented large retails, i.e. parts of different chains that operate a store. Their physical structure cold be classified as the ‘big-box’, a free-standing two story building, with a totally closed compact space (Fig. 8).

Figure 8. The first types of enclosed (big-box) malls in New Belgrade.

However, the typical representatives of the enclosed type appeared in New Belgrade few years ago. Since then, their number has increased, as well as a level and number of their activities and facilities. The design is introverted/inward-facing and its internal organization is based on theories which ‘control’ customers’ behavior (for example, the Gruen transfer - the moment when consumers respond to "scripted disorientation" cues in the environment; the effect of the transfer is marked by a slower walking pace). Like in many other cases, the mall is designed as a regional shopping hub and its building represents only a part of a larger superstructure, which also includes offices and/or residential space. The mall is up to three stories high, designed around two central atria, with a wide selection of stores, as well as with a number of entertainment facilities, fast-food outlets, restaurants and public areas (Fig. 9). The mall has its own social and functional dynamic, oriented towards the consumer. The shopping area is combined with a system of enclosed

walkways for pedestrians, which represents a modern version of the traditional marketplace. A convenient parking area is situated in an underground garage. One of the advantages of this type is certainly a permanent control of micro-climate.

Figure 9. An example/the biggest enclosed shopping mall (Usce): a/ the position in the block; b/ the connection to the historical core (via one of the major streets); c/ the internal atmosphere.

Obviously, the identified types (Table 1) are well positioned in the contemporary consumption pattern(s), but depending on their spatial and functional concept (which is the result of all inherited/imposed ideological stimuli) their attractiveness varies, as well as the level of their adjustment to current needs. Therefore, some of these shopping structures seem to be outdated or even abandoned, but the general image represents New Belgrade as a new shopping paradise. From approx. 0,5m2 of retail space per inhabitant (during the 1970s), the municipality of New Belgrade has nowadays around 1,6m2 of retail space/inhabitant, which is the highest ratio in Belgrade.

The established urban magnetism has certainly brought a significant financial benefits, but some other levels – mostly social and ecological, have to be reconsidered and thoroughly evaluated in the next phase of urban development and growth.

4.2 Shopping and environment

The current situation in New Belgrade has caused a number of environmental problems and dilemmas. Some of them are related to old/inherited types of shopping centers, their structure and performances, while others represent results of the recent urban intensification triggered by the construction of new shopping malls. The concerns about energy efficiency and environmental protection have opened a new perspective of the future urban transformation, focusing a professional and public attention to accumulated problems of pollution, waste recycling and thermal control.

The main challenges, identified after the introduction of new, 'globalized' patterns of consumption, could be divided in three groups which are mutually dependent:

- traffic – increased intensity, points of congestion, critical routs, car-friendly vs. pedestrian-friendly concept, parking capacity;
- environment – air pollution, waste recycling, climate, carbon intensive vs. carbon-free consumption;
- energy – heating/cooling, renewable sources, thermal insulation, natural systems vs high technology.

In New Belgrade, the crucial impacts could be decoded in the increased intensity of traffic and the appearance of new points of congestion. This problem is mostly related to the shopping malls of regional importance, which are positioned along strategic routes of the city, in a close proximity to the access points to New Belgrade. Since these shopping malls represent car-friendly structures, they cause major traffic congestion and obstruct expected mobility. The consequences could be also detected in air pollution and changes of micro-climate. The other types of shopping centers in New Belgrade have more pedestrian-friendly concept. However, in comparison to them, parking capacities in enclosed malls are well calculated and designed.

characteristics/ representatives	physical			Functional			social		environmental		
	surface and height	openness or closure	internal organization/concept	activities/structure	quality of activities	services	structure of users	special significance	included by project or not	microclimate	indirect impacts on the environment

block 45 and 70/extensions 	1500 – 2000m2/P	semi-open shopping centre	traditional open streets	mix-use/not satisfactory	not satisfactory	/	local level	only on local level/residents of a block	no	good/considering open/air concept	/
block 43/flea market 	23000 m2/P	open shopping centre	characteristics of traditional bazaars	mix-use/not satisfactory	average	parking	city level	meeting point	no	good/considering open/air concept	increased traffic
block 45 and 70/multicultural transformation 	10000 – 15000 m2/P+1	semi-closed shopping mall	traditional streets and squares	retail and wholesale	not satisfactory	parking/inadequately dimensioned	regional level	meeting point/symbol – element of new identity	no	bad	increased traffic
block 16 and 67/new city markers 	50000 – 85000 m2/P+2	enclosed	traditional streets and squares	mix-use/satisfactory	good	parking, business, residential	city and regional level	meeting point, element of new identity	yes	good	increased traffic/air pollution

Table 1: Main types of commercial spaces in New Belgrade and their characteristics.

Regarding energy consumption, new enclosed malls are better designed than other types. The attention was mostly payed on thermal insulation. However, the latest standards of energy efficiency are not applied and there are still no attempts to orient/shift existing shopping centers to renewable sources of energy or (re)use of natural materials. The territory of New Belgrade is covered with remote heating system. However, all shopping centers use unsustainable systems of cooling.

The differences between identified types of shopping centers certainly direct future actions but the introduction of new environmental standards and their adjustment to local conditions should become an imperative for every process of renewal and/or transformation. The magnetism of consumption could also be used as an instrument of public promotion and education – suggesting and testing an environmentally conscious approach through various campaigns and activities.

5 CONCLUSION: FACING THE EFFECTS

The latest type of shopping malls, which is inserted into the urban tissue of New Belgrade, has become a landmark on several levels – local, city and regional. The changes in consumption patterns have also resulted in different urban morphology and functional structure, but in general, transformations could be decoded in several spheres:

- economy (higher rates of land and apartments in the surrounding area);
- society (new elements of multiculturalism/cosmopolitanism);
- space/activities (space attractiveness, intensification of pedestrian flows, articulation of meeting points, structure and quality of activities);
- environment (new standards and challenges).

Simultaneously, the contemporary urban needs, new inhabitants and recently improved attractiveness of New Belgrade have instigated some modifications of old types of shopping centers, as well as a new life of ex-community centers (initially with cultural activities). These new forms of shopping actually upgrade the previous content, providing a number of additional activities and public/communal facilities - such as libraries, theaters, banks, recreational units, pubs, groceries and even some civic initiatives (for ex. New Belgrade's Cultural Network), etc. As the trend grows, other facilities are usually developed around the existing centers increasing the significance of the center among local residents and other users on the city level (Fig. 10).

Figure 10. a/the local community center in block 45 - the public event 'New Belgrade – the city of the open heart'; b/reconstructed movie theater - multipurpose hall.

The shopping landscape of New Belgrade, currently composed of old and new types of commercial spaces, still needs to be thoroughly evaluated and subordinated to an integral vision of development. The physical, functional, social and environmental elements of each type provide a comprehensive image of a current situation and/or undertaken actions, while the synergy of global trends and local economy direct further guidelines. However, the magic of consumerism remains. Nowadays, it is in a glitzy package wrapped with mixed-use and new aesthetic, but the ultimate sensation and excitement are guaranteed.

You just have to pay for the spell.

1 ABSTRACT

According to Florida (2003), a better functioning city, offering high quality life style and amenities, can attract a huge number of creative people who in turn can influence businesses to locate there. In the tourism literature it has been mentioned that among the limited things the tourists want a city to have are good public transport, less congestion, safety, and night life. Therefore, it seems that the prospective permanent settlers and visitors look for a few common qualities in a city. Both of these groups of people have the potential to boost the economy and quality of life of a city.

Campuses of many universities across the world are located in a major city. Auckland is one of them. It locates two universities in the heart of the city. Among these two, The University of Auckland is the prime one with over 30,000 students studying on the City Campus. With so many students commuting to the university and spending a significant portion of their time in the city, they are likely to make an impact on the way the city functions.

Auckland is New Zealand's premier city and has been recently rated as the third-best city of the world to live in as per Mercer's rating. However, a record number of people have left New Zealand shores in recent times. Auckland is beset with some problems, such as traffic congestion and it hardly functions as a 24/7 city. Through literature review and a recent survey of the students at The University of Auckland, which mainly examines their commuting behaviour, this study tries to find out whether the university can facilitate Auckland to function better and thereby attract more tourists and reverse the brain-drain.

2 INTRODUCTION

In his legendary study, Florida (2003) observed that Pittsburgh had been losing talented young people from the core of the city and the surrounding areas since 2000. This was contrary to the fact the city became the top ranked liveable city in the USA in 1986 and continued to be ranked high since then. Their departure has been accompanied by a relocation of new companies to other regions and plateauing of the economy. Florida found that young people might even be moving to much smaller cities like Austin for lifestyle reasons including great night life. He termed these people, who were highly educated and drawing a handsome salary, as creative class. They are engaged in different types of work across different industries. The corporate profits from their input and economic prosperity increasingly depend on them. From Florida's study, it seems that for a city to prosper economically it must retain and attract quality workforce by providing amenities desired by them.

Along with the permanent residents, the temporary visitors or tourists are also important for the economy of a city. Coincidentally, the amenities that attract urban tourism are somewhat common to the ones desired by the creative class (Florida, 2003). Among the limited amenities cherished by the tourists in a city are nightlife, good public transport, shops and restaurants (Enright & Newton, 2005).

Auckland has been recently ranked as the third best liveable city as per Mercer Rankings. Unfortunately, it does not guarantee that the city would experience a huge economic growth. In fact, like Pittsburgh the signs are not encouraging for Auckland. Recently there has been a trend of a huge number of people leaving Auckland for other countries, especially Australian cities (Inkson et al., 2004). It is time that attention is given to a few key aspects of the city that could enhance its attractiveness to the creative people as well as the tourists, as tourism is one of the largest foreign currency earners for New Zealand.

Auckland is one of the few major cities in the world that has two universities located in the Central Business District (CBD) – The University of Auckland (UoA) and Auckland University of Technology (AUT). UoA is one of the leading universities of the world and New Zealand's largest with over 33,000 students. Cities function as complex sytems (Batty, 2008), but it is difficult to study the urban phenomenon as a whole (Lefebvre, 2003). In this study, we mainly focus on two aspects of a city, public transport and nightlife, and try to determine the ways UoA could facilitate Auckland to function better. Besides literature review, a recent survey of students regarding their commuting behaviour is used for this purpose.

3 NIGHLIFE AND 24-HOUR CITY

The city centre has been experiencing the loss of its status as the hub of the retail, business, entertainment and cultural activities for the surrounding areas since the early 1950s in the US and later in the advanced western countries (Thomas & Bromley, 2000). In recent years there have been initiatives in some of these countries to revitalise the Central Business District (CBD). Revamping the nightlife economy and extending the operation of the downtown for even up to 24 hours have commonly featured in the solutions to the problem (Bianchini, 1995; Hollands & Chatterton, 2002; Roberts & Turner, 2005).

There have been a number of research carried out in different cities in Britain in recent times, with a view to adopt the '24-hour city concept' and address issues related to it, using the lessons learnt from the European cities since the late 1970s (Heath, 1997; Hollands & Chatterton, 2002; Roberts & Turner, 2005; Thomas & Bromley, 2000). From his literature review, Heath (1997) listed the reasons for adopting the 24-hour city strategy in Britain, which included safer city, economic regeneration and city image. The last aspect is important for giving a competitive edge to a city (Lovatt & O'Connor, 1995). The initiatives based on the strategy included prolonging the activity period and introducing a variety of evening and nighttime activities to cater to different categories of people (Thomas & Bromley, 2000). One of the issues that needed to be addressed first was to fill the void in time between closure of offices and shops and early evening services, such as restaurants, theatres, cinemas and concerts. This could be done by extending the shopping hours and promoting a café culture (Bianchini, 1995; Heath, 1997; Thomas & Bromley, 2000).

The integration of office hours with the evening activities would also address the important issue of safety in between 5pm, when the offices and shops usually close, and 7pm, when the diners, cinema- and theatre-goers set into the city, who are later followed by pub and club clients (Thomas & Bromley, 2000). The city centre is sparsely occupied during 5-7pm, leading to a concern about the safety by the potential visitors, especially in winter. The perception of lack of safety has discouraged people, living in the suburbs, to visit the central city and reduced the amount of pedestrianised activities. For example, Thomas and Bromley (2000) report from a survey of potential shoppers in New York that 63 percent of the sample did not visit the city centre regularly owing to fear for safety. In another survey conducted in Birmingham, it was found that 69 percent of the respondents refrained from visiting the CBD at night. Similar findings were found from a survey in Swansea. In Britain, the reduction in natural surveillance due to the loss of people living in the core of the city is often associated with worsening of the safety factor. The decrease in natural surveillance in evening often leads to avoidance of the central city by the public.

In line with Florida (2003), Hollands and Chatterson (2002: 292) mention that 'young urban service workers, graduates and students, knowledge professionals and cultural intermediaries' are the main consumers of a city's nighttime and cultural economy. Thomas and Bromley (2000) conducted a survey in Swansea to learn about the pattern of evening and night use of the city centres. The respondents who visited central Swansea in the evening mainly went to the theatres, restaurants, shopping malls, cinemas and pubs. Each of these venues had different appeal to different categories of people. For example, both middle and youthful age groups resorted to latenight shopping, while cinemas, pubs and clubs attracted the youthful age group (16-29 years) more. Hollands (2002) also mentions that young adults are more likely to visit pubs and nightclubs compared to the general population. He indicates that young people have been found to be attracted to café type bars in recent times. In order to increase the social mix, the activity patterns in the central city could be diversified through street entertainment and festivals, and creatively organised functions in venues like museums, galleries and leisure centres (Thomas & Bromley, 2000).

Nearly half of the survey participants in Swansea avoided bus for their trip to the CBD, due to concern for safety. The steps for expansion of the nighttime economy needed to be complemented by improving the access to the area through adequate public transport provision (Hollands & Chatterton, 2002; Thomas & Bromley, 2000). Thomas and Bromley (2000) particularly put emphasis on increased surveillance on board and at major transport terminals.

The 24-hour initiative and vibrant nightlife have negative aspects as well, such as violence, disorder and crime (Chatterton, 2002). Especially, late hour trading has given rise to alcohol consumption in many cities across the world (Peters, 2010). Some of the incidents at nighttime are linked to alcohol drinking. Mostly male and youth were found to be associated with heavy drinking in Britain (Bianchini, 1995).

4 URBAN TOURISM

Urban tourism means tourism in the city (Law, 2002). Law (2002) mentions that large cities attract a number of visitors. They visit central cities due to their diverse functions and varieties of activities (Lawton & Page, 1997). The tourists definitely need transport to move around and travel to different destinations. Albalate and Bel (2010) report that urban tourists prefer to avoid private transport due to high cost, effort and hassles associated with driving. They are more likely to use public transport. In one study it was found that three-fourth of the tourists in Manchester used public transport (Thompson & Schofield, 2007). In fact, Public transport plays a big part in urban tourism development as it can even influence destination choice and raise the image of a city (Albalate & Bel, 2010; Thompson & Schofield, 2007). Tourists are becoming more environment-concerned these days and attach importance to sustainable modes (Baysan, 2001).

In order to attract more visitors through maiden visits, repeat visits and referrals, a city needs to demonstrate its competitive edge (Enright & Newton, 2005). Transportation facilities, along with shopping and nightlife feature in the factors influencing competitiveness of destinations in a study by Enright and Newton (2005). Nightlife is ranked highly for two cities – Hong Kong and Singapore - in the statistical analysis conducted by them.

Auckland contributes a big chunk to New Zealand's tourism revenue with a share of 27 percent (ARC, 2009). Lawton and Page (1997) conducted a survey with the tourists in downtown Auckland and found that most of the respondents had strong educational background and there were 32 percent professional or managerial workers. Coincidentally, their profile is consistent with the creative class people defined by Florida (2003). Among the activities or attractions the tourists wanted to visit, shopping was the most favourite choice followed by bar/nightclub, museum and art gallery. It seems the visitors are more interested in the activities of the city centre and attracted by its nightlife. The extension of the operation time of the city centre favours the tourists (Deffner, 2005). However, there is a little concern about safety in Auckland. While discussing the results of two surveys, Barker and Page (2002) mention that Auckland was rated the lowest among nine major national destinations with regard to safety in a survey of tourists, and in another survey 71 percent of the respondents were of the opinion that the level of safety needed to be improved in the CBD. In their own survey of tourists, they found that 10 percent feared for safety at some point in their trip.

5 AUCKLAND CBD AND THE UNIVERSITY OF AUCKLAND

The CBD is the hub of business, culture, recreation and leisure in Auckland (Auckland City Council, 2003). It is a triangular area covering 433 hectares of land (Fig. 1).

Fig. 1: Map showing The University of Auckland and Auckland University of Technology within Auckland CBD. (source: generated by the authors using Auckland Council GIS Viewer)

The number of tourists staying in the city centre has been increasing gradually over the years and doubled between 1991 and 2001. So has their duration of stay. Auckland CBD is New Zealand's largest centre in terms of employment with about 78,000 workers at the moment, increasing by 30 percent in the last ten

years. It has maintained a stable share of around 25 percent employment of Auckland City over the years. Tertiary education contributes to 5.7 percent of the centre's employment that makes it the fourth largest industry there. Area-wise the education sector uses around 15 percent of CBD's office space. This sector has experienced growth in the CBD and took 29 percent share of total education industry's employment in the Auckland City in 2002. The number of educational institutions in the central city stood around 100 that year. These include private secondary schools, private training establishments, and public tertiary institutions. Among these, UoA and AUT are the largest ones with current enrolments of about 19,000 and 30,000 students respectively. They are located in the central-east part of the CBD (Fig. 1). The University of Auckland is one of the leading universities of the world and the largest in New Zealand. It has 5 campuses with the main one in the downtown occupying 20.3 hectares of land (The University of Auckland, 2010). Unlike other universities, UoA operates from 8am to 6pm, with classes mostly taking place between 9-5. Most of the university offices also operate from 9am to 5pm. This pattern of operation deprives the university to bridge the time gap between the closure of business and nighttime activities in the city centre. Moreover, the students and staff are compelled to commute during the morning and evening peak hours, contributing to the congestion in the CBD.

6 THE SURVEY OF THE UOA STUDENTS

A random questionnaire survey was administered on the students of UoA in 2010 at a common space on the City Campus, which attracts visits by most of the students on a regular basis. The main purpose of the survey was to investigate the commuting behaviour of the students. There were 249 respondents. The survey provides some data which gives insights into some of the issues investigated in this paper.

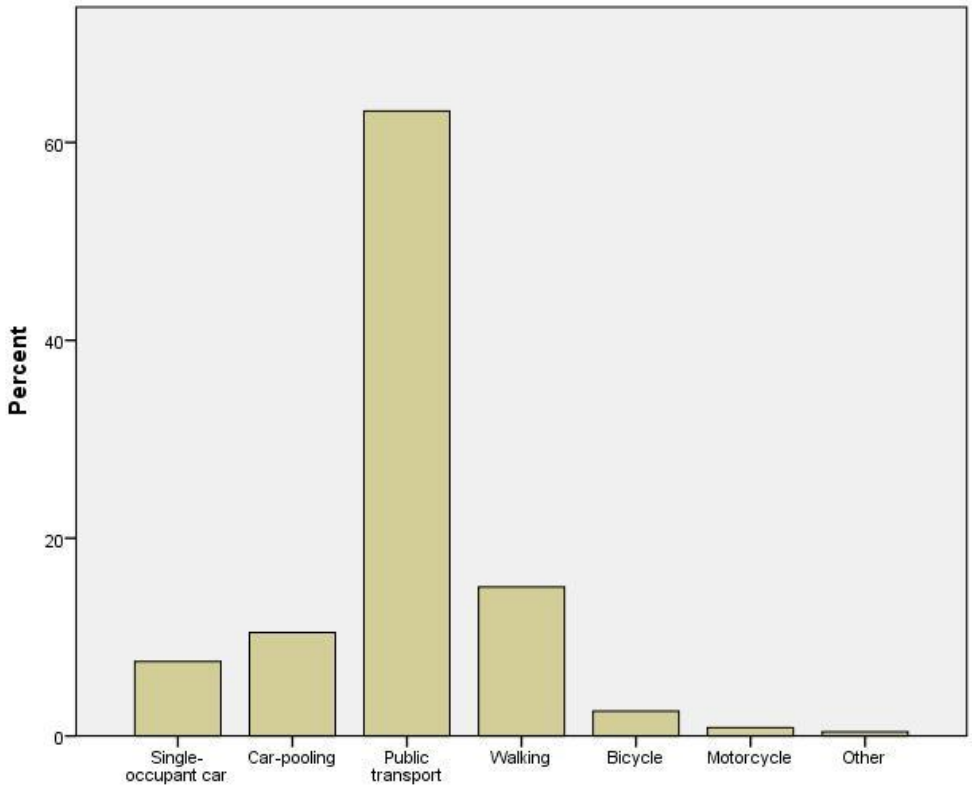

Fig. 2: Major mode usually used by the students to commute to The University of Auckland (source: survey conducted by the authors, 2010)

Fig. 2 shows the modal shares for the main mode used for commuting to the university. Contrary to the trend found in Auckland, the students used public transport extensively with more than 63 percent of the students using either bus, train or ferry to commute to the university. The modal share for bus was the highest with 51 percent. While this is positive for public transport patronage in general, there is a concern when we look at their commuting times in Fig. 3. It can be observed that 75 percent of them travelled to the university between 7-9am, which is considered the morning peak for Auckland (Ceder, Net, & Coriat, 2009).

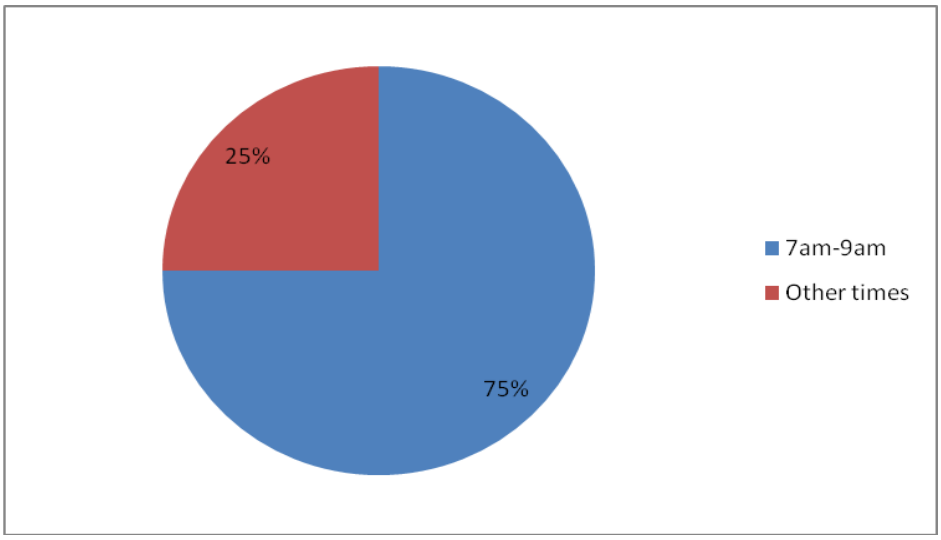

Fig. 3: Period of the day when students commute to The University of Auckland (source: survey conducted by the authors, 2010)

Though overall public transport usage is low in Auckland with a modal share of 4% (Auckland Regional Council, 2010), buses are usually crowded in the morning peak hours. This might deter some of the potential commuters from using the buses and some of the existing bus riders might consider switching to private vehicles. In the survey, we asked the students to indicate what they perceived as the main problems of morning peak-hour travel. More than 50 percent of the respondents mentioned congestion and about one-fifth mentioned inadequate public transport (Fig. 4). It is not surprising given their experience of travelling in crowded buses in the morning.

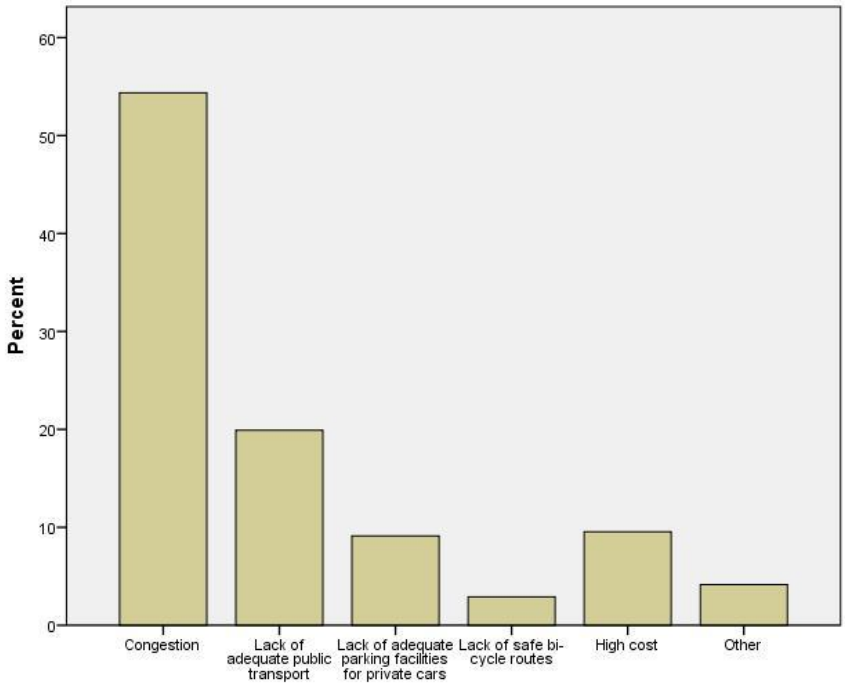

Fig. 4: Students' perception of main problems of morning peak-hour travel in Auckland (source: survey conducted by the authors, 2010)

If it was possible for the students to travel to the university after the morning peak period, it would mitigate some of the problems associated with morning peak-hour commuting to the CBD and public transport patronage in the off-peak period.

7 DISCUSSION AND CONCLUSION

With so many students studying at The University of Auckland, they can contribute to better functioning of the city centre if the operation period of the university is extended like many other similar universities of the world (e.g., The University of Sydney, Australia). One of the main hurdles for the nighttime economy to

flourish is the period after the offices and shopping centres in the CBD close. As the streets become empty the people are hardly encouraged to visit the CBD in the late evening to participate in different nighttime activities. Due to lack of patronage, some of the activities which could have run in late evening do not operate. Like some other cities, Auckland also faces the problem as most of the offices and shopping centres close between 5-6pm. As per previous studies, one way of mitigating this problem is to bridge the gap between closure of offices and evening dining time by extending the shopping time and café culture. The students could play a role here through their presence on the campus and movement through the CBD. As a large proportion of students use public transport, it is likely that most of them access the service at Britomart, the transport hub of the city, and at other locations of the CBD. Their presence and movement would increase the natural surveillance, which has been identified as a key factor for people to feel safer and encourage them to visit the city centre, especially since the university students have a good image in the eyes of the public. The students themselves could be the customers of the shopping centres and café and participate in the nighttime activities. By encouraging more people to stay on and enticing more people to visit downtown in the evening, the nightime economy could flourish and the nightlife could be made exciting and entertaining through varied activities.

Longer operation of the university would also allow flexibility in class hours and the students would be able to commute to the university after morning peak period. That would make the buses less crowded in the peak period and encourage office goers to ride buses more. It would also solve some of the problems relatad to shortage of public transport patronage in the off-peak period, especially in the evening, leading to balancing the demand throughout the day. As a result, it would help the public transport operators to offer better and frequent services, and reduce the dependency on subsidy. The central city would be greatly benefitted from the better service.

A vibrant nightlife served by a high quality public transport is likely to attract more tourists to Auckland and also fulfil the expectations of the creative class people. By having more overseas visitors and retaining and attracting highly talented people, the economy of Auckland could experience better growth.

Changing Sub-Urban Land Uses to Urban

Despina Dimelli

(Dr Despina Dimelli, National Technical University of Crete, dimelli@arch.tuc.gr, dimellidespina@yahoo.gr)

1 ABSTRACT

The constant population increase of big cities has led to their sprawl towards areas that are close to the big centers. Places that used to be sub-urban or they were used as recreation places are through time changing and are mutating to urban areas as they accommodate increasing population.

The initial planning for these areas was based on their small population that was estimated to be increasing with slow pace. The rapid increase that was not predicted by planning found these areas not prepared for these changes. The arbitrary constructions combined with the lack of recent plans have led to the creation of unplanned areas were land uses are allocated randomly.

The aim of the current paper is to investigate the land uses kinds and posts in the sub-urban areas of the Athenians basin, that have during the past ten years mutating in urban areas. The paper will focus on the kind and the way new land uses have been allocated in these areas where planning does not exist. Finally it will evaluate if these land uses unplanned changes through time have covered the needs of the "new urban" population.

2 THE CREATION OF THE SUBURBS

The word suburb derives from the Latin word suburbium that means under the city. It is not recent, as in Rome, the capital of the Roman Empire; rich people moved to the hills of the city, away from the poor and there they constructed their luxury villas. Today, the word suburb is used to describe an area that is separate and in a commuting distance from the existing urban area but co-functions with it. This happens because suburbs are mainly residential areas that have not been developed autonomously, but are functionally connected with the urban core that concentrates the majority of functions.

Suburbs are the answer to the constant land demand versus the urban sprawl. They first emerged in the 19th and the 20th century because of the rapid population increase in the big cities taking advantage of the improved road and rail transport. They are organized, low-density areas that are designed in order to contain the urban sprawl and the exurbia development that is taking place particularly in the United States.

The creation and the development of the suburbs is taking place in three distinct stages. It begins as a residential phenomenon, encouraged by government expenditures on highways, favourable mortgage policies, and mass-produced suburban housing allowed for greater affordability. The fact that lower than in the city land values and easy automobile access exist, leads in the second stage when large-scale enterprises move in the suburbs. This second phase of suburbanization is also characterized by the relocation of manufacturing establishments to the suburbs, driven both by availability of cheap land and proximity to an increasingly suburbanized workforce. In the third stage, administrative functions begin to relocate to suburban office space and begin to spread beyond the urban cores. The three stages have been accomplished in the suburbs of the United States in the last years. In addition, many similar cases of three stages suburban development have been recorded in Europe.

In Greece, suburbs were initially planned cores that were distant from the central area and were intended for high-income class as vacation areas. Through the years the intermediate areas were constructed so the suburban areas became parts of the urban continuous, that is constantly sprawling in the big urban centers of Greece. The case of Kifisia is characteristic as it was the vacation area of rich Athenians and today is a part of the urban continuous of the Athens capital. Today the trend of the capital's population is to move to areas of the Mesogia plain that are connected with new infrastructures network and have the advantages of low-density development.

The research will focus on this new kind of suburbs that used to be villages or recreation areas distant from the urban centers but in the last twenty years are mutating to urban areas with the allocation of new functions and the arrival of new residents that are encouraged by the newly created infrastructures.

3 SUBURBAN DEVELOPMENT IN GREECE

Greece is a 130.100 km2 country that presents a wide variety as its geomorphology is concerned. The rapid movement of population towards the big urban centers that took place in the last century with intensity that varied according to the economic, political and other circumstances led to the dissertation of the mountainous areas and the gigantism of the urban areas. The framework for the urban policies in Greece began in 1920 with legislation that influenced in a big decree the cities of today. According to this decree, the areas around the existing cities could be constructed with some restrictions that were most of the times ignored, with the tolerance of the state and the inefficiency of the controlling mechanisms. This fact, for almost a century, has led to urban sprawl, which today is the main way for cities extension. Today, the existing legislative urban framework that is based on incrementalism has worsened the cities expansion. It is characteristic that the two largest urban centers of Greece are expanded in the way that is shown in Figure 1 (Athens expansion) and Figure 2 (Thessaloniki's expansion).

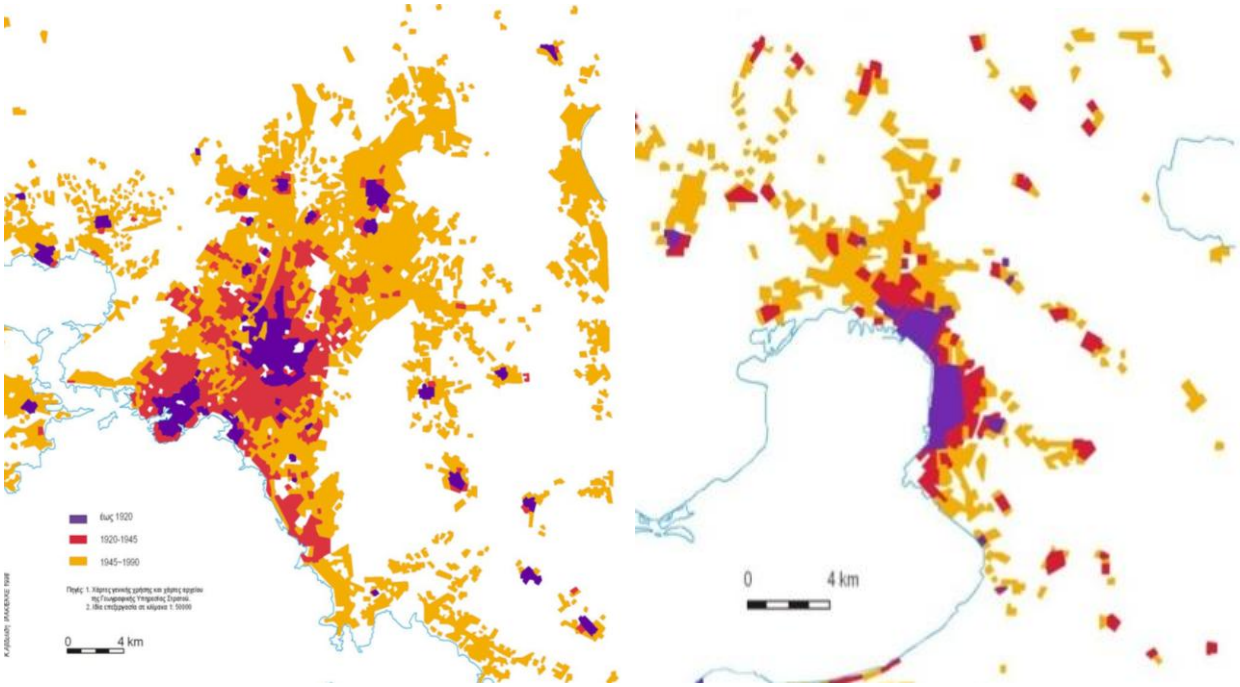

Figure 1 (left): Athens expansion. Figure 2 (right): Thessaloniki's expansion.

As it is shown in the above figures, except from the areal continuous that is presented, new suburban poles were since 1920 created. The research will focus on two types of suburban areas.

The first type is the villages that were distant from the urban core that were autonomous settlements isolated from the then shaped urban areas. The need for new urban land gradually mutated these areas that today function as suburbs of the central core.

The second type that will be examined is the coastal suburban areas, which were developed as recreation areas. These coastal areas today have mutated in urban areas that are constantly attracting new residents.

4 THE CASE STUDY

The case study of the current research is the settlements-suburbs that are developed in the Mesogia plain (Figure 3). They are divided in two types. The interior areas, that used to be small villages of Athens and their economy was based on agriculture and livestock-farming and the coastal settlements that were developed as recreation areas, where Athenians residents used to go for their vacation. These areas used to have a steady pace of development until the 21st century when infrastructures were developed. The new airport that was constructed and was supplemented by a new rail connection and a highway that served the basin with the wider area, led in a rapid population increase that was not expected. So, as planning was lacking, land uses followed a "laiser faire", for their allocation.

The current research will evaluate the changes of land uses in these two types of settlements and investigate if they have mutated to urban areas or they still have their initial functional character. The records from the 1991 and the 2001 population and employment censuses will be used are. The statistical technique that will

be used is Principal Components Analysis, which will reveal if land uses structures have been developed or if functions kind and allocation are random. This is possible because for these areas, informed plans still do not exist and the existing urban legislative framework provides the freedom to the majority of land uses to be allocated wherever they prefer.

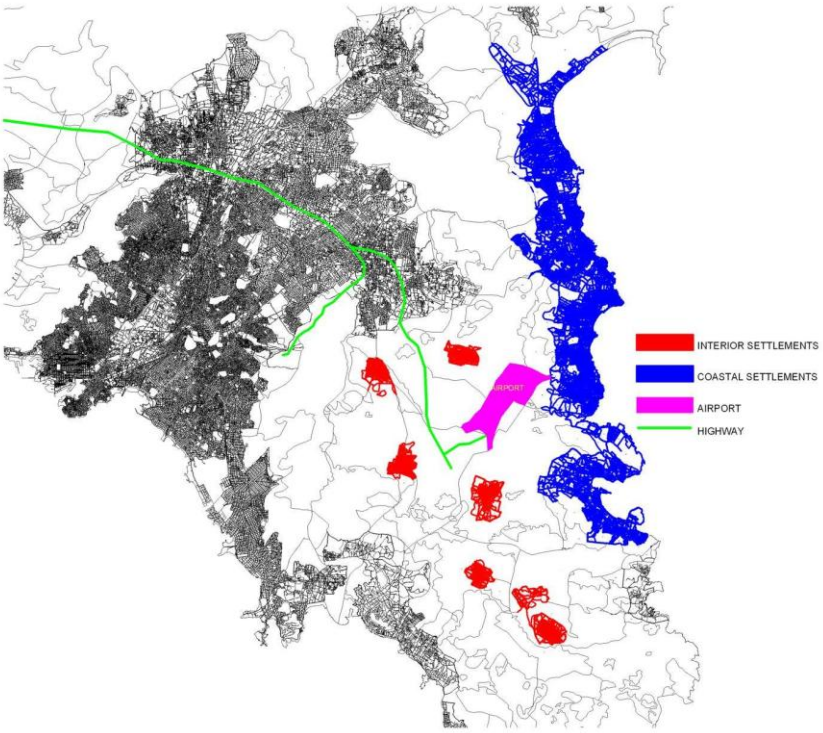

Figure 3: The areas of the case study.

4.1 The interior suburbs

The six interior suburbs that will be examined are Spata, Koropi, Peania, Markopouloo, Kalivia and Keratea (Figure 4). These settlements used to be small villages with economy based on the production of goods that intended for the big city.

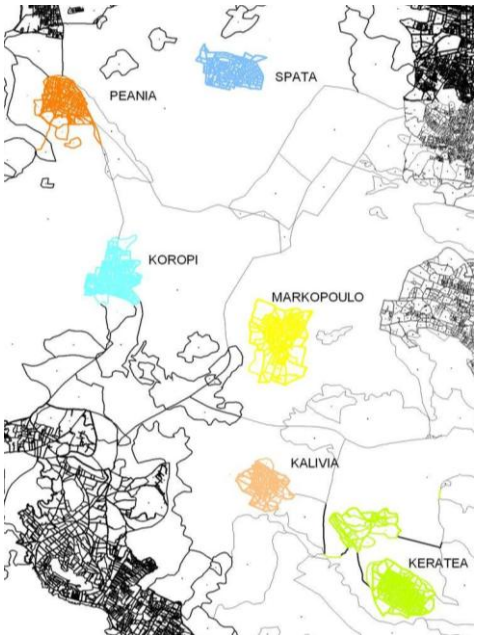

Figure 4: The interior suburbs.

These areas population has rapidly increased in the last twenty years and the employment on the tertiary sector on some of them has doubled during the examined decade. The fact that the Greek state had not

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

predicted this rapid increase is shown by the lack of flood preventing and sewerage network while illegal constructions are constantly created around these settlements without planning.

The detailed changes of population and employment in the six areas are shown in Table 1. The changes that have been recorded show that in all sectors the employment has increased. It is the tertiary sector where more new employees are recorded. A more detailed investigation shows that this increase is not caused by big enterprises but from small new activities that are allocated in these areas. As for their kind, the new activities are mainly public infrastructures as schools and administrative units but also retail trade services. Therefore, supralocal activities have not been developed but the majority of functions aims to the satisfaction of these areas residents needs.

SETTLEMENTS	DATES	POPULATION	EMPLOYEES	MANUFACTURE AND INDUSTRIES	TERTIARY SECTOR
SPATA	1991	7.796	2.355	597	1.758
	2001	10.203	3.119	883	2.236
	2001 - 1991	2.407	764	286	478
PEANIA	1991	9.727	2.532	592	1.940
	2001	13.013	4.337	1.502	2.835
	2001 - 1991	3.286	1.805	910	895
KOROPI	1991	16.813	3.407	1.515	1.892
	2001	25.325	4.766	2.067	2.699
	2001 - 1991	8.512	1.359	552	807
MARKOPOULO	1991	6.716	2.330	775	1.555

	2001	7.430	2.430	902	1.528
	2001 - 1991	718	296	62	234

Table 1: The changes in the six interior settlements.

Kalivia settlement has the biggest population increase while Koropi (Figure 5) is the most populated area. The execution of Principal Components Analysis in Koropi, the settlement where the majority of employment is concentrated, shows that in 1991, a date when still planning did not exist, 18 groups of functions are recorded.

Figure 5: Koropi settlement

The first and most frequently faced grouping of functions is composed by incompatible functions that are allocated in Koropi's centre. It is a phenomenon of many small Greek settlements, the majority of urban

activities that are not compatible, are concentrated in the centre, while in the rest areas, houses and other small activities are allocated.

One decade later, the groupings that are shaped are not different. Still incompatible groupings are composed and are allocated in the settlements core with a random way as regulations in the kind and post of functions have not revealed. The fact that new activities are allocated in the settlement and restrictions do not exist has led to an erratic development that is characterizing the majority of the Greek cities and is through time incrementally controlled.

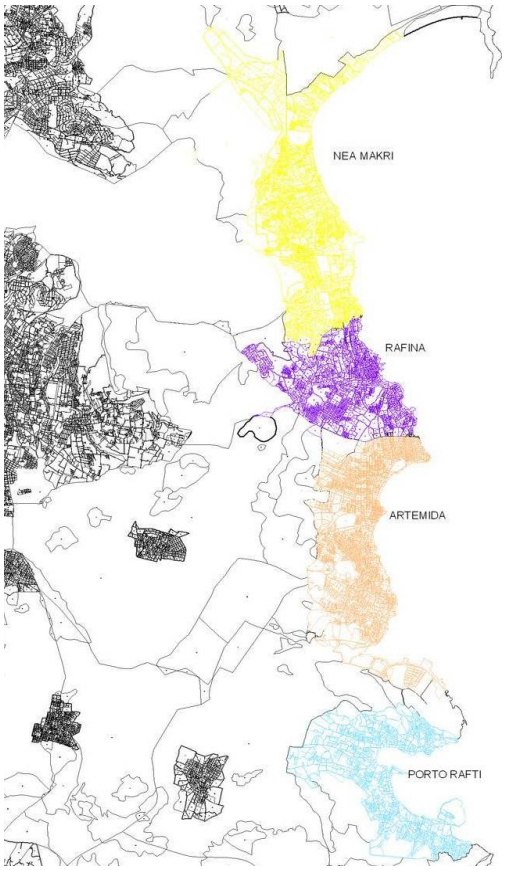

Figure 6: The coastal suburbs

COASTAL SETTLEMENT	DATE	POPULATION	EMPLOYEES	MANUFACTURE AND INDUSTRIES	TERTIARY SECTOR

4.2 The coastal suburbs

The four coastal suburbs that are examined, have diachronically shaped a continuous in the east coast of the basin (Figure 6). Initilally they were cores that are sprawled in the coastal area taking advantage of the freedom that has been provided. They are preffered because of their adjacency with the sea and they have gradually mutated to main residence areas.

It is characteristic that on the contrary with the interior suburbs, a more intense population increase is realised, while the employment has increased in a slower pace (Table 2). The settlement that will be examined is Artemida which concentrates the majority of population.

The biggest increase is recorded in the tertiary sector, as uses of trade and services have been allocated. The manufacture and the industrial sectors have also increased but with a slower pace. The examination of the structures of land uses that have been shaped will be revealed with the use of Principal components analysis on Artemida's recorded employment of 1991 and 2001.

Figure 7: The Artemida sprawl

The Principal Components Analysis that is realised in the 1991 employment shows that the allocation of functions is completely random (as 23 groupings have revealed from 49 activities) and they are allocated in a scattered form with small concentrations in the coastal zone.

The corresponding Analysis in the 2001 employment shows that a grouping of tertiary activities has been shaped but is still allocated in a scattered form. So, it seems that some activities tend to create cores of similar or related functions but they still have not shaped areas with specific functional character. If we take into consideration that the majority of constructions were illegal and planning for this area is recent, the fact that functions tend to auto-regulate is a sign of urban development.

5 THE EVALUATION OF THE MUTATION OF SUBURBAN TO URBAN DEVELOPMENT.

The process of urbanization is a complicated procedure that is influenced by many factors. The research tried to examine if areas that have recently concentrated new residents, have mutated to urban or if they still have their initial character. It focused on the areas that accept pressures on land demand and searched for the changes that have been realised in them.

The research examined two types of areas, the interior and the coastal. The interior areas were closer to the urban centre, the capital of Greece and they were functioning for two centuries with economies based on rural and livestock-farming activities. The coastal areas were distant from the centre and they were exclusively recreation areas with very small permanent population.

It is concluded that it is more difficult for the interior areas to mutate to urban than the coastal, as land uses are concerned. The interior areas have concentrated a variety of new activities that are randomly allocated in the total of the area. They have also not shaped groupings of uses. This can be explained by the fact that it is more difficult for areas that have been functioning in a certain way for years to adjust in new conditions.

This phenomenon is overloaded by the fact that urban plans do not exist so a regulative framework that would manage the kind and the allocation of the new activities is lacking.

On the contrary, the coastal areas have concentrated not only new residents but also activities that tend to auto-regulate as during a decade they have shaped groupings of activities that are still randomly allocated. They have the characteristics that make them more attractive for new residence areas and they are more easily adjusted in the new conditions, as they have not yet been shaped.

Therefore, in the Greek suburbs the first stage of development, the population's increase has been achieved, while the second and the third stage have been accomplished up to a point, as land uses still have not shaped the structures and the areas that would mutate their suburban functional character to urban.

City Region of Short Distance for ALL? Planning the 'Everyday' for a Diversity and Mixity of Users in Functional Areas

Heidrun Wankiewicz

(Mag. Heidrun Wankiewicz, planwind.at – planning-management-research, Bergheimerstr. 42, 5020 Salzburg, wankiewicz@planwind.at)

1 ABSTRACT/KURZFASSUNG1

The region/city of short distances is mostly linked to small scale and neighbourhoods and planning focus is local at the level of a quarter. But: women and men, girls and boys in the 21st century are no longer reduced to a quarter/¬village but are living in functional areas which includes several quarters, village and neighboured city, the whole country and with support of social media, Europe and the world.

Demographic change remixes the cities and city regions: Ageing society, migration flows from rural to urban, multiple residences, changes in working life careers and changes in partner and family models as well as a shift in societal roles of women and men, young and old as well as the related spatial impacts and demands for updating infrastructure are necessary. Looking at these dynamics from a gender planning prospective means, recognizing a growing diversity of time space patterns, looking very closely at users' needs and integrating the „everyday" of daily routines and the spatial requirements of the care economy like social infrastructure and services into spatial concepts. As a planner, I am interested in the interplay between changes in time space patterns (going regional to functional areas) and the necessary adaption of instruments for a gendered planning approach local to regional scale.

Rethinking planning for changing population is in focus of two research and planning projects of the author: „DEMOCHANGE – adaptation strategies to spatial planning and regional development" (Alpine Space countries, www.demochange.org) and an ESF-founded project on "Gender equality in Bavarian rural areas".

Examples and experiences of the authors work from these two projects and further examples from Spain and Finland shall bring some evidence for adapted planning approaches and pathways for the much needed innovations in planning theory and practice for a participative approach for a user oriented infrastructure planning.

Following key questions will be treated:

(1) Which infrastructural needs are emerging and which planning instrument can enhance to plan for functional areas?

(2) How can basic infrastructure co-developed and maintained in times of budget cuts without ?

(3) The everyday at regional scale? How can we plan for functional areas?

(4) What does "integrative planning" and "transdiciplinary" mean in practice?

2 NEIGHBOURHOOD IN FUNCTIONAL AREAS – A GENDER PLANNING APPROACH

It is assumed that spatial planning is intended to provide equal living conditions for all, to combat spatial and social disparities and to ensure equal access to services and labour markets, and that it incorporates the public interest into the development of land by suppressing selfish actions (Fainstein 2009).

It is generally assumed that gender planning supports the everyday life of women and men and opens up perspectives for sustainable development at a communal and regional level (Fainstein and Servon 2005, Horelli and Wallin 2009). Suitable spatial conditions may, for example, alleviate the everyday life of men and women through short distances and good public transport connections and accessibility, through appropriate open spaces, local proximity and a range of infrastructures (Zibell 2006, Damyanovic 2007).

Women have still to combine housework, family work and paid work. They look after children or persons in need of care, manage the household, are gainfully employed and undertake all the trips related to these duties. If planning efforts are to succeed in providing a better quality of life for men and women, it is imperative to include the principles of gender (and diversity) in planning tasks.

[1] The paper is based on a presentation held on Oct 4 2011 at Universitat Politechnica de Catalunya in Barcelona at the ETSAB (=Escola Tècnica Superior d'Arquitectura de Barcelona) during a conference on Urban studies, gender and feminism.

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

But from a feminist perpective, these societal roles of women and men cannot be accepted and confirmed as gendered roles but they have to be de-constructed and changed (Massey 2004, Fainstein & Servon 2005).

Figure 1: Gender planning – key concepts and elements (photo Wankiewicz 2004)

Furthermore, spatial conditions, time space patterns and the scale of daily routines and activities of women and men, boys and girls are changing (Tummers 2007a and b)

In the paper I argue that space time patterns for care economy and for work, recreation and community work and citizens participation are changing from local and neighbourhood areas to regional scales the so called "functional areas".

To give an example about functional areas from the Demochange project: The map shows daily working commuters in 68 communities in Pinzgau, Lungau and Pongau. The spatial commuter patterns show, that the 68 communities – representing the local and the neighbourhood – are oriented towards 6 – 8 working centres, their functional areas. The same upscaling from neighbourhood level to functional areas is happening for care infrastructure, for public and private services and for shopping centres. We can also see a geographical change of personal networks (family, friends and business networks) from neighbourhood and local scale to regional, national and global scale (Demochange Salzburg 2011).

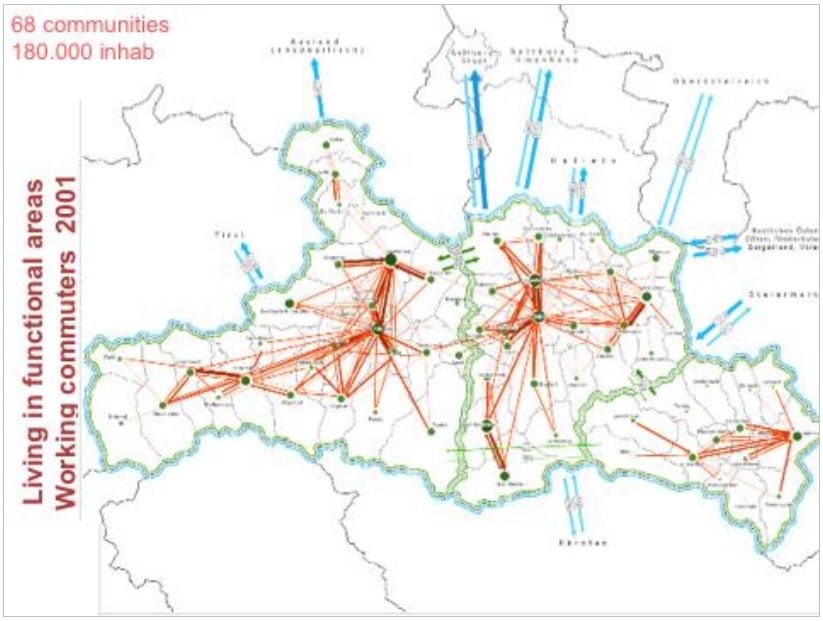

Figure 2: Daily working commuters between communities of the southern districts of Salzburg: Pinzgau, Pongau. Lungau (line sizes shows the number of commuters. (Demochange Salzburg – map iSPACE 2011).

Hence, it is enormously important to upscale a gender planning approach from neighbourhood and local scale to strategic and regional scale: according to Larssons, the integration of gender planning approaches is neglected for spatial strategies and comprehensive planning concepts (Larssons 2006, 25ff). It is much more difficult to ask for the visions and experiences of people, women and men, girls and boys at this complex planning scale. But an essential condition for delivering good local gender planning concepts is the integration of the "everyday" and of the experiences and know how of women and men into strategic planning concepts.

Larssons and others describe the difficulties and obstacles within our planning cultures to involve people into plan making and to transfer the collaborative planning approach from local and neighbourhoods scale to city regions and beyond (Healey 1994, Jacobs 1961). The big challenge is to overcome administrative boundaries from the very strong municipal level – which have much power in planning legislation and implementation in most of the European countries – to weak regional level or functional areas without any administrative or legal power.

The following chapters show several practical examples and propose some core elements and the potential of an upscaled participatory gender planning approach for functional areas.

3 PRACTICAL EXAMPLES OF "PLANNING FOR FUNCTIONAL AREAS"

3.1 Bavaria – gender equality in rural areas[2]

The project has been initiated by the Bavarian State Ministry for Labour, Family and Women as "gender atlas". Atlas means just mapping and analysing data to know more about inequalities of women and men in Bavaria. The author was involved as gender expert for the Grontmij Gmbh Munich in both stages, in project design and in implementation.

One effort of the project team was to involve people into the development and the analysis of the Bavarian districts and communities. So a series of workshop with stakeholders from district level in five so called "reference districts" has been organized. About 160 civil servants, policy makers, heads of local and regional associations and vocational training and educational institutions have been involved into a "reality check": this means to check the results of the quantitative statistical analysis with the perception and qualities as seen from their professional view. In further workshop they brought in their experiences and interests on the definition of a set of goals and fields of action.

The second aim of the team Grontmij – Magel – planwind for the project was to sensitize on the gendered distribution of paid and unpaid (care) work. Then to set benchmarks and to initiate discussions in order to have some impact on policy makers and equality policies.

So the spatial analysis of the Bavarian communities (more than 2800 communities) and districts not only shows the situation of women and men, but also highlights the differences between women and men: Based on the methodology developed in 2007 by the German Federal Institute of Research on Building, Urban Affairs and Spatial Development (BBSR 2007) for a german atlas of gendered differences – the so called "difference map" shows how big are the differences between the sexes. Figure 3 shows the difference of percentage of women and men aged 15 – 65 working in industry and production in district of Oberallgäu, Bavaria: between 13 and 33% more men are working in this sector than women (dark blue)

One important element of the project was to bring into discussion the unequal distribution of care and family work and to show regional differences between metropolitan areas and rural areas.

To give an example: figure 4 shows that more than 90% of parents on parental leave for caring for their young children are women (left map) and less than 30 % even less than 10 % of these parents have been men.

[2] ESF-funded project. Warum Frauen nicht arbeiten können und Männer das Geld verdienen. Mehr Chancen¬gerechtig¬keit im ländlichen Raum Bayerns durch Vereinbarkeit von Familienarbeit, Erwerbs¬arbeit und Freiwilligenarbeit. English translation of the title „Why women cannot work and men earn the money. More equality justice in rural Bavaria through balanced care work, paid work and voluntary work" (author's translation) Munich http://www.stmas.bayern.de/gleichstellung/atlas. online Access 22.09.2011

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

This big difference also has been shown in a difference map to highlight the big inequalities and the gendered distribution of tasks between care work and paid work.

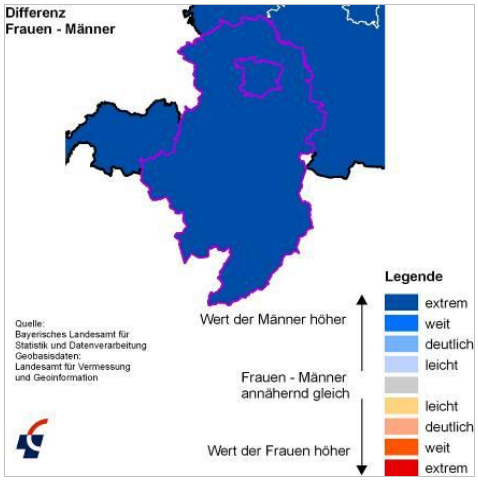

Figure 3: Difference in percentage between women and men working in industry, production and building enterprises in district of Oberallgäu (blue means: value of men higher, red means values of women higher) (Grontmij-Magel-planwind 2011)

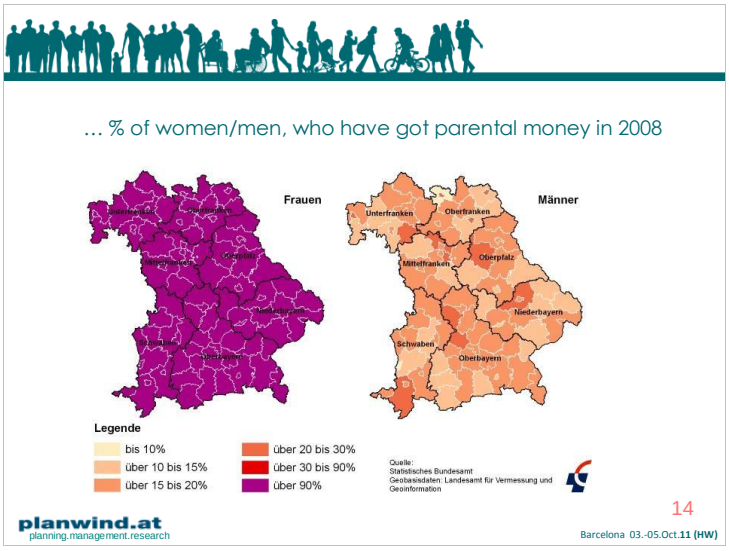

Figure 4: Gendered distribution of child care work between women (map on the left side) and men (right side). The map shows the percentage of women/men of all women aged 15 – 65 being in parental leave. (Grontmij, Magel, planwind 2011)

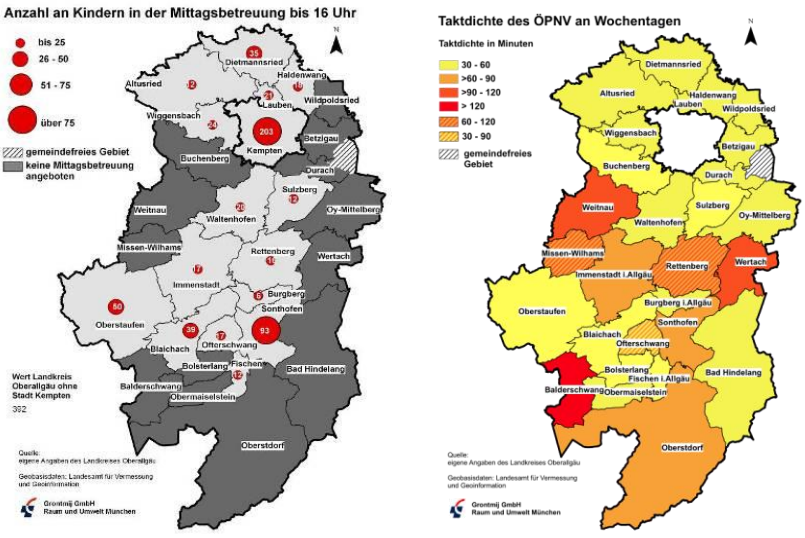

Figure 5: Left: Day care infrastructure with lunch and opening hours till 4 p.m. for children aged 0 – 15 in district Oberallgäu. Size of the cercle according to the number of children. 12 communities are without any day care offer (dark grey areas) Right: Bus schedule at weekdays – dark red colors show frequence less then all 120 minutes (Grontmij, Magel, planwind 2011)

Finally, in four Bavarian districts the statistical analysis has been deepened and linked to spatial conditions and to public and private infrastructures: infrastructures like shops and services for daily needs, the location number, type and the opening hours of child care facilities, the location of schools, the frequency of public transport services at weekdays and at the weekends, the number of households with broadband internet access, etc..

The analysis and the mapping of these infrastructures was done for district level (between 20 – 29 communities) and not only for community level to be close to the concept of functional areas. By this, a discussion about accessibility and quality of services, autonomous mobility of children and adults (without car) and the lack of infrastructures and services could start for district level and for local level. The project focus was limited to research and basic discussions.,

Figure 5 shows two examples of infrastructures closely linked: day care infrastructure with lunch for children aged 4 – 15 and frequency of bus services on weekdays in communities.

3.2 To summarize

The project gives a first overview on gender differentiated statistics in Bavarian districts and communities with focus on imbalances and inequalities in care work, labour market, income, participation in political decision making, education and mobility. But: the quality of statistical data is not satisfying: very few data are available for community level to give detailed information about the local level and show differences and qualities within districts. Within the project, it was not possible to analysis the spatial situation and the location, number and quality of public infrastructure for Bavaria, but only for

Participation and involvement of people only was possible for the spatial analysis and a general set of goals and measures.

It is just a starting point for regional and local gender planning projects to co-create the essential infrastructures for everyday life and to initiate projects for more equality between women and men.

4 DEMOCHANGE SALZBURG.[3] A PARTICIPATORY APPROACH FOR CO-CREATION OF INFRASTRUCTURE AT LOCAL LEVEL FOR FUNCTIONAL AREAS

DEMOCHANGE – demographic change in the Alps is an INTERREG IV B – Alpine Space project funded by EU 2010-13. 13 partners from Germany, Austria, Slovenia, Switzerland and Italy cooperate to raise awareness, decide on strategies and pilot actions to face the challenge of ageing, multicultural and gendered societies. In focus of the project are the spatial effects of demographic change and the development of strategies and measures in spatial planning and in regional development. The author is project manager and gender planning expert for the federal state government of Salzburg, department of spatial planning.

Each of the 13 partners started a participatory process in a so called model region to co-develop a common diagnosis of the challenges and options (regional analysis), to choose a focus issue and than to co-develop appropriate strategies and measures with regional and local policy makers.

Salzburg model region is the southern rural part of Land Salzburg. Three very different districts in size, in accessibility, in landscape, built environment and cultural life. 184.000 inhabitants (2008) – this is about 40% of Land Salzburg population – 68 communities. This means 66 male mayors and 2 female mayors, in total 68 local administrations and community councils governing communities from 250 up to 15.000 inhabitants with 8 regional centres with more or less urban housing, shopping and service structures.

Not only the size but also landscape and settlement structure, accessibility, economic and social structure of the communities are different. From suburban situation – 30 minutes driving or public transport distance from city of Salzburg – to remote and periphery situation with travelling distance up to 2 ½ hours to city of Salzburg.

Economically, the region is highly touristic with strong winter tourism industry: in some smaller communities the number of tourists per inhabitants is very high, e.g. in the ski resorts of Region Amadé, in Obertauern, in Kaprun-Zell/See and in Saalbach-Hinterglemm. There is also summer tourism linked to national park ‘Hohe Tauern’, hiking, climbing, mountain biking and trekking activities.

[3] Details on project structure, partners and results see www.demochange.org (international webpage) and www.demochange.at (Salzburg webpage)

There is a considerable number of industry and commerce enterprises, in building sector, in metal construction (Liebherr cranes), plastic industry (Senoplast), aluminium industry (SAG-Lend) and skiing industry (Atomic & Blizzard – already in international ownership).

Strong changes in age structure, migratory movements, labour and family models: The population in the 3 districts has been growing within the last 20 years, it is foreseen that till 2030 the population stays stable. There is only one region which looses population and is shrinking a long term – the district of Lungau (district of Tamsweg). The average age of the population in the model region now is 40 years, 2032 it will rise up to 45 – 47 years.

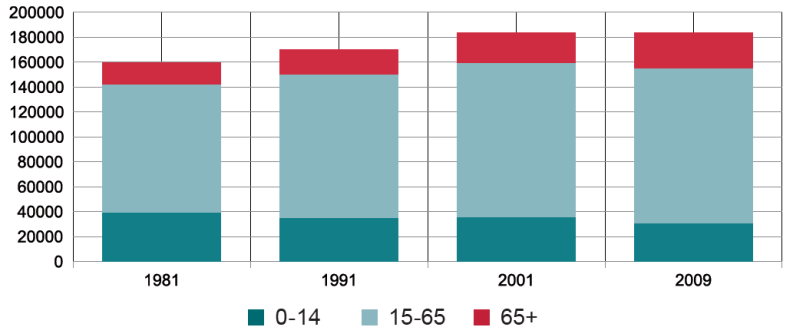

Figure 7: Change in age structure 1981 – 2009 per age cohorts in the Salzburg model region. (Statistik Austria 1981,1991, 2001, 2009, Demochange Salzburg, 2011)

We see strong migration movements from small communities to centres, loss of services and infrastructure in smaller communities and growth of shopping areas and infrastructure in the regional centres. We see strong in-migration of work-force since the seventies into tourism and industry: from ex-Yugoslavia, Germany and Turkey. We also see in migration from Germans, Dutch and British newcomers who first bought secondary homes, than stay as new residents, this brings more diversity of nationalities, lifestyles and family models. We see out-migration of young people, more women than men, following higher education opportunities, urban cultures of cities and job offers. This causes a mismatch between job offers and job demand as well as educational careers of young people (see UPIRS 2011).

Family models have been changing, from couple 2 children models to "patchwork families" with children from different parents, single mothers, LAT partnerships (="living apart together") and lesbian-gay partnerships. Female participation in the labour market – strongly demanded by EU and chambers of commerce to fill the gap in workforce – is raising but still restricted if women become mothers: part time work is female, child care is still mother's affair and day care for children aged 3 and less and full day care is only offered in district centres. Same for day care for elderly and ambulant assistance and terminal "hospice" care.

Figure 8: Public participation for co-developing infrastructure at local and subregional level . focus group interviews with young girls and boys (picture Demochange/ Kurt Kaindl 2011).

4.1 The pilot action "Public participation in Fusch and Lend (Unterpinzgau region)" builds on the two focus questions of the DEMOCHANGE project in the Salzburg region:

- How to define and keep quality of life and basic services in small communities with shrinking budgets in competition with the regional centres?
- Which strategies and measures for mobilizing civil society together with politicians in small communities to face regional dynamics on a boarder crossing level?

Main aim is to mobilize citizens for action in two very small and shrinking mountainous communities, Fusch and Lend. The focus is first to co-define quality of life and standards in social and supply infrastructure, second to co-develop models of implementation and maintenance for these infrastructures in times of budget cuts and recession.

Methodologically, in each of the communities a public debate/citizen forum as well as a survey of different social population groups has been carried out. The results are used as basis for a wider discussion with local and regional decision makers to upscale the question of infrastructure to the functional area.

Extended concept of demographic change: To address the challenges within the model region and in these communities, it has been useful to use a broader understanding of the demographic change concept: Merging the complexity of demographic change with the complexity of social change processes and bring these changes in wider discussion among politicians, regional developers, local stakeholders and the general public. This means not only analysing and discussing demographic trends in population development, like low fertility rates, changes in age structure, shrinking or growing population. But also looking closely at societal changes – caused by the progress in gender equality and in shifting gendered roles. Societal changes described as individualisation, lifestyles, polarisation between social groups. Societal change caused by migratory flows from rural to urban and from urban to rural, European and global migratory flows. Change of labour & working conditions for women and men and new information and communication technologies (Definition based on ZGB 2005).

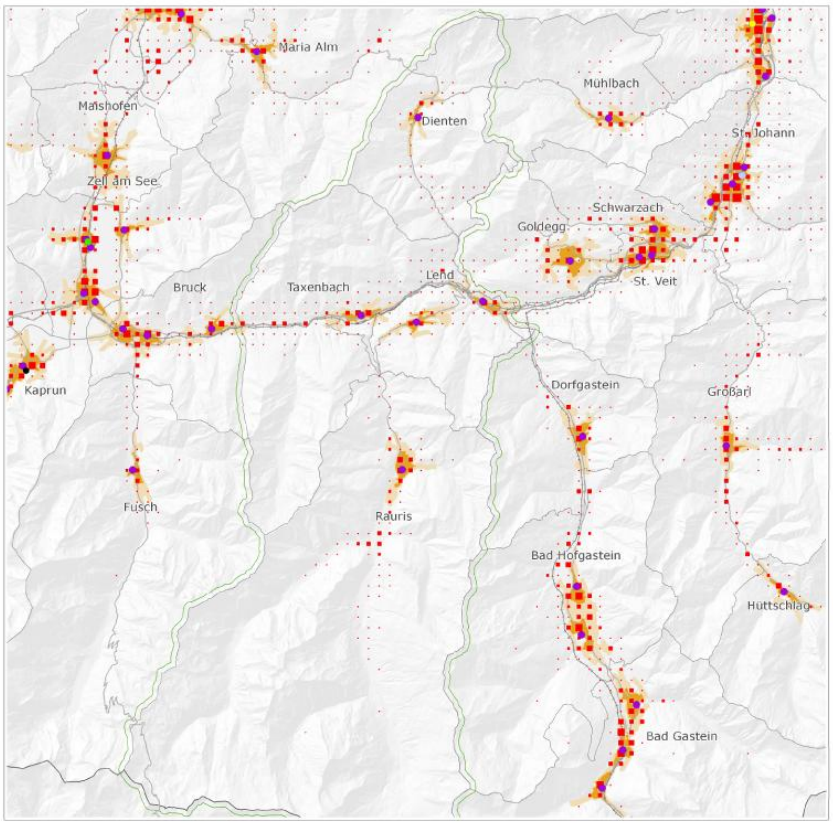

Figure 9: Demochange Model Region Pinzgau. Distribution of residents (size of orange squares show the number of residents), care and educational infrastructure (colored cercles) in communities (typed name of the community) in Lower Pinzgau region, Salzburg: (Demochange Salzburg., map iSPACE-2011)

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

Further the distribution of services and the number of residents within easy access (pedestrian distance) has been mapped to discuss accessibility and mobility issues within the community and in the region (see Figure 9).

Finally, the extended concept of housing from Barbara Zibell has helped a lot to understand the wider spatial implication of infrastructures beyond the building, beyond neighbourhood (see Figure 10). 'Housing' includes the quality of the building as shelter and home. It also includes the function of housing as place of recreation but also as place of (care) work and by this the need for accessible infrastructure. And on top of the triangle, housing includes the social process of integration, growing up into a family, into a neighbourhood, settling/immigrating into a neighbourhood, into a city, region and state.

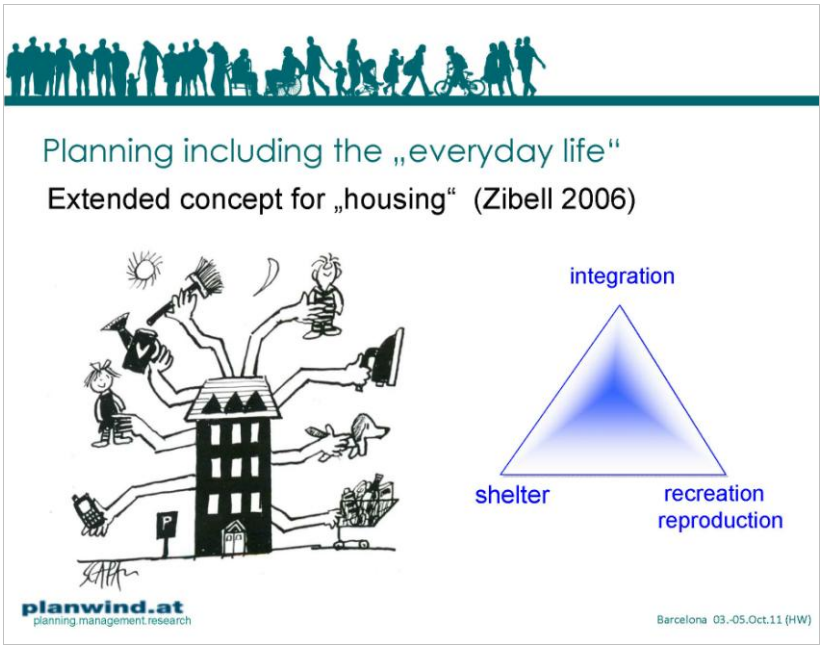

Figure 10: Extended concept of housing applied for the Demochange project for planning the everyday for Pinzgau region (Zibell 2006, Cartoon by Scapa 1999).

4.2 To summarize

DEMOCHANGE project by integrating social change into the concept of demographic change makes it possible to work on gender planning issues for local and regional planning tasks. By this, the Demochange approach brings back the essential of spatial planning principles and legislation: spatial planning as a task to provide spatial structures for equal living conditions, appropriate number and quality of housing, care, services and educational infrastructure and to (co-)develop new infrastructures for the interests of everyday life (Larssons 2006).

Concerning the pilot actions for co-creation of infrastructure: it is difficult to upscale the discussion and the participatory process from local and community scale to functional areas and regional scale: functional regions are clearly in the heads and everyday lives of citizens; but planning for these regions is still a challenge.

5 PUBLIC TRANPORT SCREENER (PTS) – ACCESSIBILITY FOR ALL CITIZENS TO BUSES IN CITY REGIONS

The research project Public Transport screener[4] is the last example of a planning approach to improve infrastructure offers and accessibility in functional regions is. Research Studio iSPACE realizes the project in cooperation with 3 complemen¬tary business partners: TraffiCon, Prisma solutions, planwind.at.

PTS develops target group specific spatial planning tools for the assessment and planning of accessibility of public transport stops and the quality of service within public transport. A special focus is given to people

[4] PTS-Public Transport Screener is funded by Austrian Ministry for Transport, Technology & Innovation in the 3rd Call for ways2go in 2010 and is cofinance by the research team Reseach Studio – iSpace, TraffiCon, PRISMA solutions and planwind.at. (for more information on the project see http://www2.ffg.at/verkehr/projektpdf.php?id=765&lang=en)

with mobility impairments like senior citizens with walkers and wheelchairs but also parents with push chairs and children bikes. On the basis of existing scientific findings, specific requirements of mobility as well as aspects of traffic and urban and regional planning are merged. By this a demography-oriented evaluation and planning model for the accessibility and quality of services within public transport is generated within the project PublicTransportScreener.

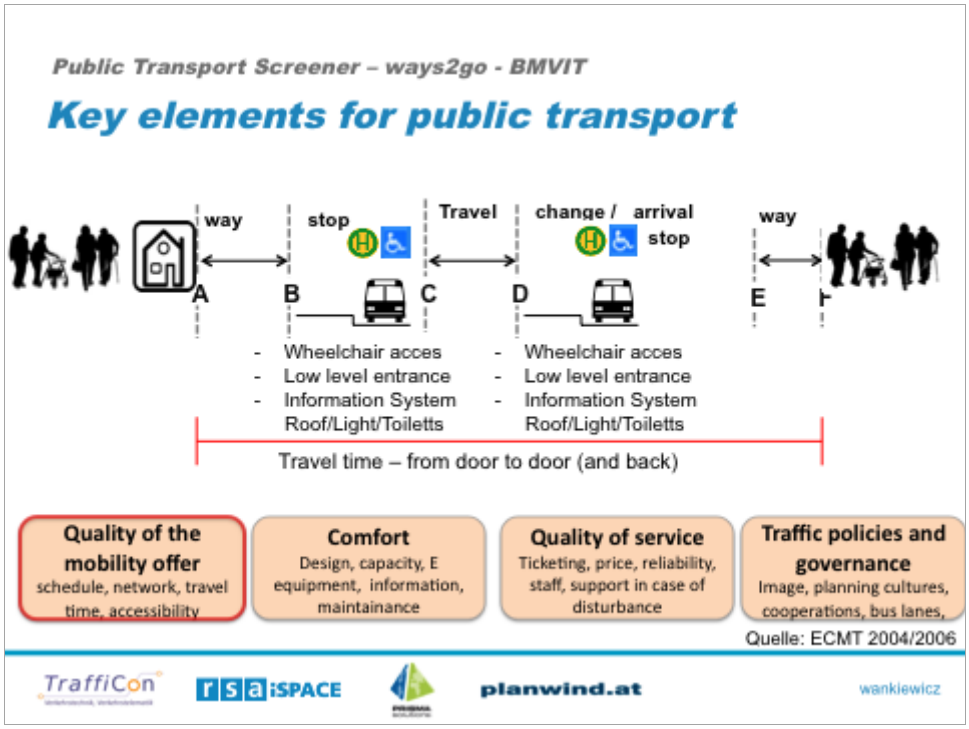

Figure 10: Key elements for assessing the quality and accessibility of public transport offers within the project PTS.

A target group specific assessment of the quality of services (e.g. service interval, travel-time) will be carried out via an interlinkage of traffic demand and offers of public transport. The imple¬men¬tation and evaluation of PTS is done in the Greater Salzburg Region for a Bus offer which crosses the whole region from more rural area Mondsee till urban Salzburg.

5.1 To summarize

For me as a planner, I am very concerned about the priorities of infrastructure planning and applying technical tools like GIS and Webapplications. Being the ("social") planner within the research team, I argue not using out of sight users needs and priorities: The interesting thing for me as a planner is the big gap between the potentials of the data—application on the one hand and the reality and the human side. As shows the project Public Transport Screener and other infrastructure projects for barrier-free and accessible mobility offers for a diversity of people: it is much more important to have a basic frequence and service quality than to have an 'app' for the schedule and the ticketing. There is no use to have an app about the quality and accessibility of bus stations (barrier-free) if there a no busses adapted to wheelchair users and walking frame users (which is the case for the chosen bus line). Finally, the service quality of bus drivers and the politeness and patience of passengers who not only accept longer stops to wait till aged people with walking frames, parents with push chairs and people with heavy luggage enter the bus but even give a helping hand to them. So it is evident, that planning infrastructure for the everyday for a mixed and divers city and city region has to integrate people into a participatory approach for assuring needs oriented planning.

5.2 Further examples for planning the everyday for a mixed city region

The number of (gender) planning approaches for functional regions which go beyond local level and is aiminga at a diversity of users and – by this – supported mixity – are limited. To the author's knowledge the following examples have to be mentioned:

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)

- Spatial Strategy for the Greater Salzburg region – binding for local level, no participatory approach (Land Salzburg – GenderAlp! project, Wankiewicz 2009)
- Zuid Holland – Room for everyone's day, a complementary spatial strategy and a Do it yourself tool developed by a participatory approach the "group decision room" (Tummers & Wankiewicz 2008, Provincie Zuid-Holland)
- Perspective Munich 2030 – Greater Munich spatial strategy with a broad participatory approach for the long term development of city of Munich and its neighbour communities.
- Helsinki community development for co-creation of infrastructure with focus on health and happiness (Horelli 2009)
- The Vienna Strategy plan including strategic elements of gender mainstreaming and gender planning

6 CONCLUSIONS & OUTLOOK

If we want to plan for the "just city" or the "just region" (Fainstein 2009) –we need a gender planning approach at all scales: local planning needs good structures and spatial strategies at regional level in the functional areas. The regional plans and spatial strategies set the framework for the local and neighbourhood planning. If accessibility within the city and the city region is not assured, local activities cannot be successful.

If we want to reach the vision of a just city/region with mixed uses and mixed population, spatial planning has to adopt a holistic approach: crossing boundaries between communities, city and surrounding regions, what we call "functional regions" instead of administrative boundaries.

A holistic approach also means crossing boundaries between sectors like social infrastructure planning, family policies, transport planning, built environment and equality policies. But also: involving people to ask for their needs, their quality standards and their definition of accessibility, mixity and userfriendly environments and service offers.

If we want to develop a just and divers (mixed) city/region, we have to experiment with participatory and collaborative planning approaches, experiment with the knowledge, the visions and successful policies of citizens of both sexes as residents, as members of grassroots groups, as commuters how to plan AND govern a functional region, a city region (cf. Andrews/Tummers 2006).

We need methods and instruments for involving people and their experiences as everyday users into comprehensive planning like we have for local and neighbourhood level. We need a "Jane's walks" or the methods of Col-lectiu punt6 (cf. Muxi Martinez & Ciocoletto 2009) or other successful neighbourhood planning approaches for large scale functional regions. Planning is about people – webtools and gis-tools are only supporting instruments. To quote Fainstein in this matter from her paper on the equal just city 2009:

In furtherance of democracy:

Plans should be developed in consultation with the target population if the area is already developed. The existing population, however, should not be the sole arbiter of the future of an area. Citywide considerations must also apply. (Fainstein 2009)

Transdisciplinarity, as defined and put into practice by Cassinari et. al (2011) could be the key concept to assure user satisfaction and to support diversity and mixity in the city.

1 ABSTRACT

Urban planners become more aware that climate change is likely to have influence on the liveability in cities. Therefore, the number of planning authorities increases that want to evaluate the climatic effects of urban developments. However, the information required to do so is often not easily available. Remote sensing data provides independent, area wide and up-to-date spatial information. Therefore, this contribution addresses the question if remote sensing techniques can help to optimise mitigation strategies for climate change in cities. Several parameters describing the urban climate can be directly mapped by remote sensing, such as albedo and surface temperature. However, the main use of remote sensing is expected in the mapping of the urban land cover and morphology. The urban climate is strongly influenced by the spatial characteristics of the city. Area wide maps of spatial parameters such as impervious surface or vegetation fraction can provide insight in expected climatologic situations because of the strong relationship of these spatial parameters to climate and humidity. Climate models, used to evaluate different planning scenarios, can make advantage of accurate spatial description of the area of interest. However, existing climate models will need adaptation to be able to use the remote sensing data.

2 INTRODUCTION

The awareness about climate change and its possible consequences for urban areas is growing. The prospects of global warming will be specifically dramatic in urban areas (KUTTLER, 2004). In Germany this resulted in an increasing interest of planning authorities who want to evaluate the climatic effects of their planning activities. Their objective is to maintain the liveability of cities in the future. With climate changes such as the expected increase of hot summer days (DWD, 2011), it is important to create places with reduced temperatures and to facilitate corridors of fresh air.

To assess the consequences of climate change for urban areas and to develop effective mitigation strategies, information is required on the possible changes of the climate and on the effect of changes in the city structure and land use (new buildings, parks, streets) on the local climate. By combining this knowledge, it can be learned which urban changes will likely aggravate unwanted climatic effects and which urban changes can mitigate them. The local climate depends on the regional climate and the local surface and morphology characteristics, such as the size, number, shape and orientation of buildings and other urban objects, the materials used or the amount and type of vegetation (OKE, 1988a; OFFERLE ET AL., 2007; CHEN ET AL., 2009). The interaction between those variables, determine the actual temperature, the wind speed, humidity and air quality. In table 1 it is shown for a selection of urban spatial characteristics how they contribute to these four main climate surface parameters. Information on these four main climate parameters can be derived directly by using in situ measurements, indirectly by using indicators or based on simulations. In situ measurements, for example by weather stations, are highly accurate and often provide long time series of data. The variation over time is relevant to understand the relations with human activities and seasons or to monitor the change of the situation. However, the spatial variation of the values of the parameters is important to gain an overall impression of the complex climatic structure of the city as well (XU ET AL., 2008). This information can seldom be provided by in situ measurements, because the observational network is often too coarse. Measurements with equipment installed on vehicles are an improvement, but still cannot provide area wide coverage (WENG, 2009). By making use of spatial indicators, parameters such as temperature, humidity etc. can be estimated area wide. Many studies have been carried out to quantify the relationship between the surface parameter and the climate parameter of interest (e.g. WENG ET AL., 2011, ZHANG ET AL., 2009). Finally, powerful tools to study both the actual and future climate are models and simulations. Models allow the assessment of many different situations while requiring a limited amount of in situ measurements. For example, SHASHUA-BAR & HOFFMAN (2003) and ZHANG ET AL. (2004) studied the influence of street and building geometry (street canyons) and trees on air temperature and wind using numerical modelling.

Area-wide spatial knowledge is of crucial importance to understand the climate situation in cities, but such information is often too generalized, outdated or not even available. Remote sensing data provides independent, area wide and up-to-date spatial information on the earth's surface. Remote sensing data is thus suitable for the mapping of surface characteristics which influence the urban climate (see table 1). Hence, this contribution addresses the question to which extend remote sensing can help to find out what the effect of climate change on urban areas will be. For that purpose we provide and discuss examples of relevant remote sensing products from literature and several studies in the city of Munich, Germany.

3 MEASURING CLIMATE PARAMETERS

Remote sensing makes use of the electromagnetic radiation reflected or emitted by the Earth's surface (LILLESAND ET AL., 2004). Different surface types reflect, absorb or emit the radiation (light) with different intensity in different wavelengths. This information is used in the analysis of remote sensing data to map different land cover types. The net radiation is an important parameter in the urban energy balance which describes the heat fluxes. The net radiation is the sum of the incoming minus the reflected short-wave radiation (albedo) and the incoming minus the out-going long wave radiation (thermal radiation) (OKE, 1988b).

Surface albedo is a key terrestrial variable controlling the surface energy budget. It is defied as an Essential Climate Variable (ECV) by the Global Climate Observing System (GCOS, 2011). There are several global albedo products available, such as those derived from the MODIS satellite (SCHAAF ET AL. 2002) or from the Meteosat and GOES satellites (GOVAERTS ET AL. 2008). Although these products are updated regularly (at least weekly), the spatial resolution is very coarse (> 1 km). For the calculation of the urban energy balance, higher resolution data is required. In RIGO & PARLOW (2007), Landsat data (30 m) is used to derive the albedo of the city of Basel, Switzerland. The objective was to calculate the ground heat flux, which contributes significantly to the development of urban heat islands. To calibrate their models, they used ground measurements. Figure 4c shows an example of the surface albedo for a building block in Munich, derived from airborne HyMap data with a spatial resolution of 4 m.

The thermal radiation measured by remote sensors is usually converted into surface temperature. Surface temperature is important for the estimation of the energy budget and for bio-climatic studies, among others (MITRAKA ET AL. 2012). Figure 1 shows the surface temperature of the city of Munich for a summer day in 2007 as recorded by two different sensors. The whole city is recorded by the space borne Landsat sensor, with a spatial resolution of 60 m. A subset of the city was also recorded by the airborne Daedalus sensor with

Urban spatial characteristics	**Climate surface parameters**

Table 1: Overview of urban spatial characteristics that influence the four main climate surface parameters. H/W ratio = height/width ratio.

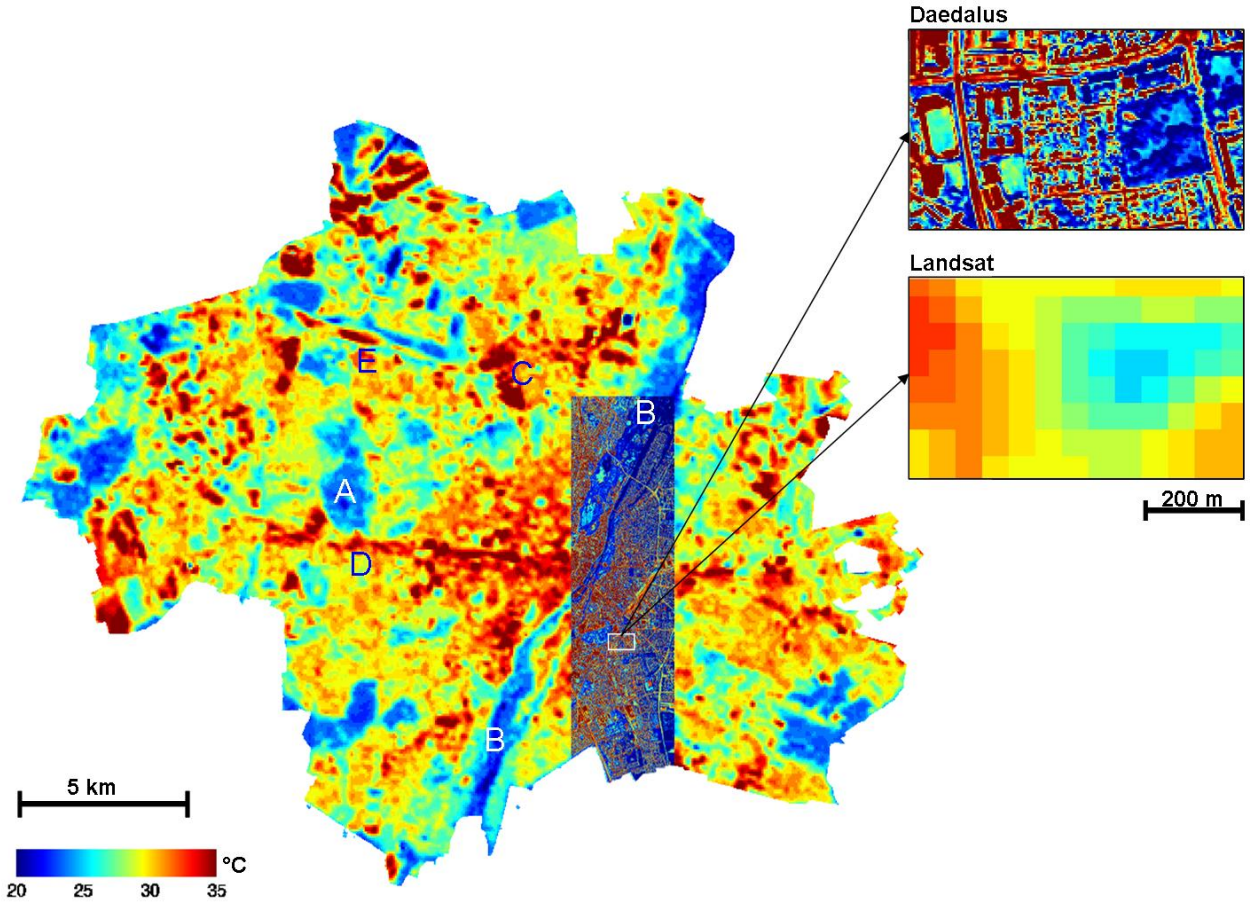

Figure 1: Surface temperature of Munich at a summer day in 2007, mapped by the space borne sensor Landsat (30 m spatial resolution) and the airborne sensor Daedalus (4 m spatial resolution).

a spatial resolution of 4 m. The image shows several interesting thermal patterns. Clearly recognisable as colder areas are for example the large park belonging to the castle Nymphenburg (A) and the flood plains along the river Isar (B). The densely built city center has high surface temperatures, as does the industrial site in the north of Munich (C). Also the two main railway tracks (D, E) with neighbouring industrial and bare surfaces are warmer than their environment and clearly recognisable as line structures. The zoom images on the right show the difference in detail between the two sensors. In the Landsat image almost no differentiation except for a larger park is possible. In the Daedalus image, on the other hand, the differences in surface temperature between buildings, vegetation and roads is clearly visible.

4 MAPPING SURFACE CHARACTERISTICS RELATED TO URBAN CLIMATE

As already shown in table 1, many surface characteristics influence the urban (micro) climate. Nine of the twelve characteristics listed in the table can be derived with remote sensing by different sensors. The retrieval of building structure, H/W ratio and sky view factor require a digital elevation model which can be derived from stereo imagery or laser scanning. Commonly, airborne sensors are used because they can provide spatial resolutions that are high enough for this purpose. Land cover, impervious area, vegetation fraction and water can be mapped with a large range of airborne and satellite-based sensors, since also satellite-based sensors provide sufficient spatial resolution for the discrimination of individual urban objects such as buildings. For the measurement of albedo, a sensor is required that records the radiation in a broad range from the visible to the short wave infrared. On the opposite, emissivity requires thermal remote sensing that records the radiation in the long wave infrared.

Since these spatial characteristics can be very well mapped with remote sensing, many studies exist in which the relation of such spatial characteristics with climate parameters are analysed. Most studies are concerned with the climate parameter temperature. For example the relationship with imperviousness (e.g. ZHANG ET AL., 2009; YUAN & BAUER, 2007; XIAN, 2008) and fractional vegetation cover (e.g. JENERETTE ET AL., 2007; WENG ET AL., 2004) has been analysed. Also the relationship of spatial characteristics to the climate parameters wind (OFFERLE ET AL., 2007; ELIASSON ET AL., 2006) or air pollution (WENG &

YANG, 2006) have been studied, although less frequently because the influence of spatial characteristics on these parameters is not as strong and often indirect via changes in temperature.

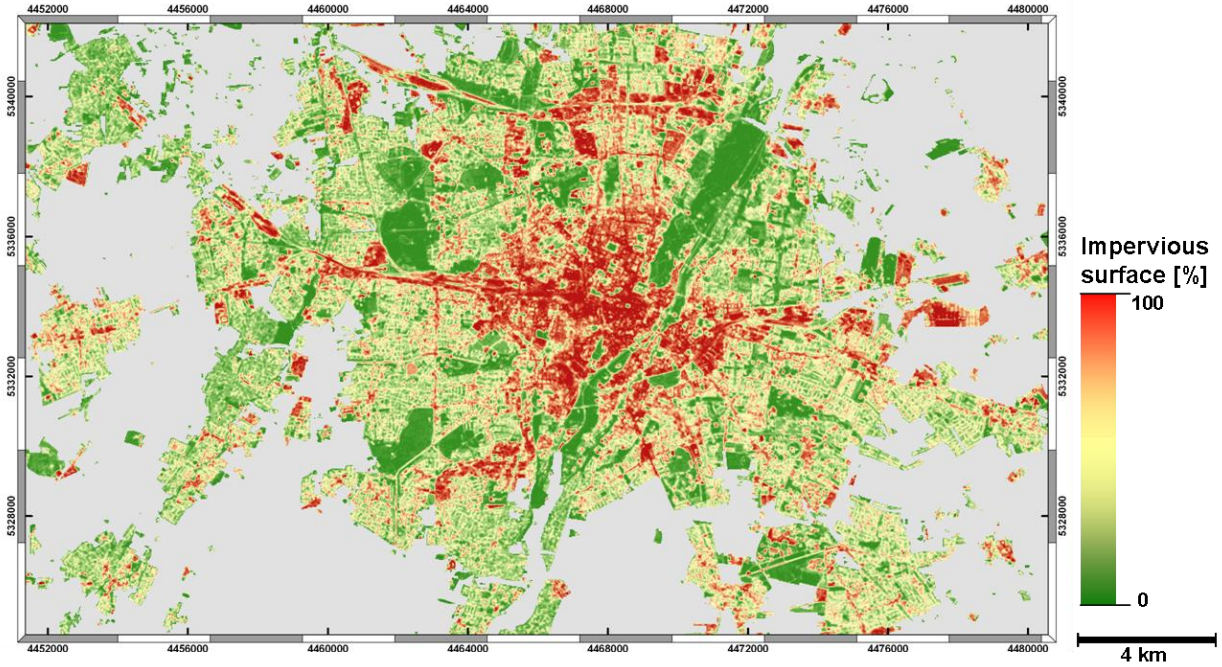

Figure 2: Impervious surface for the city of Munich, derived from space borne Landsat data.

Making use of known correlations, a map of surface parameters such as imperviousness or fractional vegetation cover provides already a lot of information on locations in the city where the (surface) temperature is likely to be higher or where the humidity will be lower. As an example, a map of impervious surface derived from Landsat data and a map of vegetation density derived from airborne hyperspectral HyMap data is shown in figures 2 and 3. They both show the city of Munich. The map of impervious surface in figure 2 has a spatial resolution of 30 m and was derived using a Support Vector Machine approach (ESCH ET AL. 2009). The city center has a much higher percentage of impervious surfaces than the residential areas in the outer districts of the city. The inverse pattern is visible in the vegetation density map (figure 3). The vegetation density is calculated using a spectral unmixing approach and is subsequently aggregated to building block level (HEIDEN ET AL., 2012). Both maps seem to indicate that in the city center higher temperatures can be expected. However, there are several areas within the center where people can retreat if it gets too hot: the small parks (green spots in figure 2) in the northern part of the city center and the large parks along the Isar, forming an SW-NE green corridor.

5 SUPPORTING CLIMATE MODELLING

The use of models is common praxis for climatologists and meteorologists. The most well-known examples are of course weather forecasting models. Dynamic models, or forward models, have the possibility of simulating ongoing processes. Because of their predictive capabilities, such models can be used to simulate different scenarios. This is a useful feature for urban planning. It allows the evaluation of climatic effects of planned urban development projects prior to the, often irreversible, realisation of a project. Many different climate models exist. They vary among others in the climate parameters they address, the spatial scale and complexity (ARNFIELD, 2003).

For the evaluation of urban developments, local scale models are most suitable. Examples of local scale urban climate models are MISKAM (EICHHORN & KNIFFKA, 2010), ENVI-met (BRUSE & FLEER, 1998) or MUKLIMO_3 (SIEVERS, 1995). The spatial environment is always one of the input parameters of climate models. Vegetation fraction, imperviousness and surface roughness are some of the parameters commonly used in climate models to describe the environment. Some models assume default values for these parameters. Other models, mainly at global and regional scale, retrieve land cover or land use types from maps or remote sensing data (e.g. GlobCover) and assign to each type a defined set of spatial parameters. Only few models allow for a detailed description of the environment and the according parameters (PINTY

ET AL, 2006). An example of such a model is ENVI-met (BRUSE & FLEER 1998). This model requires a detailed description on the location and characteristics of all urban objects in the modelled environment. In a study carried out in the city of Munich, as many input parameters as possible required by the ENVI-met model were derived from hyperspectral remote sensing and airborne stereo imagery. Table 2 shows, that more than half of the required parameters can be generated on the basis of remote sensing data. Remote sensing comes to its limits when soil or material properties are required. Due to the bird's view it is also not possible to provide data on vertical or hidden structures, e.g. building walls. Also the weather conditions cannot be derived from the remote sensing data. However, the weather conditions can be used for the description of different scenarios, to simulate different (future) climate conditions.

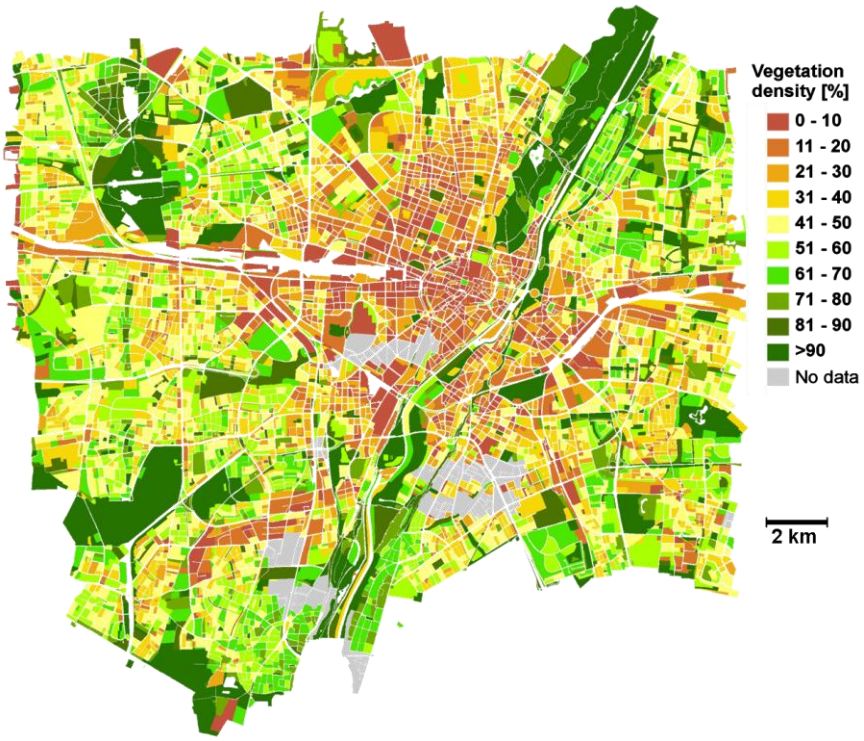

Figure 3: Vegetation density per building block derived from airborne hyperspectral remote sensing data for a subset of the city of Munich.

Input parameter		**Source**
Buildings	Location	HyMap data
	Roof material	HyMap data
	Height	Stereo imagery
	Material properties: reflectance properties	HyMap data
	Material properties: thermal inertia	Literature
Vegetation	Location	HyMap data
	Type (deciduous, coniferous, grass)	HyMap data
	Height	Stereo imagery
	Leaf area density	HyMap data
	Photosynthetic and evapotranspiration properties	Literature
Non-build surfaces	Location	HyMap data
	Type (impervious, pervious)	HyMap data
	Soil properties (hydrological)	Literature
Weather conditions	Temperature	Weather station or simulation variable
	Wind speed	Weather station or simulation variable
	Date, sun dawn, sun set	Depending on location

Table 2: Input parameters and their sources required for urban micro climate modelling with ENVI-met

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

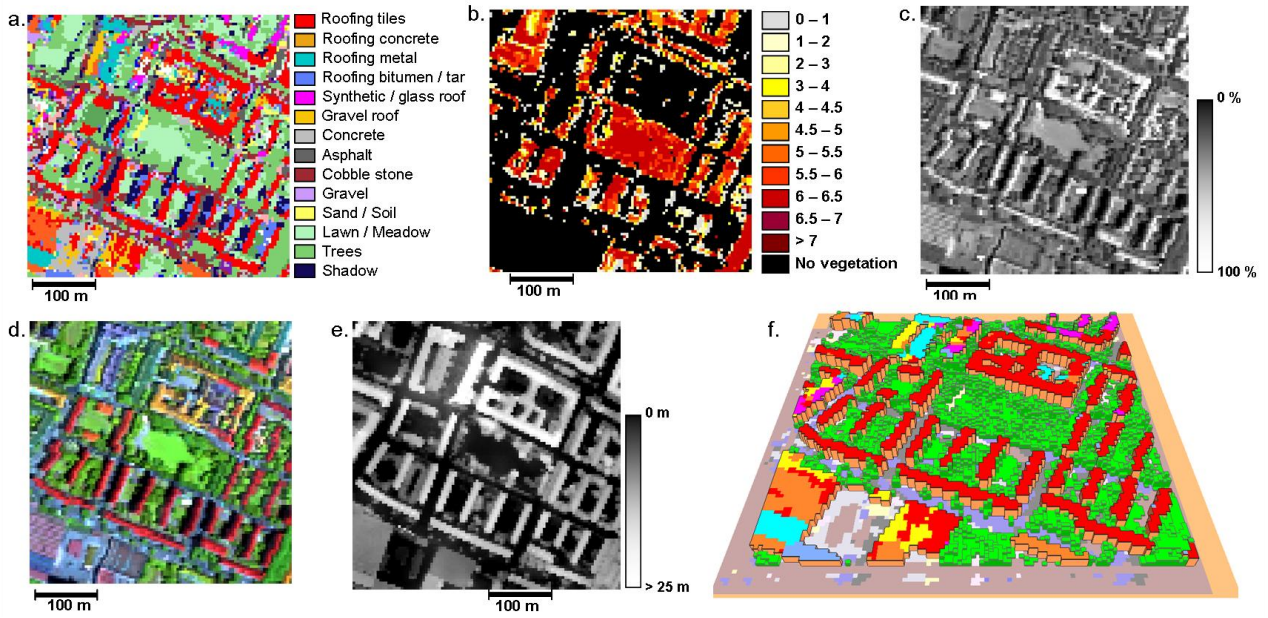

Figure 4: Input data for the micro climate model ENVI-met. Upper line: maps derived from the HyMap data: surface materials (a), leave area index (b) and albedo (c). Lower line: the HyMap subset (d) and DEM subset (e) of the study area and the final 3-D input file for the model (f).

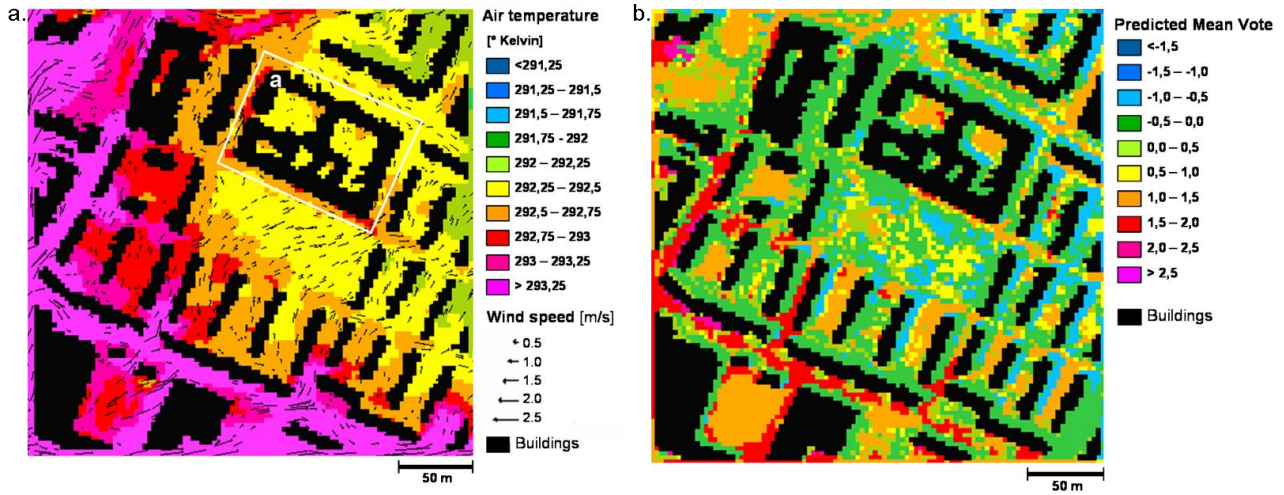

Figure 5: Simulation results of the ENVI-met model using input data from remote sensing: a) air temperature and wind speed, b) the human comfort index PMV.

From the hyperspectral data, the land cover type is derived at the level of surface materials (figure 4a). This airborne data set is also used for the retrieval of leaf area index (fig. 4b) and albedo (fig. 4c). The digital elevation model (DEM) provides the height of the buildings and vegetation (fig. 4e). The methodology is described in detail by HELDENS (2010) and HELDENS & HEIDEN (2010). This results in a 3-D input file for the ENVI-met model (figure 4f). The 3-D file is then used for the simulation of the urban micro climate over 24 hours. Because of the long computation time to date, only a small area of a few building blocks can be simulated at once. Some results of the simulation are shown in figure 5. It shows the simulated air temperature and wind speed at 15:00 at 1.5 m height. In the simulated scenario a south-western wind is assumed. Figure 5a shows that the wind influences the air temperature. In the building block marked with A the wind speed is almost zero. The temperature lays around 292.3 K (19.2 °C) in this building block. At the sun-exposed sides of the buildings the air temperature is higher: around 292.8 K (19.7 °C). It should be noted that the temperature variation within the area is all within 3°. Figure 5b shows another result from the simulations: the predicted mean vote (PMV) at 15:00. The PMV is a human comfort index, which provides information on the well-being of humans. Originally PMV was developed for the assessment of indoor climate by (FANGER, 1970), but was then adapted for assessment of the outdoor climate (BOUYER et al., 2007). The index is based on micro climate characteristics and physiological, clothing and movement

characteristics of a person. The values range from -3 (a person would feel uncomfortably cold) to 0 (comfortable climate situation) to 3 (a person would feel uncomfortably hot). Figure 5b shows that there are no very uncomfortable locations in the study area at this time of the day. However, on the west and south sides of the buildings, a person would feel slightly warm (PMV around 1.7). On the other hand, at the east (and thus shaded) sides of the buildings a person would feel slightly cold (PMV around -1).

6 DISCUSSION AND CONCLUSION

In the previous sections, a range of remote sensing products has been shown that are relevant for urban climate analysis. The large variety of sensors that are available enables the mapping of a vast number of parameters. The area-wide and large spatial coverage of remote sensing data enables the analysis of complete neighbourhoods or even cities at once. Frequent images acquisitions and automated mapping algorithms allow the fast updating of maps. Can remote sensing help to optimise mitigation strategies for the influence of climate change on urban areas? The examples in the previous sections show that except for albedo and surface temperature, remote sensing products provide only indirect information on the urban climate. In order to draw conclusions on the urban climate, in situ measurements or climate simulations are indispensable. But, since the spatial characteristics play an important role in the urban micro climate, remote sensing can certainly contribute to the assessment of the urban micro climate and its interaction with the urban environment. The combination with remote sensing data seems especially valuable for the support of in situ measurements and for the support of climate modelling.

Remote sensing-based mapping of impervious surface, fractional vegetation coverage etc. can provide a first impression where unwanted climatic conditions are likely to occur first. These locations can then be selected for in situ measurements or climate simulations. Because of the frequent and large spatial coverage of remote sensing data, detailed monitoring of urban areas is possible. This way, climatologically undesirable urban developments can be recognised fast and without extensive simulations, by using relevant spatial parameters as indicators. Time series dating back to the 1970s allow us to learn from changes in the past. Combining a time series of spatial parameters, e.g. impervious surface, with long time measurements of air temperature will provide valuable information.

A further promising application of remote sensing products for climate analysis is to use them as input data for climate modelling at different scales. This supports a fast and flexible generation of the input data for such models and enables the models to simulate the actual situation. By simulating different scenarios, it can be assessed which urban developments successfully mitigate unwanted climate change effects. However, existing climate models will need adaptation to be able to use the remote sensing data.

1 ABSTRACT

Cities are dynamic and complex in nature and have interdependent systems that are vulnerable to urban hazards and natural hazard risks (Godschalk, 2003). At one hand cities are hubs of intense resources, technological development and they offer solution to various global issues like technology for low carbon development; use of renewable resources; energy efficiency developments; green buildings and mitigation strategies at large for sustainable human development. On the other hand, cities are sources of environmental degradations and green house gas emissions. The urban areas of cities of developing countries are characterised by low density urban sprawl, fragile infrastructure, low resilience and poor coping capability of people. Thus people and development are vulnerable to disasters and climate change which wipe off years of development causing death and injury.

The need for urban disaster management emphasises on identifying and reducing risks and vulnerabilities, along with tapping potential opportunities for low-carbon urban development. Sustainability and resilience are interdependent and can be promoted through a combination of strategies such as integrated urban planning, high density compact planning, mixed land uses; identifying synergies between disaster risk reduction and adaptation; improving urban service quality and promoting green buildings and sustainable transport [1]. There is a need of paradigm shift in traditional urban planning concepts to high density compact planning, which proves to be successful emerging model for development.

In high density Compact City model, the smaller, high density cities reduce the spatial extension of cities; create places where people can live closer to work, rely less on environmentally damaging methods of transportation, and reduce the collective carbon footprint. As compared to previous planning models, the compact city model does not limit the population of a certain area; it is by default a high-density development. Nor does it persist in defining and segregating zones of activities. The limited availability of land calls for a mixed-use approach with a mixed of commercial, residential, institutional and recreational facilities.

This paper tries to explore the role of compact city development in urban disaster management and its implications in future. The paper also tries to identify the relationship of sustainable development strategies, and disaster resilience for safe future cities. Here it aims to identify the problems associated with this concept in the present context of the cities.

2 INTRODUCTION

Cities are life lines of society and are centres of technological development (UNISDR, UNHABITAT, 2011) which have the capacity to deal any kind of problem whether environmental, social or economical due to advancement of science and technology, with the concentration of human resource and political activities. It is due to these advantages it invites urbanisation which when uncontrolled poses inumerable challenges in cities and even more due to incapability of the city administrators to cope up with the pace of urbanisation. Cities have become highly vulnerable to live with poor housing, almost no infrastructure in poverty ridden areas; are sources of green house gas emissions and are impacted by more severe and frequent attack of disasters and climate change. Although with this advent devastation world administrators have realised the importance of disaster management and many national and international efforts have been taken in the context.

It is not only the mitigation strategies that are important, but the integrated approach of landuse planning that would be most effective and implementable. In this light presumably strengthening building byelaws and

[1] TERI Team (Ghate A. et al. 2010). "Climate Resilient and Sustainable Urban Development."

codes is one of the key measures of urban disaster mitigation being focused. But recent earthquake and tsunami in Japan (which has well-enforced building codes are crucial tools for mitigating disaster risk though saved many lives by reducing the death toll) gave an important lesson that we cannot "build away" all disaster risk through building codes and other structural solutions alone inspite of its best enforcement practice(Sun, 2011). Even when life can be preserved, the cost of property and other economic damages can be staggering. It is thus "the location" that is key factor in determining a community's natural hazard vulnerability. Thus the "smart growth" integrated with the disaster mitigation and climate change strategies, can result in stronger livable and highly resistant communities, with a breathable environmental has been foced in next two sections of the paper. It is important to identify the challenges while adopting smart growth especially with respect to disaster management has been discussed in the last section. This discussion gives light to the way forward in this direction.

3 CITIES ARE DYNAMIC MODELS

"The 19th century was a century of empires, the 20th century of nation states, the 21st century will be a century of cities."

Wellington E. Webb, Former mayor of Denver, Colorado

3.1 Cities as Efficient Models

Cities are intense resource centres with technological advancements and high development. They are economy generators as about 600 urban centers generate about 60 percent of global gross domestic product (GDP). By 2025, 136 new cities are expected to enter the top 600, all of them from the developing world .[2] GDP is an important indicator of development and it becomes even more when we talk about sustainable development. Strong economy of an area is an absolute contributer in making any development initiatives sucessful and in achieving sustainable disaster resistant cities.

Cities generally have complex interconnected urban functions such as sanitation, utilities, land usage, housing, and transportation, building, energy etc. which provide opportunities for improvements in the urban environment through institutional factors that include urban planning, governance, land management, legislation and financing, thus contribute in economic, social development of the region. It is because increased density and better management that reduce the cost of service delivery, promote innovation, and enable prosperity through economic development. They are centres of major political and social changes in a country [3].And play active role in global dialogues and have unique ability to respond to a global issue, such as climate change/disaster management.

They offer dynamism to deal with Environmental factors and phenomenon such as climate change, risks and hazards, quality of air, land and water etc. in terms of scale, stronger linkages, and a greater sense of urgency among residents and their local leaders (World Bank, UN 2010). Co-benefits of urban disaster management and mitigation are largest in cities(World Bank, 2010). It is these benefits of development that urban centres attract population, and are subjected to high vulnerabilities which is discussed in the next section.

3.2 Vulnerability of Cities

As cities are concentrations of resources, technology, population, they are vulnerable to greater extent. Cities of developing countries are characterised by low density urban sprawl, fragile infrastructure, low resilience and poor coping capability of people which is a resulut of uncontrolled urbanisation. By 2030 nearly 60 percent of the global population is projected to be urban with the developing world housing nearly 80 % of this population (TERI, 2010). The 20 largest cities consume 80 % of the world's energy and urban areas generate 80 % of greenhouse gas emissions worldwide(Ewing, et al. 2007.) [4].

Corelationship of urbanisation and increasing hazards: Urbanisation is thus contributing significantly to climate change and poor disaster management along with urban poverty. Urban poverty increase

[2] Dobbs R., et. Al, 2010, "Urban world: Mapping the economic power of cities"
[3] F. C. (2010). "Rapid Urbanization and Mega Cities: The Need for Spatial Information Management." ISBN 978-87-90907-78-5, the International Federation of Surveyors (FIG), Copenhagen, Denmark
[4] Reid Ewing, K. B., Steve Winkelman, Jerr y Walters, Don Chen. "Growing Cooler: The Evidence on Urban Development and Climate change." Urban Land Institute

vulnerability and fragility of socioeconomic systems resulting in extensive setbacks to development. The total poverty in India, has doubled from 15 % in the early 1960s to nearly 30 % in 2004 [5] . Majority of the urban poors are usually built on hazardous sites in high-risk locations, or located in low-lying areas prone to direct and indirect risks due to environmental degradation such as regular floods, landslides occurrences, together with lack access to basic urban services and un-regulated and unsafe construction .[6] These people cannot afford insurance, savings or asset accumulation, and their socio economic vulnerability is immense (TERI 2010). As the goverments in urban centres are unable to keep pace with urbanisation coupled with low political will power, the cities have become even worse physicaly, socially and environmentally. Administrations in large cities are often confronted with a multitude of key problems, like poor governance, high unplanned urban densities, traffic congestion, energy inadequacy, unplanned development and lack of basic services. This leads to illegal construction within the city and in its periphery, informal real estate markets, proliferation of slums, poor natural hazards management in overpopulated areas climate change and, environmental degradation.

Corelationship of climate change and disasters: About 75 per cent of the world's major natural catastrophes between 1970 and 1997 occurred in the Asia and the Pacific region, mostly in poverty-ridden developing countries (UNESCAP and ADB 2000).There has been a general upward trend in the number of natural disasters due to hydrometeorological as seen from Figure 1. Increase in no and frequency of disasters during past 4 decades is mainly due to climate change which is an impact of global warming due to increase in CO_2 emissions in the atmospheres. To mitigate as a long term strategy we need to use low carbon development strategies. This is greatly possible with the advent of technology and smart growth principles. (CRED-OFDA 2002)

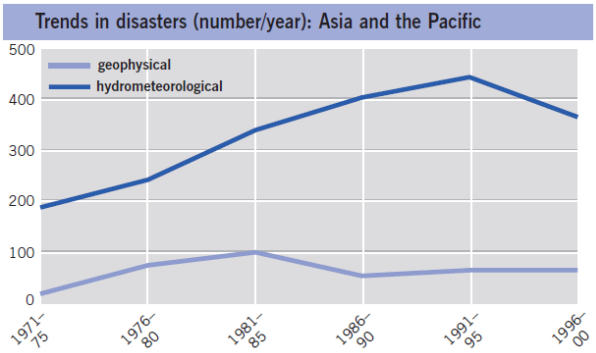

Figure 1: Increasing trends of hydrometerological Disasters in Asia and Pacific [7]

Corelationship of vulnerability and land degradation: These vulnerabilities are increased manyfold as cities often expand or grow in ways that may degrade natural buffer systems. People construct impermeable land surfaces that prevent percolation of water into the soil (Moser, 2008).The poor spatial arrangement of population and assets create risks to urban systems, to populations and to the nature and probability of hazard occurance. Constraints on the availability of land as a resource in urban areas often results in proliferation of slums and informal settlements. The combination of factors- such as faulty land use and planning, low density urban sprawl, rapid urbanisation, migration from rural areas, lack of integrated land use and transport planning that enables mass transit and efficient clustering of settlements and industries; result in unsustainable development. Sustainable development cannot be an expansive development in present context; it needs to be comprehensive (compact with smart growth principles) considering the changing environment (which triggers the disaster) and changing societal needs in terms of development. It is thus important to the impact of present development on degrading environment, which is becoming a major concern in terms or disasters and climate change.

4 DEVELOPMENT AND URBAN DISASTER MANAGEMENT

There is an indirect relationship between urban growth pattern and disaster occurrence (Dickson et al. 2010). Disaster is a function of risk and results from the complex interplay between developmental policies, existing vulnerability, population and areas exposed; hazard events, as well as climate change (World Bank, 2010). It has been observed that Africa and Asia, which have the highest rates of urban growth globally, are also experiencing the fastest rate of increase in the incidence of natural and human-made disasters over the last three decades (UN-Habitat, 2007).

4.1 Impact of disasters on development:

Natural hazards and emergency management are major issues in most cities. They have caused major losses of human lives and livelihoods, destruction of economic and social infrastructure, as well as environmental damages. In addition to the projected estimation of 100,000 lives lost each year due to natural hazards, the global cost of natural disasters is anticipated to top $300 billion annually by the year 2050. (UNISDR, WSSD, 2002). Not only this, disasters exacerbate poverty, damage infrastructure and critical facilities, disrupt business, disable lifelines vital for economic activity and service delivery. They halt or slow progress towards the achievement of the Millennium Development Goals (MDGs) [8] (Scott 2009). They delay development programs by reducing available assets and utilizing the financial resources allotted for development being used for rehabilitation and post disaster recovery. Disasters have negative impacts on environment as they affect natural resources. Changes in climate risk in particular imply that urban areas may face hazards in the future which are outside their past experience.

While no country in the world is entirely safe, lack of capacity to limit the impact of hazards remains a major burden for developing countries. An estimated 97 % of natural disaster related deaths each year occur in developing countries. Vulnerability to disasters is closely linked with population density and economic resources. The highest number of deaths occurred in South Asia (the sub-region with the highest population density and the lowest per capita income) (UNPD 2001, World Bank 2001). Given these trends, without major changes in the management of disaster risks and of urbanization processes risk to city residents will increase in the future as populations grow (World Bank 2010).

4.2 Urban Disaster Management:

Disasters can result from the way development occurs, and conversely can change the way development takes place (World Bank, 2010). The three components of disaster risk - hazards, exposure, and vulnerability are increasing in urban areas. (World Bank 2010). The disaster management needs to (1) assess disaster risks-by risk assessments and vulnerability mapping, (2)mitigate through urban planning – by mainstreaming Disaster Risk Reduction (DRR) into planning through risk sensitive landuse planning and (3) build resilience and coping capacity to combat disasters. Land use and urban development practices need to take into account susceptibility to natural hazards. The investments in new city infrastructure offer a tremendous opportunity to build sustainable (smart and efficient) and resilient cities using less energy and water especially in developing and least developed countries. Smart choices in housing, energy and public transport could reap massive local and global benefits. the right choices will save water, energy and carbon, and improve health and quality of life(Prabhakar et al., 2009) Developing resilience by capacity building, adopting strong legislative, administrative measures, decreasing carbon emissions by stratifying planning measures, going for compact development, reducing travel time; tapping dense local knowledge and adapting local strategies are some measures which are needed to be taken up in an integrated manner with the planning principles (UNDP, 2002).

5 COMPACT DEVELOPMENT AS URBAN DISASTER MANAGEMENT TOOL

Compact Development can be used as a tool for development and urban disaster management; because it specifically directs land use (directs the location and concentration of socioeconomic activities (TERI 2010) and transportation systems. Planning can reduce population vulnerability by facilitating improved access to resources, services and amenities. The urban planning approach needs to bridge the gap between urban

[8] Millennium Development Goals (MDGs) are eight goals to be achieved by 2015 that responds to the world's main development challenges. These are drawn from the targets and actions contained in the Millennium Declarations in the UN Millennium Summit in September 2000

disaster mitigation, sustainable human development and climate change. As stated earlier the new development should not increase the vulnerability to disasters, there is a need for smart principles of development.

5.1 Concept of Compact Development towards Urban Risk Reduction

The term "compact development" implies higher average "blended" densities and features a mix of land uses, development of strong population and employment centers, interconnection of streets, and the design of structures and spaces at a human scale (Ewing et al. 2007). Compact development planning help people live within walkable distances to work, shops, home, education recreation, parks and transit points. The street network can be designed to interconnect, rather than end in culs-de-sac. Finally, by building more homes, offices, stores and other destinations "up" rather than "out," communities can shorten distances between destinations. This makes neighbourhood more economically viable, allows more frequent and convenient transit service, and helps shorten vehicular trips. Compact development is a part of Smart growth.

The 10 Smart Growth Principles that have been identified by researchers and practioners are- mix land use development , take advantage of compact building design, create a range of housing opportunities and choices , create walkable neighbourhoods, foster distinctive, attractive communities with a strong sense of place, preserve open space, farmland, natural beauty, and critical environmental areas, strengthen and direct development towards existing communities, provide a variety of transportation choices, make development decisions predictable, fair, and cost effective, encourage community and stakeholder collaboration in development decisions.(emerine, et al. 2006). Based on these principles the smart growth development, helps to achieve sustainablility. It is first important to understand the benefits of "Smart Growth" (high density compact development) over Urban sprawl. When we analysez these with respect to their impact on disaster management, the influence is remarkable and has been further discussed.

5.2 Smart Growth versus Urban Sprawl

Smart growth policies are one which result in more compact, accessible development within existing urban areas. A comparitive table showing urban sprawl and compact development.

	Smart Growth	Sprawl
Density	Higher Density, Clustered Activities,	Low Density ,Dispersed Activities
Growth Pattern	Infill (brownfield) Development	Scattered , prepheiry (Greenfield) Development
Urban Form	Cluster development, High Density High rise Development	Sporadic Development, Leapfrog pattern, Commercial strip, Low Density plotted Development, Single Use Development
Land use mix	Mised landuse	Homogeneous(single use, segregated) Landuses
Scale	Human Scale, smaller buildings, blocks and roads, designed for pedestrians	Large scale, Large Blocks, Hierarchial roads, increased road areas, less details
Services(shops, Schools, parks)	Local,well distributed, smaller, easily accessible (withing walking distances)	Regional Consolidated, Stripped Development, Larger zones, requires automobile access
Transport	Multimodal transport and land- use patterns that support public transit, walking, and cycling	Automobile-oriented transport and land-use patterns, poorly suited to walking, cycling, and use of less public transit systems
Connectivity	Highly connected roads, sidewalks and paths.	Hierarchical road network with numerous dead-end streets, and unconnected paths and sidewalks
Street Design	Streets designed to accommodate a variety of activities.	Streets designed to maximize motor vehicle traffic volume and speed
Policy Formulation and Planning Process	Planned and coordinated between jurisdictions and stakeholders	Unplanned, with little coordination between jurisdictions and stakeholders
Public Places	Emphasis on the public realm (streets, sidewalks and public parks	Emphasis on the private realm (yards, shopping malls, gated communities, private clubs), sporadic public places, mostly unmaintained

Table 1: Comparison Showing Smart Growth Development and Urban Sprawl.(Ewing, 1996; Galster et al, 2001, Litman 2011)

When these are compared with respect to their impacts to disaster management (which needs comprehensive integrated planning approch), it is seen that the smart growth provides development of high density clustered activities, with strong resilient urban infrastructure (which will increase the coping capability when disasters strike), characterised by infill development, mixed landuses, local services accessible near the residential areas within pedestrian movement, multi nodal transportation which encourages walking, cycling and public transit which also prevents environmental dgradation, pollution. The connectivity of roads is simple and strongly linkes compared to hierarchical road network with numerous dead end streets; the former makes it possible to desig the evacuation routes during emergency management.

5.3 Reduction in green house gas emissions can affect intensity, magnitude and frequency of Disasters.

Disasters are impacted by climate change and urban growth pattern. Low density urban sprawl results in increase in the number and length of trips and rapid motorisation. This has resulted in dramatic rise in Green House Gas (GHG) emissions. The rate of motorisation inextricably links to urbanisation. Figure 2 shows that while urban population has increased by 50 % during 1990–2004, the number of Registered Motor Vehicles (RMVs) has risen by nearly 400 % in India.(Saxena 2008).

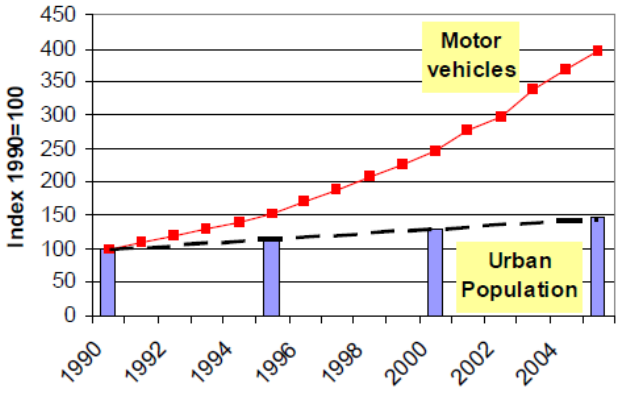

Fig. 2: Motorisation and urbanisation trends in India[9]

The transport sector is responsible for almost 25 % of global CO_2 emissions (IISD, 2004). Transport emissions are growing at approximately 2.1 % per year worldwide, and 3.5 % per year in developing countries (IEA, 2002).These impact climate change which inturn affects the frequency, magnitude and intensity of disasters especially hydro- meterological disasters like flooding, extreme temperature, high and intense rainfall etc.(Saxena, S. 2008). Growing Cooler, a study published in 2008 by the Urban Land Institute and EPA, examined the research on compact development, vehicle miles traveled, and carbon dioxide emissions to determine that more efficient development patterns could help reduce our impact on the climate. The study concluded that compact development can reduce vehicle miles traveled by 20 to 40 percent compared to conventional development patterns. Further, based on the amount of development by compact infill, the study estimated that compact development could reduce CO_2 emissions by 7 to 10 percent in 2050. As reduction in CO_2 emissions is a strategic need for urban disaster management, it can be achieved through policy measures and/or by comprehensive integrated development using smart growth principles, providing mixed landuses to reduce vehicle dependency.

5.4 Chanelling growth away from vulnerable locations

Disaster mitigation calls for channelling growth away from hazardous locations. Land scarcity enforces urban sprawl in vulnerable locations like; in floodplains, along the coast line, along the earthquake fault lines etc. As these lands are easily affordable, mostly urban poor locate themselves in such locations. Smart growth plays a role in mitigating disasters firstly compact development reduces the spatial extent, not reaching the hazardous locations, secondly by integrating vulnerability and risk maps with smart growth principles it channelizes the urban growth into safe zones within the city. Therefore it helps in creating greater resilience. A sucessful example of chanelling growth away from hazardous area, is Metro, the the Portland metropolitan area, which encourages towns to use seismic hazard maps when designating “urban reserve areas”—areas that will “eventually be brought inside the urban growth boundary” using smart

[9] http://epa.gov/dced/climatechange.htm

growth principles.(Sun, 2011). Thus integrating urban disaster management tools like risk mapping and microzonation produce technical information for the identification of hazardous areas, and serve in developing zoning regulations and establishing population density levels and also enable the managers to design mitigation action plans and support the smart growth concept. These can be very effective since they integrate socioeconomic factors and technical factors (housing, infrastructure, lifelines, and critical facilities).

5.5 "Urban resilience"- can be increased by using smart growth principles

Disaster mitigation can be achieved by making wise decisions for locationg new infrastructure and/alternatively by increasing the resilience of the existing infrastructure to incorporate the increasing demands. Compact development makes more efficient use of land and resources by reducing the environmental footprint of new contruction and preserving the open spaces(UNESCAP, UNISDR, 2010). By strengthening the existing urban infrastructure, will serve the dual purpose of catering the new development requirements , reduction in infrastructure costs and energy usage and second creating greater resilience. Smart growth acts as a boost up for other structural mitigation strategies in urban disaster management. It can benefit by inviting greater public investments, creates a stronger tax base; more employment opportunities; closer proximity to jobs and services; increased efficiency associated with using already developed land, reusing/repurposing existing buildings, and using existing infrastructure; and reduced development pressure on the edge. Several economic incentives and tax policy options may be used to direct business development toward existing communities (UNESCAP, UNISDR, 2010). Once redevelopment and infill development occurs, it intensifies calls for structural protections for urban hazard mitigation. This boosts up the economy of the region and increases its resilience and reduces socio economic vulnerability of people. This suggests that the largest potential gains in disaster mitigation can be achieved.

5.6 Reduction of impervious surface- mitigation strategy for water related disasters

Compact Development policies tend to reduce per capita impervious surface area (land covered by buildings or paved for roads and parking facilities). Benefits like better stormwater management and reduction in heat island effects can be achieved by increasing pervious surface. It leaves more land for other productive uses, like farming, it reduces the capital and operating costs of providing public infrastructure and services (such as roads, utility lines, garbage collection, emergency services and school transport). It improves overall accessibility , reduces transportation costs, including the per capita costs to consumers to own and operate vehicles, road and parking facility costs, traffic accidents, and pollution emissions. Therefore it reduces 'every day risks' in urban areas, which otherwise acts as catalysist in greater intensity risks of natural and man made hazards.

	Dispersed	Compact	Difference
Roadways	$17.6	$11.2	$6.4 (-36%)
Transit	$6.8	6.2	0.6 (-9%)
Water and Wastewater	$5.5	$2.5	$3.0 (-54)
Fire Stations	$0.5	$0.3	$0.2 (-46%)
Recreation Centers	$1.1	$0.9	$0.2 (-19%)
Schools	$3.0	$2.2	$0.8 (-27%)
Totals	$34.5	$23.3	$11.2 (-33%)

Public services infrastructure costs tend to be higher for more dispersed development.

Fig. 3: Public Services Capital Costs, Billions (IBI 2008): The City of Calgary Plan program compared the capital costs in providing infrastructure and public services [10]

The City of Calgary Plan-it program compared the costs of providing infrastructure and public services to more compact and dispersed development patterns as seen in Figure 3. The study found that the more compact land use saves about a third in capital and operating costs for roads, transit services, water and wastewater, emergency response, recreation services and schools.This not only indicates the economic savings but also the savings that would be achieved in terms of land usage(Litman 2004).

5.7 Efficient Emergency Response Management:

Compact Development improves emergency services response times as fire departments, emergency responders, and police stations are closer to the areas they serve and have more route options, easy accessibility and immediate response inability to respond to emergency calls (EPA, 2010). As the spatial extent of the city is less, the roads are shorter and wider and infrastructure are better designed, it is possible to plan the shorter evacuation routes during emergency management and the collape time of the structures (buildings) is also delayed which gives little more time to save lives. Strong infrastructure serves as a lifeline during emergency. Nevertheless there are some channenges while implemention and acceptance of this concept by people and administrators. These have been discussed in the next part.

5.8 Reduction in urban heat island effect

Microclimate of a place is greatly affected by the pattern of urban development, density of buildings(both horizontal and vertical), suface heat emissions from buildings and open spaces and carbon emissions due to human activities. One of the worst effects of urbanization is the urban heat island (UHI) effect, which develops when urban cooling rates are slower than rural ones. The compact development (high-density buildings) reduce the heat release back to space by blocking the view; dense development in urban areas, reduces wind speeds and inhibits cooling by convection as seen in Figure 4.

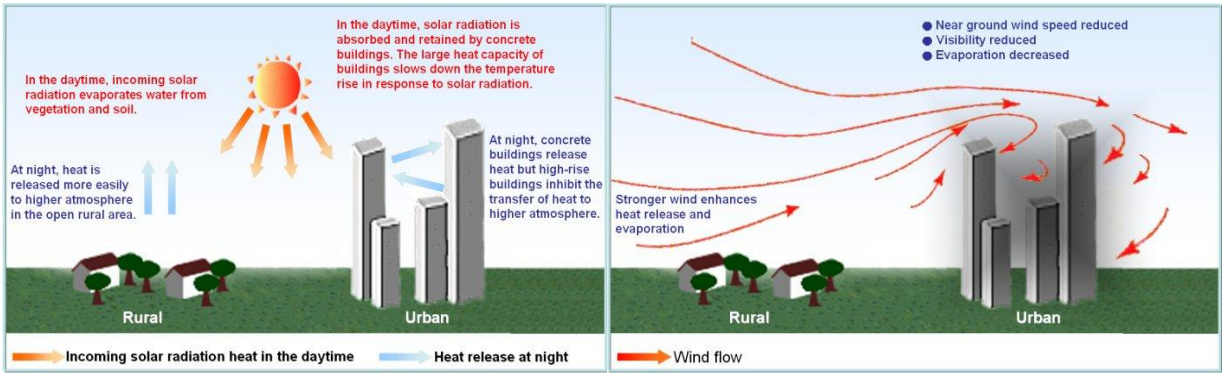

Figure 4. Urbanization effects on the heat energy balance and effects on the low level wind flow in the urban area.[11]

6 CHALLENGES

Compact Development is not popular with the managers and planners. Benefits of compact development cannot be achieved without effective participation of all the stateholders, in public, private and government domains. Urban Disaster Risk Reduction (DRR) when integrated with smart growth principles towards achieving sustainability would lead to effective urban disaster management. It would lead to communities which are more livable, cost effective and environmentally adaptive to low impact of climate change. But as rightly said "Smart Growth in dumb places"—those that are particularly disaster prone—is the antithesis of true sustainability. (Sun , 2011). This would make the communities more vulnerable. Therefore the challenges in adopting smart growth for effective DRR lie as below.

6.1 Sustainability and urban disaster risks

As many of the existing old cities are located in vulnerable locations, such as in low-lying coastal areas, along major earthquake faults, and along major rivers, and much of the land available for redevelopment and infill are often lands along waterfronts or land is particularly hazard- prone (Sun 2011). Increasing the density presents several serious challenges for managing growth in disaster risk areas as this will certainly exacerbate vulnerability of population and other elements at risk (infrastructure, lifelines, transportation, and housing, urban services). Compact development therefore must be integrated with structural and non structural measures of disaster risk mitigation. It needs to be adaptive to a given location. It should address the local issues and guide development with respect to specific urban risks through the types of projects to be adopted. Outsmart choice of density development might increase unsustainability. Secondly the smart growth needs to be supported by governance and legislation. New York, for example, recently passed the State Smart Growth Public Infrastructure Policy Act to halt public funding of sprawl by requiring state

[11] (http://www.hko.gov.hk/climate_change/urbanization_e.htm)

agencies to submit a "smart growth impact statement"for public projects and to "advance projects" that meet the state's Smart Growth criteria. . Another example is Portland, the city's Bureau of Planning and Sustainability has adopted "Neighborhood Design Policies" that encourage "new development" in areas that are losing housing and "increases in residential density" through "residential infill development."

6.2 Retreating from Hazardous areas

Retreating from the disasters areas is the most effective method of mitigating- in highly vulnerable locations or where population is extremely at risk due to greater socio economic vulnerability.Redevelopment efforts (Ieven though integrated with Disaster Risk Reduction strategies), in urban areas particularly those along coasts or inland waterways may not prove to be effective and retreating from these hazardous areas is perhaps the most cost- effective, long-term disaster mitigation strategy and is suggested by disaster scholars and practitioners. Unfortunately, retreat from hazardous areas is difficult to implement due to property rights, the costs associated with buy-outs, the likely disruption of existing community ties that relocation entails, and local political opposition to relocation efforts. (Sun 2011).

6.3 Density is a serious problem in case of failure or disaster response

Increasing density concentrates not only population but also resources—including the resources needed for effective disaster response. This concentration of response resources can be advantageous if those resources emerge from the disaster unscathed. If, however, they are destroyed in the disaster event, the resulting equipment shortages and communication failures can seriously hamper response and relief activities. Thus compact development strategies are relatively important with respect to planning of resource locations.

6.4 Current Growth patterns

The development does not take into consideration the local landuse planning, disaster management plans and the importance and involvement of Disaster Management authority into planning process which are greatly deciding factors in smart growth principle. As land-use planning is more of a state and local prerogative and approaches to land-use planning vary from state to state, national and state legislatures may be in the best position to encourage integration of hazard mitigation into land-use decisions(of smart development). When a state or locality adopts sustainability (smart growth) policies or legislation, it should include disaster mitigation as an important component and goal of sustainability and vice-versa. India, for example, should consider amending its Disaster Management Act (2005) to include attention to Smart Growth criteria in consideration to disaster risk Planning as well as UDPFI [12] guidelines in India (provides guideliens for urban Planning in India at National Level) should address the principles of Smart Growth and Disaster Management.

6.5 Evaluation of risks of redeveloping urban areas to the cost of alternative growth:

The risks of redeveloping urban areas must be weighed against the costs and risks of alternative growth patterns. For instance, planning for new urban cores in less risky locations is more weighted, rather than low density sprawling or shifting the existing urban cores toward hazardous areas through strategies like waterfront redevelopment. Sometimes the creation of urban centers of growth may be inevitable, as existing urban centers are unlikely to be able to accommodate all future growth.

6.6 Urban Form should support development in Disasterous areas

The cities which choose to redevelop particularly vulnerable areas despite the disaster risks, those redevelopment efforts should employ an urban form that either helps mitigate current risks or will facilitate strategic retreat in the future.(Sun, 2011) For example, some experts have suggested that strategic retreat can be more easily accomplished if a waterfront community is built around a series of roads (and utilities) that run perpendicular to the coast, rather than being built around a coastal road that runs parallel to the waterfront's edge. Such an urban design allows communities to make some concessions to the water over time (by ceding the property and stretches of road closest to the water) without losing all coastal access and

[12] UDPFI (Urban Development Plan Implementation and Formulation), formulated in 1996 under the Maharashtra Regional and Town Planning Act 1966, by Ministry of Urban Development for guiding urban development in India.

road and utility infrastructure. Urban redevelopment, then, can at least be an opportunity to ease the way to more permanent mitigation measures that may be necessary down the road.

6.7 Inaccurate assessment and Information may lead to vulnerable planning

Compact development can be vulnerable in disaster prone sites. Inaccurate risk assessment and information may lead to channelling growth to hazardous locations in unsustainable manner. People underestimate the everyday risks/disaster risks and incorrect risk perceptions might lead to wrong decisions associated with redeveloping or increasing the density of existing urban areas. As researchers have frequently argued, individuals faced with imperfect information about risk (and limited time, resources, and mental energy to devote to seeking out and processing further information) may form their own assessment of risk by relying on the perceived collective judgment of others.(Sun 2011).

6.8 Existing Bylaws and legislation does not support the Smart Principles

Existing byelaws and building code do not support smart growth principles. In most of the countries especially taking example of India, the building byelaws define the density of residential areas, promote setbacks in plotted development, the Floor Area Ratio (FAR) restriction is allowed maximum upto 2.5 which is only allowed in concentrated zones, promotes zoning of landuses which is against mixed landuse development, and it increases dispersed development which is against sustainability in the present context. The National Commission on Urbanisation of India (NCU, 1988) [13] recognized the need for adequate supply of land, efficiency and equity in allocation of land and promotion of flexibility in land use, thus suggested low rise development as the most efficient growth pattern.

7 CONCLUSION

Sustainability will reduce everyday risks along with mitigating the disasters and building stonger resilience to climate change.The 'Hyogo Framework for Action 2005-2015 [14] says in its priority actions that "An integrated, multi-hazard approach to disaster risk reduction should be factored into policies, planning and programming related to sustainable development,.." . Thus the protocol for disaster management calls for integrated sustainable (smart) development to be energy efficient, resilient to climate change and disasters with strong coping capability. This can be achieved successfully with the smart growth principles emphasing high density compact development. Smart growth consists of various development features that create more efficient land use patterns. Numerous studies indicate that smart growth can reduce public infrastructure and service costs, providing savings on roads, water, sewage, garbage collection, utilities, school transportation, delivery services, and parking facilities. This serves in strong economy. The major challenges associated with the concept are that there are no laws to support this planning, secondly more research needs to be done in this area to understand the various positive and negative implications(for example traffic congessition still remains the problem even though the per capita vehicle mileage gets reduced) of the smart growth. With respect to disaster smart growth need to be located in safe areas otherwise it may increase vulnerability manyfolds. More capacity building of people and administrators is needed for application of this concept. The governments need to take action on their part by changing the legislations to support and promote smart growth because if they don't do now, it will be too late tomorrow!

1 ABSTRACT

The context for this paper is a comparison of metropolitan governance of specific metropolitan regions in Germany and the United States. In Germany, the Academy for Spatial Research and Planning (ARL) describes metropolitan regions or spaces as high-density locations, which are centers of the global network of goods, capital, information and migration flows. In the United States, metropolitan regions or metropolitan statistical areas are based on the concept of a core area with a large population nucleus, plus adjacent communities that have a high degree of economic and social integration with that core. On the surface, the German definition appears to focus more squarely on building social capital and creating metropolitan governance structures capable of achieving "centeredness".

In this paper, we compare aspects of metropolitan governance for the metropolitan areas of Hamburg, Germany and South Florida, USA. To simplify the empirical analysis, we focus on a single governance function – planning for adaptation to climate change. UCINET network analysis software is used to examine the pattern of interaction among stakeholders. The software returns indicators of size, connectivity, and cluster. Each of these indicators tells us about different attributes of the governance structure. The formal null hypothesis is that all three types of measures (representations of metropolitan governance) will be identical for both metropolitan regions. The formal null hypothesis is mostly rejected. The two regions demonstrate markedly different planning networks in dealing with adaptation to climate change. The final part of the paper reflects on the general method of using social network analysis to characterize metropolitan governance structures.

2 THE QUESTION OF GOVERNANCE IN METROPOLITAN REGIONS

The first question is "what is metropolitan governance?". Most would define "governance" in relation to the "government". Government is a formal administrative structure; governance is more than that – it includes the voluntary sector, NGOs, private organizations, and intergovernmental (and multi-scalar) linkages. Williams (1971) distinguished between "systems maintenance" issues and "lifestyle" issues; the former are best accomplished at the metropolitan scale. Yet, metropolitan governance continues to elude both the public eye and the academic lens (Feiock, 2004).

The metropolitan governance literature articulates two competing or different schemes that, for the sake of simplicity, can be termed "centralized" and "decentralized". Centralized governance schemes rely on a central government. Decentralized governance schemes are witnessed by a lack of a central government. The assumption in this paper is that German cities are more likely to have central governmental structures, while the US metropolitan areas are typically devoid of such mononucleated institutions. It is an empirical question as to which system of governing is better; it is likely that there is no clear answer. For example, Salet, Kreukels and Thornley (2003) argue that there is no one best method; governance systems are idiosyncratic and contextual. The proponents for any governance system – be they public choice theorists (Ostrom, 2005, Bickers and Stein, 2002), metropolitan reformers (Oakerson, 2002), or new regionalists (Savitch and Vogel, 2000, Wheeler, 2002) are simply making pronouncements. Empirical verification is sorely missed.

To simplify matters, we have chosen to focus on the governance of a single issue: planning for adaptation to issues raised by climate change (this is, we believe a systems maintenance issue and thus appropriately organized and governed at the metropolitan scale). Our approach is to compare how planning is accomplished in two metropolitan areas similar in most regards with the exception of how planning functions are organized. In Hamburg, Germany, such planning is accomplished at the regionwide scale by a central authority; in South Florida, the planning is organized as a decentralized network of stakeholders.

This paper is organized as follows. The next section provides both the development of the comparison methodology and context including some descriptive statements about the Hamburg and South Florida metropolitan regions. This is followed by a exposition of the social network analysis approach, including a

discussion of its methodology and measures. The fifth part reports results in terms of data collection, data preparation, and computation. This is followed by a discussion of the results in terms of preliminary expectations and a reflection of the method and general conclusions about how social network analysis enhances understanding of metropolitan governance.

3 DESIGN OF THE COMPARATIVE CASE STUDY

3.1 The Design of the Comparative Case Study

There are a number of similarities and differences between the two metropolitan areas. Similarities include: rough equivalencies in terms of location (on major water bodies), function (ports trying to become knowledge centers), administrative and political complexity (multiple jurisdictions), and size (roughly equivalent). Differences include:distinct variations in both how governance is organized and in functional approach. The Hamburg region has a metropolitan wide planning agency, wherein the planning for adapation to climate change is accomplished in a "top down" fashion; while the South Florida region does not and thus such planning could be characterized as "bottoms up". Moreover, planning in Germany continues to function along technological lines; while the South Florida region seems to function along process lines. The essence of the comparative study is to calibrate and discuss differences in social network attributes between the planning systems.

The two systems are the KLIMZUG-NORD project in Hamburg and the SOUTHEAST FLORIDA REGIONAL CLIMATE CHANGE COMPACT in South Florida. Both are described more fully below.

3.2 Hamburg Metropolitan Region

The Conference of Ministers for Spatial Planning designated the Hamburg Metropolitan Region as a European Metropolitan Region in 1995. It is defined as a dense populated area with a surrounding region, which has global integration, as a result of its economic, political and traffic and international importance (Heimpold, 2006). The spatial boundary of the Hamburg Metropolitan Region is defined in the treaty from 2005 between the Freie und Hansestadt Hamburg, Niedersachsen, and Schleswig-Holstein (Grotheer 2011). It consists of fourteen administrative districts (6 within the Federal State of Schleswig-Holstein and 8 within the Federal State of Niedersachsen) and the entirety of the Federal State of Hamburg

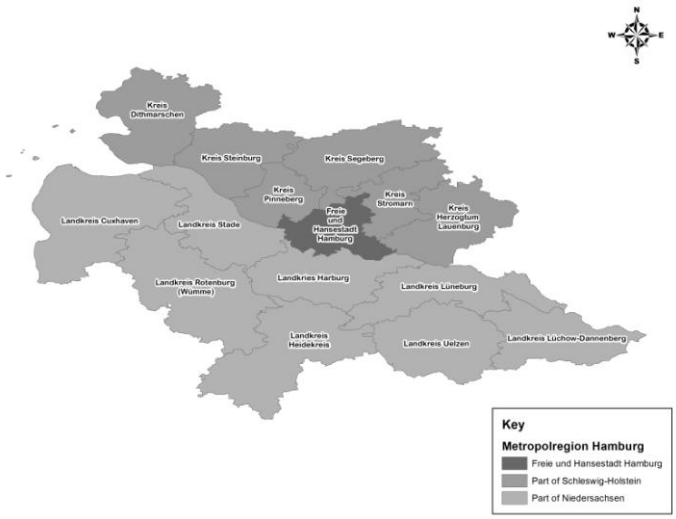

Fig. 1: The Hamburg Metropolitan Region

Overall, the Hamburg Metropolitan Region has a total population of 4,301,920, with a population density of 207 persons per km² (Statistikportal der Metropolregion Hamburg, 2012). The region extends over a large area in the North of Germany and includes very different structured sub-spaces: from the prosperous subspaces of Hamburg and its direct environs to rural and structurally weak sub-regions such as the administrative district Lüchow-Dannenberg.

The region offers a high standard of living and diversity, with a defined urban core and rural areas. The international airport, the port of Hamburg with cruise ships and international train connections define the role of the Metropolitan region in the international network. These international traffic functions are all

concentrated in the core, or the city of Hamburg (Grotheer, 2011). The region has qualified specialist companies prepared to innovate, and highly qualified research centers. For example, the 9,000 researchers and 85,000 students at 27 universities emphasize the position of the region as an academic/scientific location.

The KLIMZUG-NORD Project

KLIMZUG (Klimawandel in Regionen zukunftsfähig gestalten) is a funding initiative of the Bundesministerium für Bildung und Forschung (BMBF), which supports the preparation for adapting to climate change. The purpose of this funding initiative is to embed the awareness of the need for adaptation to climate change in our society. The BMBF is supporting seven model regions, from 2009 through 2014, with a total of approximately €83 million.

The KLIMZURD-NORD project, one of the seven national pilot projects, is focused in the Hamburg Metropolitan Region. The project is described (KLIMZUG-Nord Strategische Anpassungsansätze zum Klimawandel in der Metropolregion Hamburg, 2012) as:

"Partners of KLIMZUG-NORD are going to research the consequences of climate changes to urban areas, agricultural sites and the tidal riverbed of the Elbe within the city of Hamburg. Taking into account research data, environmental planning, city law, and economic plans, a range of action plans are going to be recommended. The target entails a coordinated action plan for the city regions, including a master plan which reaches to the year 2050."

The overall KLIMZURG-NORD project is focused on three topics – estuary river management, integrated urban development, and sustainable cultivated environment. The overall project is coordinated by "TuTech Innovation" and has a total of 76 partners and supporters. There are 25 sub-projects.

3.3 South Florida Metropolitan Region

The U.S. Office of Management and Budget and the US Census designate metropolitan areas in the United States. The area designated as the South Florida Metropolitan Region is made up of three counties (Broward, Miami-Dade and Palm Beach), and had a 2010 population of 5,564,635 (8th largest in the US).

The MSA itself is separated into three distinct divisions that fall along county lines. The Miami-Miami Beach-Kendall divison (Miami-Dade County) has a population of 2,496,435, the Fort Lauderdale-Pompano Beach-Deerfield Beach division (Broward County) has a population of 1,748,066 and the West Palm Beach-Boca Raton-Boynton Beach (Palm Beach County) divsion has a population of 1,320,134. The OMB also designates principal cities; these are: Miami, Fort Lauderdale, Pompano Beach, West Palm Beach, Miami Beach, Kendall, Boca Raton, Deerfield Beach, Boynton Beach, Delray Beach and Homestead.

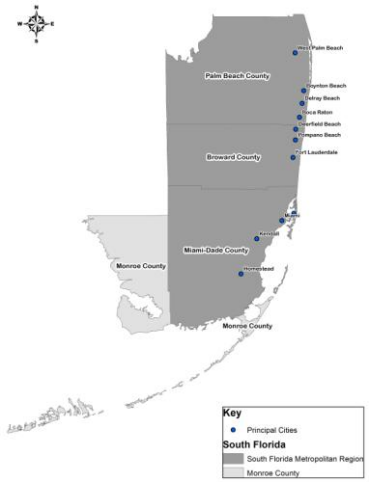

Fig. 2: South Florida Metropolitan Region.

3.3.1 Southeast Florida Regional Climate Change Compact

The Southeast Florida Regional Climate Change Compact was the principal result of the Southeast Florida Climate Leadership Summit, held in 2009. The compact's principal members are the four counties that make up the Southeast Florida region (Broward, Miami-Dade, Monroe, and Palm Beach; Monroe is the county that includes the famous Florida Keys). The compact became official with the signing in January 2010. This

compact allows the counties a framework and structure for working together by developing a coordinated response to any proposed climate legislation policies, to dedicate staff time and resources towards the creation of a Southeast Florida Regional Climate Change Action Plan, which would include mitigation and adaptation strategies, and to meet annually in Regional Climate Summits to mark progress and identify emerging issues. (SOUTHEAST FLORIDA REGIONAL CLIMATE CHANGE COMPACT, 2012)

The Draft Regional Climate Action Plan was released on December 9th, 2011 (open for public comment until March 16th, 2012). This plan is both a summary of work done and an update on what is still left to accomplish. Among the completed highlights are the establishment of a Greenhouse gas Emission base line for Southeast Florida and the creation of a unified methodology among all four counties in regards to sea level rise.

There are 91 nodes (actors) involved in three major work groups (tasked with data collection and eventual recommendations). These are: Built Environment, Transportation, and Land and Natural Systems. To date, recommendations are grouped in six categories: (1) Sustainable Communities and Transportation Planning; (2) Water Supply, Management and Infrastructure; (3) Natural Systems and Agriculture; (4) Energy and Fuel; (5) Risk Reduction and Emergency Management; and (6) Outreach and Public Policy.

4 SOCIAL NETWORK ANALYSIS: WHAT IS IT?

Social network analysis (SNA) is not new; indeed, the idea has been around for over a century. Its use as a systematic tool dates from the mid 20th century (A.J. Barnes, 1954). What began as a "metaphor" has morphed into an "approach" and is approaching "paradigmatic" status. The key difference between SNA and traditional social science analysis is the focus of measurement. In SNA, the key attribute to be measured are "links" between actors (called nodes); in traditional social science analysis, the key attributes to be measured are aspects of the nodes (income, race, gender, etc.).

This section relies on two major sources – Knoke's (1982) introduction to social network analysis and Hanneman and Riddle's (2005) manual for the UCINET program. The discussion is structured into methodological perspectives and a discussion of the specific measures and their operational versions.

4.1 Methodological Perspective(s)

Freeman (2006) and Wellman & Berkowitz (1988) distinguish major analytic tendencies. These are: (1) there is no assumption that groups are the building blocks of society; (2) a focus on the structure of ties rather than treating individuals (persons, organizations, states) as discrete units of analysis; and (3) a focus on how the network affects ties.

Generally, the shape of the social network determines a network's usefulness to its individuals. For example, prevailing wisdom suggests that: (1) smaller, tighter networks can be less useful to their members than networks with lots of loose connections (weak ties) to individuals outside the main network; (2) more open networks, with many weak ties and social connections, are more like to introduce new ideas and opportunities to their members than closed networks with many redundant ties. In terms of environment, centralized structures may perform better when there is not much in the way of upheaval or change, but when there is a lot of change, a less centralized structure may be preferrable (Knoke and Kuklinski, 1982).

4.2 Measures

SNA analysts generally focus on a number of attributes of the network, including size and core component, connectivity, and centrality and cluster analysis. We discuss each below. We used UCINET to calculate these parameters of the network. The specific measures produced by UCINET are also listed below.

Size

The size of the network is critical in defining the social structure. Larger networks require greater resources for developing and maintaining social relationships (Hanneman & Riddle, 2005). Focusing on the number of actors – size of the network, the number of possible ties and the number of actual ties – is the first step in analyzing a network. The size of a network and the number of ties is directly related, as Hanneman and Riddle note, 2005, p. 80).

"Imagine a group of 12 students in a seminar. It would not be difficult for each of the students to know each of the others fairly well, and build up exchange relationships (e.g. sharing reading notes). Now image a large

lecture class of 300 students. It would be extremely difficult for any student to know all of the others, and it would be virtually impossible for there to be a single network for exchanging reading notes. Size is critical for the structure of social relations because of the limited resources and capacities that each actor has for building and maintaining ties."

This data gives us the first critical information about the network and about the actors, specifically how many ties are possible compared to how many are present and also how many ties each actor has (Hanneman and Riddle, 2005).

Connectivity

Going a step further in analyzing a network, examining the connectivity and the distance gives a more detailed insight of the network.

The distance is the amount of steps is needed to move information from one node to another. It shows us how embedded a stakeholder is (Hanneman and Riddle, 2005). If the distance is 1 between two stakeholders, then these are directly connected and the information flow is the shortest and does not have to go through anyone else. This short path between two nodes is called a geodesic (Knoke and Kuklinski, 1982).

The maximum number of steps or "largest geodesic distance" defines the diameter of the network (Hanneman and Riddle, 2005). The average distance is the mean of all geodesic distances and gives us on average the shortest distance needed to move from one node to another.

According to Hanneman and Riddle (2005) the distance-based cohesion or "compactness" coefficient is in the range of values from 0 to 1, whereby closer to 1 the network is more cohesive or "well connected".

The density of a network is easily derived. It is the number of the present ties (a) divided by the amount of possible ties (N2-N, self-directed relations are not permissible in our case) (Knoke and Kuklinski, 1982). The dependence of the number of stakeholders, or the size of the network itself, is trivial. Thus, a large network with the same number of relationships has a lower density than it is the case in a smaller network (Schnegg and Lang, 2002).

Cluster Analysis

The clustering coefficient is a measure of the likelihood that two associates of a node are associated themselves. A higher clutering coefficient indicates a greater "cliquishness". UCINET gives us two alternative measures for clustering. Again quoting from Hanneman and Riddle, 2005, p 105,

"The "overall" graph clustering coefficient is simply the average of the densities of the neighborhoods of all of the actors. The "weighted" version gives weight to the neighborhood densities proportional to their size; that is, actors with larger neighborhoods get more weight in computing the average density."

Centrality is a rough indication of the social power of a node based on how well they "connect" to the network. The Bonacich Power coefficient measures the power of the actors. The idea is that stakeholders who have more ties than others may have a good position. But following Bonacich, a stakeholder does not have power through it is the amount of connections but due to its position in its neighborhood. If your neighbors are dependent on you, that puts you in a powerful position. Here, the amount of connections is not as important as having the right connections.

Example:	Stakeholder A	Stakeholder B	Stakeholder C
Stakeholder A		1	0
Stakeholder B	1		1
Stakeholder C	0	1	

Figure 3: How the Matrix is filled

5 DATA COLLECTION AND PROCESSING

In order to best encapsulate and capture the relationship of the actors, a matrix was used to map the connections. The matrix is a straightforward way to present the relationship among (between) stakeholders. The UCINET software uses the matrices to perform its calculations. The matrix consists of n rows and m columns. The number of stakeholders determines the size of "n" and "m". The matrix shows the relationship

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

between the members of the project by using the number 1 to represent a connection and the number 0 to represent no connection. This is done regardless of the degree of intensity of the relationship, see Figure 3.

The example matrix consists of three rows and three columns. Stakeholder B has a connection to stakeholder A and C, and thus has a "1" in its cell. Relationships between stakeholders and themselves are excluded.

5.1 Preparing the Matrix for Hamburg

The first step was to collect all stakeholders that are part of the project KLIMZUG-NORD. The project website had a subsection labeled "Partner" in which there were lists of the partners and supporters of the project, those were already briefly discussed above. These names were used to create the framework of the matrix.

After this step all sub-projects of KLIMZUG-NORD were analyzed looking for the relationships between stakeholders. If the stakeholders work together on a project, like for example the Technische Univeristät Hamburg-Harburg (TUHH) and the company Wasserbau River and Coastal Engineering, like they do in the project Hochwasserschutz an tidebeeinflussten Nebengewässern der Elbe, then there is a connection and this was recorded in the matrix. Actors that were not listed in the partner list described above but were listed as stakeholders in a specific sub-project were added to the matrix. TuTech Innovation is the coordinator of the whole project, and because of this, they appeared in every sub project. This was also true for the Bundesministerium für Bildung und Forschung, the Freie und Hansestadt Hamburg and the Hamburg Metropolitan Region. These institutions finance the project by way of the KLIMZUG funding initiative.

5.2 Preparing the Matrix for South Florida

The data collection for the creation of the matrix was done by examining the documents that the Compact had created, much in the same manner as the Hamburg portion of this analysis, and seeing which organization and/or governmental agency had collaborated on a project. The first step was to see if the counties themselves had created units for collaboration on this project. Broward County created the Broward County Climate Change Task Force (BCCCTF) and was a mix of private and public organizations. The other counties also created units but those were made up of solely county groups and did not have the diversity that Broward County did. The next step was to look at the Draft Regional Climate Action Plan, which had been put up for public review on December 9th, 2011 and is open for review until March 16th, 2012. This plan included a section titled, Contributing technical and Staff Experts. This part of the appendix broke down the contributors into three groups: Built Environment Work Group Participants, Land and Natural Systems Work Group Participants, and Transportation Work Group Participants. These three groups along with the Broward Climate Change Task Force were used as the basis for the analysis.

Organizations and/or groups were deemed to be connected if they resided on the same list of members. So everybody in the BCCCTF would be connected to everyone else in that group and would be represented with a 1 in the matrix. A member on that list would only be considered as connected to someone in another list if they were also on the other list. So if the South Florida Water Management District (SFWMD) was present in the BCCCTF and the Land and Natural Systems Work Group Participants list, then the SFWMD would be connected to every member in both of those groups. Care was taken to leave departments within a county as separate if they were listed as separate entities. So if example if both Broward County and Broward County Planning and Zoning were listed, then they would both have separate entries into the matrix. This was done as it would also allow for mapping of interdepartmental connections.

6 RESULTS

Perhaps the most compelling result from the UCINET program is a graphic representation of the SHAPE of the social network. We show this first (Figure 4), and then examine in more detail the results of the more "numeric" parameters (Table 1).

The shape of the network also gives insight into how the network functions. The results of the UCINET program for the two planning for adaption to climate change reveal vastly different shapes. The KLIMZUG-NORD network resembles a star. We believe that this result is due to the influence of both the coordinating stakeholder and the financing stakeholder that are connected to every member of the network. Indeed, an interview with the public relations office of TuTech Innovation confirms the need for a coordinating stakeholder – the face in front of the funders.

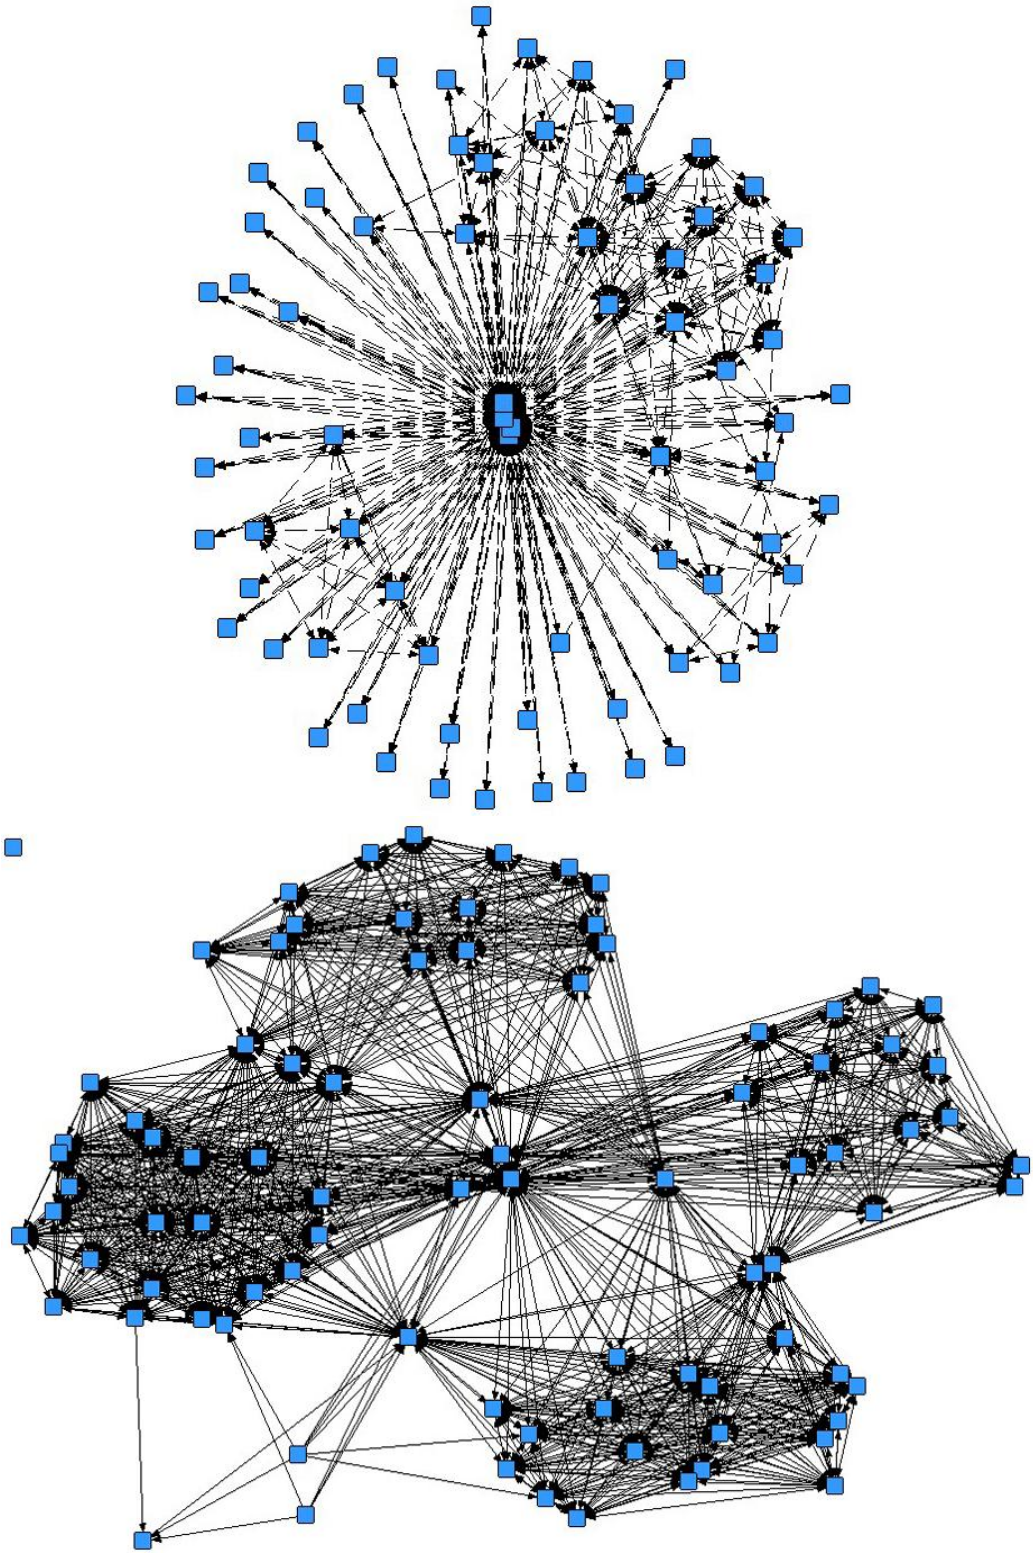

Fig. 4: Network Maps for Hamburg and South Florida

The shape of the Southeast Florida Regional Climate Change Compact network resembles a spider web with four big sub-webs connected through the main stakeholders – the individual counties. The four sub-groups represent the three technical work groups (Built Environment, Transportation, and Land and Natural Systems) but also the Broward County Climate Change Task Force. The shape shows that each group is a relatively self-contained entity.

6.1 Size Results/Analysis

The size of both planning networks is roughly similar. KLIMZUG-NORD (hereafter KN in the remainder of section 6) has 76 partners/stakeholders. The Southeast Florida Regional Climate Change Compact (herafter

Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

SFRCCC in the remainder of section 6) has 91 identified institutional partners. While these numbers are not exactly the same, they are in some sense roughly proportional. This reduces one of the sources of variation between the two case study networks.

Table 1: Coefficient and Parameter Results for Hamburg and South Florida Networks

6.2 Connectivity and Density Results/Analysis

The possible number of ties is based in part on the number of participants in the network. In our two examples, the SFRCCC network has 2,358 possible ties; the KN network has 845 possible ties.

UCINET computes a number of connectivity and density parameters. The average distance of the KN network is 1.848 compared to 1.713 for the SFRCCC network. This indicates that the average number of steps between individual stakeholders is shorter in South Florida than in Hamburg. On the other hand, the longest distance between stakeholders is longer in South Florida than in Hamburg, 5 steps to 2 steps. This might indicate that the connections in the South Florida network tend to be more local and not network wide. This can be seen in the visualization and reinforces the notion that the sub groups are self-contained.

The compactness coefficient measures how "well" the network is connected. This coefficient has a value of .622 for the SRFCCC network and a value of .576 for the KN network. This is also reinforces the fact that sub-groups in South Florida are more connected within.

The density coefficient measures how "solid" the network is. The SFRCCC has a density coefficient of 29.44% compared to the KN network derived coefficient of 15.23%. This measure reinforces the visual graphic representation of the two planning networks. The KN network operates in a hub-and-spoke fashion; stakeholders are connected by the fact that all have a common partner, which are coordinating stakeholder and the financers. This cuts down on connections between stakeholders and lowers the density. The SRFCCC network is similar to this but has more interconnectivity between stakeholders within a sub-group, which accounts for the higher density.

6.3 Centrality and Cluster Results and Analysis

UCINET returns both overall and weighted graph clustering coefficients. The weighted overall graph clustering coefficient shows a huge difference between the SFRCCC network coefficient of .767 and KN coefficient of .273. This coefficient indicates the weight densities of their neighborhood proportional to their size. In the KN network they are not dense or big neighborhoods and that's the coefficient is that low. In the case of the overall graph, the KN clustering coefficient is .896 compared to .917 for SFRCCC; these are nearly identical. This is because this value shows us the average of all the actors relating to the densities of their neighborhoods. The coefficient per stakeholder shows us that the technical groups in the SFRCCC network operate in their own neighborhood; we daresay that every technical group has its own sub-network. This is not the case in the KN network as the four most powerful players are only in one neighborhood but are connected to all other stakeholders in the network.

UCINET also computes the relative power of individual stakeholders by calculating Bonacich Power coefficients. The Bonacich results reveal that the most powerful stakeholders in the SFRCCC network are the four counties and the Broward County Office of Natural Resources Planning and Management. This is perhaps an obvious result, but encouraging in methodological terms since it captures the real organization of the SFRCCC effort. The same is also apparent in the KN network. The most important stakeholder is a university – the TuTech Innovation GmbH, which has the mission to connect Hamburg University of Technology with businesses. The TuTech acts as the coordinating stakeholder and because of this has the most power. Only the financing stakeholders – the Freie und Hansestadt Hamburg, the Bundesministerium für Bildung und Forschung and the Hamburg Metropolitan Region have the same power.

7 DISCUSSION OF RESULTS IN TERMS OF EXPECTATIONS IN THE CASE STUDY

Though nearly the same size as expected, the two social network graphic and numerical results show vastly different "shapes" and "values". One is a top-down-structure and one is bottom-up. As we learned, the shape and the institutionalization of a network is based on the genesis, the structure of stakeholders within a governance system, and the reasons why this network was implemented.

The two networks validate the assumption that German metropolitan areas are more likely to have a centralized governmental structure whereas US metropolitan areas have more decentralized structures. The KLIMZUG-NORD project is a metropolitan regional government project while the Southeast Florida Regional Climate Change Compact shows an example of a bottom-up approach. The difference is reflected in the strong suspicion that some parts of the South Florida network existed before the region-wide project. In the case of KLIMZUG-NORD we weren't able to tell if there had been such connections.

However, both networks confirm the idea that municipal governments play an important piece in the governance of metropolitan area. The most connected and powerful stakeholders are "government players". These give the resources and have access to governmental authority. In the case of KLIMZUG-NORD the stakeholders, the Hamburg Metropolitan Region and the Freie und Hansestadt Hamburg, provide the network access to the local metropolitan government or are in fact the metropolitan government. The Bundesministerium für Bildung und Forschung connects the project with the state. In the South Florida Network, the counties are the governmental authorities; this pattern points to the overarching need for interjurisdictional collaboration.

Concepts Of Urban Renewal in an Aging Society in the XXI Century – Case Studies in Polish Cities

Agnieszka Labus

(MA Agnieszka Labus, Silesian University of Technology, 7 Akademicka St., Gliwice, Poland, labusagnieszka@gmail.com)

1 ABSTRACT

In the twenty-first century many cities are at risk of losing the ability to function properly, due to progressing demographic changes. This is particularly evident in the European developed countries, where, in the cities, one observes an increasing number of senior citizens and a decreasing number of young people, both facts being the causes of the process of ageing. In modern world, we all depend on cars, while their availability to the elderly may be restricted. This results in the seniors having limited access to city services and other facilities, hindering integration with the rest of the society and exposing them to the risk of social exclusion. Modern cities require rearrangement and renewal so as to satisfy the needs of senior citizens. The purpose of this article is to indicate what actions are taken with reference to the ageing population in selected cities in Poland and what general concepts of urban renewal may be said to emerge out of these actions. The survey of Polish case studies will be compared and contrasted with similar initiatives involving age-friendly urban renewal which have been carried out in Barcelona and London as a part of the Age Friendly Cities project. The author is looking for trends and transformations in contemporary urban development taking place in Polish cities with reference to the aging population, in order to gain knowledge on what is missing in contemporary functional and spatial structure in the city and today's state of research on the subject.

2 INTRODUCTION

We are witnessing the emergence of a new era which will alter the methods of energy production. Industry will be reasonably minimized, changing the social system: there will be more and more elderly people and fewer and fewer children. This trend is associated with progressive demographic change that includes aging of the population which has been clearly visible in Europe and the U.S. for some time, affecting almost every aspect of life, from economy to culture, including the functional and spatial structure of cities. The following table shows the implications of spatial and socio-economic demographic change which include: migration, declining birth rate and ageing of the population.

Demographic change	Spatial consequences	Socio-economic consequences
Migration	Abandoning the cities and moving to other locations or suburban areas - in turn, the lack of demand for developing services leads to the shrinking of cities and suburbanization	The economic potential in the region is reduced due to migration; increase of imbalance in public finances caused by the loss of tax revenues from the working population
Declining birth rate	Decline in population contributes to the increase in empty living spaces; lack of demand for service development	Closing schools, kindergartens unemployment among teachers, paediatrician
Aging population	Increasing number of the elderly generates demand for the development of medical care, specially adapted living spaces for the elderly; development of services aimed at this social group	Collapse of the pension system; high expenditure on welfare for the retired; weakening of the economy's growth potential; losing the most energetic, enterprising and well educated.

Table 1: Demographic change and its spatial and socio – economic consequences

3 AGEING OF THE POPULATION IN THE SPATIAL CONTEXT

Ageing is a permanent feature of all visions of the future that take into account the growing number of the elderly. By 2050, most European Union countries, including Poland, may see significant changes in the demographic structure of the population. Eurostat demographic forecast indicates that by 2050 the amount of the retired population (over 65 years) in EU countries will have increased by 70 percent, causing a 12 percent decline in the number of working population (15-64 years). As a result, the ratio of the working population to the retired, which now is four to one, will only be two to one in 2050, causing difficulties in obtaining sufficiently high tax revenue needed to provide for the senior citizens. So far, the debates on how to deal

with ageing properly have focused on issues such as pensions and social security, health and social care at a national level. But now, a new approach to the challenges and opportunities posed by an ageing population gradually emerges in the European Union. We are dealing with an innovative, broader definition of the problems of ageing, including a number of issues:

- Pensions and income.
- Economy and employment.
- Health care and other services.
- Rights of individuals.
- Housing and communities.

One can notice among local authorities a growing awareness of the importance of introducing specific policy in areas such as: housing, transport, urban renewal and taking into account the growing diversity of needs of the elderly, the lonely, the disabled and those living in the poorest areas of cities. The process of ageing and its socio - economic consequences have become the objects of attention of demographers, politicians, sociologists, psychologists, geriatricians, architects, as well as urban and spatial planners. The fact that this process is an important aspect of spatial planning should not be overlooked in the global debate on the social effects of ageing. Not only will Polish society not avoid ageing, but the demographic changes in Poland will occur even faster than in other EU countries. By 2050, Poland will have recorded a rate of decline in the number of people of working age twice as high as the Western European countries. However, the Polish have not been yet affected by the urban problems that resulted in the shrinkage of the cities in Britain and Germany. On the other hand, many cities in Poland have been affected by the ageing of the population. This concerns mainly the post-war housing estates and blocks of flats of the 1960s and 1970s This is mostly due to the fact that in the last decade the financial situation of Poles has significantly improved. They have more and more cars, more and more leisure time and they increasingly move outside the cities.

As in many European cities, the phenomenon of suburbanization exists also in Poland. People move outside the city to have more living space, at the expense of increased commuting time. In Poland, local authorities do not seem to express proper concern about attracting and keeping residents longer in cities so that they could continue to invest or spend their money both on housing and urban life, while migration to the suburbs causes transformation of their surrounding which leads to the degradation of natural environment. Suburbanization incurs additional costs related either to creating new building sites in the countryside, building new roads, schools and kindergartens, or to accessing remotely located educational facilities and services. Life of a pensioner in suburban areas can be very difficult and complicated, due to limited access to services, health care, cultural events and entertainment, which may have a negative impact on the well-being of senior citizens alienating them from the social life.

4 KEY TERMS

In order to clarify the issues of ageing in relation to urban renewal it is necessary to specify the key terms: the ageing of population and urban renewal. Old age and ageing are concepts that have not been clearly defined by either the natural or social sciences. The first of these concepts is treated as a static phenomenon, a phase of life, the other is a process. Old age as a stage or status in life is static; ageing, however, regarded as a developing process, is a dynamic phenomenon. Progressing socio–economic changes, rapid technical progress (e.g. information technology), increased standard of living, development of medicine all contribute to the extension of life expectancy. As a result, the number of elderly citizens grows faster than the number of the new-born.

Ageing has changed over the centuries both in terms of its pace and form. The pace of ageing in the first few centuries AD was characterized by relatively small changes in the length of human life. A person between 27-35 years was already considered elderly. But in the twentieth century a significant change in the length of human life occurred. In 1950 the average human life expectancy was 47 years, and in 2000 it increased to 65 years. Predictions show that by the end of this century, average life expectancy will have exceed 80 years. To put it differently, in the period from 2005 to 2050, in Europe, the percentage of people over 65 years old (according to Eurostat estimates) will increase from 17 % to 30 % of the total population, while the percentage of people below 24 years will fall from 30 % to 23 %. Currently in Poland 13 % of the population

represents retirement age and by 2020 this figure will have increased to 25 % and, consequently, in 2030 one third of the Polish population will be retired. It follows that the pace of aging has been accelerating rapidly with an impact on spatial planning, what can rebound negatively on European cities.

Urban renewal is the key issue in contemporary urbanism. Its aim is to improve the quality of life of all citizens and increase the competitiveness of cities on a regional scale. Urban renewal is understood as adjusting the city to the changing needs of individuals and urban communities. Renewal is a social process that concerns the city's architecture, technical infrastructure, as well as legal, economic, administrative and political issues. Bearing in mind the changing needs and aspirations of future seniors, it is necessary to adapt the cities, in terms of their functional and spatial structure, to the ageing society, and, in a broader sense of the urban policy addressing the needs of older people, to motivate the elderly and encourage them to use what the cities offer, contributing to their integration with society. These actions are conducive to raising awareness, creating new jobs, developing the local economy, and improving living conditions in society. If the elderly are to become a significant social group in the cities whose needs and decisions will influence the structure of property market or services, then local authorities should provide them with favourable conditions of living, because otherwise they are at risk of not only losing the ability to participate in social life but also to function as individual beings.

5 CASE STUDIES

5.1 Age-friendly cities project

In Europe, numerous declarations pronounced by international organizations and governments, as well as academic conferences and innovative research programs contribute to the widespread attention drawn to this issue. The world community forums and organizations such as the UN, EU, OECD and many of their agencies have intensified their actions to respond to the challenges of the ageing population. In Western Europe many countries worked out methods and techniques of urban management with reference to ageing. New non-governmental international organizations such as the "Age-Friendly Cities" (created by WHO in 2002) are established and developed. WHO encourages local governments to plan age-friendly cities. An age-friendly city should adapt its structures to the needs of the elderly. For example, buildings in an age-friendly city should be equipped with elevators, non-slip flooring, ramps, etc. The city should also provide an adequate system of public transport (low floor vehicles, clearly displayed bus routes numbers, priority seats for the elderly). In addition, most service centres in the city should be located on the ground floors of buildings. These facilities should ensure that older people feel their needs to be acknowledged and satisfied. The "Age-Friendly Cities" program identifies the main elements of the urban environment, supporting active and healthy ageing. These are:

- access to public transport,
- friendly urban spaces and buildings,
- social support and medical care,
- location and availability of services,
- communication and better use of information technology,
- employment and social and civic participation,
- overcoming social exclusion,
- building intergenerational relationships by sharing the urban space.

5.2 Age Friendly Cities urban policy in Western Europe

Age Friendly Cities is a partnership of 35 cities from all over the world whose aim is to make urban communities better, healthier, and safer for the elderly to live and thrive. In some of the major Western European cities that take part in the project, such as London and Barcelona, the effects of ageing have already become a more serious issue than in Poland. However, as a result of participation in the Age Friendly Cities project both of them implement a policy of urban renewal with an emphasis on the needs of the senior citizens. The following section presents some of the selected projects of urban renewal carried out in those cities.

Barcelona

Currently, citizens of retirement age (65 and more) make up to 20,5 % (334,273 people) of Barcelona's population. The city has experienced fundamental changes in the structure of its population during the last three decades. There has been a significant decrease in birth rates, and a simultaneous sharp increase of the population of 65 and over. In spite of the gradual increase in the birth rate during the last decade, the youngest segment of the population (0-14 years) makes up to only 12 % of the overall population, while in 1981 it was 21,3 %. The number of citizens of 65 and over increased from 234.033 in 1981 to 334.273 in 2010, which means an increase of 40 %. The total number of Barcelona citizens decreased in that period by about 9 %. Both tendencies explain the relative increase in the number of the elderly citizens in Barcelona which grew from 13,4 % in 1981 to 20,5 % in 2010.

Access to public transport

In order to improve and facilitate the access to public transport for the senior citizens, the city officials prepared a class of documents aiming at coordinating transport-related issues: Mobility Pact: Urban Mobility Plan 2006-2012 integrated with the Mobility Act 2003 and the Sustainable Mobility Plan as well as encouraging participation of various organizations. The documents are supposed to be the instruments of urban renewal, which should facilitate the access to many places and services around the city for the elderly. This plan embraces four major issues:

- safer mobility and sustainable development (reduction of the number of car accidents and car-related pollution);
- sustainable mobility and natural environment protection: minimizing pollution (Kyoto Protocol; easier accessibility with less harmful effects on the environment);
- equal mobility (a right to mobility for all the citizens, regardless of their financial capacities and their physical fitness)
- efficient mobility related with the economic aspect of sustainable development (the ability to access every location in the city using any means of transport available).
- As a result of approving other documents related to transport, several actions were taken in the city:
- eliminating the parking of cars and mopeds on the pavements, as they used to take too much space as well as trouble the senior citizens and increase the risk of accidents,
- widening pavements in order to create a safe and comfortable pathway – defining the minimal width (for those who need additional support tools such as canes, walkers or wheelchairs)
- introducing elements of street furniture (benches, posts, railings, etc.) that separate pedestrian areas from those restricted for vehicle traffic
- improving the general accessibility: lowering curbstones near pedestrian crossing, installing escalators and elevators
- placing visual cues near pedestrian crossings informing and reminding about the need to look around for approaching vehicles before crossing the road (especially useful for those suffering from dementia or Alzheimer disease)
- eliminating bikeways located between bus stops and bus lanes
- reducing public transport fares for senior citizens

Friendly and accessible urban spaces

One example of a tool of urban renewal created by the local authorities is the Green Strategic Plan, which, along with the Safety Plan, responds to many of the demographic challenges. The plan introduces new ideas about the use of parks in the city and about the development of some functionality solutions that were earlier consulted with the elderly. The city's policy is to recognize that both parks and urban greenery in general are areas of social integration that can generate new functions and encourage new activities.

Green Strategic Plan

Barcelona is a city which requires renewal of its green space in order to improve the quality of life. The city officials recognize the emergence of new problems and challenges such as conservation of biological

diversity, climate change and various social needs. In order to respond to these challenges, some new concepts of urban green space and its relation to the city's ecology and to the social infrastructure are needed These concepts should refer to managing regional green space conservation, communication and education, historical diversity of the region, social and health-related issues, and the structure of environmental services.

The aim of the Green Strategic Plan is to take long-standing actions (5-10 years). The strategic areas included in the plan are:

- Designing large-area green spaces in accord with the ideas of sustainable development and taking into consideration such elements as environmental services, integration and the risks related to climate change
- Improving communication by means of green belts
- Encouraging the use of allotment gardens; responding to new public needs; enabling interaction and conservation of green spaces
- Preserving and appreciating the historical heritage of allotment gardens
- Conservation of the natural heritage and of the biological diversity
- Managing the green spaces in accord with the principles of sustainable development
- Offering online courses informing about the value of green spaces in the urban area
- Educating about green spaces

Housing development

The Senior Citizens Advisory Council in Barcelona has prepared a document (Assisted Housing Plan) which aims at providing seniors with a choice of their place of residence and to ensure that medical care and social security are easily accessible and located in its proximity. One of the sections of the document is devoted to the topic of housing, encouraging construction of new housing estates that would provide all the necessary services for the elderly. In order to facilitate their accessibility for the elderly, some plans of subsidizing elevator construction were introduced. These housing programs combine ideas aimed specifically at the elderly with those for the general public, related to other urban projects in various areas around the city. The city renewal plan is an excellent example of a successful attempt to encourage adaptation and integration of the new apartments or estates in a new environment. Its purpose is to create new intergenerational housing estates in order to encourage and maintain contact between different generations. The plan focuses on the specific housing needs of the elderly and on the ways of adapting new apartments to their needs by means of various forms of housing benefits and assistance, including accessibility of various initiatives such as subsidies to interior adaptation or the elevator construction. In the social housing system, the residences for the elderly in a difficult financial situation have a usable area of 40-42 square metres (bedroom, living room, kitchen and a specially designed bathroom), and common areas located on the ground floor and accessible for all the residents. The project is intended for the citizens over 65 years of age who do not need special care or assistance in their daily activities, but who need to change their place of residence due to problems with service accessibility, or whose annual income is lower than 250 % of the IPREM income indicator, which is currently 24,604.43€.

The aim of other programs is to improve the senior citizens' conditions of life and service accessibility. They include removing structural barriers in order to facilitate access to some buildings and public spaces, the interior adaptation program (removing architectural barriers, elimination of dampness, sanitary renovation, etc.). The main point of this project is to guarantee that senior citizens do not lack the basic necessities of life. This also refers to those among the elderly with restricted autonomy, for the disabled, for those with lower income and those who cannot be under the care of their families. Barcelona's officials have established the Housing Office Network, whose aim is to inform and to manage all the housing-related issues. In the neighbourhood of Poble-Sec there are over 300 elderly people living on their own and isolated from the rest of the society because of a lack of elevator. To overcome this, the authorities have introduced a system of living assistance - a list of medical centres that take care of such people. The project is called "Let's get out and about" and it enables participation in weekly trips accompanied by other seniors and volunteers. The main aims of the projects are: improving the quality of the direct environment of the elderly, guaranteeing

decent housing conditions and renewal of the public spaces, along with stimulating cooperation based on social bonds. It also promotes better relations with the environment with reference to culture, entertainment, sport and health. The project consists of three stages:

1) Accepting citizens and integrating them with their environment

2) Adaptation - improving accessibility to various facilities in the vicinity of the place of residence (medical facilities, banks, pharmacies, markets, services)

3) Integration - the residents make use of services and participate in the social life of their communities

Intergenerational Neighbourhoods

The aim of this plan is to develop and to popularize housing projects based on criteria that encourage building relations between their occupants by means of making use of common interior and exterior areas, as well as utilizing those architectural features which all residents, regardless of their age, can jointly use. The access to services is the key element, and, thus, designing and developing housing estates whose aim is to promote intergenerational relations of the tenants is of utmost importance. Another crucial issue is to rationalize the use of accessible spaces and areas, develop energy saving, as well as promote the use of renewable energy. In order to achieve these goals, the Association of Architects of Catalonia has taken certain actions that aim at popularizing the aforementioned ideas, raising the local authorities" awareness of the issues, and involving some private entrepreneurs in the project.

London

London has conducted a research (in accordance with the principles set down by WHO) related to age-friendly city issues in the northeast boroughs of Waltham Forest and Newham. Several actions whose aim is the renewal of the aforementioned boroughs were taken as a part of the Age-Friendly Cities project.

Access to public transport

Improving access to public transport is often considered as a key to becoming a successful Age Friendly City, as it makes it possible for the elderly to go outdoors, integrate with other residents, and to make use of the necessary services. Some elements of an age-friendly public transport implemented for residents over-60s include: fare reduction which makes it possible for the senior citizens to use the public transport, adapting the buses needs of the disabled, or the introduction of a door-to-door taxi service for people with limited mobility who cannot use buses.

Friendly urban spaces

The research has shown that both boroughs can offer an age-friendly physical environment. In most cases, streets and squares were equipped with appropriate streetlight; the pavements were clean and had lowered curbs, as well as ramps for wheelchairs; the car parks had a proper ratio of disabled parking spaces.

Social support and medical care

Just as in the case of Barcelona, the support of local authorities, who organize certain activities and initiatives for senior citizens, is of utmost importance. The research shows that involvement in social life is absolutely necessary for the elderly. Establishing cultural centers is one of the most important factors that could contribute to achieving this. Cultural centers located in the city area offer a wide spectrum of social events and activities. Moreover, they facilitate access to medical care and other services.

5.3 Actions taken in polish cities with regard to the aging of the population

In Poland, some cities are beginning to implement age-friendly policies, as the issues related to the aging population start to play a significant role in various spheres of public life. The changes in the attitudes of Polish pensioners demonstrated by the growing popularity of services targeted specifically at them such as easy to use mobile phones, bank accounts or summer trip offers. One of the new services is the reverse mortgage which allows them to save money rather than spend it on costly housing rents. In addition, cities start many initiatives for the elderly. Krakow, for example, was the first city in Poland, to join the Coalition for the Digital Inclusion of the 50+ Generation M@turity in the Net. Several interesting projects are carried out in the city including Krakow for Seniors, or the Senior Friendly Place competition. Lesser Poland is the only region in the country which promotes active ageing, having organized a prestigious competition for the Senior of the Year five times so far. Poznan has launched a recreation place for seniors only. In Poland there

are about 350 Universities of the Third Age, and hundreds of senior clubs. However, these examples of initiatives are aimed mostly at the active and healthy among the senior citizens. The most difficult problem to solve is to provide care for the impaired. Some cities, such as Krakow, Stargard Szczeciński and Sopot, see the growing number of the elderly in the city as a challenge and carry out actions that are directed at improving the living conditions of senior citizens, participating in research programs and projects, implementing appropriate policies.

5.4 Krakow – urban transport for the elderly

Krakow is one of the most important cities in the southern Poland, belonging to the region of Lesser Poland, which in comparison with other regions in Poland will age more slowly. One of the city's activities aimed at counteracting the negative social effects of aging is to participate in the European project AENEAS "Attaining Energy-Efficient Mobility in an Aging Society," under the Intelligent Energy Europe (IEE) program. In principle, the project has become the basis of reference for other international projects in the area of urban mobility of the elderly. The project aims at improving the attractiveness of sustainable transport as well as raising public awareness of the senior citizens' needs and problems related to travelling. Its purpose is to encourage seniors to make greater use of energy-saving forms of transportation such as public transport, cycling, or hiking. This ensures that the elderly have much more independence and flexibility in comparison to using only a private car. Driving can be difficult, sometimes impossible for the seniors who need to find a more attractive, alternative solution that they will be able to use. Krakow continuously renews its fleet of public transport through the purchase of new vehicles, such as buses and trams. The old ones are often replaced with new low-floor vehicles. They also have more secure equipment within the vehicle, including priority seating for the elderly. Additional handrails are placed near the doors. There is also an electronic visual and audible information about bus stops on the route in a growing number of trams and some modern buses. Since July 2007, residents of Krakow have had the opportunity to use TELEBUS, an innovative service by means of which passengers can call a dispatcher and book a bus pick-up at a desired destination. The Polish - Italian initiative is a pioneer in introducing "flexible bus routes" (DRT) in Poland. The service is also a very good example of technology transfer and know-how on public transport on the international scale. One of the key benefits of "flexible bus routes" is a new, positive image of public transport in Krakow, which is associated with its flexibility and adaptability to customer needs. Soon after the service was launched, it was used by about 300 customers per month, but in a relatively short time the number rose to 2000. Above all, the real reason of its success was the positive change in the attitude of the inhabitants of these districts to the new public transportation offer. To sum up, City of Krakow conducts urban renewal with reference to ageing of the population by:

- improving the safety and attractiveness of public transport,
- raising public awareness of the problems of the elderly,
- organizing various community outreach projects for the seniors.

5.5 Stargard Szczeciński – assisted living residences

Stargard Szczeciński is a medium sized city in north-western part of Poland. It is the third biggest urban center of West Pomeranian voivodeship in terms of population and one of the oldest Polish cities. One of its problems is a decreasing trend of migration to the city and negative population growth. As a result, the number of older people increases. In recent years in Poland, seniors have become an increasingly important group of consumers in the property market. More and more concepts for the creation of settlements and neighbourhoods for people of advanced age appear. These projects offer elegant middle-class housing estates located in close proximity to the metropolis, where architectural solutions to make life easier for the elderly are introduced and where easy access to medical care is provided. This allows seniors to spend their retirement in a place that gives them a sense of security. The residences of many Polish pensioners are not only too big and too expensive, but often they are not even suited to their needs. Moreover, the elderly often suffer from loneliness. At the same time, housing designed specifically for seniors and tailored to their needs constitutes only a small percentage of the total national construction. An example of this is housing for seniors in Stargard Szczeciński which was the first of this type to be designed and built in Poland. The building was founded by the Society for Social Housing which implements many social programs, including: housing for children from orphanages and for the disabled, as well as housing for people older than 55 years

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

of age. This is the first type of assisted living residences established in Poland and designed for people living there under the care of specialists. Living in assisted apartments provides the conditions for independent functioning in the environment and integration with the local community. Although the houses are located far from the city centre, and near some green areas, there is no problem with access to the services which are typically located in the centres of cities, as the assisted living residences consist of multi-family buildings with service centres and shops on the ground floors. Two-storey house consists of three segments whose scales and forms harmonize with those of neighbouring buildings. They are joined by an extended circulation path which is the axis of the complex and which merges into one whole, not only the three segments, but also the common areas. The building structure is fragmented, and the individual segments are separated from each other. As a result, they make an impression of almost independent, free-standing blocks which also blend harmoniously with the surrounding countryside. The main goal of the designers was to create a place which provides the residents both with the necessary intimacy and with the possibility of integration with their neighbours. Consequently, three types of space can be distinguished in the building: public, semi-public and private. Design work was preceded by public consultations and interviews with people who were potential tenants. During these meetings it became clear that one of the biggest problems was the lack of technical facilities, and the danger of not being able to call for help and being stuck somewhere in the building. In consequence, the system by means of which they can communicate with the volunteers who live nearby, as well as with a physician and a nurse, was created. Ultimately, in the next stage of implementation, a room for nursing procedures will be located in one of the buildings. The building in Stargard Szczeciński is a unique example of social construction, where design solutions are entirely subordinated to the program and the nature of the investment. The investor's and the designer's sensitivity to the problems of the tenants has resulted in the response of the residential environment to the needs of the senior citizens.

5.6 Sopot – public spaces

Sopot is a small city between Gdansk and Gdynia, in the middle of an agglomeration with almost one million inhabitants. The city, known as the "summer capital of Poland," is situated between the feet of the surrounding hills and the Bay of Gdansk. Due to its special micro-climate and abundant reserves of mineral water, Sopot has managed to preserve its special character and has become a famous tourist destination known throughout Europe. In addition, Sopot is one of the demographically oldest Polish cities, with a steady rate of decline in population. In 2009, for nearly 37,500 people, more than 24 % were of retirement age. Such age structure poses many new challenges to the social relations and the integration of residents. Sopot is located by the sea and has some features of a spa resort, so it could likely be a senior-friendly city and a model not only for other Polish cities, but also for the European ones. To achieve this goal Sopot uses the opportunities offered by a number of EU programs, aimed at seniors, as well as cooperation with international charities, such as the "Lions Club", "Rotary" and "Zonta". Since 2008 city of Sopot has participated in the Q -Ageing (Quality Ageing in an Urban Environment) project, whose purpose is to bring the public space to the needs and limitations of older people and to develop comprehensive, transnational solutions to the problems arising from the ageing of society in areas such as: vocational guidance for people over 50 years of age, health, entertainment and social integration of the elderly, architecture and infrastructure solutions tailored to the needs of senior citizens. Work on the preparation of the Project, initiated by a partnership of governments, institutions and NGOs from five countries (Hungary, Germany, Poland, Slovenia, Italy), began in February 2008. Sopot's priority areas are architecture and infrastructure adjusted to the needs of people with limited mobility. Local authorities take actions within the framework of the project with the support of several institutions and organizations, such as the Municipal Centre for Social Welfare, Sopot Center NGOs, local NGOs or Sopot University of the Third Age. One of the pilot projects in Sopot entails the creation of a map the city's architectural barriers and to develop guidelines to get around them. So far there have been no other attempts at devising a similar guide that would identify architectural barriers for the elderly or the disabled. It should be noted that the map of barriers is not to be merely a city map with inconvenient points marked on it. In fact, it has a rich, dynamic database containing information about the type of problem that is occurring, its detailed description and location, the proposals of possible solutions, as well as potential transport cost estimates, the hierarchy of urgency and the approximate time of arrival of an emergency service. The map will be one of the strategic documents of the city as the primary tool to assist in decisions relating to the source of investment financing, acquisition of external resources and introduction of local laws. On the barrier maps one can find mainly public facilities and urban open space

elements (e.g. streets, bus stops, parks, squares), and possibly other publicly accessible places (such as: shops, cafes, restaurants and historical buildings). More importantly, the map is a dynamic tool, and seniors themselves, as one of the most involved groups, will be able to report additional locations by means of user friendly computer terminals which are a part of the second pilot project of Q-Ageing. In some locations, there will be senior-friendly computer terminals with free Internet access which use appropriate software support (e.g. for the visually impaired). Administrators of these sites will serve to help and support those using the terminal. This will help to create the first points of the network of sites, where the senior inhabitants will be able to socialize and establish a form of mutual aid - while remaining in a safe and friendly environment. The two pilot projects will be accompanied by an awareness-raising campaign for the citizens informing them of the specificity of the social problems of the elderly. The campaign will combat social isolation of seniors and fight the prevailing stereotype of an elderly person. All of the accompanying measures are also designed to encourage seniors to go outdoors and take part in leisure activities in public places in the city.

6 CONCLUSION

These cases show that in recent times Polish local authorities in many cities have recognized the challenges of an ageing population. The growing interest in this subject among the local governments and in the academia results from their understanding of its importance in social life as well as from acknowledging the need for a long-term planning. For cities to become age-friendly it is necessary to face many different social, economic and spatial challenges.

The Polish cities participate in some of the European Commision's projects, such as AENEAS, Q-Ageing, etc. This can help to specify the course of action necessary in appropriate adaptation of the city to the needs of an ageing society. Major European cities, such as Barcelona and London implement urban policies that refer to various spatial issues related to carrying out age-friendly urban renewal. The urban renewal in the aforementioned cities is conducted in a comprehensive way and embraces many social, economic and spatial issues. The Polish cities unfortunately lack such a thorough approach which requires high-level coordination and integrity. Actions are taken in a selective and partial manner; they often refer only to very specific issues, such as housing and building of new estates for the elderly. There is no coordination of these actions on a national, regional, or even local scale. Property developers with necessary means to build such estates would often choose suburbs as its location. In effect, extending or building new infrastructure in the suburbs is essential, or otherwise, senior citizens are prone to face many difficulties related to the access to the basic necessities of life. Such approach to urban renewal results in isolation, rather than integration of the elderly. Resettling them to the suburban areas reduces their participation in social life and contact with their community, intensifying their isolation, even if they are provided with higher physical comfort. Moreover, most of the offers and services targeted at the elderly would still be located in the centres of cities, causing difficulties communication and limited accessibility.

Urban renewal with reference to the ageing population is understood as adapting the city to the changing needs of the elderly. It should, however, take into consideration such spatial planning which enables flexible shaping and using of the urban space. In other words, it is especially important to consider the functional flexibility of certain facilities: e.g. kindergartens that could easily be transformed into community centres for the elderly, and housing designed for the elderly could easily be adapted to the needs of the single residents (one person households), etc. Moreover, in order to be age friendly, cities have to notice the complexity of each of the factors. For example, social services - clubs, cultural centres are extremely important, but without adequate transport they will not function well, because older people will not be able to access them easily. Public toilets will be accessible if they are always open and well-maintained.

Any approach to creating age-friendly city should be comprehensive, hence, while speaking about the renewal of cities with reference to the ageing population, one should consider renewal on various levels covering different activities: social, economic and spatial. Urban renewal should also address the social participation of older people. Sociologists point out that ageing brings a profound change in almost all important relations. Senior citizens are an important but often neglected part of society. Encouraging mobility and more active lifestyle benefits all seniors, and the idea of age-friendly cities means a better quality of life for everyone. This approach can be described not only as an integrated urban renewal which includes both housing construction projects, institutions, networks, social infrastructure facilities and

technical support in the city, but also as a qualified restoration of the existing building structure and meaningful integration of new constructions with the existing ones, as well as economic and social renewal of the city. These actions can lead to long-term improvement in the quality of lives of all citizens, regardless of their age.

1 ABSTRACT

Environmental events are a big concern when looking at the safety and resilience of a city. This is even more true if climate change scenarios, and thus changed environmental conditions, are taken into account. Within the European FP7 Research Project SUDPLAN (Sustainable Urban Development Planner for Climate Change Adaptation) a Scenario Management System (SMS) is under development. The SMS combines large scale climate change models, downscaled model results and local high resolution simulations with interactive 3-D/4-D visualisations to facilitate the analysis of future climate change effects on city-scale environments.

The system will be applied by four european pilot cities which are part of the consortium: Stockholm, Linz, Prague, and Wuppertal. The project adresses the environmental topics air quality (e.g. temperature, emissions, etc.) and rainfall. In the case of rainfall, major concerns are combined sewage overflow (CSO) and surface run-off due to heavy rainfall events.

Due to the geographical situation of the german city of Wuppertal located in the steep, narrow, long valley of the Wupper river, the main concern regarding climate change impact is uncontrollable, extremely localized run-off from increased heavy, short rainfall events. The potential damage of public infrastructure and of private property is a major concern to the city managers. The potential needs for investments are huge, considering that the city copes with run-off from 350 kilometers of creeks (over 800 creek sections) and 650 kilometers of drainage channel system. To enhance the public awareness for investments due to future risks related to a changed climate, means to transport complex domain specific results into a clear and easy to understand "language" are needed.

In this paper we present the current results of the SUDPLAN project concerning the Wuppertal pilot. We will describe the workflow from the large scale climate model to the 3D/4D visualisation of local high resolution simulation results. We focus on the intuitive and easy to understand presentation of the effects on the resilience and safety of critical public and private infrastructures.

We combine widely used GIS features with highly interactive 3D/4D visualisation in order to provide insight into possible future problems caused by heavy rainfall events. This can be used for the analysis and comparison of simulation results from different climate and planning scenarios by domain experts (i.e. climate modellers) as well as endusers (i.e. urban planners). Moreover, the presented results are also suitable to illustrate and convey the necessity of investments even for non-experts (e.g. city administration, property owners, etc.).

2 INTRODUCTION

Environmental Information and Decision Support Systems (EDSS) are complex information systems containing complex information and performing complex workflows, that may not even be pre-defined (ad-hoc workflows). In general, these systems are composed of a number of highly heterogeneous components and tools solving a complex monitoring, analysis or decision support task. The component structure of such systems cannot really be generalized or even properly defined, because real world applications vary considerably depending on the concrete use of a concrete system. However, certain common elements are present in many systems [1,2] data management and data network components, geomatics components, decision support components, numerical simulation models and others. Even at the level of a single, stand-alone system for one single purpose, integration of data, models, visualization, analysis tools and decision support tools is often a very difficult and costly undertaking. Today's EDSS are very often hard wired ('all-in one systems'), which is not astonishing, as the complexity covered by EDSS is enormous. EDSS have to deal with complex space and time related data and its representation, furthermore they are asked to transfer a multitude of data into easy to understand visualization representation having complex algorithms in the back end – all this before the actual decision support begins.

Due to the lack of standards for data interchange hard-wiring the tools and the data in one monolithic application is still a common practice. This practice makes EDSS expensive and inflexible and this is one of the main reasons why there are not more decision support systems in real use.

In recent years an important trend in environmental informatics has been research and development on environmental information service infrastructures (in the case of geomatics components also called Spatial Data Infrastructures, SDI). The main driver for this research has been the practical need to overcome organizational boundaries in environmental management and to enable linking systems together which are operated by different organizations. In Europe, for instance, the INSPIRE Directive [3] set the goal in 2007 to establish an Infrastructure for Spatial Information in the European Union. The directive obliges member states to make available relevant geographic information for the purpose of formulation, implementation, monitoring and evaluation of Community environmental policymaking and for the citizen. Furthermore, by establishing from the onset cross-sector co-ordination mechanisms, INSPIRE aims at providing access to compatible information across sectors such as environment, transport and agriculture. INSPIRE has become a major driver for research in the area of environmental service infrastructures. This driver has triggered research in FP6 Integrated Projects OASIS [4], ORCHESTRA [5], SANY [6], OSIRIS [7] and other to achieve the overall goal of interoperability.

Projects funded through other programs contribute to the same goal, for instance SSE [8]. This research has reached a stage where generalized concepts are available, generalized architectures have been published, service specifications have been defined and service implementations become more and more available, in some cases as open source products. At the same time, the use of established industry standards, most notably those of the Open Geospatial Consortium [9], OASIS [10] and the W3C [11], has become a dominant requirement in order to achieve inter-operability amongst systems and stakeholders. More and more customers require systems which they order to comply with these standards, and at the same time the standards evolution also drives some of the technological changes, along with the ongoing research mentioned in the previous paragraphs. A common trend of both research and standards evolution is to compose systems in a loosely-coupled way through a service-oriented architecture (SOA).

These recent developments have dramatically changed the opportunities for EDSS development. The practice of monolithic systems, which integrate data and functionality into one system, built for this purpose only, will be replaced by flexible environments which make use of external resources (data, information and services), and which provide a framework for flexible delivery of functionality to end users. This means that the "software plumbing" (individual integration projects) for each individual EDSS will cease to exist. The vision of next generation EDSS is that of a dynamic composition of services in a SOA.

The dimensioning of urban infrastructure is typically based on a statistical calculation of historical time series data, e.g. to quantify the maximum river runoff during a 100 year period, the most intense rainfall occurring within a similar period or the risk for a combined air pollution and heat wave. The temperature increase, changes in precipitation and air pollution levels – both expressed as yearly totals and as extreme values – and storm frequencies expected to occur during the coming decades will invalidate those historical time series analysis and call for new statistical assessments based on forecasted weather scenarios up to and beyond 2050 [12,13]. There is a need for planning tools which will make it possible for city planners to include such analysis in a simple, early and cost-effective manner. In order to make these EDSS solutions affordable, data integration, integration of models as well as integration of other services must be possible at low cost, in an optimal case in an "on-the-fly" manner. Sustainable cities also require an integrated planning approach. They need to assess some of most important environmental factors in an early stage, in particular for applications like:

- coping with the risk for river flooding and inundations of built-up areas and other developed areas
- maximum rain intensity to be expected over sealed surfaces and for which water runoff systems must be dimensioned
- spatial distribution of air pollution, risk for extreme events and high ambient temperatures in built-up residential and work areas

The sustainability must be assured both during present and for expected future climate scenarios, as simulated by regional climate models (RCM's). Therefore the integration of RCM's into local decisions, and the integration of RCM's with local models, is a crucial factor.

2.1 The SUDPLAN Project

The SUDPLAN project aims at developing an easy-to-use web-based planning, prediction, decision support and training tool, for the use in an urban context, based on a what-if scenario execution environment, which will help to assure population's health, comfort, safety and life quality as well as sustainability of investments in utilities and infrastructures within a changing climate.

This tool is based on an innovative and visionary capacity to link, in an ad-hoc fashion, existing environmental simulation models, information and sensor infrastructures, spatial data infrastructures and climatic scenario information in a service-oriented approach, as part of the Single Information Space in Europe for the Environment (SISE). It will provide end users with 3D modeling and simulation as well as cutting edge highly interactive 3D/4D visualization, including visualisation on real 3D hardware.

The tool includes the SUDPLAN Scenario Management System with three so-called Common Services. The latter will allow downscaling of regional climate change model results to a spatial and temporal scale useful for urban planning in whatever European city. SUDPLAN Common Services include gridded information on present and future extreme rainfall, temperature, river runoff and air pollution.

Vital consequences of climate change are considered in 4 carefully selected urban pilot applications located in Austria, the Czech Republic, Germany and Sweden. The SUDPLAN Scenario Management System with Common Services information will here be used to execute and visualize results from local high resolution models and sensor systems, covering such diverse applications as: a) extreme rainfall episodes causing problems with b) uncontrollable, extremely localized runoff, and c) drainage and sewage systems, d) hazardous air pollution and high ambient temperature episodes causing health risks, e) social dynamics (movement of people) as function of climate change and quality of living.

More information about the SUDPLAN project (including demo applications) can be found on the project website http://www.sudplan.eu.

2.2 Wuppertal Pilot

The city of Wuppertal is located in the steep, narrow, long valley of the Wupper River. The location is so narrow that more than a hundred years ago, the city went in the 3rd dimension for public transport, and built the famous Wuppertal Suspension Line (Figure 1).

Figure 1: Because of the narroness (left) the city of Wuppertal decided to use the 3rd dimension for public transport (right).

Due to the geographical situation of the city, the main concern regarding climate change impact is uncontrollable, extremely localized run-off from increased heavy, short rainfall events. For instance, an event in 2007 caused heavy local damage and first went completely unnoticed in the city hall, located only 2 kilometers away, where the sun was shining. The potential damage of public infrastructure and of private property is a major concern to the city managers. The potential needs for investments are huge, considering that the city copes with run-off from 350 kilometers of creeks (over 800 creek sections) and 650 kilometers

of drainage channel system. Due to the complex geography, it is completely unpredictable where a heavy rainfall event might occur, and when it occurs it is today unknown whether there will be flood and where it will run off. Due to the huge investments required, it is also not possible to just increase the profile of all, or even only of major parts, of the drainage system. The Wuppertal pilot is therefore concentrated on heavy, short rainfall events and their impact on the infrastructure. The city administration has put a project underway to develop a master plan, during the coming 5 years, which shall identify the most vulnerable areas and shall suggest different localized planning options which are likely to prevent damage and are yet practical to be implemented, including being capable to cope with financial constraints.

3 SUDPLAN SYSTEM OVERVIEW

This section gives an overview of the complete SUDPLAN system and describes the different parts. A system overview is illustrated in Figure 2.

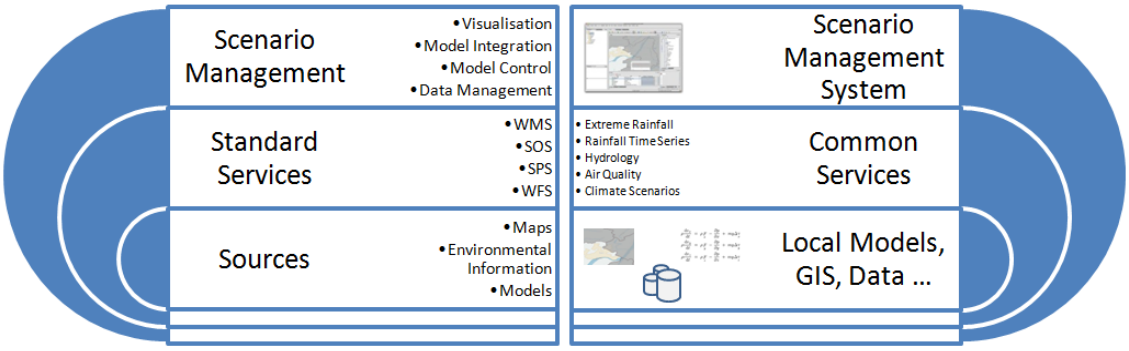

Figure 2: SUDPLAN system overview

3.1 Scenario Management System

The Scenario Management System (SMS) is the platform on which any SUDPLAN Application (or SUDPLAN System) is built. It consists of three distinct Building Blocks described in the following subsections. The SMS can be seen as a generic integration platform that will be able to facilitate climate change induced urban development planning in any city in Europe. The goal to provide a universal, flexible and adaptable planning tool is supported by the separation of the SUDPLAN System into several architectural layers as shown in Figure 2.

The top-level layer, the SUDPLAN Application itself, is the result of an extension, customisation and configuration of the underlying SMS. The SMS comes with everything needed to provide common scenario management tasks including data integration, model management and execution, workflow management, basic and advanced visualisation, and comparison of various temporal and spatial data sets, etc. It therefore relies upon standard services for data access and model management and thus greatly facilitates the task of integrating new models and data sources. Consequently, the same mechanisms used for interfacing the SUDPLAN Common Services with the SMS can be used for local model and data source integration. As shown in Figure 3, several services specified by the Open Geospatial Consortium (OGC) are supported by the SMS: Sensor Planning Service (SPS), Sensor Observation Service (SOS), Web Map Service (WMS) and Web Feature Service (WFS).

It is also possible to develop a custom model integration solution with respect to particular user requirements. The SMS Framework allows both standard and custom integration without the need to change the SMS itself. For this purpose, the SMS Framework exposes an API that enables the developers of a SUDPLAN Application to extend the SMS with their specific functionalities. The four pilot applications of the SUDPLAN project therefore validate not only the general approach of the SMS but also its adaptability/transferability and thus its applicability to any city in Europe.

SMS Framework

The Scenario Management System Framework (GUI shown in Figure 3) is the central component providing common SMS and integration functionality. Together with the Building Blocks for the integration of models through standardized services and for advanced visualisation capabilities it provides the basis for pilot

specific implementations and the necessary workflows to support the use of models as a basis for decision making.

The core functionalities provided by the SMS Framework include, for example, support for the management of models, i.e. model execution, result storage, parameterisation and basic model result visualisation (such as 1D time series, and 2D maps).

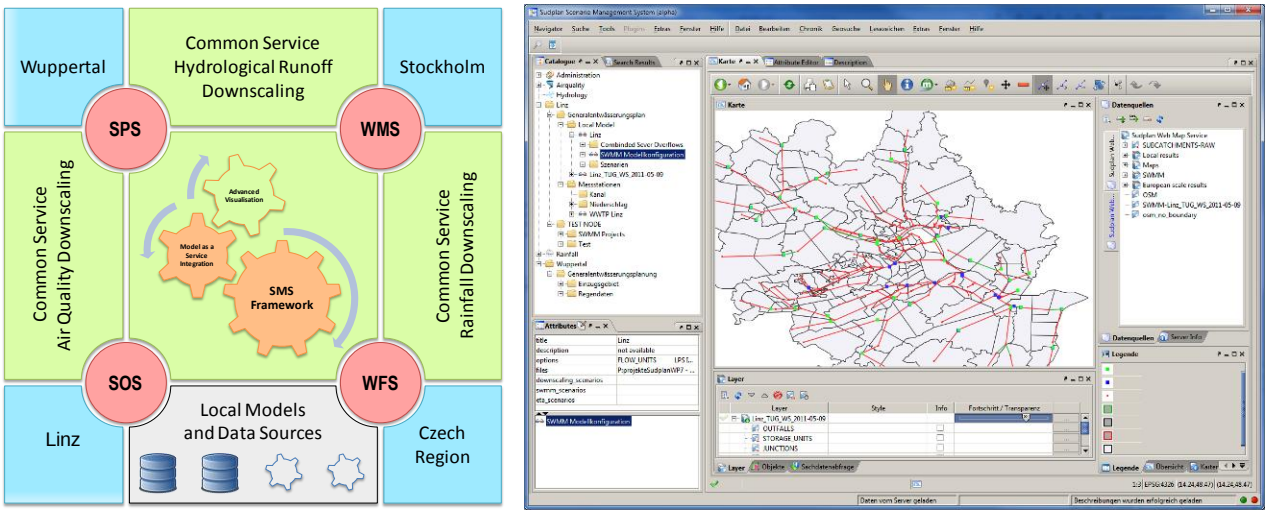

Figure 3: OGC Services Integration and SUDPLAN SMS GUI

Model as a Service

This building block of the SMS provides the means to control model implementations and access model results, including both SUDPLAN Common Services and local pilot specific models, via standardised web services. The selected standards are members of the OGC SWE [14] family, specifically SOS (Sensor Observation Service) and SPS (Sensor Planning Service), which are used for model result access and model control. This part of the SMS can be used to access the corresponding common service (section 3.3) as well as to encapsulate local models.

Advanced Visualisation

Using this building block facilitates the user of the SUDPLAN SMS the mean to interact and navigate with a virtual globe (based on NASA's World Wind SDK). Furthermore, the advanced visualisation component handles the visualization of data as well as simulation results in a geographical three-dimensional context. Moreover, the advanced visualization component provides a visualisation wizard called VisWiz. VisWiz enables the user to choose a suitable visualization technique for a data set. Even if the user is not familiar with visualisation techniques in general the intuitive VisWiz component provides the mean to visualize the data in 3D.

3.2 Climate Scenarios

Climate scenarios depict the resulting climate evolution over time, as simulated by global (GCMs) and regional (RCMs) climate models. Climate scenarios are products of certain emission scenarios that reflect different economic growth and emission mitigation agreements.

SUDPLAN uses available climate scenarios according to IPCC directed activities preparing for AR4 and currently for AR5 (through the CMIP5 coordinated model intercomparison, see http://cmip-pcmdi.llnl.gov/cmip5). SUDPLAN uses regionally downscaled (over Europe) results from some well reputed global models. Currently SUDPLAN includes the following climate scenarios downscaled by SMHI's RCA3 model:

- ECHAM5 (Roeckner et al., 2006; version: initialization 3), using A1B emission scenario
- HADCM3 (Gordon et al., 2000; version: climate sensitivity Q0), using A1B emission scenario

At the end of the project, an extended scenario ensemble will be available. Especially for rainfall downscaling, it is likely to also include the following scenarios:

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

- ECHAM5 (Roeckner et al., 2006; version: initialization 1), using A1B emission scenario
- ECHAM5 (Roeckner et al., 2006; version: initialization 2), using A1B emission scenario
- ECHAM4 (Roeckner et al., 1996), using A2 emission scenario
- ECHAM4 (Roeckner et al., 1996), using B2 emission scenario

3.3 Common Services

Common Services are the climate downscaling services for rainfall, river flooding and air quality, developed in the SUDPLAN project and accessed through the SUDPLAN platform (Scenario Management System).

Common Services allow a common urban downscaling functionality for all European cities, based on how relevant environmental factors will evolve according to different climate scenarios. The application of Common Services for downscaling of environmental factors in a new city is simple and requires a minimum of local data. The results are communicated through open standards. The following environmental factors are possible to downscale within selected climate scenarios:

- Rainfall intensity, frequency and duration, with consequences for urban storm water flooding and sewer system capacities
- Hydrological conditions in terms of river runoff and soil moisture, with consequences for river flooding, surface water resources and farming conditions
- Air quality with consequences for city population health and life quality

3.4 Local Models, Data Sources and Services

Local models, data sources and services already existing within a city's infrastructure can be easily incorporated in the SUDPLAN application through standard services provided by the SMS (section 3.1). In addition the SMS Framework exposes an API to easily extend the application according to the users needs.

4 WUPPERTAL USE CASE

The city of Wuppertal, a town with approximately 350,000 residents, is the biggest town in Germany that is situated in hill country (from 98 to 353 m above mean sea level). It is located in the steep, narrow, and long valley of the Wupper river. There are several creeks on both sides of this valley that open into the storm water sewage system before they finally end in the Wupper. During a heavy rainfall event the city's storm water sewage system is quickly blocked by those swollen creeks causing the precipitation to runoff on the surface. The storm water run-off may thereby affect valuable public infrastructure and private property. This is a major concern to the city managers. Due to the complex geography it is completely unpredictable where a heavy rainfall event might occur and therefore unknown whether there will be flooding and where it will runoff.

Figure 4: Damage due to uncontrolled storm water run-off.

Up to now the mid- and long-term planning of the storm water sewage system has been accomplished with iterative model runs of a hydrological model (for the creeks) and a hydrodynamical model (for the sewage system). This planning process is called 'Generalentwässerungsplanung' (GEP), what could be translated as 'General Drainage Strategy'. Wuppertal's first main objective is to expand the GEP: the modelling of surface

run-off after heavy rainfall events should be integrated into the process. To achieve this goal, a hydrodynamical model should be used to detect the critical spots (high risk of flooding plus valuable and vulnerable facilities).

Wuppertal's second main objective is to mitigate the risk of flooding for the detected critical spots. The traditional strategies to achieve this are either the enlargement of the profiles of the sewage system or the construction of retention basins. Given these two options the potential needs for investments would be immense, considering that the city copes with water run-off from 350 kilometres of creeks (over 800 creek sections) and 650 kilometres of sewage channel system. An alternative and much more cost-efficient strategy is to look for localised planning options which are likely to prevent damage. Examples for such structural measures are the alteration of street profiles by means of higher road kerbs or the installation of stationary (or mobile) walls. Wuppertal's third main objective is to find the most cost-efficient measures for the flood risk mitigation for each critical spot. These measures shall give a higher probability to prevent damage and should yet be practical to implement, including being capable to cope with the ever growing financial constraints of the city. Please see [15, 16] for more information on Flood risk management.

The fourth main objective is to provide the responsible planners and hydrological modellers in Wuppertal with a tool that enables them to simulate a multitude of modelling experiments with the model component for the surface run-off, both to detect the critical spots and to simulate the effects of different structural measures at the critical spots. The tool should be able to store the parameters and results of such a model run and to visualise the results. The SUDPLAN project provides such a tool – the Scenario Management System (SMS).

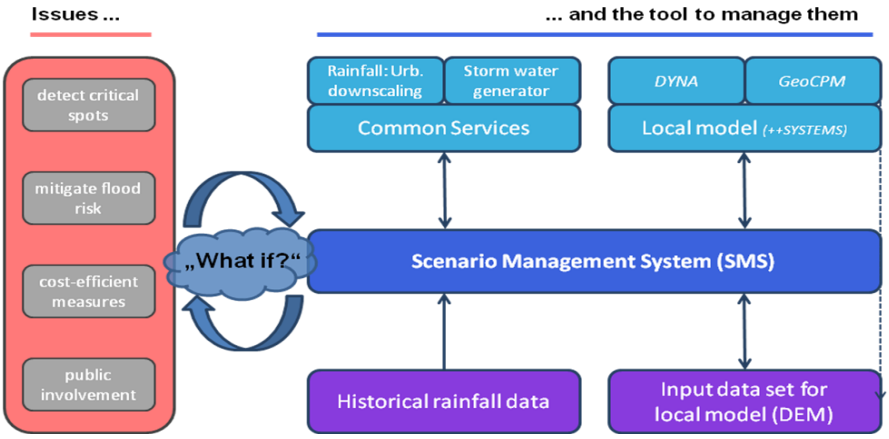

Figure 5: Wuppertal objectives and tools used for solving.

5 WUPPERTAL WORKFLOW

In this section we present the current results of the SUDPLAN project concerning the Wuppertal objectives. We describe the workflow from the large scale climate model to the visualisation of local high resolution simulation results.

Figure 5 depicts the objectives which need to be solved and the tools which are involved on the application side. All these components are incorporated within the SUDPLAN application. The general component chain used in the Wuppertal pilot is shown in Figure 6.

After selecting a climate model the Common Services for rainfall are used to project historic rain data into the future based on the chosen climate scenario. This information is then combined with input data for the local model (DEM, simulation preferences, etc.) which can be edited within the SUDPLAN SMS. After running the local models for the sewer network and the surface run-off the data can be visualized either in the 2D GIS component or with the 3D visualisation component.

In the following subsection the different steps of the workflow are briefly described and depicted with screen shots of the SUDPLAN application.

5.1 Select/Inspect Climate Scenarios (European Scale)

To get a first overview of the available climate scenarios the user can simply drag and drop the scenario from the repository onto the map component of the SUDPLAN application (Figure 7 left). By using a time slider

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

the different time steps of the results can be inspected. To get further information for a specific geospatial position/city the user can query the map to show the time series information for the selected point (Figure 7 right)

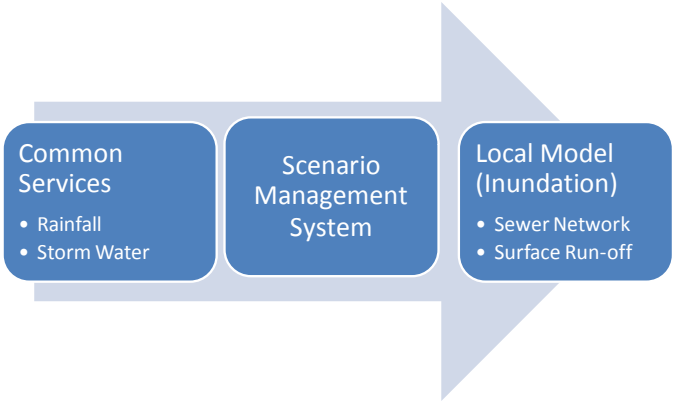

Figure 6: Wuppertal pilot component chain

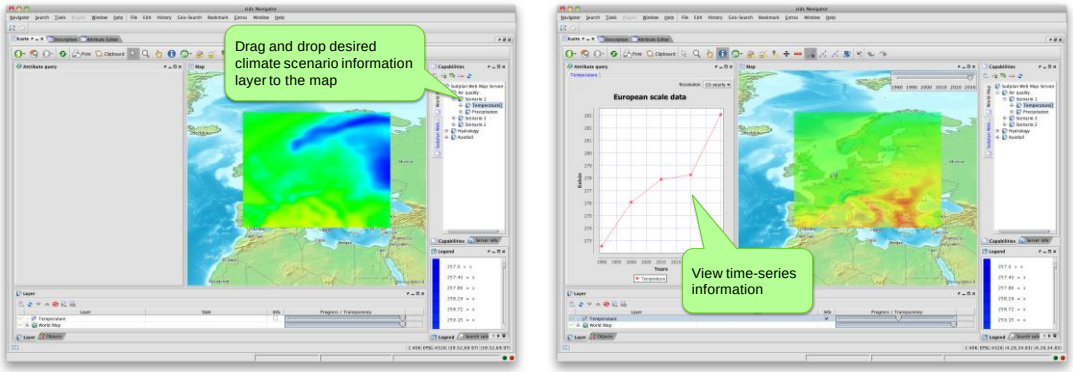

Figure 7: Inspecting a climate scenario on the European scale.

5.2 Urban Rainfall downscaling using historical time series

To downscale the selected climate scenario to the urban level using the SUDPLAN common services the user needs to provide historical rainfall data. This can be provided either as IDF curves or measured rainfall time series. In this use case historical rainfall time series are available and incorporated as local data in the SUDPLAN application.

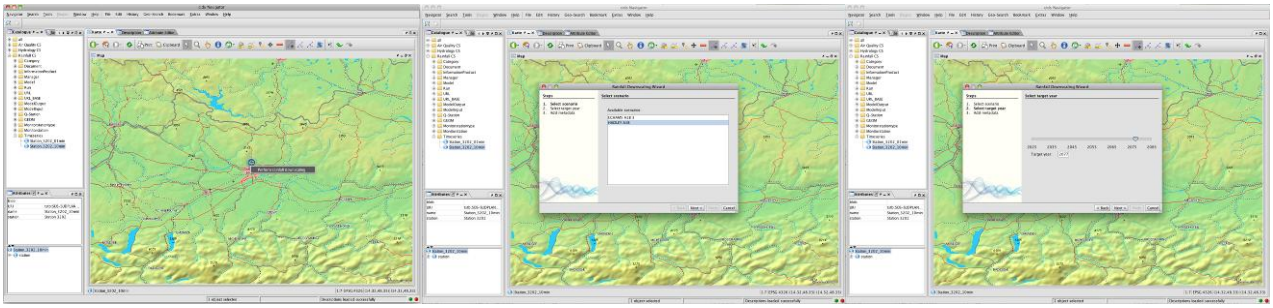

Figure 8: Using the SUDPLAN Common Services to downscale a selected RCM to a specific city using historic rainfall time series.

The user can simply drop the desired rainfall time series from the repository onto the map component. The downscaling is started by selecting the representation of the time series on the map. The user is guided through the process by a simple wizard where he can choose the climate scenario and the desired forecast period/year (Figure 8).

The historical rainfall data and selected preferences will automatically be uploaded to the Common Services and after the downscaling is finished the user is presented with the new (future) rainfall time series based on the chosen climate scenario which he can then compare to the original historical data (Figure 9).

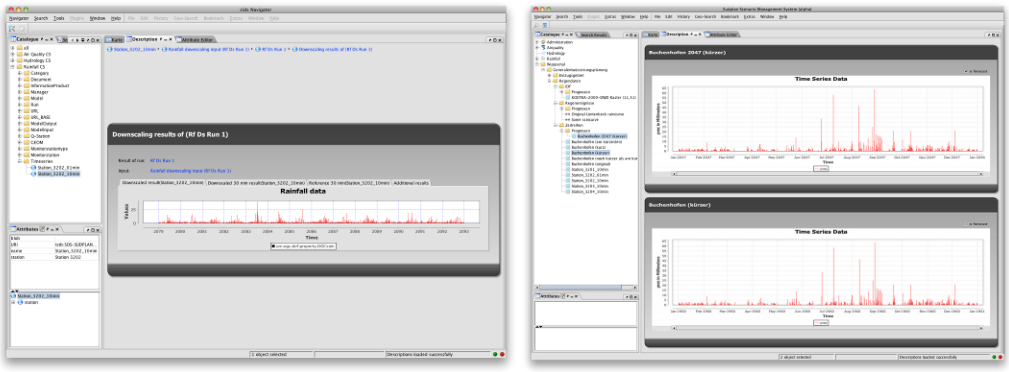

Figure 9: Rainfall downscaling result (left) and comparison of historical and future rainfall time series (right).

5.3 Running the local model

To run the local run-off model the user first selects the area of interest and a predefined configuration (GeoCPM input data, DEM, etc.). The user can inspect the data and if he wants to simulate a effects of a mitigation measure optionally manipulate the underlying DEM, e.g. raise predefined breaklines (road kerbs), etc. (Figure 10).

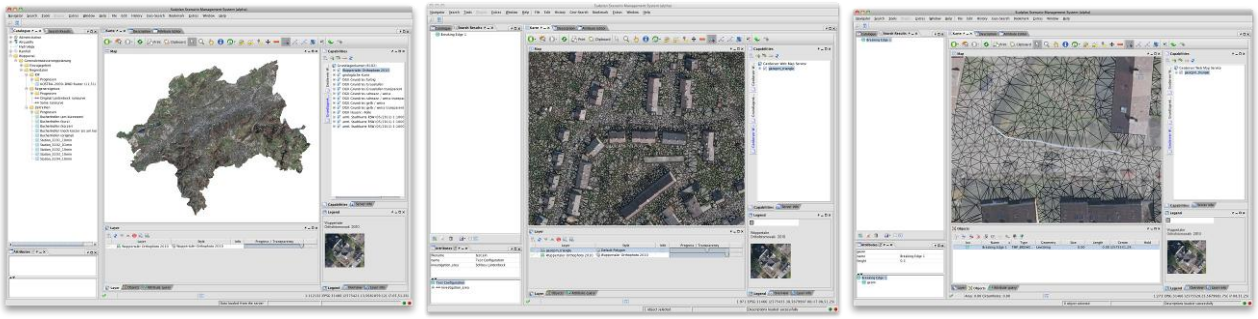

Figure 10: Selecting and manipulating the base data for the local model.

The external simulation is integrated in the SUDPLAN application through the provided API and can be started directly from within application. The user is provided with the estimated time to run the simulation and after finishing an overview of the simulation results is given (Figure 11). The simulation result is automatically added to the local repository and can be used for further inspection and visualisation.

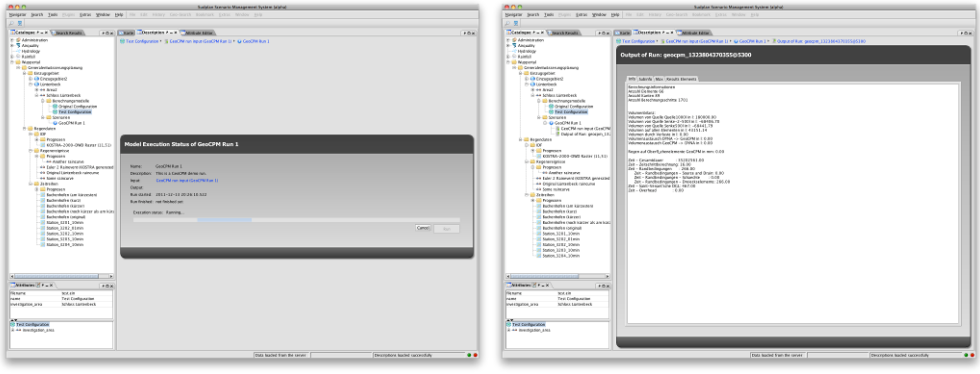

Figure 11: Running the external local model and result overview.

5.4 Visualise the results of the local model

The simulation results can be visualised either in the 2D map or with the 3D visualisation component. The results can be easily combined with additional existing data like building information, traffic data, etc. When using the 3D visualisation component the user is able to animate the model results inspect the water levels at certain important points of interest over time. In addition multivariate data can be shown with different information visualisation techniques to get a better understanding of the impact of the flooding event or the mitigation measures used for this simulation run.

6 CONCLUSION

In this paper we gave an overview of the SUDPLAN system which is currently being developed within the EU FP7 project SUDPLAN and presented details about the Wuppertal pilot which is concerned with the mitigation of the impact of heavy storm water events considering future climate change.

We presented the objectives and use case for the City of Wuppertal and described the workflow from selecting a climate scenario, downscaling this scenario to the urban scale, running the local simulation model to visualizing the simulation results, which is all combined within the SUDPLAN application.

7 FUTURE WORK

The SUDPLAN project is now in the third year of development. After developing and integrating the basic building blocks and first pilot extensions we will now focus on specialised solutions for the different pilot cities and use cases. The project status and results can be followed on the project website (http://www.sudplan.eu).

8 ACKNOWLEDGEMENTS

SUPLAN is a project co-funded by the European Framework Program 7, under challenge ICT-2009-6.4 ICT for Environmental Services and Climate Change Adaptation of the Information and Communication Technologies program, project number 247708.

Deconstructing Smart Cities: An Intertextual Reading of Concepts and Practices for Integrated Urban and ICT Development

Marc Wolfram

(Dr. Marc Wolfram, Leibniz Institute of Ecological Urban and Regional Development, Weberplatz 1, 01217 Dresden, m.wolfram@ioer.de)

1 ABSTRACT

Concepts of 'smart' or 'intelligent' cities currently enjoy great popularity. They offer frameworks for interpreting certain linkages between information and communication technology (ICT) and urban development, and put forward a particular agenda for action. In this, they claim a broad legitimacy for guiding stakeholders, drawing on findings from a number of strands of scientific inquiry. Furthermore, building on the everlasting albeit problematic promise of technology as a key to resolve pressing societal problems, they equally constitute an attractive reference for actors at all levels and across sectors. But despite their striking virulence in research, policy and practice, it remains rather open what the actual pursuit of a 'smart city' is, and therefore, which winners and losers we are to expect from realization.

Against this backdrop this paper puts forward an intertextual reading of recent contributions to the 'smart city' discourse, probing in particular the context conditions under which it has emerged, the conceptual orientations developed, and the implementation strategies derived. It appears that, while suffering from affinities to technological determinism and urban entrepreneurialism, 'smart cities' largely neglect the need to select and balance goals for integrated urban and ICT development, and to develop suitable approaches for actually doing so. Instead, by conflating the descriptive and the normative, 'smart cities' tend to substitute an orientation at societal ends by an orientation at selected means, thus supporting path optimization but structurally evading radical urban change. Hence, in order to become meaningful for enhancing sustainable and resilient local development, such concepts need to be embedded within a much wider cultural change perspective that should underpin especially the social, ecological and political dimensions of 'smart' urban development. In particular, they need to strengthen their focus on and engagement with the governance of integrated urban and ICT development.

2 INTRODUCTION: CONDITIONS FOR THE RISE OF SMART CITIES

Relationships between urban development and networked information and communication technologies (ICT) have increasingly gained attention in research, policy and practice since the early 1990s. As visionary writings on digital urban futures started to influence our cognitive maps (Mitchell 1996; 2000; Negroponte 1996), and notions of the "global city" (Sassen 2001) and the "network society"' (Castells 2000) have gradually developed into common places, this has triggered the emergence of a new field of activity, "populated by researchers and practitioners at the intersection of people, place and technology" (Foth 2009, xxix). The discussion in this field has thus revolved around diverse concepts and issues such as 'digital-', 'cyber-', 'wired-' or 'intelligent' cities and communities, local 'innovation systems' and their constitution, multiple 'e' applications (e-government, e-participation, e-mobility, e-learning, e-health, e-inclusion, etc.), increasingly including the use of pervasive computing and future internet technologies within urban areas. In this context, a mainstream appears to be concerned with shaping and deploying new technologies in cities for a range of sectoral and/or actor-specific objectives. But also more critical and empirical analyses of the socio-economic, spatial and cultural implications and interrelations of networked ICT and cities have been undertaken (Graham & Marvin 1996; 2001; Rutherford 2011). The boundaries of the object in question are therefore still rather loosely defined e.g. by conference titles referring to 'communities and technologies' or overview publications under the heading of 'urban informatics', including contributions from a wide range of (inter-) disciplinary perspectives and world regions (Ellison et al. 2007; Foth 2009).

More recently, however, a growing part of this debate about the co-evolution of urban areas and ICT appears to have centered around 'smart' or 'intelligent' cities – two concepts that are mostly used as synonyms. The very materialisation of this discourse prompts the question of what may have changed in the context conditions that shape the relationship between cities and ICT that would explain the emergence of this distinctive label? Not unexpectedly, there is no straightforward answer to this question. Rather, one has to account for a number of factors that have gradually converged towards each other, nourishing todays 'smart city' narrative and its virulence:

- Grand environmental challenges: Climate change and global resource scarcity have become dominant on policy agendas across all levels. However, key knowledge on the dynamics of these challenges and their complex interactions with socio-economic structural change has become available only during the past decade (Stern 2007), creating increasing pressures for action. The 2009 financial crisis has added to this picture, drawing attention to the vulnerabilities of the existing regime and in particular the role of cities in this (Harvey 2010);
- Urbanisation: With a growing share of urban population (e.g. in the EU from currently 75% to 85% by 2050, globally 81% by 2030) and the related increase and spatial differentiation of resource demands, environmental pressures and socio-economic inequalities, cities and urban regions are gaining further quantitative and qualitative importance when it comes to designing policy reponses to the above challenges;
- Technology convergence: ICT system components are subject to enhanced convergence and miniaturisation, facilitating the interconnection of data, soft- and hardware, as well as users. objects and environments in large-scale (mobile) networks, e.g. regarding the development of future internet and embedded systems concepts and applications (mobile broadband, cloud computing, internet of things, service-oriented architectures, Web2.0, etc.);
- Industrial convergence: As ICT components become increasingly integrated with other infrastructures and technologies (electricity grids, transport networks, building components, household applicances, etc.), major industrial branches are moving closer together. This "convergence of industrial value chains for smart urban infrastructure and applications" (EC 2011, 13) is therefore pushed by industry and governments alike to secure participation in emerging growth markets;
- Informatisation of society: Drawing on selected novel ICT solutions and their adaptation, social practices at individual, organisation (public and private) and inter-organisation level are changing, exploring new decentralised options for networked data and information collection, exchange, analysis and communication. Especially in urban contexts, new networked ICT usages are thus becoming self-evident parts of everyday practices in both professional and private milieus;

While actually none of these factors is entirely new or can be convincingly claimed to have triggered 'smart city' thinking all alone, together they have created a dynamic context within which this discourse has been able to unfold through continued reproduction across levels and sectors. Most importantly, it illustrates that the 'smart city' can hardly be claimed to represent a neutral frame for any urban ICT activities, or define merely a certain epistemological perspective in research. Rather, it clearly establishes a normative reference, since a 'smart city' should be implemented, and it demands the creation of policy addressing this need. In this sense, and before entering a detailed discussion of the concept and its current reiterations, a 'smart city' represents a positively valued, multi-objective policy strategy of integrated urban and ICT development, promising to tackle problems of economic competitiveness, social equity and environmental performance - somehow. Such a strategy attracts stakeholders for its ability to reduce complexity and provide capacity to act in situations characterised by wicked problems and uncertainty, claiming efficient (time and resource constraints) and effective intervention (extent of impacts). It is therefore also a proposition that is rather difficult to reject, thus paving the way for political majorities and implementation alliances.

In view of this rising discursive hegemony of smart cities, there is a growing need to reflect on this concept, its construction and underlying assumptions to enable transparency and new readings. What exactly is it that 'smart city' development aims to achieve, and in particular, how does it want to achieve this? Which actors and scales are involved in this agenda, and where will it lead us when implemented under real-life conditions? This paper therefore adopts a perspective of discursive deconstruction (cf. Derrida 1983; 1998; Hajer & Versteeg 2005), following intertextual relationships, in this case between science, policy and practice, in order to open up the 'smart city' label for a reinterpretation of its cultural, political, social and institutional bearings. Such relationships refer not only to text as a written expression, but also to context conditions and social practices that serve to attribute particular meanings. Discourse analysis can thus be usefully deployed here to help the identification of related effects of 'smart city' thinking and talking, such as a change of normative contents, constructing problems and solutions, supplying legitimacy and power, preparing consensus, coalitions and institutional arrangements, as well as affecting resource distribution.

To start with, section 3 will thus take a closer look at recent contributions on the topic from the scientific community to shed light on the conception of 'smart cities' and the strategies derived for their implementation. Against this backdrop, section 4 will acknowledge for the broader discursive construction of 'smart cities' in society, focusing on alignments and mutual influences between actors. Finally, this discussion will allow to draw some conclusions in section 5 on the need to question 'smart city' reiterations for the sake of transparency and accountability, and to pay increasing attention to the role of governance practices for shaping the multiple relationships between cities and ICT.

3 SCIENTIFIC CONCEPTIONS OF SMART CITIES

Reviewing scientific publications for the usage of 'smart city' notions quickly illustrates that so far very few have actually sought to theorise this concept or discuss its usage as such (Komninos 2002; 2006; Hollands 2008; Deakin 2011; Allwinkle & Cruickshank 2011). The current Wikipedia entry created as recently as in 2007 equally draws on these as central references (Wikipedia 2012). However, the vast majority of contributions referring to 'smart cities' today uses the concept only to discuss certain sectoral, technological or methodological aspects thereof, which does not contribute substantially to enhance the comprehension of the phenomenon in question. Nevertheless, such discursive 'free-riding' serves of course to indicate topicality and relevance of the respective research undertaken vis-a-vis a booming societal discourse (Figure 1). At the same time, it indicates that 'smart city' operates as an empty signifier in that conceptually almost any issue of ICT in an urban context may be framed by it, ranging e.g. from electricity grids and public lighting to spatial data infrastructures or social media.

Notwithstanding the large amount of work that has dealt with the broader issue of co-evolution between society, cities and ICT from a variety of perspectives (cf. Graham 2004; Foth 2009), the question here is whether a distinctive understanding of 'smart cities' as a scientific object and program can be recognised already. As we will see, this is increasingly the case, although some important indefinitions remain. The following two paragraphs will thus briefly trace those contributions that have sought to conceptualise 'smart cities', first asking for the research perspective constructed, and second for the approaches derived to implement such concepts in practice.

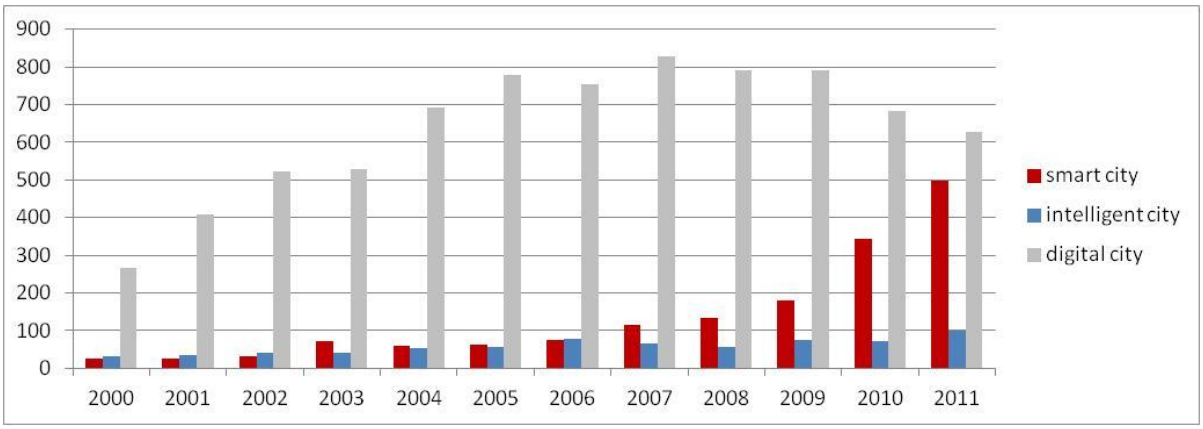

Figure 1: Rise of the „smart city" concept in scientific discourse - total search results (http://scholar.google.de - 2.3.2012)

3.1 Ontological and epistemological orientations

Considering the topics addressed and references used, it is the gradual convergence of two major strands of research and their core concepts that appears to characterize present 'smart city' thinking (Komninos 2006, 4). In the first place, evolving out of administrative and information system sciences, there is a broad concern with digital cities. These are conceived of as an open repository of diverse online applications linked to local government, although without necessarily addressing any relationships between them. This includes especially virtual city representations, e-government services, as well as interactive platforms and their combinations in support of various public policy goals, such as place marketing, social inclusion or environmental awareness (cf. Ishida & Isbister 2000). On this subject, the main research orientations are to identify and develop new internet applications for local governments, and to assess their efficiency and effectiveness in the light of the respective policy goals addressed. The digital city strand of research has therefore tended towards technological determinism, following the hypothesis that ICT will somehow impact

on social and cultural urban practices in cities, rather than vice versa, while also being highly optimistic about this impact. This perspective has increasingly been criticised for its disregard of the social construction processes that shape technology usage (Aurigi 2005, 200) - a criticism that has given rise to more qualitative approaches, analysing the interplay of ICT, developers, users and institutions in local settings (see contributions in: Tanabe et al. 2002; Koizumi & van den Besselaar 2005). Also mainstream digital city research now usually includes at least some form of a 'disclaimer' in terms of technological determinism, but its basic positive assumption that ICT usage will improve a city's performance in the policy areas addressed, which in turn requires the identification of barriers to implementation and measures to overcome them, has largely been maintained. At present, we find this perspective reified through future internet research, driven by new technologies seeking for (urban) problems to be solved (cf. Komninos et al. 2011; Pallot et al. 2011).

The second important research strand has been inspired by Lundvall's conception of innovation systems (Lundvall 1985; Lundvall & Johnson 1994), echoed especially in business studies, economics and economic geography. Here, the starting point is the identification of 'innovation' as the main trigger of economic growth under conditions of globalisation. Such innovation is characterised as a socially embedded and spatially structured learning process determined by the formation of knowledge networks between key actors - government agencies, knowledge organisations, businesses, funding bodies, intermediaries (Morgan 1997). These networks in turn are seen to depend on social and human capital, local institutional settings, as well as culture and ICT, reaching out from the local to the global scale (Cooke & Morgan 1993; Lundvall & Johnson 1994; Komninos 2009a). Research in this field has therefore been trying to identify, describe and model these networks and their conditioning factors in a systemic perspective in order to provide orientations for urban policy, with the ultimate aim to strengthen the competitive position of cities and regions (cf. Moulaert & Sekia 2003). Apparently, this perspective implies a normative selectivity in terms of both the goals addressed and the actors involved.

As illustrated especially through the work of Komninos (2002; 2006; 2008; 2009b), the idea of the 'smart city' emerges from linking the ontological and epistemological perspectives of the innovation system with those of the digital city. Hence, a 'smart city' is conceived of as a specific type of innovation system, namely one that is deeply rooted in urban spaces, their institutions and actor networks, while also fostering the use of novel web-based ICT applications to support the pertinent interaction processes, learning and creativity. As the digital city, its development is therefore principally open to any societal goals linked to it, but due to its focus on innovation systems, priority is given implicitly to competitiveness and economic growth. Furthermore, 'smart cities' coincide with both conceptual sources in identifying enhanced ICT adoption as a core instrument to achieve societal objectives, while largely neglecting related negative or rebound effects (e.g. social exclusion, overcompensation, ICT carbon footprint). Consequently, 'smart city' research is addressing especially the identification and analysis of the preconditions and factors that influence a successful implementation of this agenda in order to guide practical development. Alternative pathways that would not strongly focus on the exploitation of ICT are even discarded from the outset as an existential threat for cities and regions (Eger & Becker 2000, 2).

This basic orientation already formed the starting point of the influential "Smart Communities" program, initiated in 1997 by the International Center for Communication at San Diego University. It says to respond to the need "to help communities worldwide better understand the important role of technology, economic development and importantly, creativity and innovation to success and survival in the new global economy." (Smart Communities 2011). More recently, the same perspective has been presented as a "new planning paradigm" for urban-regional development and innovation management that "updates older arguments about telcoms in the city, cybercities and digital cities" (Komninos 2009b, 338), thus underlining the above normative assertion and promptly doing away with more critical approaches (here referring explicitly to Graham & Marvin 1996).

Some authors have also tried to provide more specific directions regarding the selection of policy domains a smart city should address. For instance, Giffinger et al. (2007) identify six characteristics - economy, people, governance, mobility, environment, living – in which a smart city should be "well performing in a forward-looking way" (ibid. 6), measured by a total of 73 indicators. These six characteristics are then used as a "solid background" by Caragliu et al. (2011) to analyse correlations between urban wealth and five other selected indicators, namely employment in culture and entertainment industry, multimodal accessibility, length of public transport network, e-government services and education levels. Although this selection

exposes major gaps regarding both the six domains referred to (e.g. environment, living) and key sustainability issues (e.g. inclusion, equity, quality of life), the positive correlations identified are then seen to "clearly define a policy agenda for smart cities" (ibid. 77). It is interesting to denote that although ICT does actually not play a prominent role in these two interpretations of 'smart cities' (only two of the indicators identified by Giffinger et al. (2007) relate to "ICT infrastructure availability", while Caragliu et al. (2011) consider just "transactional e-government services" in this respect), both references figure in the context of the technology-led 'smart city' debate. Here it appears that, technology aside, what remains of the 'smart city' seems to be an investment program for strengthening certain location factors or "capital stocks" (ibid. 77) that does clearly support urban competitiveness, but leaves entirely unclear whether or how urban sustainability is also supported. Rather, by establishing policy priorities and instruments, 'smart cities' seem to replace sustainability as a development goal and problem-solving concept, including its much more demanding requirements of balancing ecological, social and economic development, ensuring intra- and intergenerational equity, and fostering cultural and institutional change (cf. Majer 2007; Nielsen et al. 2010).

3.2 Strategies for implementation

Given the ontological and epistemological frame sketched above, 'smart city' conceptions also entail a particular understanding of how their implementation should be approached and enhanced in practice. While this question is hardly addressed as such, discussions mainly revolve around two complementary implementation settings in terms of the scale addressed and the type of actors involved, namely the triple-helix model and open innovation ecosystems. Drawing on empirical and analytical grounds, these two concepts are put forward in a prescriptive manner to guide 'smart city' development. Both types of implementation strategies display particular strengths for addressing certain aspects of integrated urban and ICT development, but they also raise questions concerning their legitimacy as specific modes of governance and their ensuing repercussions on urban planning and policy in general.

Shaping 'smart city' alliances: The triple-helix model

Following the engagement of innovation systems research with different modalities of knowledge production, the triple helix model focuses in particular on relations between universities, industry and government at an urban and regional scale (Shinn 2002). Its proponents maintain that the characteristics of the network formed by these three key actor groups is what conditions organised knowledge production, economic wealth creation as well as development control ("reflexive overlay") in urban regions (Leydesdorff & Deakin 2011, 56). The triple-helix is thus understood as a selection environment for knowledge creation and innovation, ushering in place-based strategies to exploit local creativity and social capital to achieve a "new urban vitality" i.e. growth (Lombardi et al. 2012, 16). Particular attention is therefore paid to the design of interactions between industry and university with a view to knowledge generation, between university and government regarding mutual learning, and between government and industry for creating market affine institutions (Lombardi et al. 2012, 8). In this, ICT is attributed a crucial importance mainly because it can configure and intensify such interactions e.g. through corresponding knowledge management and exchange platforms.

While the triple-helix model is formally conceived of as an analytical device to measure and compare the degree of 'smartness' cities have achieved, it equally aspires to outline a framework for action (Caragliu et al. 2011, 77). For instance, arguing strictly against "entrepreneurship-based" and "market-dependent" approaches, Leydesdorff and Deakin suggest that these should be "replaced with a learning organisation of policy makers, academic leaders and corporate strategists" (2011, 59). This particular alliance is stipulated to form a new kind of governance blueprint for steering 'smart' urban development, emphasising reflexive arrangements to generate and exploit intellectual capital. Yet, whether such elitist and corporatist coalitions do reflect the demanded "cultural reconstruction at the bottom" (ibid. 57) certainly depends on where that 'bottom' line is drawn. In practice, they are unlikely to be less biased by the respective motives and resources of the parties involved than the 'entrepreneurial city' or 'urban growth coalitions' criticized (cf. Hall & Hubbard 1996; Harding 1991). Hence, if informed by the triple-helix model, urban planning and policy making runs the risk of reifying the kind of neo-liberal distorsions it (hopefully) wants to avoid. And while the model implicitly assumes that by focusing on ICT-enhanced knowledge production, creativity and learning, cities could simply "grow smarter", doubts remain regarding its capacity to resolve fundamental

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

goal conflicts in urban development, ensure representation and legitimacy, and thus direct urban innovations towards sustainability.

Designing service incubators: Open innovation ecosystems

While the triple-helix addresses the creation of an urban-regional governance framework and practices that enable smart growth, open innovation ecosystems focus on the concrete identification and design of new products, services or infrastructures at the scale of real-life settings. They draw on a variety of concepts and approaches developed in business and information system studies such as 'open innovation', 'lead-user involvement', 'crowdsourcing' or 'participatory design' (cf. von Hippel 1986; Asaro 2000; Chesbrough 2003). In addition to the interaction environment itself, such ecosystems also encompass the required technologies and infrastructures, partners providing specific expertises, as well as a supporting organization and methodologies for iterative co-creation and learning. They build on a partnership among businesses, government and academia, while also involving citizens and civil society stakeholders in as far as they represent certain end-user groups. Typically, the design process then runs through several loops of needs analysis, system design and evaluation, oriented at the overall principles of "openness" (include new users), "realism" (focus on real users in real-life situations) and "empowerment" (motivate and engage users) (Bergvall-Kareborn & Stahlbröst 2009). At present, already a large number of examples for such open innovation ecosystems can be found in cities around the globe, addressing a variety of domains and applications (e.g. e-government, health, mobility, energy-efficiency, tourism - cf. ENoLL 2012; LivingLabs Global 2012).

Regardless whether the approach as such actually succeeds in creating innovative services that are meaningful for those users involved, and in developing a business cases for durable operation, it is clear that the focus on particular needs or opportunities has to be rather narrow from the outset. Hence, open innovation ecosystems such as living labs (Folstad 2008) or 'communities of practice' (Deakin et al. 2011) are only able to deliver innovations for objectives selected beforehand on the basis of the partnership arranged – they do not perform such selection themselves. The very creation of a living lab depends on the initiative of interested stakeholders interacting in an urban-regional selection environment, thus shaping their configuration and orientation. Moreover, there are further filters in place that format such open innovation ecosystems. For instance, a strong technology push from industry currently favours the creation of urban living labs around future internet applications (Pallot et al. 2011). Also, regarding the users involved it appears to be difficult to avoid domination by technically mature and curious people who seek to actively influence societal developments (Bergvall-Kareborn & Stahlbröst 2009, 367). In addition, with a view to "realism" as a principle the focus on products or services and taking selected end-user needs as a starting point, more systemic innovations cannot be addressed as such. This implies that despite a strong emphasis on openness, user involvement and empowerment, open innovation ecosystems remain rather limited in their scope, remit and aspirations. Ironically enough, the lack of a coherent typology or evaluation framework for open innovation ecosystems currently impedes learning from the plethora of experiments performed worldwide. It is therefore difficult to empirically assess even basic relations between innovation subjects, actor constellations, methods and outcomes.

4 SMART CITY DISCOURSE FORMATION AND LABELLING PRACTICE

As discussed above, researchers from a wide range of disciplines have contributed to gradually shape a scientific conception of 'smart cities' over the past decade, including a distinctive raison d'être and particular modes of implementation. Yet, rather than providing a framework for critical analysis, the key motive for this has been to establish the evidence basis for a growth-oriented and technology-driven policy agenda. As Allwinckle and Cruickshank argue for the selection of papers they discuss (2011, 9), research now appears to "offer a language, a syntax, and a vocabulary by which to understand the emerging policy debate on smart cities." Apparently, this perspective omits precisely the crucial role that policy and practice themselves have played in the production and reproduction of 'smart city' concepts - which renders the suggested analytical devices rather short-sighted. To explore such relationships we thus need to acknowledge for the contributions of other societal actors more explicitly and in an intertextual perspective.

Regarding the role of industry, it is the large IT and telecom corporations that figure in a prominent position here. Already in 1995 the Intelligent Communities Forum (ICF) was set up by the World Teleport

Association (WTA), an organisation of satellite communication industries and businesses. As the organisation's name indicates, it is urban areas that were quickly identified to offer a crucial market development and growth potential for ICT products and services. Today the ICF forms a network also including about 90 local authorities. It conducts studies, disseminates results and grants an annual community award. Since 2006, a preselected group of 21 candidate authorities to this award is promoted under the label of "Smart21". The ICF posits that intelligent communities "are those which have [...] come to understand the enormous challenges of the Broadband Economy, and have taken conscious steps to create an economy capable of prospering in it." (ICF 2011). Correspondingly, broadband connectivity, knowledge workforce, innovation, digital inclusion and marketing are identified as the key factors for assessing progress on this path. Emphasis is put on collaboration "among government, businesses, universities and institutions", as well as on leadership and sustainability - although the latter refers essentially to durable service provision and business models (ICF 2011).

A qualiatively different message has then been launched by the Global e-Sustainability Initiative (GeSI), another influential network formed in 2001, bringing together the largest IT and telecom companies worldwide in partnership with NGOs as well as the UN Environment Program. GeSI declares to promote "products, services and access to ICT for the benefit of human development and sustainable development" (GeSI 2011). In 2008, GeSI commissioned the "Smart2020" study that has raised much interest. This study has attempted for the first time to quantify the global CO2 emission reduction potential of ICT usage, while also discussing the growth of ICTs own carbon footprint (The Climate Group 2008). The principal reduction potential was identified in the application domains of logistics, buildings, electricity grids, motor systems and dematerialisation. In particular, the study highlights the key role of urban areas since this is where the above domains converge, as well as the need for closer cooperations between industry and (local) government for implementing measures. Consequently, a "Smart2020" initiative was kicked off as a follow up on this study, promoting pilot and transfer projects in this field (The Climate Group 2012)

This specifically urban focus of ICT deployment linked to grand environmental challenges has increasingly been taken up by various major solution providers. For instance, Cisco Systems' "Connected Urban Development" initiative pursues "a future where the intelligent use of networking architectures can transform society not only by boosting productivity and spurring economic growth, but also by supporting environmental sustainability and enhancing the quality of life in urban environments" (Cisco 2012). Concretely, it addresses four application domains (work, mobility, energy and buildings) and is realised in partnership with cities from across multiple countries. In 2010, IBM launched its "Smarter Cities Challenge", offering a total of $50 million support for 100 cities worldwide, selected through a competition until 2013. The nominees need to cover a certain range of ICT applications in city management, infrastructure and human services (IBM 2012). Also Siemens has jumped the train, now promoting its products and services under the umbrella of "Sustainable Urban Development". The company has also published a "Green City Index" that ranks 30 European cities according to their performance in selected domains (CO2, energy, transport, buildings, water, waste and land use, air quality, environmental governance) (Siemens 2009).

While slightly differing in their scope, the core narrative of these industry-driven initiatives and networks seems clear: In order to maintain competitiveness and be able to respond to the grand environmental challenges, a turn towards networked urban ICT solutions is inevitable i.e. "cities must become smarter" (IBM 2012). Seeking to align with (local) government policy priorities in terms of energy efficiency and climate change mitigation, a supply-driven conception of smart cities thus emerges. It is promoted through global marketing campaigns, including instruments of city competition as well as tools for city self-assessment and benchmarking. But while considerable verbal pressure is put on urban decision makers to create 'smart' programs, a consistent conceptual frame for these is not suggested. Application domains vary simply depending on the respective company's product portfolio, and issues concerning the local process of 'smart' development are hardly addressed at all. The only constituent element necessary to drive implementation seems to be the kind of alliance demanded by the triple-helix model.

In Europe, this emphasis on urban ICT applications for both economic development and as a response to environmental challenges is equally what underpins recent government initiatives concerning smart cities. In particular the European Commission is leading the way in this matter, given the maturity of its initiatives and also due to English communication practice contributing to adjust terminology across member states. Two complementary EC initatives shall be highlighted here as they capture the prevailing ideas and objectives

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

linked to 'smart cities' at this level. Since 2009, the EC supports a large number of 'smart city' pilot projects demonstrating future internet applications through its "ICT Policy Support Program" (EC 2012a). As cities are free to address the local policy domain and goals they choose, this funding strand is guided only by particular technologies (i.e. future internet – each call also addresses selected technologies e.g. RFID, mobile LTE) and a certain partnership and development model (open innovation ecosystems). In 2011, the EC has additionally launched a major "Smart Cities and Communities Initiative" through its 7th Research Framework Program, supporting R&D projects that address the use of ICT for energy efficiency and climate change mitigation (EC 2012b). Here, the core aims are derived from environmental policy goals, but the means to achieve them are predefined as large-scale urban ICT deployment in the energy, transport and building domains. Cities are thus required to form networks and partnerships with industry and research in order to be able to benefit from EC funding. This not only illustrates how EC policy increasingly points towards urban ICT deployment as a key solution to resolve environmental problems and foster competitiveness. It equally underlines that this turn towards the 'smart city' is accompanied by particular approaches for implementation at the local level, contributing both conceptually and resourcewise to underpin the alleged synergetic coalitions to govern urban change.

Ultimately, the decisive pull for the 'smart city' discourse to thrive had to come from cities themselves. In fact, the number of cities adopting policies that target 'smart' development has been growing fast, without necessarily referring to a shared understanding of this concept. In his review of practical examples from around the globe, Hollands (2008) underlines that at the core of the 'smart city' label used by local authorities lies a focus on networked infrastructures and ICT in particular as an instrument for urban development and for improving the economic, social and cultural condition of cities in a global marketplace. Furthermore, he identifies four distinctive features of such policies 1) Market-led development, granting businesses, research organisations and technology providers a prominent place in the design of new governance arrangements; 2) High-tech and creative industries, following concepts of the 'learning region' and 'creative city' (Florida 1995; 2003; Landry 2000); 3) Learning, education and social capital, to enable the local workforce to be part of the 'knowledge economy', and to develop e-government applications for local communities to "learn how to learn" (Coe et al. 2001, 13); and 4) Social and environmental sustainability, maintaining that ICT can make important contributions to address issues of social inclusion, ressource consumption and emission reduction. Considering the recent wave of EC-funded smart city projects in Europe, an update of this spectrum may well reflect a shift in emphasis here from creativity and learning towards global environmental challenges, thus echoing the more recent initiatives from ICT industries.

Most importantly, while the above seems to depict a certain spectrum of objectives and approaches, Hollands emphasises that "not all the elements mentioned here have equal weighting in the labelling process" (2008, 310). He criticises that, behind the self-congratulatory rethoric of cities claiming to be or become 'smart', there is an underlying agenda that matters when it comes to implementation: In the absence of a widely recognised definition of what it means to become a 'smart city' and without any effective mechanisms to balance community, government and business goals, 'smart city' policies in practice thus tend to foster a particular kind of urban entrepreneurialism, seeking to strengthen hard and soft location factors (Hollands 2008, 304). In this context, what falls especially short of consideration are not only the wider implications of ICT for social, cultural and political development in cities e.g. regarding participation, transparency, social inclusion or spatial segregation. Also in environmental terms the almost exclusive focus on selected grand challenges deflects from a range of urban environmental issues that escape the logic of energy and carbon reduction actions, partly or entirely, such as ecosystem service provision, environmental risk management, climate change adaptation or biodiversity maintenance.

5 CONCLUSIONS: DECONSTRUCTING SMART CITIES

This paper has presented an intertextual reading of current contributions to a broad societal discourse referring to the development of 'smart cities'. The starting point has been the recognition of a number of driving factors and pressures that contribute to defining a distinctive issue called 'smart city', placing it high on the agenda of research, policy and practice. This includes especially the imminent grand environmental challenges, pointing towards cities and urban areas as a key to address them; the convergence between information and communication technologies and between major industry branches, enabling increasingly

mobile and networked ICT while also opening up new growth markets for multinational corporations; and finally the diffusion and adoption of ICT applications in urban society, linked to a widening range of social practices. This context has provided a fertile ground on which the current discourse around 'smart cities' has been able to grow dynamically - and with a good prospect for further expansion in the years to come.

To initiate a fruitful deconstruction of this dominant discourse, the focus has been twofold: On the one hand, scientific conceptions of 'smart cities' and related research agendas have been reviewed in order to capture the various genuine knowledge sources upon which 'smart city' claims are built and justified. On the other hand, the propositions and initiatives devised by key industry players, the European Commission and cities have been discussed with a view to the respective motives linked to 'smart cities' and the mechanisms in place for practical realisation, affecting resource availability, partnerships and institutional arrangements.

By juxtaposing the above components it appeared that at the surface, the narrative of the 'smart city' is addressing the broad deployment of advanced ICT applications potentially affecting a wide array of urban sustainability issues. It evokes a picture of urban areas and activities highly networked through infrastructures and devices to enable more efficient operations and informed decision making in key domains – energy, mobility, buildings, governance – while enhancing the attractiveness and competitiveness of the location. It is this everlasting promise of technology as a key to resolve pressing societal problems that constitutes the ultimate vision of the 'smart city'. And it is this vision that results to be sufficiently attractive and convincing for public and private actors across scales, capable of mediating between their interests.

Nevertheless, even though the 'smart city' operates as a floating signifier that paves the way for broad implementation coalitions, it may not necessarily be an empty one. Looking at its trajectory in scientific work, industry initiatives and policy design, there is an underlying agenda which results to be be far more narrow but at the same time well equipped with the means required for enhanced realisation: 'Smart cities' have to respond by priority to the imperatives of economic competitiveness and global environmental change. To achieve the related policy goals, they must turn to ICT deployment as a key policy instrument, valued exclusively for its expected positive contribution. Further, to foster implementation 'smart cities' are required to push for veritable innovation systems through triple-helix alliances that select application fields and enable implementation, using open innovation ecosystems for creating new products and services.

While necessarily simplifying, this synthesis illustrates that the current 'smart city' discourse may in fact imply a less visible but ultimately heavy burden for cities, their stakeholders and citizens. At a time where urban areas are facing complex uncertainties and struggle to become more sustainable and resilient, it promotes a rather particular and uniform development pathway that in fact tends to marginalise complementary objectives, alternative approaches, as well as likely negative effects. It equally raises doubts whether or how the supply-driven logic promoting specific application fields and technology solutions can be overcome, which represents a major risk of creating lock-in situations and preventing more systemic and radical urban change. Furthermore, with a view to the specific design of the related governance structures and practices, 'smart cities' inherently suffer from a limited capacity to deal with contradictory goals and broader sustainability issues. As a result, they equally lack a proper legitimacy that could firmly root them in the wider context of urban development and its challenges.

This immediately raises the question of how cities could possibly escape such formatting of their activities? Strategies are needed that allow to leave the trodden path of 'smart city' development in order to effectively balance objectives in terms of local and global sustainability, and create novel justifications for integrated urban and ICT development practices. To start with, this requires placing the different options and implications of urban ICT usage next to other policies and measures. It implies to open up 'smart city' development to citizen and stakeholder deliberation, developing a shared understanding of problems and risks and contributing to the co-creation of local visions. It demands to conceive of this as an integral part of a much broader governance system designed for instigating urban change. Such a collective deconstruction of 'smart cities' seems necessary in order to respond to place-specific conditions and requirements, considering e.g. different world regions, contexts of growth or shrinkage, or diverging sustainability levels, and therefore to equilibrate the 'smart city' agenda in terms of actor coalitions and policies devised. In particular, to transcend current mainstream thinking also requires to acknowledge for diverging interpretations of 'smart cities' more explicitly. Faint signs of these have started to emerge already in dispersed arenas, focusing e.g. on social and institutional conditions for learning and innovation processes in

cities (Campbell 2012), on "green" technologies for improved environmental performance (Ercoskun 2011), or on urban ecosystem services and sufficiency (Lim & Liu 2010). Another good example is the Californian "Smart Communities Network", which displays a rather different notion of city 'smartness', essentially providing examples, guidance and tools for practitioners to develop local urban sustainability projects (NCAT 2012). Seemingly, this suggests a very different definition of a 'smart city' that may in fact help to recalibrate ongoing efforts in this direction: A 'smart' city is a city that knows how to become sustainable and resilient – which will most probably imply, but not depend on, the usage of advanced ICT.

1 ABSTRACT

Wollten Mitte der 1990er Jahre Tourismusverwaltungen noch eine Präsenz im Internet, so steigt heute die Nachfrage nach mobilen Dienstleistungsangeboten. Die mobile Information ist wichtig für eine zeitgemäße Vermarktung von Tourismusdestinationen, denn Touristiker müssen ihre Gäste auch per Smartphone und mobilem Internet über ihre Angebote informieren.

Doch welche Instrumente sind hier die richtigen, wie können bereits existierende Informationen mobil verfügbar gemacht werden und wie können effektive mobile Dienstleistungsangebote mit regionalem Charakter geschaffen werden? Gerade regionale Tourismusinstitutionen haben es oft schwer mit dem Sprung in das mobile Internet. Wie ein regionales, mobiles Informationssystem für Touristen auf- und ausgebaut werden kann, zeigt das Projekt Pfalzfinder im Landkreis Germersheim: Durch die Verknüpfung mit der vom Südpfalz-Tourismus e.V. eingeführten Datenbank Deskline 3.0 sind alle regionalen Akteure wie Direktvermarkter, Gastronomen, Hoteliers sowie Sehenswürdigkeiten in den mobilen Service des Pfalzfinders eingebunden. Per QR-Code können Touristen diese Informationen direkt vor Ort auf ihr Handy laden. Für die Verwaltung der Standorte wurde darüber hinaus ein Point-of-Interest-Management-System entwickelt, das von der Einpflege von Texten, Bildern und Videos bis zur automatischen Generierung einer Hinweistafel inklusive QR-Code alle notwendigen Aufgaben für die Erzeugung neuer Informationsstandorte übernimmt. Somit kann der Ausbau des Systems von verschiedenen Akteuren vor Ort vorgenommen werden und ist nicht an eine zentrale Verwaltung gebunden. Ziel des Pfalzfinders ist es, ein mobiles Serviceangebot zu schaffen und damit touristische Destinationen und lokale Akteure in einer der aktuellen und zukünftigen technischen Entwicklung angepassten Art und Weise zu bewerben. Insbesondere aufgrund der Verknüpfung zu einer bestehenden und ständig aktualisierten Datenbank ist das System mit nur wenig Aufwand auf andere Regionen und Städte übertragbar.

2 MOBILE ANWENDUNGEN IM TOURISMUS

2.1 Anforderungen an mobile Anwendungen im Tourimus

Eine berechtigte Frage bei der Entwicklung eines (regionalen) mobilen Tourismus-Informationssystems ist seine Daseinsberechtigung, denn das mobile Internet bietet auch ohne die Entwicklung von weiteren Plattformen oder Anwendungen Möglichkeiten, Informationen in Abhängigkeit des eigenen Standortes zu ermitteln. Es existiert bereits eine Vielzahl an Informationsdiensten, die im Sinne der Touristeninformation genutzt werden können. Alleine die mobile Plattform der Online-Enzyklopädie Wikipedia, Google Maps bzw. Google Places oder die Anwendung Qype stellen dem Suchenden eine Vielzahl touristisch relevanter Informationen in Abhängigkeit seines Standortes zur Verfügung. Doch gerade in der Menge der Informationen liegt das Problem, denn für den Touristen als Endnutzer ist (zunächst) nicht der volle Umfang an Informationen relevant. Je nach Ausrichtung des Tourismus im jeweiligen Zielgebiet und den damit verbundenen touristischen Zielgruppen ergeben sich spezifische Anforderungen an Informationstiefe und die Art der Darstellung von Informationen. Doch nicht nur die touristische Zielgruppe bestimmt die Anforderungen an ein mobiles Informationssystem, ebenso sind Bedürfnisse der lokalen Akteure und Dienstleister zu berücksichtigen, die ja letztlich von der mobilen Vermarktung ihres Angebotes profitieren sollen und damit positive Effekte im Hinblick auf regionale Wertschöpfung und Steigerung des Bekanntheitsgrades von Region und Angeboten erzielen sollen.

Die Schwierigkeit liegt hier insbesondere in der Bereitstellung von spezifisch lokalen Informationen, die sich auch im „stationären“ Web nicht ohne aufwendige Internetrecherche erreichen lassen, beziehungsweise nur dann auffindbar sind, wenn der Internetuser mittels gezielten Suchbegriffen hiernach sucht. Gerade aber die spezifisch lokalen Informationen können für den Touristen vor Ort von besonderem Mehrwert sein –

beispielsweise das kleine Spezialitätengeschäft um die Ecke oder die alte Kunstschmiede in 500 Metern Entfernung. Diesen kleinen regionalen Akteuren fällt es oft schwer, sich im mobilen Web so zu positionieren, dass eine standortbezogene Suchanfrage Informationen über ihren Betrieb oder ihre Produkte bereitstellt. Fragt somit der Nutzer vor Ort Informationen mittels den beschriebenen Anwendungen wie „Google Places“ oder ähnliches ab, gehen für ihn zum Großteil die Informationen mit Mehrwert verloren. Weiterer Nachteil dieser Informationsrecherche ist das mögliche Informationsüberangebot – es werden zu viele Informationen oder Point-of-Interests (POIs) im näheren Umkreis angezeigt, die den Touristen vor Ort überfordern. Neben der Vielzahl und der Unübersichtlichkeit der POIs ist keineswegs die Qualität der Standortinformation gesichert. In den POIs lassen sich Informationen hinterlegen, die dem Touristen vor Ort gegebenenfalls keinen Vorteil bringen, oder völlig falsch sein können. Beispielsweise ist jeder Inhaber eines YouTube-Accounts in der Lage Videos zu verorten – genau diese Videos können dem Touristen dann vor Ort über die Standortinformation mittels GPS-Signal angezeigt werden – auch wenn das Video keinen touristisch relevanten Inhalt besitzt. Stattdessen muss gewährleistet sein, dass die bereitgestellten Informationen über eine hohe Qualität verfügen, eine dauerhafte Aktualität aufweisen und alle Belange und Besonderheiten der jeweiligen Tourismusregion berücksichtigen. Diese Vorgaben werden nur gewährleistet, indem Akteure und Touristiker aus der Region gleichermaßen für die Informationsinhalte und deren Bereitstellung verantwortlich sind.

2.2 Native App vs. Mobile Webseite

Mobile Informationssysteme sind technisch zu Unterscheiden zwischen einer nativen Application (App) und einer eigenen mobil optimierten Internetseite. Native Applikationen sind Programme, die für jedes Smartphone-Betriebssystem zu entwickeln sind, mobile Webseiten funktionieren dagegen unabhängig vom jeweiligen Betriebssystem .

Werden derzeit mobile Informationssysteme oft mit der Entwicklung einer nativen App gleichgesetzt, so gilt es doch die Vor- und Nachteile einer nativen App mit Alternativlösungen wie beispielsweise eben einer Web-App oder mobilen Internetseite abzuwägen. War es bisher nur möglich mit Hilfe nativer Apps einen Zugriff auf Funktionen wie beispielsweise den GPS-Empfänger des Smartphones zu erhalten, ist dies nun dank html5 auch bei web-basierten Anwendungen der Fall [WÜRSTL 2012]. Die Vorteile liegen auf der Hand: Müssen native Apps in verschiedenen Versionen auf die unterschiedlichen Betriebssysteme der sich auf dem Markt befindlichen Smartphones angepasst werden, so kann mit einer einzigen browserbasierten Web-App nahezu der volle Funktionsumfang unabhängig vom verwendeten Betriebssystem genutzt werden. Somit ist die Entwicklung eines mobilen Informationssystems für eine breite Nutzergruppe auf Basis einer mobilen Webseite wesentlich schneller und kostengünstiger zu realisieren – und damit auch für kleinere Tourismusregionen finanzierbar. Allerdings gibt es derzeit auch bei Web-Apps Grenzen, insbesondere im Hinblick auf innovative Techniken: Augmented Reality Anwendungen, die mit Hilfe der GPS Daten, des digitalen Kompass und des Gyrosensors arbeiten, sind derzeit nur über native Apps zu realisieren [HEISE 2011]. Es gilt demnach bei der Konzeption eines mobilen Informationssystems klar zu definieren, welche Anforderungen auf Basis der touristischen Zielgruppe, den Bedürfnissen der lokalen Akteure und den touristischen Leitbildern einer Region erfüllt werden müssen.

Denn oftmals können mittels einer Web-App alle im Rahmen eines regionalen mobilen Informationssystem erforderlichen Informationen zur Verfügung gestellt werden – von textlichen Standortinformationen über Audioguides bis hin zu Videos. Ferner können auch Karten und Routen die Zielfindung des Anwenders vor Ort deutlich erleichtern. Verfügt das Smartphone über eine Navigationsfunktion kann der Nutzer auch mit der Web-App mittels Echtzeitnavigation zu dem vorgesehenen Ziel gelotst werden. Dementsprechend kann anhand einer Web-App eine breite Zielgruppe mit den wesentlichen Informationen vor Ort erreicht werden – unabhängig vom verwendeten Betriebssystem des Smartphones. Der Nutzer ist somit in der Lage mit dem Informationssystem zu interagieren, ohne sich vorher eine gesonderte App installieren zu müssen. Sofern das System, wie im hier vorgestellten Pfalzfinder mittels QR-Codes den Standort des Nutzers ermittelt, ist lediglich ein Barcode-Reader und ein Internetzugang des Mobiltelefons erforderlich. Diese Voraussetzungen erfüllt heutzutage fast jedes Mobiltelefon. Weiterer entscheidender Vorteil einer Web-App in Kombination mit QR-Codes ist, dass der Nutzer nicht zwingend im Vorfeld seiner Reise über die Verfügbarkeit des Informationssystems informiert werden muss. Dank der Hinweisschilder in der Region mit entsprechendem QR-Code erfolgt der Hinweis auf das System direkt vor Ort – der Nutzer kann das System somit sofort

nutzen. Eine vorgeschaltete Marketingkampagne ist demnach nicht zwingend notwendig. Im Gegensatz hierzu, muss der Nutzer einer nativen App im Vorfeld Kenntnis über eben dessen Existenz haben und sie sich auf dem eigenen Smartphone installieren [vgl. BREMMER 2011]. In den Appstores von Apple oder Android finden sich bereits jeweils über 26.000 verschiedene Apps mit dem Schwerpunkt Reisen und Tourismus – bei dieser Vielzahl ist eine App einer kleineren Tourismusregion kaum wahrnehmbar.

Doch letztlich entscheidet der Endnutzer über den Erfolg oder Misserfolg eines mobilen Informationssystems, dabei ist es nahezu unerheblich, ob eine native App oder eine Web-App verwendet wurde. Viel wichtiger ist der Mehrwert, den ein mobiles Informationssystem dem Nutzer bietet. Ein Mehrwert ist insbesondere dann gegeben, wenn das (regionale) mobile Informationssystem spezifische Informationen über touristische Destinationen zur Verfügung stellt, die sonst nur durch mehrfache Filterung von Suchabfragen in verschiedenen (mobilen) Informationsportalen zu finden sind und die Darstellung dieser spezifischen Information in einer zielgruppengerechten und anschaulichen Art und Weise vorgenommen wird (z.B. in Form von Infotainmentvideos).

3 DER PFALZFINDER

Mit dem Pfalzfinder wurde im Landkreis Germersheim durch den Südpfalz-Tourismus e.V. in Zusammenarbeit mit Mar.Vis ein mobiles Informationssystem konzipiert, dass speziell auf die touristischen Rahmenbedingungen des Landkreises ausgerichtet ist und die Bedürfnisse der lokalen Akteure ebenso berücksichtigt wie die der touristischen Endnutzer. Derzeit befindet sich das System in der Umsetzung und soll Ende April 2012 offiziell gestartet werden.

3.1 Funktionsprinzip

Das System des Pfalzfinders basiert auf drei wesentlichen Elementen: Einer mobilen Webseite, einem Hinweisschild mit Quick-Response-Code (QR-Code) und einem internetfähigen Kamerahandy auf Seite des Nutzers. Um die Darstellung der mobilen Webseite optimal auf die Displaygröße der vom Nutzer verwendeten Endgeräte anzupassen, werden entsprechende „Browserweichen“ implementiert. Diese gewährleisten, dass die Benutzeroberfläche auf nahezu jedem Mobiltelefon, egal ob Smartphone oder „normales“ Handy, in optimaler Weise dargestellt wird und kaum ein Unterschied zu einer nativen App erkennbar ist.

Nach Abfotografieren und automatischem Entschlüsseln des QR-Codes auf den Hinweisschildern wird der Nutzer auf eine mobile Webseite geleitet. Diese enthält fünf anwählbare Buttons:

- Standortinformation

Hier erhält der Nutzer textliche Informationen zu seinem aktuellen Standort. Im folgenden Untermenü kann sich der Nutzer den Standort auf einer Karte (GoogleMaps) anzeigen lassen. Optional besteht die Möglichkeit im Untermenü einen mobilen Infotainment-Film oder einen Audioguide über den Standort abzurufen.

- Direktvermarkter

Die Direktvermarkter stellen einen wichtigen Vertriebszweig für landwirtschaftliche Produkte im Landkreis dar, zusätzlich handelt es sich aufgrund von vielfältig angebotenen Veranstaltungen um eine wichtige touristische Attraktivität im Landkreis Gemersheim – entsprechend wurden die Direktvermarkter als eigener Menüpunkt in das Informationssystem aufgenommen. Unter diesem Menüpunkt erhält der Nutzer eine Liste der Direktvermarkter in einem definierten Umkreis und nach Entfernung sortiert. Klickt der Nutzer einen Anbieter der Liste an, erhält er weiterführende Informationen über den ausgewählten Direktvermarkter wie zum Beispiel Name, Adresse, Kontaktdaten, Sortiment oder aktuelle Informationen und Veranstaltungen. Bei Click auf den Button „In Karte anzeigen“ gelangt der Nutzer auf eine Kartendarstellung, auf der der Standort des Direktvermarkters und der eigene aktuelle Standort angezeigt wird. Durch die Navigationsfunktion und Routenplanung von GoogleMaps kann der Nutzer die Echtzeitnavigation zum ausgewählten Direktvermarkter starten.

- Gastronomie

Analog zum Menüpunkt „Direktvermarkter“ erhält der Nutzer hier eine Liste von Gastronomiebetrieben, ebenfalls nach Entfernung sortiert. Auch bei diesem Menüpunkt besteht die Möglichkeit weitere

Informationen zu erhalten (Name, Angebot etc.) und sich direkt zu dem jeweiligen Betrieb navigieren zu lassen.

- Sehenswürdigkeiten

Der Menüpunkt Sehenswürdigkeiten stellt ebenfalls textliche Informationen über die nächste Sehenswürdigkeit im definierten Umkreis des Nutzers zur Verfügung – ebenso die Navigationsfunktion. Unter der Rubrik „Sehenswürdigkeit“ bietet es sich insbesondere an, multimediale Inhalte wie Audioguides, Videos oder 3D-Modelle als zusätzliche Information bereit zu stellen.

- Unterkünfte

Neben der Information zum Anbieter und der Navigationsfunktion zu der Unterkunft, besteht hier eine direkte Buchungsmöglichkeit des Hotels oder des Gasthofes über die Verknüpfung mit dem Buchungsmodul von Deskline 3.0 (siehe 3.2).

Abbildung 1: Benutzeroberfläche des Pfalzfinders mit den anwählbaren Buttons

3.2 Datengrundlage und Informationsquellen des Pfalzfinders

Dem Pfalzfinder liegt als Datengrundlage die von der Rheinland-Pfalz Tourimus GmbH verwendete Datenbank und Buchungsplattform Deskline 3.0 der Feratel AG (http://www.feratel.de/) zu Grunde. Über eine Datenbankschnittstelle greift der Pfalzfinder auf das System zu und ruft darüber die Informationen zu verschiedenen Destinationen in der Umgebung ab, beispielsweise Hotels und Gastronomie. Ein großer Vorteil dieser Datenbankverknüpfung ist die Gewährleistung der geforderten Informationsqualität des Pfalzfinders, denn die Datenbank Deskline 3.0 wird seitens des Südpfalz-Tourismus e.V regelmäßig aktualisiert.

3.3 Backend: Das Point-of-Interest-Management-System

Für den Ausbau des Systems und zur Ergänzung weiterer Standorte (QR-Schilder) wurde zu dem Informationssystem ein Online-Managementsystem entwickelt. Diese Plattform ermöglicht den lokalen Akteuren (Vertreter des Südpfalz Tourismus e.V.) den Pfalzfinder eigenständig und ohne spezielle Programmierkenntnisse zu erweitern. Die Plattform ist mit einem Log-In-Filter versehen, somit haben nur berechtigte Personen die Möglichkeit, weitere Standorte in das System zu integrieren. Dies ermöglicht ein zentrales Management des mobilen Informationssystems sowie den zielgerichteten Ausbau und sichert gleichzeitig die Qualität der Inhalte, da nur touristisch verantwortliche Personen neue Standorte in das System einpflegen können. Zudem besitzt das POI-Management System eine eigene Datenbank, die regelmäßig mit den Datensätzen aus Deskline abgeglichen wird. Der Vorteil in der Erstellung einer eigenen Datenverwaltung innerhalb des POI-Management-Systems (POI-MS) liegt in der schnelleren Bereitstellung

der Daten im mobilen Frontend: Relevante Datensätze müssen nicht durch separate Abfragen an Deskline 3.0 vom Server der Pfalztouristik übernommen werden, sondern können nach regelmäßigem Abgleich direkt vom Hosting-Server des Pfalzfinders übernommen werden. Somit werden letztlich die Informationen schneller auf das Mobiltelefon des Endnutzers geladen. Die Aktualisierung der POI-Datenbank bzw. der Abgleich zwischen der POI-Datenbank und Deskline 3.0 erfolgt automatisiert alle 24 Stunden.

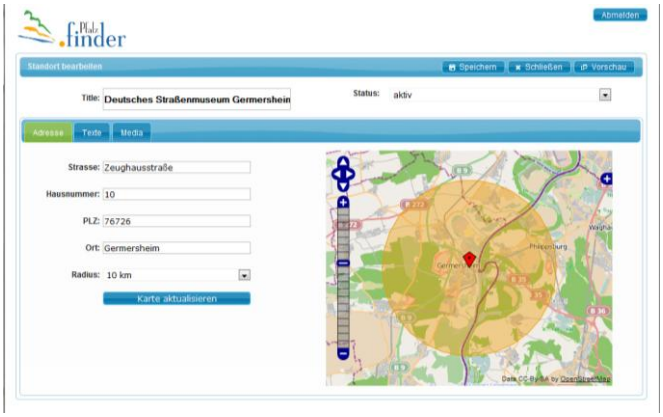

Abbildung 2: Das Point-of-Interest-Management-System des Pfalzfinders

3.4 Funktionsweise des Point-of-Interest-Management-Systems

Schritt 1: Log-In-Filter

Das POI-MS entspricht in seiner Funktion einer regulären Webseite, die mit einem Log-In-Filter versehen ist. Der POI-Manager muss sich hier per Benutzername und Passwort anmelden, um einen neuen Standort im System hinzuzufügen. Das System lässt sich auch um eine Benutzerverwaltung ergänzen, wodurch mehrere POI-Manager gleichzeitig im System arbeiten könnten und jeder neue Standort wäre einem definierten Benutzer zuzuordnen – im Sinne der Qualitätssicherung der bereitgestellten Informationen.

Schritt 2: Eingabe eines neuen Standortes

Soll der Pfalzfinder nun um einen weiteren Standort ergänzt werden, kann mit Hilfe eines Kartenmoduls (oder der Eingabe von Koordinaten) der neue Standort im System festgelegt werden. Gleichzeitig lässt sich der Radius festgelegen, in dem nach touristischen Destinationen gesucht werden kann. Dies ermöglicht z.B. die Eingabe eines geringen Radius bei Standorten in Städten und Dörfern mit vielen Destinationen im direkten Umfeld, sowie die Eingabe eines großen Radius bei Standorten „im freien Feld“. Dies gewährleistet die präzise Darstellung von Destinationen ohne ein Überangebot an Informationen zu schaffen.

Schritt 3: Eingabe von Informationen über den Standort

Hier können Informationen über den aktuellen Standort des Nutzers (=Standort des Hinweisschildes) eingegeben werden. Der Umfang der textlichen Information wurde durch die Festlegung einer maximalen Zeichenanzahl begrenzt, sie kann jedoch durch Hyperlinks erweitert werden. Dies gewährleistet eine kompakte Erstinformation und bei Bedarf die Abfrage weiterer Informationen. Die Eingabematrix der Standortinformation bietet ferner die Möglichkeit, Bilder und Videos zu integrieren. Die Eingabematrix für Videos bietet neben der Upload-Funktion von Dateien in verschiedenen Formaten (.mpg, .3gp) auch die Verknüpfung von YouTube-Videos per Eingabe der jeweiligen Video-ID. Der Nutzer kann somit selbst entscheiden, ob er ein Video nur ansehen oder auch downloaden möchte.

Schritt 4: Vorschau und Kontrolle

Die neu eingegebenen Information sowie der gewählte Standort und gewählte Umkreis werden in einem Vorschaufenster angezeigt. Der POI-Manager kann hier noch einmal alle relevanten Daten auf Richtigkeit überprüfen und ggf. Änderungen vornehmen. Beim Click auf den nächsten Schritt (Schildauswahl) wird aus den Daten automatisch eine URL und der passende QR-Code generiert.

Schritt 5: Auswahl des QR-Hinweisschildes

Der POI-Manager kann nun aus einer Auswahl definierter Schildgrößen wählen, die die notwendige Flexibilität für unterschiedliche Standorte bietet.

Schritt 6: Mobile Vorschau, QR-Linkcheck & Druckdatei

Im letzten Schritt kontrolliert der POI-Manager die Darstellung des Hinweisschildes und die Darstellung der Standortinformation. Dabei erfolgt die Darstellung der Standortinformation in gleicher Weise, wie auch der Endnutzer sie auf seinem Mobiltelefon sehen wird. Parallel dazu kann die druckfertige PDF-Datei des Hinweisschildes heruntergeladen werden.

4 UMSETZUNG DES PFALZFINDERS IN DER PRAXIS

4.1 Standorte der Beschilderung

Die Umsetzung des Pfalzfinders im Sinne der Positionierung von Hinweisschildern befindet sich derzeit in Vorbereitung, ein offizieller Start des Systems ist für Ende April 2012 geplant. Zu Beginn werden Schilder entlang des Rheinradweges aufgestellt, im Laufe des Jahres sollen weitere Radwege mit Hinweisschildern ausgestattet werden.

Zur Gewährleistung des vollen Funktionsumfangs des Informationssystems müssen die Standorte der Hinweisschilder verschiedene Voraussetzungen und Kriterien erfüllen:

- Mobilfunknetzabdeckung:

Vor Ort muss eine gesicherte Mobilfunknetzabdeckung, von allen vier in Deutschland vertretenden Mobilfunkanbieter vorhanden sein. Idealerweise ist der Mobilfunkstandard UMTS verfügbar, der eine schnelle Datenübertragung ermöglicht. Für Standorte, an denen kein UMTS-Netz zur Verfügung steht, sollte mindestens das GPRS-Netz mit dem Datenbeschleuniger EDGE bereitstehen – die Übertragungsraten sind zwar bereits deutlich langsamer als im UMTS-Netz, reichen allerdings noch aus um rein textliche Informationen zu übertragen. An solchen Standorten sollte allerdings auf die Bereitstellung von Videodateien aufgrund von langen Ladezeiten verzichtet werden

- Frequentierung:

Eine hohe Frequentierung an Touristen und Freizeitsuchenden ist entscheidend für die Effizienz des Pfalzfinders. Hierbei sollen nicht nur Rad-, sondern auch Wander- und „Autotouristen“ die Möglichkeit haben, das System zu nutzen. Daher bieten sich Standorte wie Rastplätze, Aussichtspunkte, Kreuzungspunkte verschiedener Rad- oder Wanderwege und bestehende Informationspunkte für die Aufstellung der Hinweistafeln an.

- Aufenthaltsqualität

Die Standorte der einzelnen Stationen des Pfalzfinders müssen über eine gewisse Aufenthaltsqualität verfügen. Schließlich sollte sich der Nutzer an dem jeweiligen Ort wohl fühlen, um sich mit den bereitgestellten Inhalten informieren zu können.

- Beschilderung

Die Schilder mit den QR-Codes müssen so aufgestellt werden, dass sie deutlich erkennbar und ohne Probleme zugänglich sind. Entsprechend bietet es sich an, bereits bestehende Hinweisschilder und Informationstafeln um die QR-Code-Hinweistafeln zu ergänzen. Des weiteren ist zu gewährleisten das die Schilder auffällig platziert werden.

- Infrastrukturelle Anbindungen

Die Standorte des Pfalzfinders sollten so ausgewählt werden, dass sie über eine Anbindung an die umliegenden Orte, Direktvermarkter und Sehenswürdigkeiten verfügen.

4.2 Ausbaustufen und Erweiterungen

In der ersten Ausbaustufe des Pfalzfinders erstrecken sich die einzelnen Stationen entlang des gesamten Rheinradweges. Insbesondere wurde dabei auf eine gesicherte Mobilfunknetzabdeckung geachtet. Allerdings stellt sich das Problem, dass nicht an allen Stationen eine gesicherte UMTS-Netzabdeckung vorhanden ist. Längerfristig gesehen kann diese Problematik aufgrund des Netzausbaus mit dem neuen Mobilfunkstandard LTE (Long-Term-Evolution), der auch im ländlichen Raum sehr schnelle Datenübertragungsraten gewährleisten soll, vernachlässigt werden. Dann können auch die Stationen an denen nur ein EDGE-Mobilfunknetz verfügbar um multimediale Inhalte erweitert werden.

Für die flächendeckende Verfügbarkeit des Pfalzfinders sollen im weiteren Projektverlauf weitere touristisch attraktive Standorte, die ebenfalls über eine ausgesprochen hohe Frequentierung verfügen, mit QR-Code-Schildern ausgestattet werden (z.B. Freizeitparks, Schwimmbäder, historische Bauten in den Ortschaften). Letztendlich sollen alle Sehenswürdigkeiten und touristische Destinationen im gesamten Landkreis Germersheim mit dem System ausgestattet werden. Der Ausbau des Systems wird insbesondere durch das Point-of-Interest-Management-System garantiert und kann zügig erfolgen. Hier können ausgewählte, lokal engagierte Akteure sowie die Mitglieder des Südpfalz-Tourismus e.V. schnell und einfach neue Standorte generieren und garantieren dabei gleichzeitig als touristische Fachleute die Qualität der Inhalte sowie den idealen Standort. Gleichzeitig ist mit der automatischen Schildergenerierung ein kostengünstiger Ausbau des Pfalzfinders zu einem flächendeckenden mobilen Informationssystem gewährleistet – es fallen lediglich die Druckkosten für die QR-Code-Schilder an.

Durch das Point-of-Interest-Management-System und der Web-App bietet das System Pfalzfinder generell umfassende Möglichkeiten zur Erweiterung. Neben der problemlosen Erstellung von neuen Standorten und der leichten Erweiterung der Standortinformationen mit multimedialen Inhalten wie Infotainmentvideos, bietet der neue Webstandard html5 in Zukunft noch weitaus mehr Möglichkeit des Einbindens neuer Anwendungen, denn es ist zu erwarten, dass die in 2.2. angesprochenen Defizite hinsichtlich des Zugriffs auf einige Funktionen des Smartphones überwunden werden. Dann ließen sich auch beispielsweise Augmented Reality (AR) Anwendungen realisieren, ohne dass eine gesonderte native App programmiert werden muss. Mittels AR können dem Nutzer zusätzliche und besonders interessante Standortinformationen bereit gestellt werden – beispielsweise lassen sich nicht mehr existente Bauwerke als 3D-Modell in das Live-Bild der Smartphone-Kamera einblenden

5 ZUSAMMENFASSUNG

Das Beispiel des Projektes Pfalzfinder zeigt, wie eine verhältnismäßig kleine Tourismusregion ein mobiles Informationssystem realisieren kann, das exakt auf die Bedürfnisse der touristischen Zielgruppe und der lokalen Akteure abgestimmt ist. Die technische Umsetzung mit Hilfe einer mobilen Webseite, eines angeschlossenen POI-Management-Systems und der Schnittstelle zu Deskline 3.0 gewährleistet die Erreichbarkeit einer möglichst großen Gruppe an Endnutzern, die flexible Erweiterung durch die lokalen Akteure und die dauerhafte Aktualität und Qualität der angebotenen Informationen. Somit profitieren nicht nur Touristen vor Ort von einen Informationen mit Mehrwert, sondern auch die regionalen Akteure, die nun mit dem Pfalzfinder eine effektive Möglichkeit besitzen, ihre Angebot zu vermarkten. Insbesondere die landwirtschaftlichen Direktvermarkter dürften hiervon profitieren, da Touristen nun auf die oft abgelegenen Höfe hingewiesen werden und durch die Navigationsmodule des Pfalzfinders diese leichter erreichen können.

Allerdings stellt der Pfalzfinder in seiner derzeitigen Ausrichtung nur eine spezifische Lösung für den Landkreis Germersheim dar. Es gilt demnach bei der Konzeption von (regionalen) mobilen Informationssystemen explizit auf die Bedürfnisse der lokalen Akteure und der definierten Zielgruppen zu achten. Nur wenn die Kategorisierung der Inhalte und die Ausgestaltung von Informationen auf Basis einer fundierten Analyse der Region und des Angebotes erfolgen, kann ein regionales mobiles Informationssystem Erfolg haben.

Der Weg zum Smart Citizen – soziotechnologische Anforderungen an die Stadt der Zukunft

Bettina Mandl, Petra Schaner

(MMag. Petra Schaner, AIT Austrian Institute of Technology, Giefinggasse 2, 1210 Wien, petra.schaner.fl@ait.ac.at)

1 ABSTRACT

Die Bereitstellung von Infrastruktur und sozialen Dienstleistungen sowie die Gewährleistung einer hohen Lebensqualität für eine wachsende und immer stärker diversifizierte Stadtbevölkerung stellen vor dem Hintergrund der Umweltbelastungen und des steigenden Ressourcenverbrauchs eine der größten Herausforderungen für Städte dar. In Hinblick auf die ökologische, ökonomische und soziale Stadt der Zukunft wird dem Konzept der Smart Cities deshalb großes Potential zugeschrieben. In diesem Zusammenhang werden häufig neue Technologien, besonders im Bereich IKT, Energie und Mobilität entwickelt und eingesetzt, wobei jedoch gesellschaftliche und nutzerorientierte Ansprüche zu wenig beachtet werden. Das führt zu dem Problem, dass diese neuen Technologien nicht angenommen werden oder nicht die gewünschten Erfolge erzielen. Voraussetzungen, um die technologischen Entwicklungen zu etablieren, sind einerseits die interdisziplinäre Zusammenarbeit von Politik, Wirtschaft und Wissenschaft, um eine gemeinsame Vision, Vorgaben und regulative Grundlagen zu schaffen, ein hohes Bildungsniveau (Human- und Sozialkapital) sowie die Berücksichtigung der Diversität der Stadtbevölkerung. Andererseits ist vor allem die Einbindung der Stadtbevölkerung in Entscheidungsprozesse sowie die Etablierung von Technologien, die Bewusstseinsbildung und Partizipation in der Bevölkerung erhöhen, ausschlaggebend.

Um herauszufinden, wie diese gesellschaftlichen Ansprüche in Hinblick auf eine nachhaltige Stadtentwicklung umgesetzt werden können, wurden 20 Experteninterviews mit Stakeholdern aus verschiedenen Bereichen geführt, um den bisherigen Einsatz von Technologien durch die Bevölkerung sowie die Bereitschaft der Gesellschaft zur Nutzung dieser Systeme zu erheben. Dabei zeichneten sich Forderungen nach einem Smart Citizen, einem mündigen, selbstbestimmten und für Umweltbelange sensibilisierten Bürger ab, der gewillt ist, aktiv am Stadtgeschehen teilzunehmen und nachhaltig zu handeln. Aufbauend auf den gewonnenen Erkenntnissen wurde ein dreistufiger Prozess (Problemorientierte Bewusstseinsbildung, Akzeptanz der technologischen Erneuerungen, langfristige Umsetzung einer nachhaltigen Stadtentwicklung) abgeleitet, der den Weg der Bürger in Richtung dieses Smart Citizen beschreibt.

2 EINLEITUNG

Seit 2008 lebt mehr als die Hälfte der Weltbevölkerung (3,3 Milliarden Menschen) in Städten bzw. Megastädten und die Tendenz ist steigend, 2030 werden es rund 5 Milliarden Menschen (80% der Weltbevölkerung) sein. Diese Entwicklung führt zu einer Veränderung der städtischen Strukturen, die neue Herausforderungen entstehen lässt. Mit dem rasanten Bevölkerungswachstum gehen Probleme wie Umweltbelastungen, Armut, Überalterung der Bevölkerung, Segregation, wirtschaftliche, soziale, politische und ethnische Ungleichheiten, Wohnraummangel, steigender Ressourcenverbrauch oder Schwierigkeiten in der Bereitstellung von Infrastruktur, sozialen Dienstleistungen und der Daseinsvorsorgen einher (UNFPA 2007). Um vor dem Hintergrund des steigenden Ressourcenverbrauchs und der Umweltbelastungen eine hohe Lebensqualität für eine immer stärke diversifizierte Stadtgesellschaft zu gewährleisten, wird dem Konzept der Smart Cities, das den Ansatz einer ökologisch, ökonomisch und soziale gerechten Stadt vertritt, großes Potential zugeschrieben. Während in Caragliu et al. (2009, S. 6) neben technologischen Entwicklungen Investitionen in Human- und Sozialkapital, nachhaltiges wirtschaftliches Wachstum, hohe Lebensqualität, schonender Umgang mit Ressourcen und partizipative Governance gefordert werden, beschäftigen sich sehr viele „Smart Cities“ Projekte ausschließlich mit der Entwicklung und Umsetzung neuer Technologien in den Bereichen Energie, Mobilität und moderner Informations- und Kommunikationssysteme (IKT). Gesellschaftliche und nutzerorientierte Ansprüche werden dabei zu wenig beachtet. Dies führt zum Problem, dass diese neuen Technologien nicht angenommen werden bzw. nicht die gewünschten Erfolge erzielen.

Um Lösungsansätze entwickeln zu können, die gesellschaftliche und technologische Ansprüche in Hinblick auf eine nachhaltige Stadtentwicklung vereinen und eine ökologisch, ökonomisch und sozial verträgliche Stadt der Zukunft ermöglichen, wurden 20 Experteninterviews mit Stakeholdern aus den Bereichen Stadtplanung und –verwaltung, Energie, Mobilität, Gebäude- und Infrastrukturmanagement geführt. Ziel der

Erhebung war es festzustellen, auf welche Weise Technologien eingesetzt werden können, wie die Bereitschaft der Gesellschaft zur Nutzung dieser Systeme forciert werden kann und welche Voraussetzungen und Rahmenbedingungen dafür gegeben sein müssen. Der Rest dieses Papers ist folgendermaßen strukturiert. In Abschnitt 3 werden technische und gesellschaftliche Voraussetzungen sowie Rahmenbedingungen für nachhaltige Städte der Zukunft beschrieben. Darauf und auf den Ergebnissen der Experteninterviews aufbauend, wird im Abschnitt 4 auf den Prozess zum Smart Citizen, den intelligenten und informierten Bürger, der bereit ist Verantwortung für seine Stadt zu übernehmen, eingegangen.

3 SOZIOTECHNOLOGISCHE VORAUSSETZUNGEN UND RAHMENBEDINGUNGEN

Um eine ökologisch, ökonomisch und sozial nachhaltige Stadtentwicklung unter Einbindung der Stadtgesellschaft gewährleisten zu können, müssen sowohl technologische Voraussetzungen wie auch gesellschaftliche und regulative Rahmenbedingungen gegeben sein.

Abbildung 1: Tagcloud – Handlungsfelder für eine nachhaltige Stadt der Zukunft. Datenquelle: Experteninterviews

Expertinnen und Experten sehen den Handlungsbedarf von Städten der Zukunft vor allem in den Bereichen Energie, Mobilität, Wirtschaft und Bildung. Die Maßnahmen in diesen Bereichen zielen darauf ab, die Klimaziele (Kyoto-Ziele) zu erreichen, einer hohen Lebensqualität inklusive lebenswerter öffentlicher Räume sowie eine transparente und effektive Stadtsteuerung und Verwaltung mit Partizipationsmöglichkeiten zu gewährleisten (vgl. Abbildung 1). Die Handlungsfelder sind daher sehr unterschiedlich und erstrecken sich von Infrastruktur und Daseinsvorsorge (Energie, Mobilität, Ver- und Entsorgung) über Wirtschaft und Forschung, Bildung und Kultur sowie Governance bis hin zum Bereich der Umwelt und Ressourcenschonung.

3.1 Technische Voraussetzungen

Die technische Voraussetzung für intelligente und nachhaltige Städte der Zukunft besteht laut Expertenmeinung vor allem in der Systemintegration über IKT-Systeme und der Vernetzung der unterschiedlichen Bereiche wie z.B. in der Vernetzung von Daten aus den Bereichen Energie, Verkehr, Ver- und Entsorgung für Stadt- und Raumplanung und zu Verbesserung der Lebensqualität der Bewohnerinnen und Bewohner. Basistechnologien sind eine flächendeckende Abdeckung mit Bereitbandkommunikation, intelligente Verteilungsnetze für die Energieversorgung und –verteilung, moderne Sensornetze, die über Machine-to-Machine-Kommunikation Vorteile in den Bereichen Energie, Logistik, Verkehrstechnik und Verwaltung mit sich bringen sowie eine City Data Cloud als hocheffiziente IT-Struktur, die staatliche und unternehmerische Informationen und Daten einer Stadt integriert (Schieferdecker et al. 2011, S. 15-16).

Aufgrund des steigenden Energiebedarfs, vor allem an Strom, müssen neue technologische Möglichkeiten gefunden werden, diesen Bedarf umweltverträglich zu decken. Technische Entwicklungen in den Bereichen der Gebäudeintegration von Energieerzeugungstechnologien, Technologien zur kaskadischen Ressourcennutzung (Abwärmenutzung aus Industrieprozessen, Abwasserkanälen, Biogaserzugung aus Kläranlagen oder biogenen Abfällen, Wiederverwerung von städtischen Ressourcen wie z.B.Bauschutt) sowie zur Energie- und Stoffspeicherung stellen Lösungsansätze dar. Performanceindikatoren sowie eine

Abschätzung der Technikfolgen zählen zusätzlich zu den notwendigen Schritten, um über technologische Ansätze ökonomisch, ökologisch und sozial gerechte Städte zu ermöglichen (Saringer-Bory et al. 2011).

Weitere Forderungen im Zusammenhang mit Smart Cities beziehen sich auf eine integriete Raum-, Verkehrs- und Energieplanung. Auf technologischer Seite gibt es hierfür auch schon Ansätze wie LIVE! Singapore, ein Plattform die das Leben in der Stadt in Echtzeit wiederspigeln soll und zum Ziel hat, Entscheidungsträgern neue Perspektiven zu eröffnen und Bürgerinnen und Bürgern neue Services zu bieten. Das innovative an dieser Plattform ist die Einbindung der Bewohnerinnen und Bewohner der Stadt, die über Smartphones oder das Mobilfunknetz als wichtige Informationsliferanten ins System eingegliedert werden (Kloeckel et al. 2011). Für die Stadtbevölkerung sind Technologien zur Kommunikation und ganz besonders für die Informationsbeschaffung (Energieverbrauch, Verkehrsinformation, Partizipationsmöglichkeiten, etc.) von Bedeutung. Dazu müssen jedoch Methoden zur Datenauswertung und Interpretation entwickelt werden, die das Verständnis der urbanen Komplexität für die Bevölkerung sowie für die Entscheidungsträger erleichtern.

Für einen Großteil der befragten Expertinnen und Experten ist die Frage nach nachhaltigen, zukunftsfähigen Städten keine technologische. Ihrer Meinung nach werden Technologien im Zusammenhang mit Smart Cities oft überschätzt, da die meisten Technologien bereits vorhanden sind und nur noch besser vernetzt und ausgebaut werden müssten. Demnach ist nachhaltige Stadtentwicklung keine rein technologische Problemstellung sondern vielmehr eine gesellschaftliche bzw. eine der Technikakzeptanz. Viele Technologien werden und wurden schon entwickelt, werden jedoch nicht angenommen oder erzielen nicht die gewünschten Erfolge. Dies ist darauf zurückzuführen, dass einerseits zu wenig Bewusstseins zur Verhaltensänderung bei der Bevölkerung sowie wie bei den Akteuren seitens der Stadt vorhanden ist und dass andererseits bei der Entwicklung der technologischen Lösungen zu wenig auf die nutzerorientierten und gesellschaftlichen Ansprüche eingegangen wird.

3.2 Gesellschaftliche Voraussetzungen

Nachhaltige Städte der Zukunft setzen vor allem gesellschaftliche Veränderungsprozesse voraus. Das Ziel dieser Prozesse sind Smart Citizens, intelligente und informierter Bürger, die breit sind in einer Kultur der Beteiligung und Partizipation, (ökologische) Verantwortung zu übernehmen und die Stadt nach ihren Bedürfnissen nachhaltig zu gestalten.

Um eine zukunftsfähige Stadtgesellschaft zu erreichen, sind einerseits Veränderungsprozesse und Bewusstseinsbildung bei den Entscheidungsträgern und andererseits bei der Bevölkerung selbst notwendig. So ist eine interdisziplinäre Zusammenarbeit von Politik, Wirtschaft und Wissenschaft von besonderer Bedeutung, um gemeinsame Visionen, Ziele und Vorgaben sowie regulative Grundlagen für die Stadt der Zukunft entwickeln zu können. Zudem muss der gesellschaftliche Rahmen, der sich durch eine immer diversifiziertere Gesellschaft und einer Pluralität der Lebensstile auszeichnet, beachtet werden. Die Basisvoraussetzungen für eine zukunftsfähige Stadtgesellschaft sind eine gerechte Wohlstandsverteilung, die Gewährleistung der Daseinsvorsorge, ein ausgezeichnetes Bildungssystem, welches „lebenslanges Lernen“ ermöglicht sowie die Einbindung der Bevölkerung in Partizipationsprozesse.

Um Bewusstseinsbildung zu schaffen und einen Wertewandel in der gesamten Gesellschaft zu ermöglichen ist laut Expertinnen und Experten besonders auf die unterschiedlichen Lebensstile der Stadtbewohnerinnen und Stadtbewohner sowie auf die Förderung der sogenannten Urban Diverstity zu achten. In der Soziologie wird „Lebensstil“ als „der regelmäßig wiederkehrende Gesamtzusammenhang der Verhaltensweisen, Interaktionen, Meinungen, Wissensbestände und bewertenden Einstellungen eines Menschen“ (Hradil 2005, S.46) bezeichnet, der nach Pierre Bourdieu (1987) von der klassenspezifischen sozialen Lage (Beruf, Einkommen, Bildung, Arbeitsplatz, Wohngegend, Freizeit) abhängig ist und bestimmte Verhaltensweisen (Kultur, Nahrung, Selbstdarstellung, Denk- und Handlungsmuster) mit sich bringt (Christmann 1999). Werden nun Maßnahmen zur Bewusstseinsbildung und Verhaltensänderung gesetzt oder geplant, muss auf die unterschiedlichen Lebensstile der Menschen geachtet werden, um einen möglichst großen Teil der Stadtgesellschaft erreichen zu können. Besonders wichtig dabei ist die Aufbereitung von Informationen, welche unbedingt auf die Bedürfnisse der Bevölkerung abgestimmt werden müssen, um keine Gruppen auszuschließen.

Urban Diversity wurde bereits in den 1960er Jahren von der Stadt- und Architekturkritikerin Jane Jakobs als Grundlage für Lebensqualität, Wirtschaftswachstum und die Attraktivität von Städten bezeichnet. In ihren

Werken fordert sie eine vielfältige, gewachsene städtische Struktur, mit Funktionsdurchmischung und hoher Dichte, die lebendigen Nachbarschaften in kleinteiligen, ungeplanten Quartieren ermöglicht (Jacobs 1961). In dieselbe Richtung gehen auch die Forderungen der Expertinnen und Experten, so wird unter dem Schlagwort „Stadt der kurzen Wege“ eine intelligente Stadtplanung mit hohen Dichten, Funktionsdurchmischung und ein lebendiger öffentlicher Raum gefordert. Dies hat die Erhöhung der Effektivität des öffentlichen Verkehrs, eine Verkehrsreduktion, Einsparungen im Energiebereich sowie ganz besonders die Erhöhung der Lebensqualität durch „Grätzelbildung“, Gemeinschaft und Kommunikation innerhalb des Stadtviertels zum Ziel. Die dadurch entstehende Identifikation mit der eigenen Wohnumgebung fördert wiederum die Bereitschaft, Eigenverantwortung für den eigenen Lebensraum bzw. die eigene Stadt zu übernehmen und aktiv zu werden.

Dies führt zu einer weiteren, äußerst wichtigen gesellschaftlichen Voraussetzung: der Einbindung der Stadtbevölkerung in Entscheidungsprozesse. Erfolgreiche Bürgerpartizipation kann jedoch nur dann stattfinden, wenn eine sogenannte „Kultur der Partizipation“ vorhanden ist, was wiederum vor allem eine gut gebildete, informierte und eigenverantwortliche Bevölkerung bedingt. Die Stadtgesellschaft muss sich mit ihrem Lebensraum identifizieren, die Probleme der Stadt erkennen und offen und flexible genug sein, um Veränderungen und Neues zuzulassen. Andererseits muss auch seitens der Entscheidungsträger Vertrauen in das Urteilsvermögen der Bevölkerung gegeben sein, d. h. Probleme, Anliegen, Verbesserungsvorschläge müssen ernst genommen und Projekte, die unter Einbindung der Bevölkerung geplant wurden, umgesetzt werden.

3.3 Soziotechnologische Voraussetzungen

In der Literatur wird der Begriff „soziotechnologisch“ bzw. „soziotechnisch“ immer im Zusammenhang mit dem Begriffen „System“ oder „Prozess“ verwendet. Er geht auf den soziotechnischen Gestaltungsansatz des englischen Tavistock Institutes, das sich mit sozialwissenschaftlicher Forschung und Arbeitsorganisation befasste, zurück. Demnach zielt ein soziotechnischer Prozess auf eine gemeinsame Optimierung sozialer und technischer Systeme ab (Maucher et al. 2002) und kann als Bindeglied zwischen Mensch, Technik und Organisation verstanden werden (Sylvester 2008). Die Stadt kann als soziales System gesehen werden, bei dem starke Verflechtungen mit Technologien zu erkennen sind. Eine optimale Verbesserung des Systems, d.h. die Entwicklung zu einer ökologisch, ökonomisch und sozial nachhaltigen Stadt, kann daher nur erfolgen, wenn soziale bzw. gesellschaftlich und technologische Veränderungen aufeinander abgestimmt passieren.

Besonders in den Bereichen der Bürgerpartizipation und Bürgerinformation aber auch im Verkehrssystem (Ticketing, Routenplanung,…), in der Bildung, im Energiebereiche, etc. kommen in der Stadt immer häufiger neue Technologien zum Einsatz. Viel zu oft werden diese Technologien entwickelt und eingesetzt, ohne die gesellschaftlichen und nutzerorientierten Ansprüche zu beachten. Das führt zu dem Problem, dass diese nicht angenommen werden oder nicht die gewünschten Erfolge erzielen. In diesem Zusammenhang ist die Technikakzeptanz innerhalb der Bevölkerung von besonderer Bedeutung. Unter Technikakzeptanz wird die „grundsätzliche Aufgeschlossenheit gegenüber technsichen Innovationen“ verstanden, die „einerseits Voraussetzung für einen sachlich-aufgeklärten Meinungsbildungsprozess und andererseits wesentlicher Bestandteil […] wirtschaftlicher Modernisierung und Wettbewerbsfähigkeit eines Standorts ist“ (Kornwachs et al. 2011, S. 7). Mehrere Gründe führen dazu, dass neue technologische Lösungen nicht akzeptiert werden: Diese sind einerseits die Angst, die Kontrolle über die eigene Lebenswelt zu verlieren sowie die Furcht vor realen oder vermuteten Umweltproblemen, negativen Gesundheitsauswirkungen oder Eingriffe in die Privatsphäre. (Kornwachs et al. 2011). Andererseits schrecken Personen vor neuen Technologien zurück, wenn diese sehr kompliziert sind/erscheinen bzw. die potentiellen Nutzerinnen und Nutzer mit diesen nicht vertraut sind. Zudem sind fehlende Transparenz (Datenschutz, Schutz der Privatsphäre) oder unzureichendes Verständnis für den Nutzen der Technologien Gründe dafür, dass es zu einer Ablehnung kommt.

4 DER WEG ZUM SMART CITIZEN

Aufbauend auf den oben dargestellten Erkenntnissen zu technologischen, gesellschaftlichen und soziotechnischen Voraussetzungen für eine Smart City zeichnet sich ein dreistufiger Prozess zur Förderung der Akzeptanz und aktiven Umsetzung nachhaltiger Maßnahmen in der städtischen Bevölkerung ab (vgl. Abbildung 2). Im folgenden Kapitel soll näher auf die einzelnen Stufen (problemorientierte

Bewusstseinsbildung, Akzeptanz der technologischen Erneuerungen, langfristige Umsetzung einer nachhaltigen Stadtentwicklung) eingegangen werden.

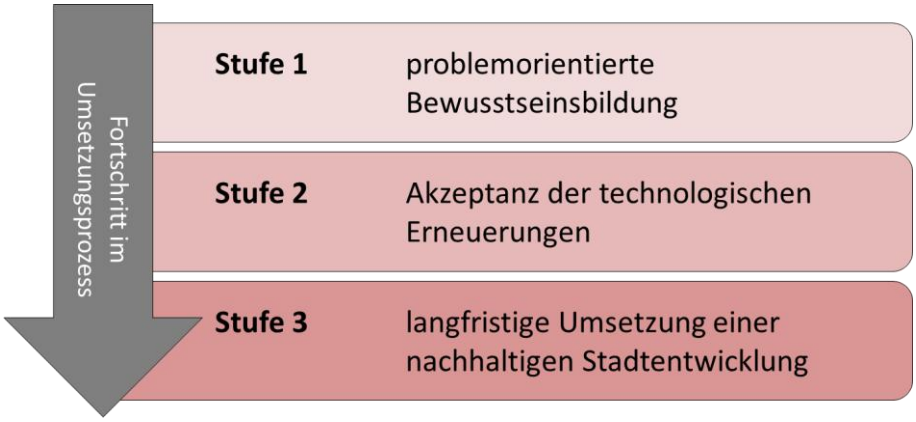

Abbildung 2: Übersicht über die Prozessstufen

Dabei ist es von Bedeutung, negative Assoziationen der Bürger, die durch Veränderungen in ihrem direkten Lebensumfeld hervorgerufen werden, zu vermeiden und stattdessen positive Anreize für nachhaltige Verhaltensweisen zu schaffen. Nur so kann sichergestellt werden, dass (technische) Neuerungen einerseits angenommen und in den Lebensalltag integriert werden und andererseits zu einer bewussten Teilnahme der Bürger bei der Umsetzung nachhaltiger Strategien motivieren.

4.1 Problemorientierte Bewusstseinsbildung

Der erste und wesentlichste Schritt, der von einem Großteil der Expertinnen und Experten aller Bereiche identifiziert wurde, ist jener der problemorientierten Bewusstseinsbildung in Hinblick auf Themen der Nachhaltigkeit (vgl. Abbildung 3).

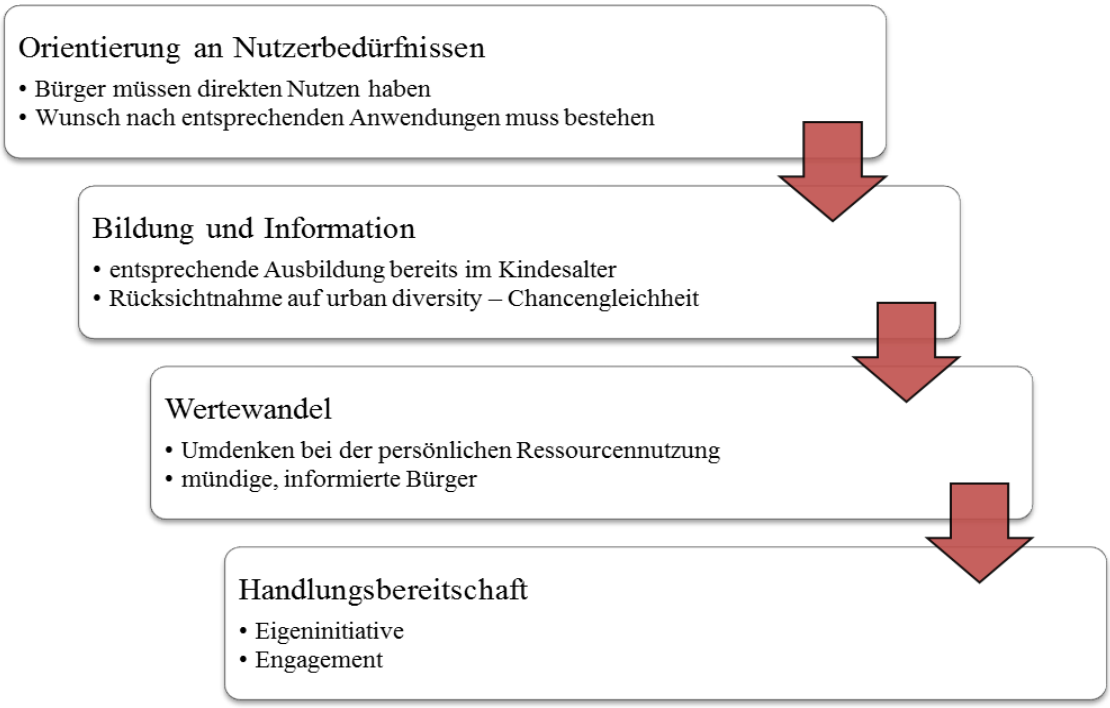

Abbildung 3: Stufe 1 – Bewusstseinsbildung

So wird vermehrt darauf hingewiesen, dass der Einsatz der Smart City-Technologien den Bürgerinnen und Bürgern einen direkten Nutzen bringen muss, der den Wunsch nach entsprechenden Anwendungen fördert. Um diesen Bewusstseinswandel in der Bevölkerung herbeiführen zu können, ist es nach Ansicht der Experten nicht zielführend, technologische Entwicklungen am technisch Machbaren zu orientieren, sondern auf tatsächliche Nutzerbedürfnisse einzugehen.

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

Ebenso muss auf Seiten der Bürger ein Verständnis für städtische Problematiken geschaffen werden, welches dazu führt, dass ein selbst initiiertes Umdenken in Hinblick auf das eigene Verhalten stattfindet. Von Experten aus dem Forschungssektor geht hierbei beispielsweise die Forderung nach einer zielgruppenspezifischen Bildung und Information in Bereichen wie Energieverbrauch oder Mobilitätsnutzung aus. Als Beispiel wurde hier etwa ein öffentlich zugängliches Informationssystem genannt, welche die Feinstaubbelastung, den ökologischen Fußabdruck des Einzelnen in Bezug auf das jeweilige Mobilitätsverhalten sowie andere ökologische Parameter darstellt. Ziel dieser Maßnahme soll es beispielsweise sein, die Bürgerinnen und Bürger zu einem Umdenken bei der Verkehrsmittelwahl zu motivieren.

Dabei herrscht bei den Befragten Einigkeit darüber, dass eine solche Verhaltensänderung vor allem einen individuell wahrnehmbaren Nutzen für die Bürger haben muss. Um dies zu gewährleisten, bedarf es einer Orientierung der Bewusstseinsbildungsmaßnahmen an den unterschiedlichen Zielgruppen und Lebensstilen der Menschen. So muss nach Ansicht von städtischen Interessensvertretern eine nachhaltigkeitsorientierte (Aus)Bildung bereits im Kindesalter ansetzen, um bereits jungen Bevölkerungsschichten entsprechende Vorbilder im Umgang mit natürlichen Ressourcen zu liefern. In diesem Sinne äußerten die befragten Expertinnen und Experten auch den Wunsch nach Investitionen in das Bildungssystem sowie in eine gezielte Lehrer- und Pädagogenausbildung; auch der Begriff des „lebenslangen Lernens“ wurde mit diesem Bildungsprozess in Zusammenhang gebracht. Zudem wurde die Einbeziehung und Chancengleichheit weniger privilegierter Gesellschaftsschichten in den bzw. im Bewusstseinsbildungsprozess gefordert. Wie von Nachhaltigkeitsforschern und Raumplanern unterstrichen, ist somit ein neuer Bildungsansatz notwendig, der durch gezielte Informationen zu städtischen Problembereichen verantwortungsbewusste und „mündige Bürger“ hervorbringt und das Potential besitzt, die Eigeninitiative und das Engagement der Bevölkerung zu steigern.

4.2 Akzeptanz der technologischen Erneuerungen

Existiert bereits ein Problembewusstsein für Themen der städtischen Nachhaltigkeit, bedarf es auch einer möglichst flächendeckenden Akzeptanz der Bevölkerung für die neuen Technologien, welche in Smart Cities eingesetzt werden (vgl. Abbildung 4).

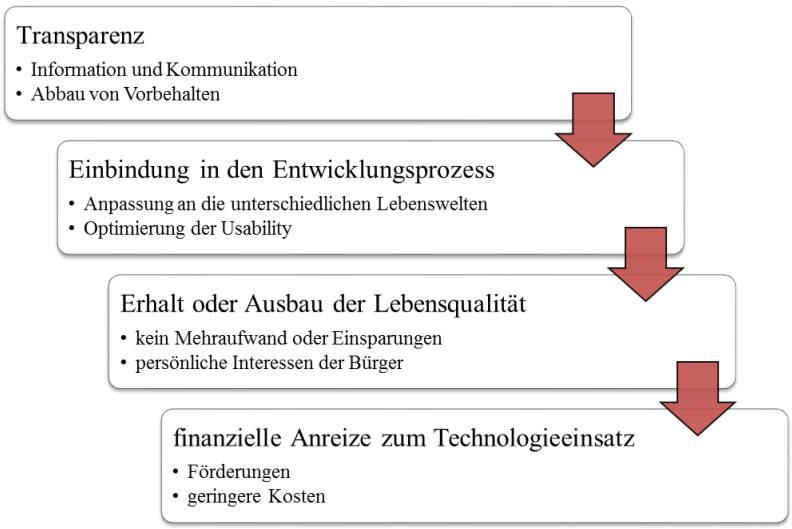

Abbildung 4: Stufe 2 – Akzeptanz technologischer Erneuerungen

Auch hierbei stellen Information und Kommunikation wesentliche Kriterien dar, weil die dadurch entstehende Transparenz Expertinnen und Experten zufolge die Vorbehalte gegenüber neuer Technologien eindämmt. Diese Transparenz sollte sich dabei sowohl auf geplante (auch weniger „populäre“) Maßnahmen als auch auf die Entscheidungsprozesse, die zur Etablierung der Maßnahmen führen, beziehen. Die Konsequenzen der Erneuerungen für das eigene Leben bzw. den eigenen Alltag sollten daher von den Anbietern sowie Akteuren aus Politik, Wirtschaft und Gesellschaft möglichst verständlich kommuniziert werden. Neue Technologien müssen als Hilfsmittel zum besseren Verständnis komplexer Systeme verstanden werden und die entsprechende Nutzerfreundlichkeit aufweisen. Wie schon bei der Bewusstseinsbildung ist auch hier eine Anpassung an die unterschiedlichen Lebenswelten potentieller

Nutzerinnen und Nutzer notwendig, um auch weniger technikaffinen Bevölkerungsschichten die Handhabung zu ermöglichen. Besonderer Stellenwert kommt in diesem Zusammenhang der Usability, der Nutzerfreundlichkeit zu. Als möglicher Ansatzpunkt zur Optimierung der Usability wurde hier von einigen Interviewpartnern eine Einbindung der unterschiedlichen Akteure in den Entwicklungsprozess der zu nutzenden Technologien vorgeschlagen. Ebenso muss für die Nutzer Datenschutz und Sicherheit in der Anwendung gewährt werden.

Zudem darf nachhaltiges Verhalten für die Bürger nicht mit einem Mehraufwand oder Einsparungen im persönlichen Bereich verbunden sein, was zu einer Assoziation des Lebensstilwandels mit Einschränkungen des persönlichen Komforts und der Lebensqualität führt. In diesem Zusammenhang wurde von mehreren Experten unterstrichen, dass eine ökologisch, ökonomisch und sozial nachhaltige Stadt der Zukunft die Lebensqualität aller Bewohner erhöht, jedoch auch enormes Konfliktpotential mit sich bringt. So sind für gewisse Personengruppen durchaus unpopuläre Maßnahmen wie die Forcierung des Umweltverbundes auf Kosten des motorisierten Individualverkehrs, etc. notwendig. Als Lösungsansatz wurde hier jedoch auf eine zielgruppenorientierte Bewusstseinsbildung (vgl. 4.1) verwiesen. Im Allgemeinen müssen die öffentlichen Interessen von Entscheidungsträgern in Hinblick auf urbane Entwicklungen mit den persönlichen Interessen der Bürger vereinbar sein. Dies kann etwa durch den Einsatz gezielter Anreize und Förderungen geschehen, mit denen der Einsatz nachhaltiger Technologien (z.B. Photovoltaik- oder Solarzellen) „belohnt“ wird. Wie von einigen Befragten festgehalten, lässt sich Akzeptanz in vielen Fällen auch über den Preis bzw. Kosten erreichen, wenn die entsprechenden Technologien einen finanziellen Vorteil in der Anwendung nach sich ziehen.

4.3 Langfristige Umsetzung einer nachhaltigen Stadtentwicklung

Eine letzte Stufe stellt der Umsetzungsprozess dar, der nicht nur durch wirtschaftliche, wissenschaftliche und politische Stakeholder, sondern auch durch die Bürgerinnen und Bürger als Nutzer der Technologien getragen wird (vgl. Abbildung 5).

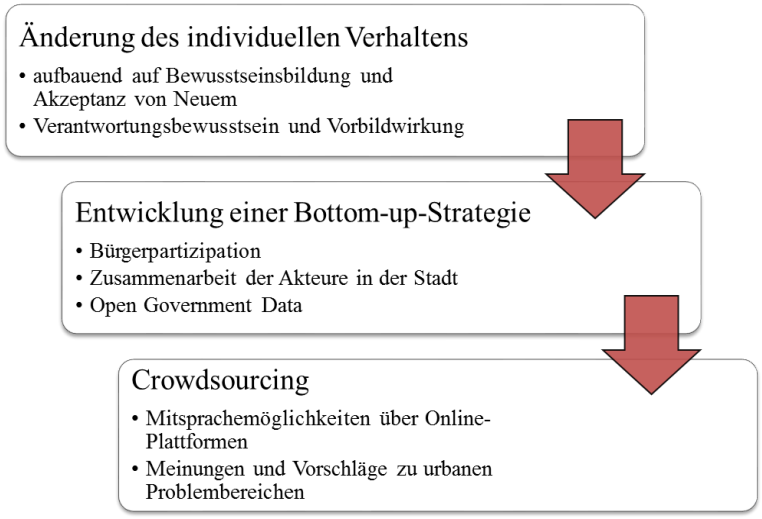

Abbildung 5: Stufe 3 – Langfristige Umsetzung von Maßnahmen

Dabei zeigt sich die Bedeutung der ersten zwei Stufen deutlich, da ein entsprechendes Bewusstsein für eine nachhaltige Stadtentwicklung und die Akzeptanz der damit verbundenen Veränderungen im persönlichen Umfeld wesentlich für eine sinnvolle Nutzung der zur Verfügung stehenden Technologien sind. Konkret bedeutet dies, dass eine Bereitschaft zur Verhaltensänderung vorhanden sein muss, um Maßnahmen zur Reduktion des Stromverbrauchs oder des CO2-Ausstoßes aktiv einzusetzen, auch wenn diese Maßnahmen vielleicht im Widerspruch zu bisherigen Verhaltensmustern stehen. Wie von einem der befragten Experten erwähnt, sieht das Konzept des „Smart Citizen“ vor, dass „jeder bei sich selbst beginnt“, sich also seiner Verantwortung für die Umwelt bewusst ist und eine Vorbildwirkung auf andere hat.

Wie bereits im vorigen Punkt ausgeführt, sehen Expertinnen und Experten aber auch die aktive Einbindung der Bevölkerung als wesentlichen Aspekt an, der die Bürgerinnen und Bürger über ihre Rolle als Anwender städtischer Technologien hinaus auch als Feedback- und Input-Lieferanten in Erscheinung treten lässt. Ein Stichwort, welches die befragten Experten in diesem Zusammenhang besonders häufig nannten, war jenes

der Bürgerbeteiligung, die es den Bürgern ermöglicht, selbst Ideen einzubringen. In vielen Fällen wurde diese Form der Einbeziehung als entscheidender Aspekt der Demokratieentwicklung genannt, der wesentlich zur Schaffung „intelligenter Bürger“ beitragen soll. Vor allem in Hinblick auf den permanenten Umbruch, dem Smart Cities unterliegen, wurde von Seiten der Politik und der Planer eine bottom-up-Strategie gefordert, die den Bürgern eine aktivere und verantwortungsvolle Rolle zugesteht und eine Zusammenarbeit der Akteure in der Stadt untereinander sowie mit der Stadtgesellschaft möglich macht. Um dies zu gewährleisten, tritt wieder die bereits im vorigen Schritt erwähnte Informationstransparenz in den Vordergrund, da eine qualifizierte Teilnahme an partizipatorischen Entscheidungsprozessen einen integrativen Blick auf die Problemstellung erfordern. Ein solches Informationsangebot steht den Bürgern beispielsweise in Form von Open Government Data online zur Verfügung. Wie vermehrt festgehalten wurde, muss sich die Bevölkerung selbst eine Meinung bilden können, Teil einer „flexiblen und offenen Gesellschaft“ mit einem hohen Maß an „Empowerment“ werden zu können.

Neben der klassischen Partizipation spielt aber auch „crowdsourcing“ eine wesentliche Rolle, welches die Mitsprachemöglichkeiten der Bürgerinnen und Bürger auf eine neue Ebene verlegt. Auf diese Weise steht für Interessierte die Option offen, über Online-Plattformen Meinungen und Vorschläge zu urbanen Problembereichen auszutauschen und die sonst meist nur auf einen Teil des Planungsprozesses eingeschränkte Beteiligung auf den gesamten städtischen Raum auszudehnen. Auch kann Feedback so schneller an die zuständigen Abteilungen weiter geleitet werden. Für die Akteure in der Stadtverwaltung bedeutet das jedoch, dass Meinungen und Vorschläge nicht nur gesammelt werden, sondern auch einer genauen Studie unterzogen werden müssen, um qualifizierte Beiträge direkt einbeziehen zu können. Nur so kann gewährleistet werden, dass engagierte Bürger, die ihre Ideen öffentlich kundtun, auch weiterhin zur Teilnahme motiviert werden können.

5 FAZIT

Wie anhand der Aussagen der befragten Expertinnen und Experten festgestellt werden konnte, bedarf der Entwicklungsprozess einer Stadt zur Smart City vor allem einer engagierten Bürgerschaft, die dazu bereit ist, sich auf neue Entwicklungen einzulassen und diese auch anzuwenden. Bewusstseinsbildung muss somit einerseits dem Abbau von Vorbehalten gegen neue Techniken und andererseits der Entwicklung eines Bewusstseins für nachhaltiges Verhalten dienen. Nur so kann in weiterer Folge eine Akzeptanz für urbane Entwicklungen, die sich außerhalb altbewährter Bahnen bewegen, in der Bevölkerung erreicht werden (vgl. Abbildung 6).

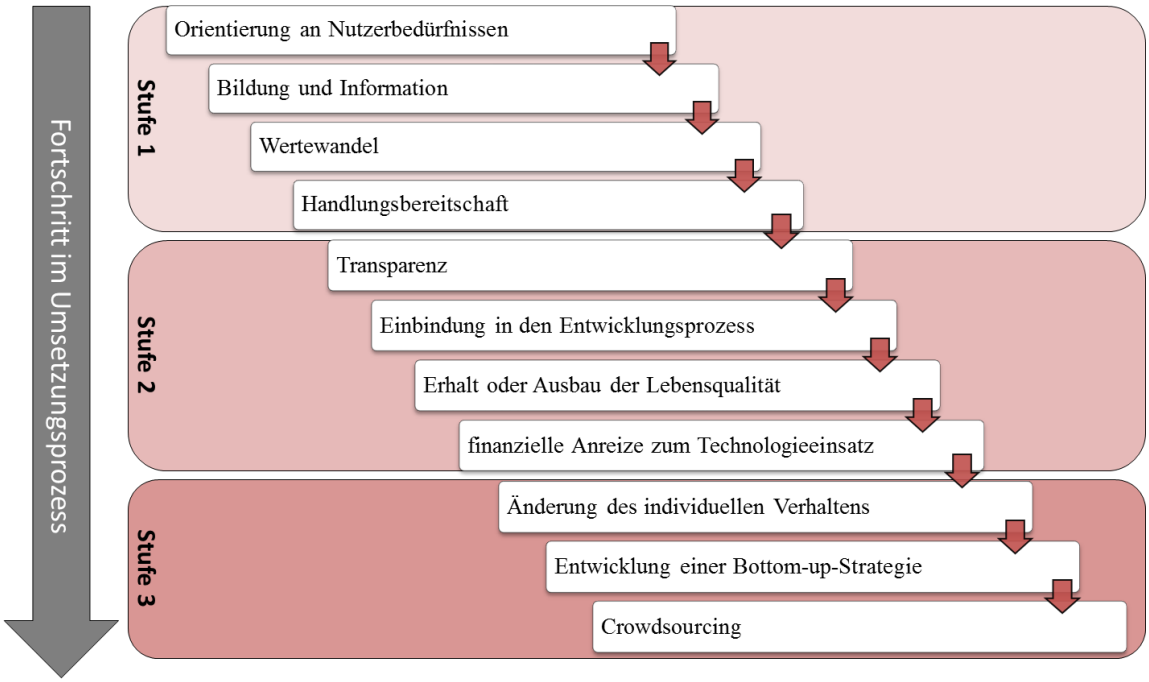

Abbildung 6: Zusammenfassung der Prozessstufen

Um dies zu erreichen, ist es für politische und wirtschaftliche Entscheidungsträger sowie für Technologieunternehmen notwendig, sich an den Nutzerbedürfnisse der Bürgerinnen und Bürger zu

orientieren und Entscheidungsprozesse sowie Informationsquellen transparent zu gestalten. Einige der Expertinnen und Experten sprachen sogar die Forderung nach einer aktiven Einbindung der Bevölkerung bei der Entwicklung von Maßnahmen und dem Einsatz partizipativer Ansätze aus. Hierbei ist es die Rolle der Verwaltung, die einzelnen Bevölkerungsschichten zielgerichtet (über den Einsatz verschiedener Methoden und Medien) zur Teilnahme zu motivieren und ihre Ideen auch aktiv aufzugreifen, um die Bereitschaft zur Meinungsäußerung durch konkrete Umsetzungsmaßnahmen zu stärken. Erste Ansätze in diese Richtung bieten in Wien beispielsweise die Mitte März 2012 eingerichteten Partizipationsportale „Wiener Charta" sowie „Wir sind mehr", die den Bürgern einen öffentlichen Austausch über stadtrelevante Themen erlauben. Längerfristig ist bei Projekten dieser Art jedoch zu bedenken, dass auch Bevölkerungsschichten, die vom privaten Technologieeinsatz ausgeschlossen sind, Zugang zu Informations- und Kommunikationsmedien haben müssen, um der Verwaltung ein sozial ausgewogenes Interessensbild der Gesellschaft zu liefern. Auch spielt hierbei die Wahl geeigneter Selektionsschemata für die Auswahl von Ideen eine wesentliche Rolle, da nicht alle Bürger durch eine einzige Lösung zufrieden gestellt werden können.

Zusammenfassend lässt sich somit festhalten, dass es für die Entscheidungsträger im Smart City-Entwicklungsprozess wesentlich ist, eine bottom-up-Strategie einzusetzen, die es den Bürgern ermöglicht, an der Strategiefindung mitzuwirken und dadurch ein Bewusstsein für eine nachhaltige Lebensweise und die dafür notwenigen Änderungen im eigenen Verhalten aufzubauen. Dabei ist es jedoch wesentlich, auch weniger priviligierte Bevölkerungsschichten durch die Bereitstellung ensprechender Informationstechnologien am Partizipationsprozess teilhaben zu lassen. Unter diesen Voraussetzungen kann es auch langfristig zu einem Umdenken in der Gesellschaft kommen, so dass diese dem von Expertinnen und Experten vielfach heraufbeschworenen Begriff des „Smart Citizen" auch gerecht werden kann.

1 ABSTRACT

The Republic of Korea has established a diversity of strategies to cope with the climate change through a new policy paradigm called 'low-carbon green growth' since the past 2008, and it is being realized. This new paradigm suggested a far-reaching developmental guideline of low-carbon and green city creation, and for its concrete realization appeared the very Urban Renaissance Project.

This study is the result drawn through this Project, and its ultimate purpose is to develop a system that can compare & analyze the degree of micro-climate change consequent upon diverse planning elements in a project target site. Actually, it's true the elements belonging to micro-climate are really diverse. However, this study carried out its research by confining the micro-climate to wind and temperature for the sake of realizable possibility and concreteness. As a case target site for system evaluation, this study set the Urban Renaissance Zone in Gwangju Metropolitan City of central district of Korea. The developmental contents of the system and system evaluation results are summed up as follows:

First, this study designed the urban micro-climate management system so that macro-scale analysis module and micro-scale analysis module can be interlocked on the basis of the 3-dimensional virtual machine, through which it's possible to analyze cold wind formation & its flow at a wide area level and also to analyze the wind flows at a microscopic level.

Second, this study designed the system composition by dividing it roughly into data sector, analysis sector and expression sector for making it possible for its users to handle with ease.

Third, this study dealt with system management process. In all planning process, this study preferentially conducted the analysis of cold wind formation and wind flows at a wide area level, on the basis of which this study conducted the analysis of wind flows at a microscopic level, and then finally drew the optimum alternative for creating low-carbon and green city.

Fourth, this study drew the results of Pilot Study for evaluating the urban micro-climate system. First, there increased the wind by 0.6 m/s, and decreased the temperature by 0.4 °C through the creation of Traditional Theme Street. In case of Streamlet Street, there increased the wind 0.12 m/s, and decreased the temperature by 0.3 °C. In addition, in case of Central Square, there increased the wind by 0.26 m/s, and decreased the temperature by 1.0 °C. Additionally, through the creation of Waterfront Park, there appeared the greatest increase in the wind by 0.99 m/s while the temperature was found to decrease the most by 0.7 °C, showing that green space combined with waterfront creation was the most effective in improving micro-climate.

Through the results mentioned above, this study was able to understand the potential for the stability & applicability of the Urban Micro-Climate Management System. Nevertheless, this research thinks that should the reliability in the drawn result value and speed for drawing the analysis value back up, it could be a system with higher practical use, and additionally, if the practical function like the analysis of greenhouse gas emissions should be added, the effective value of this system would be more augmented.

2 INTRODUCTION

The microclimatic environmental change has recently caused the problems, such as wind flow impediment and heat island phenomenon due to the high-rise/high-density centered urban development, and this has been recognized as the reason that impedes the residential environment in the surrounding areas, as well as the developing areas themselves. Therefore, the environment factors (securing wind road and enhancement of heat island) have been truly proposed as the planning considerations in the legislation system related to the urban plan, in recent. However, it is true that it is never enough to evaluate and reflect these urban microclimate environmental factors by linkage with the actual planning process. Especially, as the effects by

the change of urban microclimate should be sufficiently reviewed and considered in the planned/comprehensive manner prior to implemetation of urban development project, the effective enhancement can be expected due to its nature. Because of this, it can be said that the sufficient effects can be seen only if the relevant factors of the urban microclimate should be predicted/evaluated and controlled in advance in the systematic/comprehensive manner when establishing all types of the urban regeneration projects.

Therefore, this study has an ultimate purpose of developing the technologies that can be generally operated in the process of applying this to each type of urban regeneration project by building the system that can control and manage the relevant problems related to urban microclimate due to urban regeneration projects perfectly and comprehensively, and is intended to contribute to building the low-carbon and green city with creating the pleasant urban environment as the environmental factors related to the urban microclimate are sufficiently reflected on the plan through this.

3 URBAN MICRO-CLIMATE MANAGEMENT SYSTEM (UMCMS)

3.1 System Concept and GUI

System Concept

The urban microclimate management system is a system to expand the liquidity of wind by predicting/analyzing the wind environment and the heat environment in priority among various urban microclimate factors and to focus on evaluating and designating the planning technique and the related factors necessary for this that can lower the strength of the heat island. This system has been interlocked with Macro-Model for wind flow analysis in the macroscopic level, Micro-Model for wind flow analysis in the microscopic level, and Thermal-Analysis Model for heat environment analysis in the microscopic level, based on the 3-dimensional virtual machine, and has been drawn up to allow various thermal maps to be drawn up through this.

The flow of system for the microclimate analysis is shown as following. Firstly, the analysises in the regional level, such as cold wind forming analysis, cold wind flow analysis, and cold wind velocity analysis, have been conducted, based on the land cover and the geographical data. Next, the wind analysis is conducted, here with needs of building structures, building materials and meteological data. Based on these data, analysis of wind flow and pollutants distribution within the specific object site is to be conducted. Finally, the system has been comprised of the system that can propose the plan for building the optimal green city through linkage with the wind environment by conducting the heat environment analysis. However, the heat environment analyzing function has been in the status of showing only possibility of realizing the function, as a testing phase, and in the status with substantially little reliability on the results.

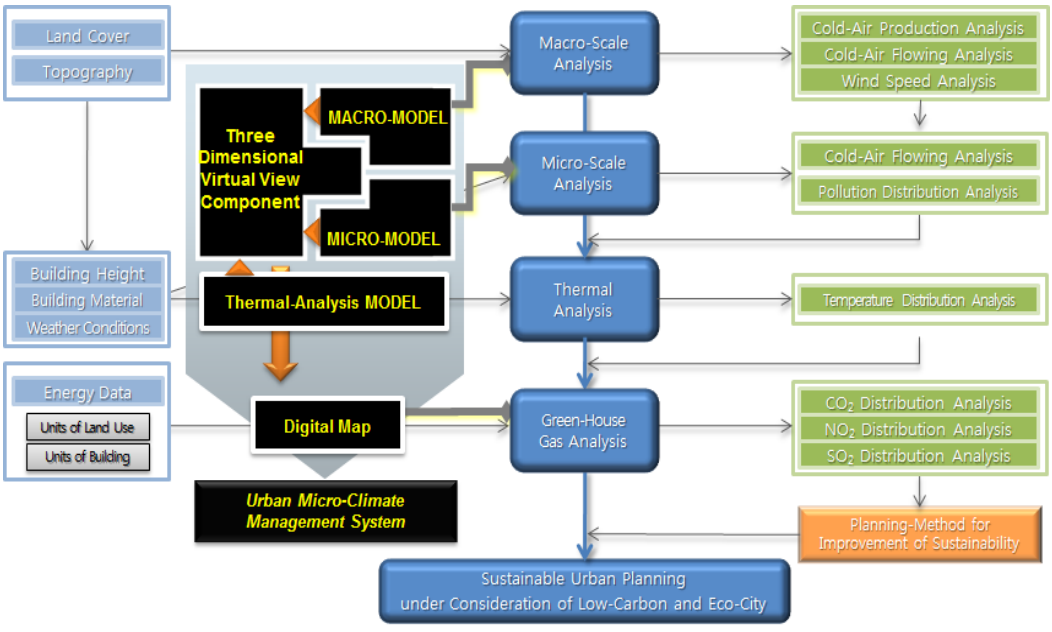

Fig. 1: System Concept and Workflow

System GUI

The most important matter in the urban microclimate management system is that the convenience should be provided to the users by top priority when utilizing the system. Therefore, the urban microclimate management system has a merit that it has been designed to enable all the functions to be implemented in the single platform with removing the difficulties that various models should be utilized in turn according to the necessary functions.

The main screen has been intuitively and simply comprised of Menus, Layer Control Window, and Map Display Window to improve convenience and identification. The menu for improving convenience of the system has been simply comprised of File, Data, Analysis and Display.

File Menu has been consisted of Submenu, such as Open and Save, which is the menu that all the programs have in common, generally. Data menu is largely divided into creation and extraction of data, and submenu below this has been consisted to create and extract the topography, image, land cover, and building data.

In Analysis Menu, the submenu has been composed to analyze wind environment, heat environment, and green house gasses emissions. In other words, we have comprised a submenu for separate analysis of cold wind flow and pollution sources below the wind environment menu, a submenu for analysis of temperature distribution below the heat environment menu, and sub/submenu for analysis of green house gasses emissions. We have divided the analyzed results into sectors of land status, wind environment, thermal environment, and status of green houses emission, as expressing parts, and consisted of the sub/submenu to draw up the specific thematic map related to each below it.

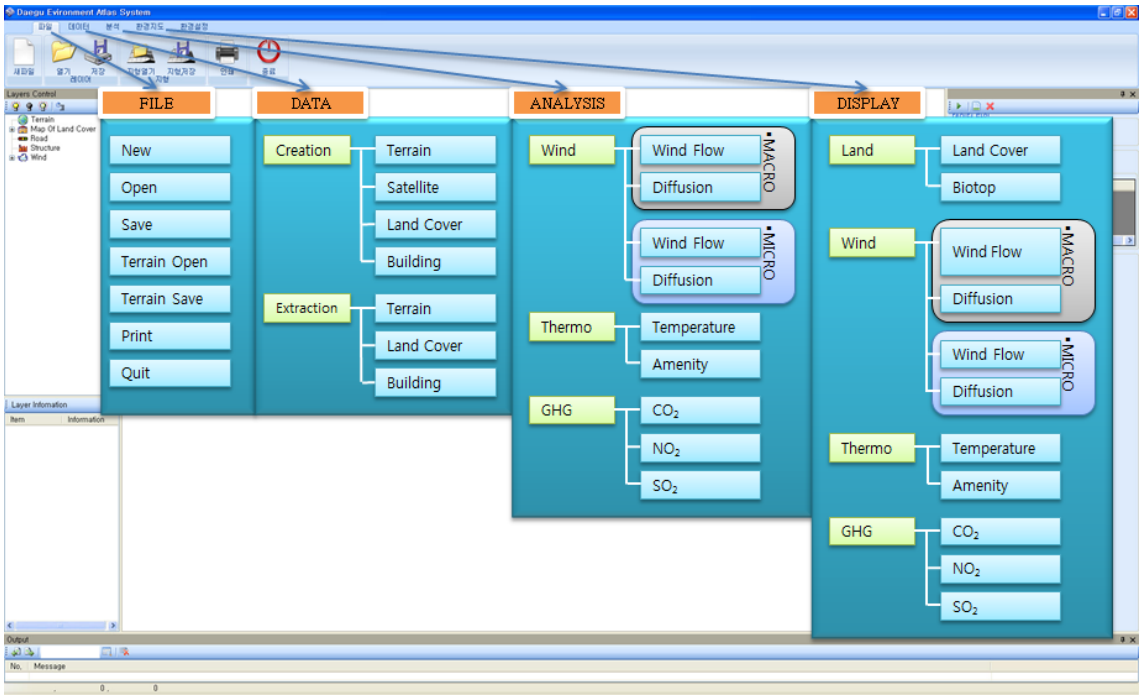

Fig. 2: System GUI

3.2 System Workflow

As aforementioned, the analyzing process of the system is substantially important to operate the microclimate system efficiently and draw the optimal result through this. Therefore, we intend to mention the specific details related to this in this chapter.

Cold-Wind Flow Analysis (Macro Scale)

As a first process for analysis of the microclimate, this means the process of analyzing the occurring areas and flows of the cold or fresh wind in the regional level. The cold wind blows to downtown ordinarily with forming in the mountain areas in the vicinity of downtown at night. As this cold wind has a crucial role in solving various environmental problems that the existing city has, the analysis of creation and flow should be conducted by top priority. Along with this, the results of analysis are utilized as the basic data for analysis of the optimal wind flow in the microscopic level that will be conducted in the next phase.

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

To analyze the creation and flow analysis of the cold wind in the regional level, the data related to topography on the object site, land cover and buildings, and the analysis of where the cold wind creates and flows in, is conducted based on this.

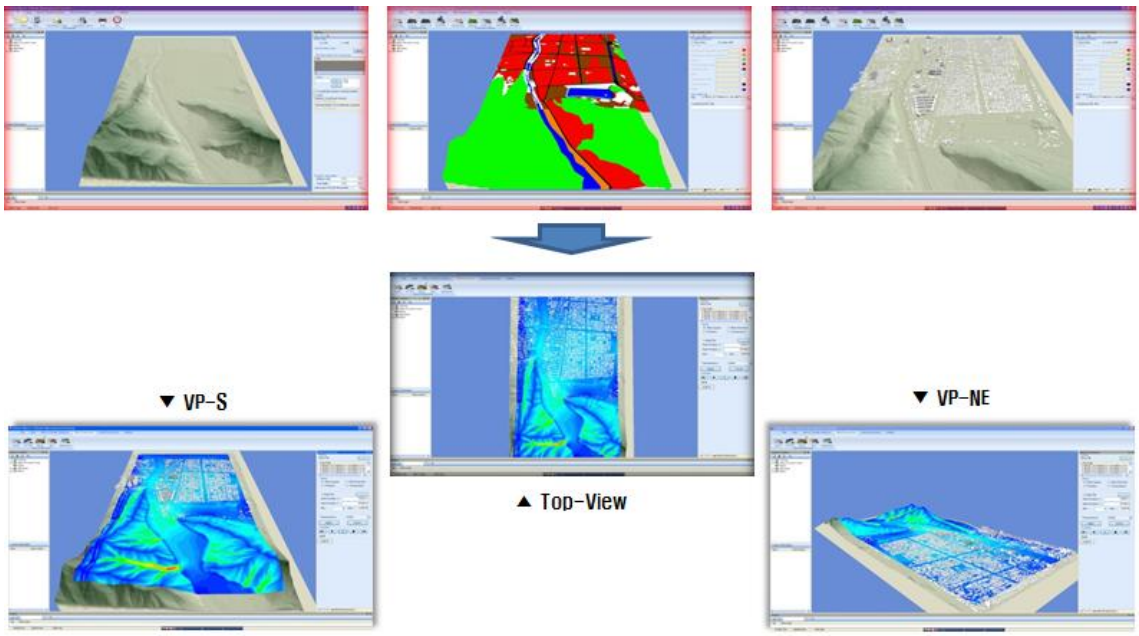

Fig. 3: Cold-Wind Flow Analysis (Macro-Scale)

Wind Flow Analysis (Micro Scale)

This is a phase of conducting an analysis of wind flow in the microscopic level, as the second process of the urban microclimate management system. To analyze the wind flow in the microscopic level, the data that are previously built in the macroscopic level can be utilized as they are. However, a step to set the main wind direction as the initial input values considering the cold wind flow results that have been drawn in the macroscopic level and the specific scope that is intended to be analyzed are necessary in addition.

We can draw the results of wind flow analysis in the microscopic level through this process, and can observe and assess the specific wind flow within the complex as shown in below picture.

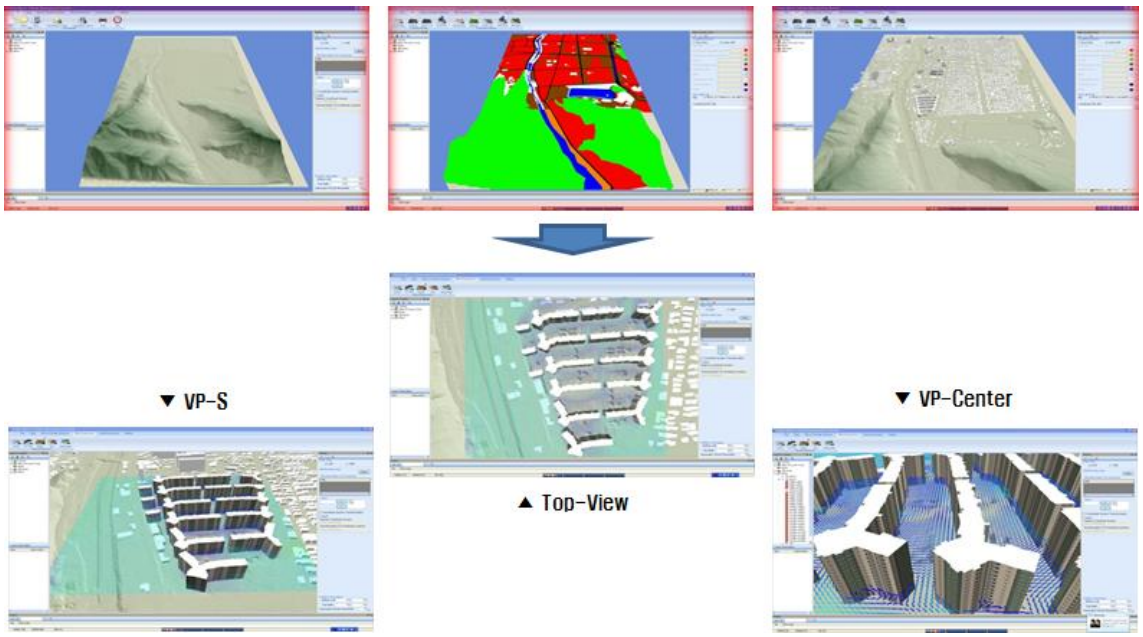

Fig. 4: Wind Flow Analysis (Micro-Scale)

Thermal Environment Analysis (Micro Scale)

Next is the thermal environment analysis phase. The analysis in this study is a phase of testing the possibility of further expansion of the system functions as aforementioned, and we intend to mean that we have checked

the linking possibility with other modules up to now and mention that the analysis results still have a low reliability in advance.

For the thermal environment analysis, the data built in the microscopic level can be utilized as they are, and we can add the data related to the building materials more here. We can conduct the thermal environment analysis in the microscopic level through this. The results are shown as the below figure, and we can estimate and assess the change of the thermal environment according to the array of complex and type and materials of buildings.

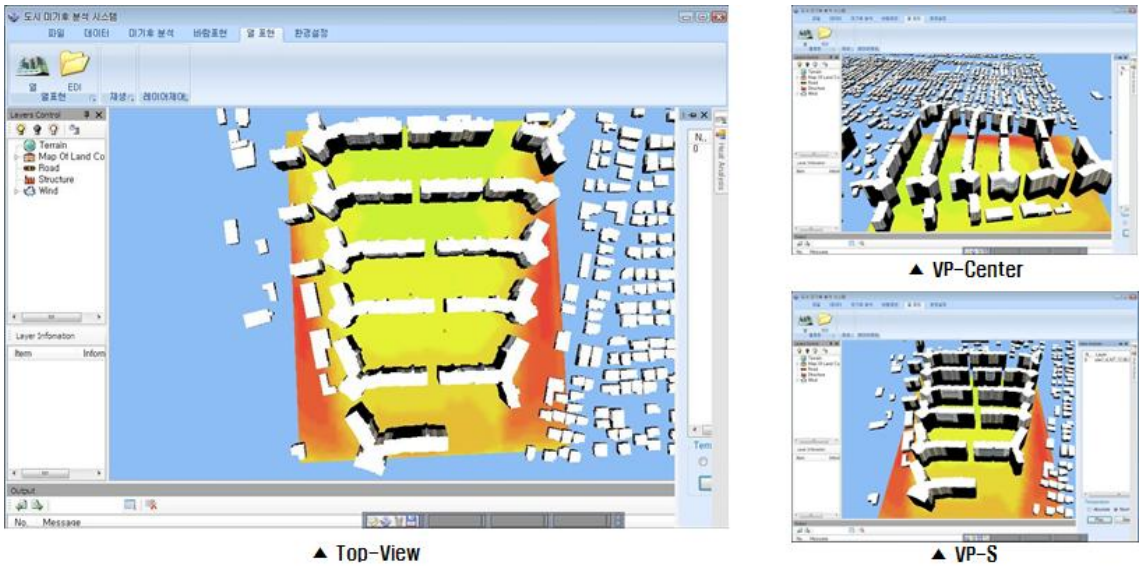

Fig. 5: Thermal Environment Analysis (Micro-Scale)

4 PILOT STUDY WITH UMCMS

In this chapter, we deal with the contents related to the Pilot Study to see the possibility of utilizing the previously developed microclimate management system, and intend to explain with focusing on the general status, planning details, and the results of the Pilot Study for the exampled site.

4.1 Outline of Study Area

Location

The exampled site is a regeneration project district within Gwangju Metropolitan City when has played a central role in the southwest areas, as one of 6 metropolitan cities in Korea. The details are shown in the below table, and this site is a place where the city regeneration project has been propelled after being designated as the demonstration project for residential environment enhancement from Ministry of Land, Transport And Marine Affairs with the reason of the quality declination of the residential areas due to the enhancement of the current decrepit buildings and the poor infrastructures.

Articles	Details
Location	Whole Area of No.202-27, Yangnim-Dong, Namgu, Gwangju Metropolitan City
Area	128,873m^2
Population	2,420 People
Household	1,133 Houses

Table 1: Summary of Study Area

Fig. 6: Location Map of Study Area

Climates Status

As to the detail climates in the exampled areas, the average temperature is 14.6 ℃ for one year in the object site and the vicinity of it, and the main wind is indicated as blown from north-northwest and south. As to the wind velocity, the blown wind in 0.5 m/s to 2.0 m/s velocity has taken up the largest portion by 54.3% of total.

Articles	Details
Average Temperature	14.6℃
Relative Humidity	68%
Main Wind Direction	NNS, S
Frequency of Wind Velocity	0.5-2.0 m/s: 54.3%
Frequency of Non Windy Condition	11.34%

Table 2: Climates Status of Study Area

4.2 Urban Regeneration Planning of Study Area

Purpose of Planning

The exampled site is a typical urban residence, in which is located in Nam-gu of Gwangju Metropolitan City, with the lining of decrepit buildings in current. Because of this, it is a district where a variety of programs have been propelled to promote the urban regeneration as the downtown of Gwangju Metropolitan City has been depressed. Also, the qualitative enhancement of the residence environment has been required as all the infrastructures necessary for the residential life have been substantially appalled. Besides, as there are many facilities that have substantial values historically in the object site and the vicinity of it, the necessity of their preservation has been also suggested. Therefore, it is a ultimate purpose of the urban generation project for this exampled site to improve the qualitative enhancement of residential environment by enhancement of the appalled infrastructure and improvement of decrepit buildings, and further to promote the urban regeneration through the linkage with the facilities that have historical and cultural values.

Details of Plan

Various specific plans for the exampled site have been established and propelled to achieve the purpose of the plan. If the details of the plan related to this study among them are put together, they are shown as followings.

Traditional Theme Street: The planning factor for utilizing the natural materials in the existing asphalt-centered street and realizing the traditional street by planting the street trees in the surroundings.

Streamlet-Street: The planning factor for providing the water-friendly space by building water-friendly space in the existing dreary street, especially, a small stream in the middle or at the edge of street.

Central Square (Community Center): The planning factor for restoring the center point and symbolism for local communities by using the environment-friendly or natural coating materials.

Traditional Parking Lot: The planning factor for restoring the traditionality by installing the traditional fence with using the pavement materials with permeability in the existing concrete-centered parking lots.

Waterfront Park: The planning factor for providing space where the residents can have an easy access and enjoy the rest as improving the space around the existing river.

Pocket Park: The planning factor for providing various resting space for residents within the object site.

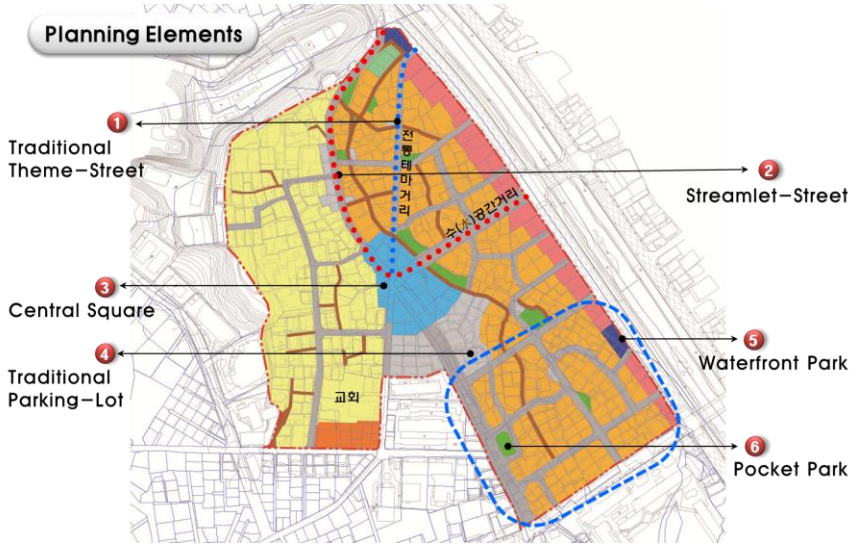

Fig. 7: Planning Details of Urban Regeneration Project for Study Area

4.3 Evaluation of Micro-Climate according to Urban Regeneration Planning

In this chapter, we intend to introduce the results of analyzing and assessing the degree of urban microclimate change according to the major planning factors related to the urban microclimate among various planning details of the urban regeneration project for the exampled site.

Planning Element 1: Traditional Theme-Street

The traditional theme street has a feature that the Korea beauty has been added by using stones, which is a natural material, not an artificial material for the materials for existing road pavement, and building the street trees and flower garden around it. It is a specialized street planned with 230m in total length and 10m in width(Fig. 9).

Seen the results of analyzing the degree of the urban microclimate change due to building this traditional theme-street, the wind velocity has increased as the wind velocity prior to the plan was indicated as 0.87 m/s of daily mean temperature, and the one after planning was indicated as 1.47 m/s of daily mean temperature. The temperature has been analyzed as reduced by 0.4 ℃ in average, as it is 26.8 ℃ of daily mean temperature prior to building the traditional theme-street, and 26.4 ℃ of daily mean temperature after building it. These velocity improvement and temperature falling effect can be said as the result that gives an awareness of importance of the road pavement materials and road width when improving the urban microclimate.

	Average Wind-Speed(m/s)	Average Temperature(℃)
Before	0.87	26.8
After	1.47	26.4

Table 3: Effect of Enhancing Urban Microclimate According to Building Traditional Theme-Street

Planning Element 2: Streamlet-Street

The streamlet-street is a planning factor that has been built to provide the more pleasant water front space to residents who live within the exampled site. The street has been planned with 250m in length and 6m in width along with Korean traditional floor pattern considering the traditional style(Fig. 10)

Seen the degree of urban microclimate change according to building the streamlet-street, the wind velocity has been indicated as increased by 0.25 m/s in daily average, and the temperature change as reduced by 0.3 ℃ in daily average.

	Average Wind-Speed(m/s)	Average Temperature(℃)
Before	1.13	26.6
After	1.25	26.3

Table 4: Effect of Enhancing Microclimate According To Builing Streamlet-Street

Fig. 8: Example of Traditional Theme Street

Fig. 9: Example of Streamlet-Street

Planning Element 3: Central Square

The central square established to play a central point role in the community of residents and to impose the symbolism within the exampled site, is due to be built as 5,950 m2 in total areas and is planned to equip with fountains, resting spaces, playgrounds and community centers as detail facilities(Fig. 11).

Seen the effect of improving the urban microclimate through these central squares, the velocity has been indicated as increased by 0.26 m/s in daily average, and the temperature as reduced by 1.0 ℃. Especially, when comparing the temperature change with other planning factors, it has shown the relatively high reduction effect. This can be concluded as the areas where the natural coating materials have taken up are relatively larger. Eventually, it is judged that the natural coating materials should be positively introduced to improve the temperature.

	Average Wind-Speed(m/s)	Average Temperature(℃)
Before	1.20	26.8
After	1.46	25.8

Table 5: Effect of Enhancing Microclimate According To Builing Central Square

Planning Element 4: Traditional Parking-Lot

This is a traditional parking lot planned to restoring traditionality by using the traditional fence and the floor pattern along with using the pavement materials with permeability in the existing concrete-centered parking lot(Fig. 11). The degree of urban microclimate change according to this is shown as followings. 6,070m2 of the total areas have been planned by being divided into 3 places within the exampled site. However, to conduct the specific and accurate analysis, we have conducted the analysis by selecting one traditional parking lot located in the center within the exampled site that has taken up 2,960m2 areas. Firstly, the wind

velocity has indicated the improvement effect by 0.18 m/s, showing 1.22 m/s after applying the plan to the previous 1.04 m/s, and the temperature has indicated the temperature falling effect by 0.3 ℃, showing 26.3 ℃ after applying the plan to the previous 1.04 m/s.

	Average Wind-Speed(m/s)	Average Temperature(℃)
Before	1.04	26.6
After	1.22	25.3

Table 6: Effect of Enhancing Microclimate According To Builing Traditional Parking-Lot

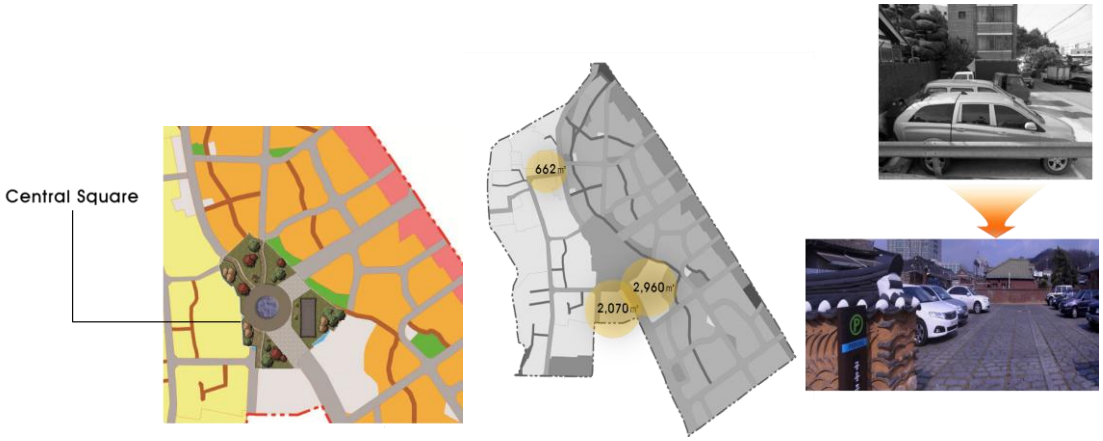

Fig. 10: Example of Central Square (Left) / Allocation and Example of Traditional Parking-Lot (Right)

Planning Element 5: Waterfront Park

The waterfront park planned to provide an easy access and space for enjoying rests to residents is a substantially important planning factor to residents when improving the spaces around the existing stream located in the east side of the exampled site. Therefore, it can be expected that the expecting effect for the degree of urban microclimate change is substantially huge in general, according to building the water front park. The analysis result according to this has also shown the degree of enhancement relatively better than other planning factors. Seen the result, the wind velocity has shown the enhancement effect by 0.99 m/s in daily average and the temperature has shown the one by 0.7 ℃. In other words, it can be judged that the results are showing the biggest enhancement effect in wind velocity and the second biggest effect next to the central square in temperature.

	Average Wind-Speed(m/s)	Average Temperature(℃)
Before	0.36	26.9
After	1.35	25.2

Table 7: Effect of Enhancing Urban Microclimate According to Building Waterfront Park

Planning Element 6: Pocket Park

The result of the degree of the urban microclimate change according to the pocket park planned to provide various resting spaces to residents within the exampled site is shown as followings.

Firstly, the wind velocity has shown the enhancement effect by 0.77 m/s, changing from 0.34 m/s to 1.11 m/s, and the temperature has shown the same enhancement effect as the waterfront park, changing 27.0 ℃ to 26.3 ℃. They can also be the result of empasizing the importance of the natural coating materials or nature-friendly structures more and more.

	Average Wind-Speed(m/s)	Average Temperature(℃)
Before	0.34	27.0
After	1.11	26.3

Table 8: Effect of Enhancing Urban Microclimate According to Building Pocket Park

If summarizing by putting together the degree of urban microclimate change according to various planning factors within the exampled site as above, it is shown as followings.

The common features of the planning factors, such as traditional theme-street, streamlet-street, central square, traditional parking-lot, waterfront park, and pocket park, is to replace and use the artificial coating materials actively to natural coating materials and to recommend the proper density. With the result of analyzing the urban microclimate within the exampled site utilizing the microclimate management system through these common features, it has been assessed that the average wind velocity has shown as increased by 0.2 m/s in daily average, changing from 0.82 m/s before the project to 1.12 m/s after the project, the average temperature has the temperature reducing effect by 0.57 °C, changing from 26.78 °C before the project to 26.21 °C after the project.

5 CONCLUSION

The construction of the low carbon and green city is a strategy established by the urban development policy due to the policy paradigm of low carbon and green growth in Korea, and one of the projects suggested to realize this specifically is a very urban regeneration project. However, it is the current status that there is lack of quantative assessment tools for the enhancement effect according to the urban regeneration projects, especially the assessment tools for urban microclimate. Therefore, we have developed the tools for assessing the urban microclimate comprehensive, and further percussed a possibility of utilizing the assessment tools by designating the actual exampled site.

With the result of it, it has been shown that there are enhancement effects in urban microclimate, such as wind and temperature, according to various planning factors, and that utilization of natural coating materials rather than artificial materials and securement of the waterfront have substantial effects on enhancement of the urban microclimate. It has been also assessed that the quantative results shown through utilizing the system have shown the enhancement effect by about 0.2 m/s in daily average for wind and the temperature falling effect by 0.57 °C in daily average for temperature.

We could acknowledge the possibility of stability and utilizability of the urban microclimate management system through these case studies. However, it is suggested that this system can have a higher utilizabilty if immediacy for drawing the analyzed values and reliability for the drawn result values can be backed up. Beside of this, if the practical functions, such as the emission analysis of green house gasses, are added more, the effective values of the system is expected to be expanded more and more.

6 ACKNOWLEDGEMENT

This research was supported by Basic Science Research Program through the National Research Foundation of Korea (NRF) funded by the Ministry of Education, Science and Technology (2011-0003986)

DGNB Zertifizierungssystem: Neubau gemischte Stadtquartiere

Stephan Anders

(Dipl.-Ing. Stephan Anders, Deutsche Gesellschaft für Nachhaltiges Bauen e. V., Kronprinzstraße 11, 70173 Stuttgart, Deutschland, s.anders@dgnb.de)

1 ABSTRACT

Unser ökologischer Fußabdruck übersteigt die Fähigkeit der Erde zur Regeneration derzeit um rund 30 %. Wenn unsere Ansprüche an den Planeten weiter mit der gleichen Geschwindigkeit zunehmen, bräuchten wir im Jahr 2030 den Gegenwert von zwei Planeten, um unseren Lebensstil aufrechtzuerhalten. (vgl. WWF 2008) Städte könnten bei der Diskussion um eine nachhaltige Entwicklung eine Schlüsselrolle einnehmen, denn sie bieten beispielsweise die Möglichkeit Energie-, Abfall und Verkehrssysteme effizienter zu nutzen und somit den Energiebedarf pro Person zu senken.

Es zwängt sich die Frage auf, nach welchen Prinzipien Städte und Stadtquartiere entwickelt werden müssen, welche den Bewohnern eine hohe Aufenthaltsqualität bieten, gleichzeitig jedoch energieeffizient und ressourcenschonend sind?

Mit dieser Fragestellung wurde im Frühjahr 2009 bei der Deutschen Gesellschaft für Nachhaltiges Bauen (DGNB) eine Arbeitsgruppe gegründet, welche das Ziel verfolgte ein Zertifizierungssystem für nachhaltige Stadtquartiere zu entwickeln. Die Marktversion des Systems soll nun im Juni 2012 auf der Messe CONSENSE in Stuttgart präsentiert werden.

Entsprechend der DGNB Grundsätze bildet das Stadtquartiersprofil eine sinnvolle Ergänzung zu den Gebäudeprofilen, indem insbesondere der Bereich zwischen den Gebäuden und der Quartiersstandort bewertet wird.

Abb. 1: DGNB Logo

Auch in diesem System wird den Themen Ökobilanz und Lebenszykluskosten besondere Beachtung geschenkt. Zusätzlich werden neue stadtquartiersspezifische Themen, wie beispielsweise die Veränderung des Stadtteilklimas, Artenvielfalt und Vernetzung, die Qualität der Verkehrssysteme, Regenwassermanagement oder auch übergeordnete Konzepte für den Umgang mit Energie, Wasser und Abfall in die Betrachtung mit einbezogen. Die Gebäude selbst müssen für eine Quartierszertifizierung nicht zertifiziert sein und werden nur mit Basiswerten in der Bewertung berücksichtigt.

Da sich die Entwicklung von Stadtquartieren über einen langen Zeitraum erstreckt, wird neben dem Vorzertifikat (Phase 1) auf Ebene des städtebaulichen Entwurfs, ein weiteres Zertifikat für die Planung (Phase 2) eingeführt, für welches mindestens Baurecht vorliegen muß und die Ausführungsqualitäten vertraglich gesichert sind. Den Abschluß bildet das Zertifikat für das zumindest 75 % fertig gestellte Quartier (Phase 3). Das Vorzertifikat ist dabei 3 Jahre, das Zertifikat für die Planung ist 5 Jahre und das Zertifikat für das Quartier ist unbegrenzt gültig.

Zusammen gefasst bietet das vorliegende System vielfältige Möglichkeiten. Es unterstützt Kommunen und private Entwickler, schon im Planungsprozess, Optimierungspotentiale zu erkennen und zu beheben und schafft Transparenz bei den zukünftigen Nutzern des Quartiers. Nicht zuletzt beugen attraktive und lebenswerte Stadtquartiere soziale „Schieflagen“ vor und halten dieses über lange Zeiträume hinweg stabil und damit nachhaltig.

2 EINLEITUNG

Unser ökologischer Fußabdruck übersteigt die Fähigkeit der Erde zur Regeneration derzeit um rund 30 %. Wenn unsere Ansprüche an den Planeten weiter mit der gleichen Geschwindigkeit zunehmen, bräuchten wir im Jahr 2030 den Gegenwert von zwei Planeten, um unseren Lebensstil aufrechtzuerhalten. (vgl. WWF

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

2008) Städte könnten bei der Diskussion um eine nachhaltige Entwicklung eine Schlüsselrolle einnehmen, denn sie bieten beispielsweise die Möglichkeit Energie-, Abfall und Verkehrssysteme effizienter zu nutzen und somit den Energiebedarf pro Person zu senken. Nicht zuletzt lebt mehr als die Hälfte der Weltbevölkerung in Städten. Dieser Anteil soll nach Prognosen der UN (vgl. UN 2009) bis zum Jahr 2050 sogar auf 70 % ansteigen.

Jedoch ist die Einsparung von Energie und Ressourcen nur ein Aspekt unter vielen. So unterstützt die Dichte von Städten beispielsweise auch die soziale Interaktion der Bewohner untereinander und ermöglicht es den Kommunen eine Vielzahl sozialer und kultureller Angebote zur Verfügung zu stellen, welche in weniger dicht besiedelten Gebieten schlichtweg an der Finanzierung scheitern würden.

Neben diesen positiven Aspekten können, insbesondere in Städten, auch Vielzahl von Problemen auftreten, welche sich im besonderen Maße in den rasant wachsenden Metropolen der dritten Welt zeigen. So haben beispielsweise eine Vielzahl der Stadtbewohner mit Lärm und Smog zu kämpfen oder verfügen nicht über ein ausreichendes Angebot an privaten und öffentlichen Freiflächen.

Es zwängt sich die Frage auf, nach welchen Prinzipien Städte und Stadtquartiere entwickelt werden müssen, welche den Bewohnern eine hohe Aufenthaltsqualität bieten, gleichzeitig jedoch energieeffizient und ressourcenschonend sind?

Mit dieser Fragestellung wurde im Frühjahr 2009 bei der DGNB eine Arbeitsgruppe gegründet, welche das Ziel verfolgte ein Zertifizierungssystem für nachhaltige Stadtquartiere zu entwickeln. 2010 wurden die erarbeiteten Kriterien erstmalig an realen Projekten getestet und auf der CONSENSE 2010 präsentiert. Die Erkenntnisse aus dieser ersten Evaluation wurden in die Kriterien eingearbeitet und mit einem unabhängigen Expertengremium diskutiert. Im Januar 2011 ist die Pilotphase mit 13 angemeldeten Projekten gestartet, welche im Oktober 2011, im Rahmen der ExpoReal in München, die ersten (Vor-) Zertifikate für Stadtquartiere erhalten haben. Aufgrund der großen Nachfrage an dem System und um weitere Erkenntnisse und Daten von den Projekten zu generieren, wurde die Pilotphase verlängert. Im Juni 2012 sollen die überarbeiteten Kriterien auf der Messe CONSENSE 2012 vorgestellt werden.

Folgende Projekte haben an der DGNB Pilotphase „Neubau gemischte Stadtquartiere“ teilgenommen:

Vorzertifikat: Planung (Phase 1)

- Aarau (CH), Torfeld Süd (4,43 ha)
- Babenhausen, Kaserne (56,75 ha)
- Bedburg, Bedburger Höfe (20 ha)
- Esch-sur-Alzette (LU), Belval (112 ha)
- Esslingen, Weststadt (9,8 ha)
- Köln, Waidmarkt (1,4 ha)
- Luxemburg, Ban de Gasperich (77,8 ha)
- Offenbach, Hafen (27,9 ha)
- •Stuttgart, Milaneo (4,8 ha)

Zertifikat: Erschließung (Phase 2)

- Düsseldorf, Le Quartier Central (28 ha)
- Frankfurt, Europa-Viertel West (67 ha)

Zertifikat: Quartier (Phase 3)

- Berlin, Dom Aquarée (2,5 ha)
- Berlin, Potsdamer Platz (13 ha)

3 STAND DER FORSCHUNG

Die Themen Audit, Benchmarking, Ranking, Rating, Screeing und Zertifizierung erfassen, nicht zuletzt in Zeiten knapper öffentlicher Kassen und der Forderung nach einer quantifizierten Wirkungsmessung, immer mehr gesellschaftliche Bereiche und haben etwas verspätet auch das Bauwesen erfasst (vgl. DV 2010, S. 6-

13). Die verspätete Entwicklung von Zertifizierungssystemen hat insbesondere in Deutschland damit zu tun, dass es ohnehin schon hohe gesetzlich verankerte Baustandards gibt. „Dennoch zeigen alleine die Entwicklungen der 1990er Jahre im Osten Deutschlands, aber auch laufende Vorhaben in allen Teilen Deutschlands, dass die gesetzlichen Vorgaben eine zukünftige Entwicklung nicht immer hinreichend gewährleisten können und Raum für Fehlentwicklungen lassen." (DV 2010, S. 37)

Auf Ebene der Gebäude gibt es derzeit weltweit eine Vielzahl an Zertifizierungssystemen mit unterschiedlichen Schwerpunkten (vgl. Ebert 2010), von welchen, gemessen an der Anzahl der zertifizierten Gebäude, in Europa die Systeme BREEAM, LEED, HQE und DGNB am häufigsten verwendeten werden (vgl. RICS 2011).

Auf Stadtquartiersebene ist die Anzahl an unterschiedlichen Zertifizierungssystemen derzeit noch überschaubar. Die vorhandenen Systeme, wie beispielsweise das Zertifizierungssystem LEED for Neighborhood Development (LEED-ND) oder BREEAM Communities, kommen hauptsächlich aus dem angloamerikanischen Raum (vgl. DV 2010, S. 8) in den deutschen Markt. Jedoch befinden sich auch in anderen Teilen der Welt Zertifizierungssysteme für Stadtquartiere in der Entwicklung, wie das aus Abu Dhabi stammende PEARL COMMUNITY Rating System zeigt.

Allen vorhanden Systemen gemein ist, dass diese in spezifischen kulturellen, klimatischen und rechtlichen Kontexten entwickelt wurden und nicht ohne weiteres auf deutsche bzw. europäische Verhältnisse übertragbar sind. So kommt auch die Kommission für Zertifizierung in der Stadtentwicklung zu der Feststellung das die „Anwendung von unter anderen rechtlichen und fachlichen Voraussetzungen entwickelten Zertifizierungssysteme für Neubauvorhaben […] in Deutschland nicht sinnvoll ist." (DV 2010, S. 10)

4 SYSTEM

4.1 Abgrenzung

Entsprechend der DGNB Grundsätze bildet das Stadtquartiersprofil eine sinnvolle Ergänzung zu den Gebäudeprofilen, indem hierbei insbesondere der Bereich zwischen den Gebäuden und der Quartiersstandort betrachtet wird. Diese Faktoren beeinflussen maßgeblich die Qualität eines Stadtquartiers und definieren den Rahmen für eine nachhaltige Entwicklung der Gebäude. Ebenso werden übergeordnete Konzepte beispielsweise für den Umgang mit Energie, Wasser und Abfall betrachtet. Die Gebäude selbst müssen für eine Quartierszertifizierung nicht zertifiziert sein und werden nur mit Basiswerten in der Bewertung berücksichtigt.

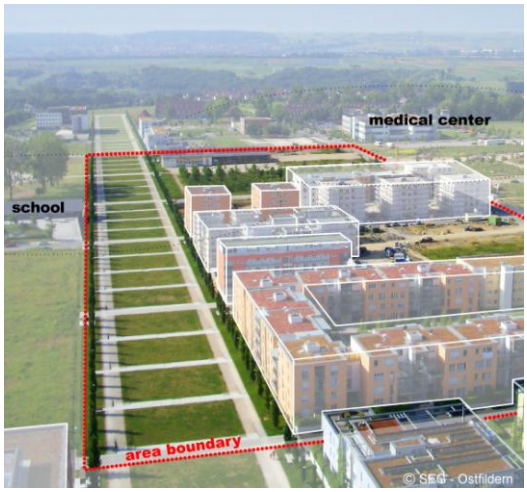

Abb. 2: Betrachtungsbereich des DGNB Nutzungsprofils „Neubau gemischte Stadtquartiere" (exemplarisch)

4.2 Bewertungsstufen

Da sich die Entwicklung von Stadtquartieren über einen langen Zeitraum erstreckt, in welchen oft auch die Eigentümer wechseln, wird neben dem Vorzertifikat (Phase 1) auf Ebene des städtebaulichen Entwurfs, ein weiteres Zertifikat für die Planung (Phase 2) eingeführt, für welches mindestens Baurecht vorliegen muß und die Ausführungsqualitäten vertraglich gesichert sind. Den Abschluß bildet das Zertifikat für das zumindest

75 % fertig gestellte Quartier (Phase 3). Das Vorzertifikat ist dabei 3 Jahre, das Zertifikat für die Planung ist 5 Jahre und das Zertifikat für das Quartier ist unbegrenzt gültig. (siehe Abbildung 3)

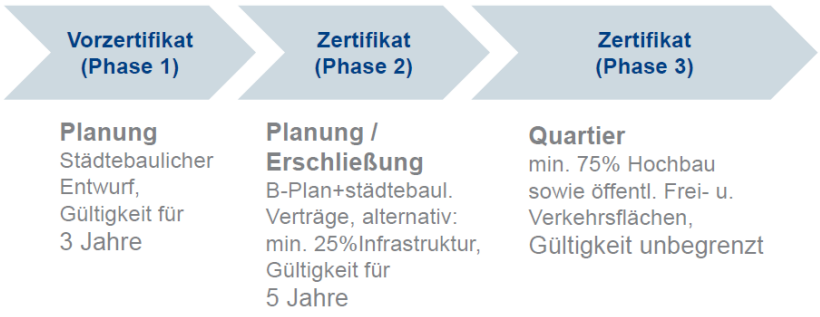

Abb. 3: Bewertungsstufen des Stadtquartiersprofils

4.3 Mindestanforderungen (Pilotphase)

In der Pilotphase wurden bewusst nur wenige Mindestanforderungen definiert, welche die Projekte zu erfüllen hatten. So konnte das System an einer großen Bandbreite unterschiedlichster Quartiere getestet und Rückschlüsse für die Überarbeitung gezogen werden. Die Mindestanforderungen bei der Pilotphase an ein Quartier war, das dieses mindestens ein Hektar groß ist, über öffentlich zugängliche Räume verfügt und einen Wohnanteil von mehr als 15 % und weniger als 85 % aufweist. Zusätzlich war eine Anforderung, dass alle Eigentümer des Gebietes mit der Zertifizierung einverstanden sind.

4.4 Gewichtung

Die Gewichtung der Hauptkriteriengruppen (siehe Abbildung 4) ist gleich der Systematik der DGNB Gebäudeprofile und beruht auf einem Gleichgewicht der ökologischen, ökonomischen und soziokulturellen und funktionalen Qualität. Einziger Unterschied bei dem Stadtquartiersprofil ist, dass die bei den DGNB Gebäudeprofilen separat ausgewiesene Standortqualität, in die Kriterien integriert ist. Die Lage hat somit wesentlichen Einfluss auf die Gesamtbewertung des Stadtquartiers.

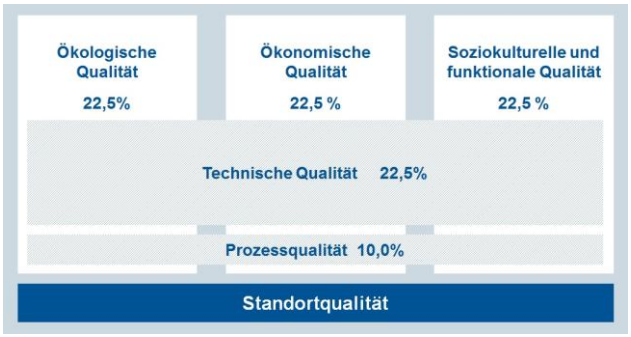

Abb. 4: Gewichtung der Hauptkriteriengruppen

4.5 Ziele und Kriterien

Die übergeordneten Ziele des DGNB Nutzungsprofils für Stadtquartiere sind die Umwelt und natürlichen Ressourcen zu schonen, den Komfort und das Wohlbefinden der Nutzer des Quartiers zu stärken sowie die anfallenden Kosten über den gesamten Lebenszyklus zu minimieren.

Hierfür wurde ein stadtquartiersspezifischer Kriterienkatalog entwickelt, welcher sich an den Grundzügen der DGNB Systematik orientiert, jedoch inhaltlich komplett neu erarbeitet ist. So wird auch in diesem System den Themen Ökobilanz und Lebenszykluskosten besondere Beachtung geschenkt. Zusätzlich werden neue Kriterien, wie beispielsweise die Veränderung des Stadtteilklimas, Artenvielfalt und Vernetzung, die Qualität der Verkehrssysteme oder auch das Regenwassermanagement in die Betrachtung mit einbezogen. Abbildung 5 zeigt, den Kriterienkatalog welcher in der Pilotphase verwendet wurde sowie die Gewichtung der einzelnen Kriterien innerhalb der Hauptkriteriengruppen.

Hauptkriteriengruppe	Kriteriengruppe	Nr.	Kriterium	Gewichtung
Ökologische Qualität (22,5%)	Wirkungen auf die globale und lokale Umwelt	ENV1.1	Ökobilanz	3
		ENV1.2	Gewässer- und Bodenschutz	2
		ENV1.3	Veränderung des Stadtteilklimas	3
		ENV1.4	Artenvielfalt und Vernetzung	2
		ENV1.5	Berücksichtigung von möglichen Umwelteinwirkungen	2
	Ressourceninanspruchnahme und Abfallaufkommen	ENV2.1	Flächeninanspruchnahme	3
		ENV2.2	Gesamtprimärenergiebedarf und Anteil erneuerbarer Primärenergie	3
		ENV2.3	Energieeffiziente Bebauungsstruktur	2
		ENV2.4	Ressourcenschonende Infrastruktur, Erdmassenmanagement	2
		ENV2.5	Lokale Nahrungsmittelproduktion	1
		ENV2.6	Wasserkreislaufsysteme	2
Ökonomische Qualität (22,5%)	Lebenszykluskosten	ECO1.1	Lebenszykluskosten	3
		ECO1.2	Fiskalische Wirkungen auf die Kommune	2
	Wertentwicklung	ECO2.1	Wertstabilität	1
		ECO2.2	Flächeneffizienz	3
Soziokulturelle und funktionale Qualität (22,5%)	Soziale Qualitäten	SOC1.1	Soziale und funktionale Vielfalt	2
		SOC1.2	Soziale und erwerbswirtschaftliche Infrastruktur	2
	Gesundheit, Behaglichkeit und Nutzerzufriedenheit	SOC2.1	Objektive / Subjektive Sicherheit	2
		SOC2.2	Aufenthaltsqualität in öffentlichen Räumen	2
		SOC2.3	Lärm- und Schallschutz	2
	Funktionalität	SOC3.1	Freiflächenangebot	3
		SOC3.2	Barrierefreiheit	2
		SOC3.3	Nutzungsflexibilität und Bebauungsstruktur	2
	Gestalterische Qualität	SOC4.1	Städtebauliche Einbindung	3
		SOC4.2	Städtebauliche Gestaltung	2
		SOC4.3	Nutzung von Bestand	2
		SOC4.4	Kunst im öffentlichen Raum	1
Technische Qualität (22,5%)	Technische Infrastruktur	TEC1.1	Effiziente IT und Kommunikations-Infrastruktur	1
		TEC1.2	Energietechnik	2
		TEC1.3	Effiziente Abfallwirtschaft	2
		TEC1.4	Regenwassermanagement	3
	Technische Qualität	TEC2.1	Demontage-, Trenn- und Recyclingfreundlichkeit der Infrastruktur	1
		TEC2.2	Instandhaltung, Pflege, Reinigung	2
	Verkehr / Mobilität	TEC3.1	Qualität der Verkehrssysteme	3
		TEC3.2	Qualität der MIV-Infrastruktur	1
		TEC3.3	Qualität der ÖPNV-Infrastruktur	1
		TEC3.4	Qualität der Radverkehr -Infrastruktur	1
		TEC3.5	Qualität der Fussgänger-Infrastruktur	1
Prozessqualität (10%)	Partizipation	PRO1.1	Partizipation	3
	Qualität der Planung	PRO2.1	Verfahren zur Konzeptfindung	2
		PRO2.2	Integrale Planung	3
		PRO2.3	Kommunale Mitwirkung	2
	Qualität der Abwicklung und Bauausführung	PRO3.1	Steuerung	2
		PRO3.2	Baustelle, Bauprozess	2
		PRO3.3	Vermarktung	2
		PRO3.4	Qualitätssicherung und Monitoring	2

Tab. 1: Kriterienübersicht des DGNB Nutzungsprofils „Neubau gemischte Stadtquartiere“, Stand Januar 2012

4.6 Bewertung innerhalb der Kriterien

Die Kriterien selbst setzen sich meist aus mehreren Indikatoren zusammen. So wird beispielsweise in dem Kriterium „Freiflächenangebot“ zum einen die private und öffentliche Freifläche pro Brutto-Grundfläche, jedoch auch die fußläufige Erreichbarkeit der einzelnen Freiflächen bewertet. Hierfür wurde wenn möglich für jeden Indikator ein Grenz-, Referenz- und Zielwert definiert. Der Grenzwert muss von jedem Projekt erfüllt werden um zertifiziert werden zu können. Der Referenzwert ist gleich zu setzen mit dem gesetzlichen Standard für den jeweiligen Indikator und der Zielwert ist gleich einem anerkannten Richtwert bzw. Best-Practice Beispiel aus der Praxis. Somit werden auch in dem DGNB Stadtquartiersprofil keine einzelnen Maßnahmen, sondern nur das Gesamtergebnis bewertet und den Planern die notwendige Freiheit für innovative Quartierskonzepte eingeräumt.

	Punkte
Zielwert (Richtwert bzw. Best-practice Beispiel)	100
Referenzwert (gesetzl. Standard)	50
Grenzwert (Mindestanforderung)	10

Tab. 2: Bewertung innerhalb der Kriterien

4.7 Erfüllungsgrade und Auszeichnungen

Entsprechend der für jedes Kriterium vergebenen Punkte und der jeweiligen Gewichtung, errechnet sich der Gesamterfüllungsgrad für das Quartier sowie für jedes der fünf Hauptkriteriengruppen. Dieser zeigt, ob und in welchem Ausmaß die vorgegebenen Anforderungen erfüllt sind. Ab einem Gesamterfüllungsgrad von 50 % erhält das Quartier das DGNB Zertifikat in Bronze. Ab einem Erfüllungsgrad von 65 % wird das DGNB Zertifikat in Silber vergeben. Für ein DGNB Zertifikat in Gold muss ein Gesamterfüllungsgrad von 80 % erreicht werden (siehe Abbildung 5).

Um einer ausgewogenen Verteilung der Punkte gerecht zu werden, gibt es zusätzlich den Mindesterfüllungsgrad bei allen fünf Hauptkriteriengruppen. Wenn ein Projekt beispielsweise die Auszeichnung in Gold erreichen möchte, muß es in allen fünf Hauptkriteriengruppen einen Erfüllungsgrad von mindestens 65 % erreichen. Somit könnte ein Quartier welches aus ökonomischen Gesichtspunkten eine sehr hohe Qualität aufweist, jedoch im soziokulturellen und funktionalen Bereich unter 65 % liegt keine Auszeichnung in Gold erhalten.

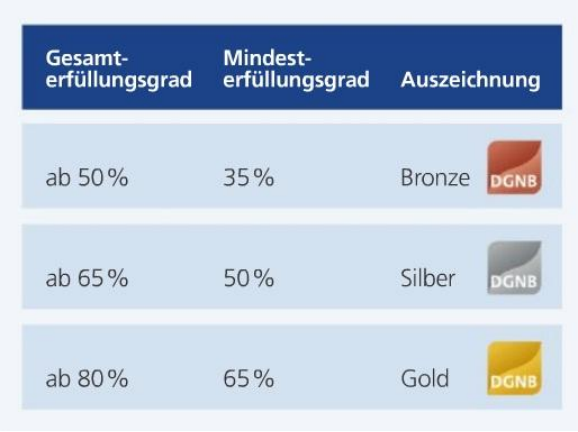

Abb. 5: Erfüllungsgrade und Auszeichnungen

4.8 Kosten der Zertifizierung

Bei den Kosten einer Zertifizierung muß zwischen direkten und indirekten Kosten unterschieden werden. Unter die direkten Kosten fallen die Zertifizierungsgebühren, welche an die DGNB zu entrichten sind und u. a. für die anonyme Prüfung der durch den Auditor eingereichten Unterlagen verwendet werden, sowie das Honorar für den von der DGNB ausgebildten Auditor, für die Zusammentragung der für die Zertifizierung notwendigen Unterlagen. Die Zertifizierungsgebühren hängen von der Größe und der Zertifizierungsstufe des Projektes ab und variierten in der Pilotphase von 3.000 bis 25.000 Euro für DGNB Mitglieder. Bei den

Honorarkosten für den Auditor können keine generellen Aussagen getroffen werden. Diese hängen stark von dem vereinbarten Leistungsbild sowie der Komplexität und bisherigen Dokumentation des Projekt ab.

Des Weiteren können die definierten Qualitätsziele auch indirekte Auswirkungen auf die Planungs- und Baukosten haben. So wird beispielsweise die Verwendung von Straßenleuchten mit LED-Technologie die Baukosten erhöhen, sich jedoch langfristig über geringere Nutzungskosten und eingesparte Emissionen postiv auswirken. Diese Betrachtung über den gesamten Lebenszyklus wird in de DGNB Nutzungsprofilen besondere Beachtung geschenkt.

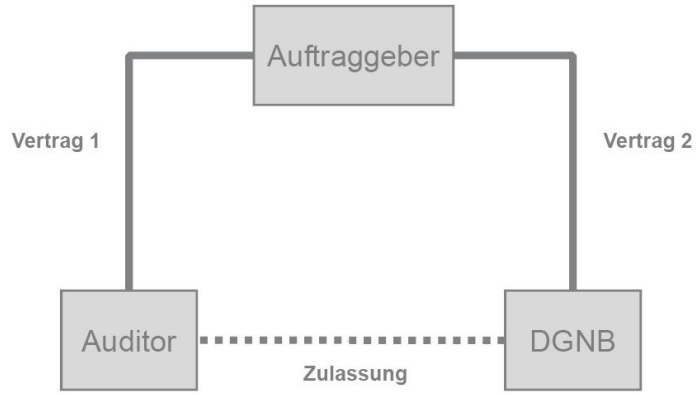

Abb. 6: Verhältnis Auftraggeber/Auditor/DGNB

5 RESULTATE

5.1 Erreichte Zertifizierungen

Auf Basis des Gesamterfüllungsgrads erreichten 6 von 13 der bisher ausgewerteten Projekten die DGNB Auszeichnung in Gold. Weitere 7 Projekte erreichten die Auszeichnung in Silber. Die Auszeichnung in Bronze wurde unter den ersten Projekten noch nicht vergeben. Die bisherigen Erfahrungen bei der DGNB haben jedoch gezeigt, dass die Projekte, welche sich an einer Pilotphase beteiligen und den damit verbunden höheren Aufwand nicht scheuen, ohnehin meist sehr ambitioniert sind und damit auch sehr gute Ergebnisse erzielen.

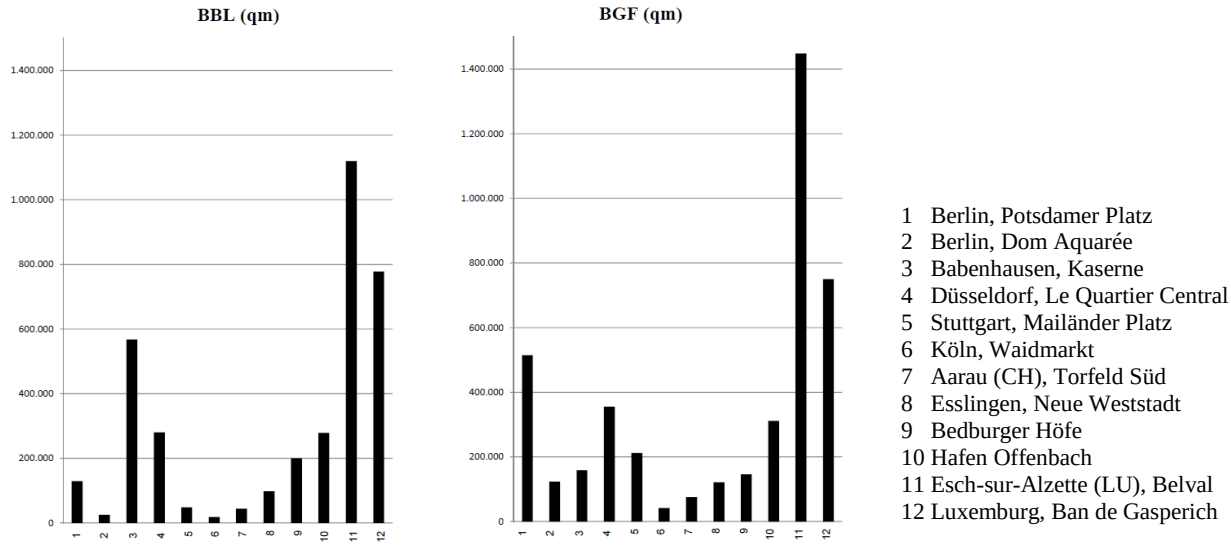

Abb. 7: Flächenvergleich der Pilotprojekte

5.2 Flächenvergleich der Pilotprojekte

Die Größe der Pilotprojekte variiert enorm (siehe Abbildung 7). Das kleinste Projekt „Waidmarkt“ in Köln, mit 1,4 Hektar Bruttobauland (BBL), steht im Kontrast zu dem größten Projekt „Belval“ in Esch-sur-Alzette (Luxemburg) mit einer Größe von 112 Hektar (BBL). Ähnliches gilt für die Brutto-Grundfläche (BGF) der

Projekte. Auch hier erreicht das Projekt in Esch-sur-Alzette mit einer Fläche von 1.448.661 qm den höchsten Wert und das Projekt in Köln mit 42.150 qm den niedrigsten Wert.

6 ZUSAMMENFASSUNG UND SCHLUSSFOLGERUNG

6.1 Kriterienkatalog als Kommunikations- und Steuerungsinstrument

Nachhaltige Stadtplanung stellt die an der Planung beteiligten Personen vor eine komplexe Herausforderung, welche die interdisziplinäre Zusammenarbeit aller erfordert. Es gilt mit Bürgern und Verwaltung gemeinsame Ziele zu definieren, daraus konkrete Projekte abzuleiten und die Wirksamkeit dieser in regelmäßigen Abständen zu evaluieren. Zertifizierungs- und Bewertungssysteme bieten eine Möglichkeit diesen Prozess zielführend zu unterstützen. So kommt auch die Kommission „Zertifizierung in der Stadtentwicklung“ zu dem Ergebnis, dass Zertifizierung als prozessuales Verfahren implementiert werden sollte (vgl. DV 2010, S. 34). Auf Ebene des Quartiers eröffnet der vorliegende Kriterienkatalog somit die Möglichkeit die Auswirkungen verschiedener Planungsvarianten auf die Nachhaltigkeit eines Quartiers zu bewerten, ggf. zu optimieren und transparent zu kommunizieren. Ebenso stellt der Kriterenkatalog eine Möglichkeit dar, diesen als Planungsleitfaden in jeder Phase eine Quartiersentwicklung zu verwenden (vgl. Koch, Neumann, 2011)

6.2 Größe der Projekte

Rückblickend muss festgestellt werden, dass die Kriterien zwar von allen Projekten angewendet werden konnten, jedoch der damit verbundene Bearbeitungsaufwand sehr unterschiedlich war. Dies war zum einen dem Projekt selbst (Komplexität, Zertifizierungsstufe, etc.) sowie der bisherigen Dokumentation, jedoch auch der Größe des Projektes, geschuldet. Zukünftig soll der Zusammenhang zwischen Projektgröße und Bearbeitungsaufwand auf ein Mindestmaß reduziert werden. Ebenso gilt es, im Hinblick auf die Internationalisierung des Systems, eine Maximalgröße zu definieren bis zu welcher das Projekt als Stadtquartier zertifiziert werden kann und ab wann andere Bewertungsverfahren angewendet werden müssen.

6.3 Kosten-Nutzen-Zertifizierung

Die direkten und indirekten Kosten einer Zertifizierung wurden im Punkt 4.8 ausführlich dargestellt. Erste Untersuchungen auf Ebene der Gebäude zeigen jedoch das beispielsweise die Herstellungskosten bei zertifizierten Gebäuden nicht zwangsläufig höher sein müssen als jene bei nicht zertifizierten Gebäuden (vgl. Rotermund 2011). Gleiches kann auf Stadtquartiere übertragen werden.

Den eventuellen Mehrkosten gegenüber steht der enorme Nutzen, welchen eine Zertifizierung mit sich bringen kann. Eine Zertifizierung ist primär eine transparente und unabhängige Qualitätsauszeichnung, welche es dem späteren Nutzer ermöglicht die Qualität eines Quartiers objektiv beurteilen zu können. Mit einer höheren Qualität einhergehend ist das höhere Wohlbefinden und Produktivität der Nutzer des Quartiers sowie die Erhöhung der Marktchancen bei Verkauf und Vermietung. Nach einer Studie von Roland Berger sind Mieter dazu bereit durchschnittlich 4,5% höhere Mietkosten für nachhaltige Immobilien zu bezahlen (vgl. Roland Berger 2010). Dies trägt u.a. dazu bei die Risiken einer Quartiersentwicklung zu minimieren. Nicht zuletzt können durch die frühzeitige Betrachtung des Quartiers über den gesamten Lebenszyklus hinweg Emissionen reduziert und Kosten eingespart werden.

7 AUSBLICK

7.1 Marktversion

Aus den Erkenntnissen welche im Laufe der Pilotphase gewonnen worden sind, werden die Kriterien derzeit intensiv diskutiert und anschließend überarbeitet. Das Ziel ist die überarbeiteten Kriterien auf der Messe CONSENSE im Juni 2012 in Form eines Handbuchs präsentieren zu können. Anschließend soll dieses System in regelmäßigen Abständen evaluiert und optimiert sowie eine Ausbildung zum DGNB Auditor für Stadtquartiere aufgesetzt werden.

7.2 Neue Systemvarianten

Das vorliegende System ist für den Neubau von Stadtquartieren entwickelt worden und lehnt sich dabei an das Idealbild der kompakten und durchmischten europäischen Stadt an. Jedoch besteht die Möglichkeit, dass auch kleinere monofunktionale Gebiete, wie beispielsweise ein innerstädtisches Wohnquartier, zertifiziert werden können, wenn durch ihre Lage eine Nutzungsmischung auf Stadtteilebene gegeben ist.

Zukünftig soll das System internationalisiert, die Übertragbarkeit auf Bestands- Gewerbe und Industriequartiere evaluiert und ggf. neue Systemvarianten entwickelt werden.

7.3 Weiterer Forschungsbedarf

Daten für Infrastruktur und Freiraum

Die verfügbaren Daten für Herstellungs- und Nutzungskosten, aber auch zur Ermittlung der durch den Bau und Betrieb verursachten Emissionen, beschränken sich derzeit hauptsächlich auf den Gebäudebereich. Daten für den Bereich der Infrastruktur und dem Freiraum sind dagegen nur sporadisch vorhanden. Dies liegt u.a. daran das der Bau von Grün-, Frei und Verkehrsflächen im Regelfall eine öffentliche Aufgabe ist und die Daten für Herstellung und Nutzung dieser Flächen meist bei unterschiedlichen Ämtern einer Stadt archiviert sind und dem Datenschutz unterliegen. Insbesondere für den Nutzungsbereich ist es schwer Daten für die Pflege und Instandhaltung, beispielsweise von einem Quadratmeter Weg mit spezifischen Eigenschaften, zu ermitteln, da die damit verbunden Kosten für Personal und Material nur insgesamt vorliegen und nur schwer auf eine Bezugseinheit gebracht werden können. Ebenso hängen diese stark von dem jeweiligen Pflegestandard und den spezifischen Lohnkosten der Region ab. Eine systematische Aufarbeitung und Bereitstellung dieser Daten, wie dies im Gebäudebereich für die Kosten der Fall ist (vgl. BKI), fehlt für den Bereich der Infrastruktur und dem Freiraum bisher gänzlich.

Bewertung sozialer Nachhaltigkeit

Die Bewertung von Kriterien im sozialen Bereich, wie beispielsweise der Aufenthaltsqualität in öffentlichen Räumen oder die gestalterische Qualität eines Stadtquartiers, ist quantitativ nicht möglich. Im Hinblick auf die Internationalisierung des Systems gilt es hierbei, auf Basis von wissenschaftlichen gesichertern Erkenntnissen, geeignete Indikatoren für unterschiedliche Regionen der Welt zu finden, welche gleichzeitig die klimatischen und kulturellen Unterschiede berücksichtigen.

1 ABSTRACT

Continuing pressure on urban areas due to growing population and further urbanization affects urban quality. Many cities and agglomerations try to cope with negative effects of urban sprawl by further densification of existing built-up areas. As a consequence green and open spaces are disappearing. Among other ecological and socio-economic urban qualities, this is affecting the sense of a place and place attachment of the local inhabitants. However, there are no indicators available, which allow in planning processes for an effective assessment of the impact of further densification on the urban landscape's identity. One challenge is that assessing the impact on the landscape's identity requires both objective and subjective approaches. Objective approaches are well established, for example, in environmental impact assessments untypical elements of a landscape contributing to a loss in landscape aesthetics and character are evaluated. However, these approaches are rather applicable on the rural than on the urban landscape. Furthermore, subjective approaches still lack of suitable tools for integrating individual perceptions of stakeholders into the evaluation process.

In this paper we present an approach based on GIS- and rule-based interactive modeling and visualization tools, which allows for objective and subjective assessment of the urban landscape's identity in participatory planning processes. For the case study of Schlieren, an agglomeration of the city of Zurich (CH), we show exemplarily the implementation of this approach. Combined assessment of hard and soft factors of urban green and open spaces contributing to the urban landscape's identity provides a powerful tool to identify local thresholds of urban densification, and thus proactive planning of sustainable urban development taking into account the residents' requirements directly.

2 INTRODUCTION

In Switzerland, official settlement development concepts focus on a higher utilization of built-up areas (Bundesamt für Raumentwicklung ARE 2009). The main goal of this strategy is to contain urban sprawl (Gennaio et al. 2009) by increasing densities in existing built-up areas of cities and agglomerations. There are evident benefits of planned densification, e.g. support of regional thinking and controlling, setup of priorities, development of economy, sustainable and optimized transportation connections (Bundesamt für Raumentwicklung ARE 2009). However, urban densification may also entail threats to urban quality.

An important factor of urban quality is the sense of place and the people's place attachment, defined as "the positive emotional bonds that develop between individuals and their environment" (Brown & Raymond 2007: 89). Changing urban environment – e.g. due to increasing floor area ratios in land use plans - can have an impact on the people's place attachment. Thresholds with regard to this aspect are not yet known. Existing planning instruments for securing spatial identity are predominantly based on objective indicators. These comprise, for example, the amount of recreation offers or the connectivity of foot and bike paths in or next to the settlement areas (Bundesamt für Raumentwicklung ARE 2003). More recent approaches stress the relationship between social aspects of urban densification and the people's identity with their area (Bundesamt für Raumentwicklung 2011). The significance of relationships between soft and hard factors are too important to be disregarded (Soini et al. 2012).

For solving most of the challenges in future urbanization, spatial knowledge of both urban and spatial planning and stakeholders are required (Taubenböck & Esch 2011). The emphases of individual and

emotional (soft factors) compared to physical (hard factors) indicators are still unknown so that they are not yet taken into account in urban planning processes comprehensively. Moreover, subjective perception contributes to individual place identity (Soini et al. 2012). In order to achieve an urban densification, which is accepted by the people and is identity generating, the subjective perception has to be integrated into the assessment of urban densification proposals.

We present the framework for preparing 3D visualizations linked to objective indicators that offers suitable means for assessing both the soft and hard indicators for the quality of urban densification. First, a literature review is given on the theory of landscape perception and indicators to measure a landscape's potential to generate identity. Then, a case study area in a suburban region in Switzerland, the community of Schlieren, is presented. In the methods section, the framework is described and results of preliminary 3D visualizations linked with objective indicators are given. These are discussed with regard to their suitability and further development possibilities for future application as assessment instruments.

3 THEORETICAL FRAME

3.1 Landscape perception

As Rodewald (2011) describes, there is a three-component view of a place (Figure 1). The first component is evolution based and allows for »reading« the landscape. This view supports orientating oneself and gathering information on a situation in a landscape. The second view component is for receiving colors and aesthetical stimuli. Through this a place gets its characteristic appearance. The third component of our viewing is linked with individual cognitions. A symbolization and identification gives any place a special importance, which depends on preferences, values, preconceived imaginations and individual signs. This third component converts a place to an emotional place, which gets a personal recognition value. Such a sensual, informative and associative view generates the sense of a place.

Girot and Wolf (2010) describe the three components as analytical, physical and poetical view. The analytical view measures the spatial composition and builds relationships between objects. The physical one is described as a corporal experience of cognition. The individual touch is here given by the poetical component, which combines the viewing results to something new and gives them a distinctive attribute for dealing with compositions in landscape.

Figure 1: Illustration of the three component view of landscape perception.

Such subjective parameters should be considered to guarantee comprehensive planning for sustainable urban developments. This requires making aesthetical effects of future developments measurable and visible (Meijer et al. 2011).

3.2 Indicators for a landscape's potential to establish identity

In practice and research, visual impacts are indicated by observers' expressions of preference or judgments/ratings of visual aesthetic quality, which include scenic quality, visual quality and scenic beauty as well (Daniel & Meitner 2001). These preferences are not yet linked with more comprehensive tools, which allow for analyzing both the sense of a place and other factors of urban quality, e.g. urban density, costs for green space infrastructure, energy efficiency and others. Providing tools for subjective and objective assessment, which allow a weighting of different indicators, could support trade-off decision making and the identification of thresholds for aesthetical aspects.

The concept of ecosystem services (ESS) offers a vast systematic framework for goods and services to humanity. The ESS can be categorized into provisioning services (e.g. wild foods, crops, fresh water and plant-derived medicines), regulating services (e.g. filtration of pollutants by wetlands, climate regulation through carbon storage and water cycling, pollination and protection from disasters), supporting services (e.g. soil formation, photosynthesis and nutrient cycling) and cultural services (TEEB 2010). The latter comprise landscape and place identity as well as spiritual and aesthetical services (de Groot et al. 2010). The principal of valuing ecological landscape components by ESS allows a new approach to quantify and bring landscape in comprehensible indicators for enabling a trade-off of several socio-economic values (Grêt-Regamey et al. 2008, 2012).

In urban areas, the ecosystems services depend on the quality of the following major ecosystems: street trees, lawns/parks, urban forests, cultivated land, wetlands, lakes/sea, and streams. Services provided by these ecosystems are, for example: air filtration, micro climate regulation, noise reduction, rainwater drainage, sewage treatment, and recreational and cultural values (Bolund & Hunhammar 1999). In fact, ecosystem services provided by urban green space patterns can provide healthy environments and physical as well as psychological health benefits to the people residing within them. A healthy environment can also contribute an improvement of socio-economic benefits (Tzoulas et al. 2007). The number or area of culturally important landscape features or species support the service of providing signs of cultural heritage and identity (de Groot et al. 2010). Since land use management affects the provision of mainly regulating and cultural ecosystem services (van Oudenhoven et al. 2012), it is very important to develop suitable approaches for integrating the assessment of the impact of landscape changes on the identity into urban planning.

4 CASE STUDY AREA

The 3D urban model is developed for the case study area Limmattal (valley of the river Limmat), an agglomeration in the northwest of Zurich (Figure 2). Special focus will be laid on a dwelling zone in the community of Schlieren. It comprises an area of about 6,38 km² and a population of 16'100 (about 2'462 inhabitants/km²) (Statistisches Amt des Kantons Zürich, 2010).

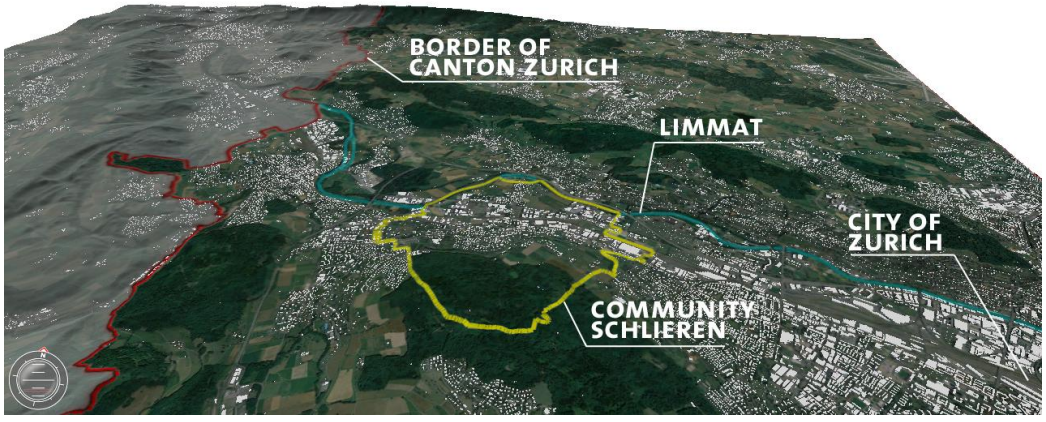

Figure 2: Overview of the community of Schlieren (yellow line) situated in the valley of the river Limmat. Red line marks the border of Canton Zurich with the city of Zurich in the lower right corner of the figure.

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

Schlieren is a Swiss city in the agglomeration of Zurich. It combines residential areas, industry and, at the river Limmat, important recreational area for the core center of Zurich city in tight space. Since the 1960s the population increased rapidly up to 10.000 inhabitants (Statistisches Amt des Kantons Zürich, 2010) due to relocation of industry to the agglomerations and good traffic connections to Zurich. Today, it has an important role as transit area and as arising living space for a heterogeneous population. Currently, Schlieren has an annual growth of 800 people and an increase of 4'000 inhabitants was registered for the last seven years. The problem of such a moving in is that living space for only 2'500 people is in planning (Vögli 2012). Thus, this focus area is ideal for analyzing different possible future situations and development strategies in order to cope with the development pressure.

5 METHODS

A participatory approach is necessary for detecting accepted thresholds of densification in dwelling zones taking into account place attachment (de Groot et al. 2010). 3D visualizations of the urban landscape offer high potentials to effectively support such participatory processes (Xu & Coors 2012). New and innovative steps in data acquisition and mapping offer a flexible back-end for land use modeling and 3D visualization (Grêt-Regamey & Wissen Hayek 2010). An interactive approach might be important for a high rate of return and variety of indicator information from the participants (Belton & Elder 1994; Bruigat & Chittaro 2008; van Schaik 2010).

Taking into account these requirements, we set up an interactive collaborative modeling and visualization platform linked with objective indicators of identity and urban density. The preliminary platform was tested with stakeholders with regard to its suitability for participative assessment. The final platform shall be suitable for identifying trade-offs and thresholds associated to urban densification scenarios and place identity. In the following, the major components of this platform (Data acquisition and mapping, Procedural 3D visualization, Participative assessment) are described (Figure 3).

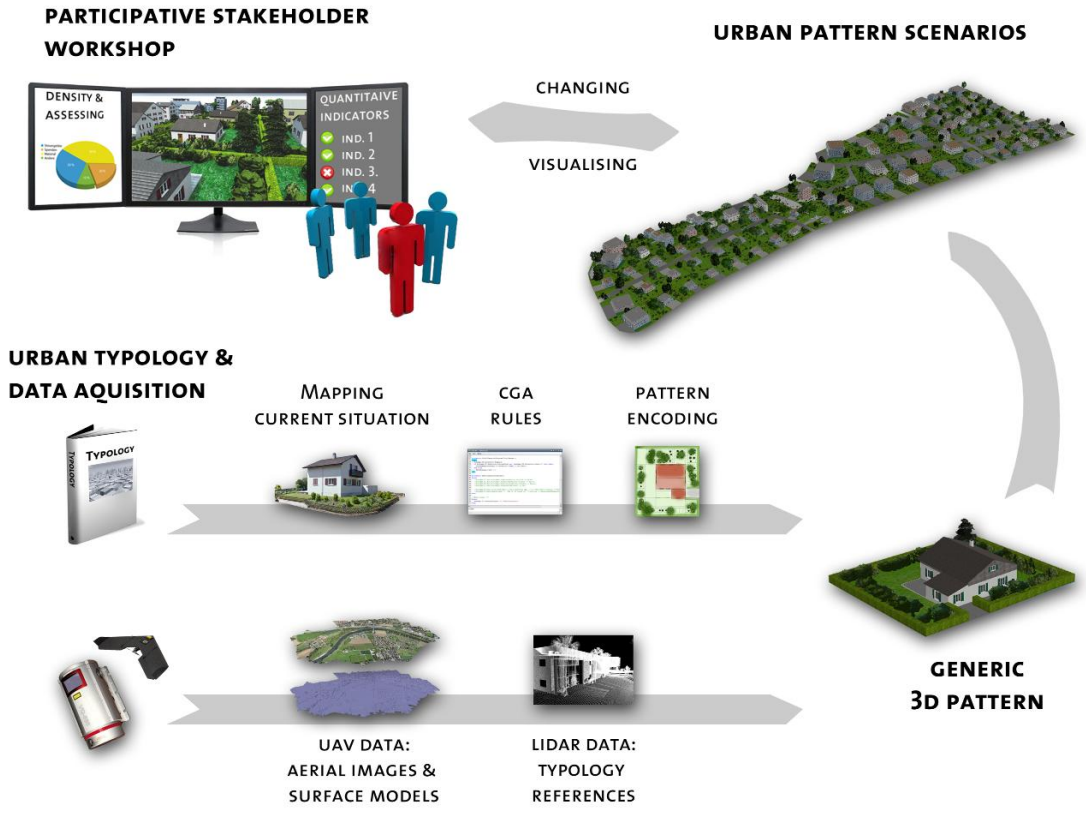

Figure 3: Framework demonstrating the strings of data acquisition and 3D pattern generation suitable for interactive scenario visualization in participative stakeholder workshops or interactive choice experiments.

5.1 Data Acquisition & Mapping

On the one hand, modeling approaches are necessary in order to assess and communicate consequences of complex urban system scenarios and calculate meaningful indicators. On the other hand, realistic 3D visualization with a high level of detail is necessary to assess effects of landscape change scenarios on the landscape view and the people's landscape perception (cf. Wergles & Muhar 2009).

For these reasons, we focused on highly accurate data acquisition methods for accurate modeling and realistic 3D visualizations. To this end, modeling and 3D visualization is based on two methods of data acquisition. We generate high accurate and up to date elevation models and aerial images by implementing (1) a terrestrial laser scanner (TLS) (Riegl VZ-1000) and (2) an unmanned aerial vehicle (UAV).

(1) A terrestrial laser scanner scans with a horizontal and vertical moving laser beam over the landscape. Through detection of the back-reflected laser beam from objects, the distance to these target points can be calculated by time-distance method. The device registers in this way point clouds of landscape objects, which are hit by laser. Depending on the defined scan resolution (moving speed of laser beam on horizontal and vertical axes) a dense point cloud is created, in which each single point has its own geo-referenced xyz-coordinate through GPS localisation of the scanner position itself. With a mounted camera on top the point cloud can be colorized by the RGB values of the photos (Lemmens 2011).

(2) The unmanned aerial vehicle consists of a modified camera, GPS autopilot and radio module. Linked with a ground-based notebook, the fly path for the airframe is defined. The UAV flies autonomously by defined waypoints and heights over the terrain and takes images. Through exact trigger-coordinates and attitude of the images by GPS-autopilot and inclination sensors, a afterwards auto-processing of control points is possible to generate geo referenced surface models and orthophotos (Figure 4), (Manyoky et al. 2011).

Figure 4: Processed high resolution digital surface model (DSM) with orthophoto texture of an Unmanned Aerial Vehicle (UAV). The data shows a part of the case study area of Schlieren (Canton Zurich, Switzerland) and has an accuracy of 8 centimeters (DSM and orthophoto).

Both data pools are complementary, which simplifies the acquisition and modeling parts. Aerial images are used for GIS data processing (orthophotos, digital surface/elevation model) as well as for typology mapping next to field work. Point cloud data gathered from terrestrial laser scanning is used for generating elevation models and for generating 3D building objects (direct implementation of architecture details by manual and automatic modeling tools). Particular strength of these acquisition methods is that they offer a new level of detail and spatial coverage in up-to-date basic data.

Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

5.2 Procedural 3D visualization

3D visualizations have been proved to be supportive tools for participatory landscape planning workshops (Pettit et al. 2011; Wissen Hayek 2011). For 3D visualization of urban densification scenarios, we implement a procedural urban modeling approach using CGA shape grammar implemented in ESRI's CityEngine system (www.esri.com/cityengine). The software can quickly visualize urban environments including green spaces in interactive three-dimensional views with a high level of detail (Neuenschwander et al. 2011; Wissen Hayek et al. 2010) enabling for evaluation of alternatives and iterative design workflows (Halatsch et al. 2008; Ulmer et al. 2007).

In field mapped building types (e.g. single-family houses, multi-family houses) are encoded as CGA rules. Combining rules for building types leads to rule sets for urban patterns, in our case a dwelling zone. The density aspects are integrated in those rule sets. Executing these rules, 3D urban patterns are generated. Rule parameters can be changed interactively, which allows for iteratively assessing alternatives in real-time to detect the trade-offs between urban densification and place identity. These quantitative parameters offer stakeholders the possibility to check the basic assumptions of the scenarios and thus can contribute to the transparency of the visualization model. Through a live reporting option of quantitative indicators in ESRI's CityEngine system, iterative analyses based on objective indicators are possible. In our preliminary model, we calculated floor area ratios, population densities, population of dwelling zone, green space, green space maintenance costs, potential habitat population, infrastructure costs, for an indicator-based comparison of scenarios.

Newer features in ESRI's CityEngine support import of geo-located Google Warehouse buildings (http://sketchup.google.com/3dwarehouse). However, 3D object models can also be generated from the TLS and UAV data. The data can be easily prepared and processed to get high detailed 3D objects and ground data. This workflow is useful for modeling static non-CGA based buildings, which won't be influenced in scenarios and support the stakeholders' in orienting themselves and thus contribute to the suitability of the model for assessing place identity (Figure 5).

Figure 5: Colorized point cloud from terrestrial laser scanning (left), static 3D building object model based on point clouds (mid), example of a building type generated in the CityEngine system implementing CGA shape grammar rules (right).

Furthermore, there is high potential to automate CGA rule processing and reconstruct buildings by detection tools (Mathias et al. 2011, Becker 2011). This automatic detection methods offer new flexibility in generating a larger set of CGA building rules for more detailed scenarios with realistic appearance. In this way, rules can be automatically detected out of real architectonic patterns. With an integration of such detection technologies in the data acquisition workflow, the creation of present conditions in CGA would highly reduce manual visualization work. The scenario setups would base on detected CGA grammar out of real field data by modifying rule parameters.

5.3 Design of a participative assessment of place identity implementing the tools

Expectations with regard to the landscape scenery differ between heterogeneous population groups (Soini et al. 2012). To this end, participation of a broad population should be aimed at, to collect these various individual opinions and conceptions about threshold values of landscape components concerning place identity. In combination with the interactive modeling approach, online surveys can facilitate an extensive participation. Van Schaik (2010) has shown that interactive 3D visualization for public consultation has a broad acceptance – also of older people – and that it can be offered also in a "survey mode" with back-channel for user comments, questions, preferences and critics for a qualitative data collection.

Technical options increase the quality of feedback (quantitative and qualitative data) on thresholds and trade-offs. The possibilities of NVidia's RealityServer (www.mentalimages.com) supports CityEngine models in interactive and photorealistic web-application and low system resources (e.g. mobile devices) through cloud computing. This setup can bring the CityEngine models as interactive experiments online. Thus, all interviewees can define their own thresholds and supply a high return-rate and extensive data of individual trade-off decisions.

5.4 Pre-Test Design

We conducted a pre-test for assessing preliminary results of implementing the presented framework focusing on the interactive procedural 3D visualization with linked objective indicators. The pre-test was set as interview with the goal to identify the critical steps and technical issues in participative application of the tool and get also first comments and critics of potential users. It was not set up as representative study. Five experts were interviewed to get information on their impressions of the model. The interview was divided in three stages: introduction, presentation and interview.

In the introduction part, the interviewee was introduced to the topic, the visualization method and goals of the interview. The second part comprised a presentation of the case study area, scenarios, thematic integration, theoretical impacts of indicators and technical background. In the actual interview we asked first for the interviewee's ambitions of interacting with the model (indicator setting and navigation). After demonstration of indicator influences by interactive modeling, we asked for stating preferences for a scenario referring to the indicators. Finally, the provided level of detail was assessed by the interviewees.

6 PRELIMINARY 3D URBAN VISUALIZATION MODEL AND PRE-TEST RESULTS

First visualizations and pre-test results show a quite good acceptance of interactive modeling with ESRI's CityEngine system. In a first interview series with stakeholders and experts it was said that interactive modeling helps to understand the presented scenarios (see example in Figure 6).

In these interviews, the participative part was applied as a semi-interactive survey. This means, the model parameters were directly shown in CityEngine. Positive feedback from stakeholders supports that this helps to understand the scenarios and their coherence with the indicators. The option to change camera positions within the visualization to get a close distance view to dwelling zones of special interest or positions with special view axes (Figure 7) was rated as a positive feature.

Figure 6: Example of a densification scenario generated in ESRI's CityEngine of the case study area in Schlieren.

However, the interviewees did not want to navigate themselves through the model and change between the scenarios. Because of the interview structure and option for model interaction after only a short theoretical introduction, the participants asked rather for being navigated through the model.

The most adverse point identified in this pre-test was the complexity of the CityEngine's user interface. Because of this and the big variety of indicators, the stakeholders were deterred to modify them and set up their own scenarios. It was not directly clear for them, where they have to set the parameters, because there are no options for designing any custom bars or buttons for indicator setting. For presentation mode a full-screen option with custom possibility for rule and indicator setting is still missing in CityEngine.

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

Although the CityEngine system generally supports interactive change of scenes, for real interactivity in participatory situations the need of system recourses is a hindrance. For generating the scene, a 24GB Ram Workstation with high-performance GPU and CPU was used. For large-scale visualization with included vegetation such a configuration is necessary to handle the changed model parameters re-rendering rapidly. In interview situation we had to use a mobile device, which has a comparatively bad system performance. Therefore, a preparation of the scene was inalienable – the renderings for all scenarios were done before the interviews and interactively modifying and re-renderings were only done for selected lots.

Figure 7: Example of different close up camera positions of two scenarios generated in ESRI's CityEngine.

7 DISCUSSION AND CONLUSION

Our goal was to set up a framework suitable to integrate objective and subjective indicators for assessing urban landscape identity in participatory settings. To this end, we elaborated a workflow combining sophisticated data acquisition and 3D modeling and visualization approaches.

Implementing the framework resulted in 3D visualizations with a rather high level of detail, which were linked to a set of indicators. The used techniques allowed visualizing large landscapes as static high realistic visualizations, which can display relevant aspects for assessing landscape identity. With regard to the visualization workflow, (semi-)automatic generation processes for CGA rules should be implemented in order to generate even more realistic landscapes with reduced effort.

In the pre-test, the interactive modeling supported the interest of interviewees and helped them to understand scenario parameters. However, they did not try to interact with the setting of indicators or change the parameters themselves, which considerably can be ascribed to the complexity of the interface (van Schaik 2010). Further software options of the CityEngine are desirable, such as e.g. hiding complex parameter windows that are confusing for the interviewees. Next to already known benefits of visualizations as communication tool for common strategy development in stakeholder workshops (Figure 8, left), the software design allows new approaches for stakeholder involvement (Figure 8, right), which might be suitable for citizen-sourcing (Nam 2012; Fritz et al. 2012).

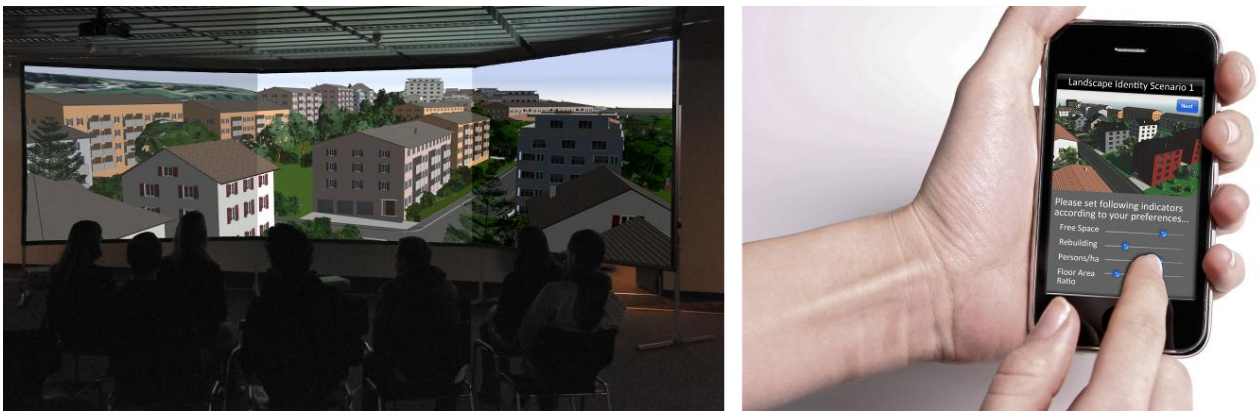

Figure 8: Future application of interactive modeling in stakeholder workshop (left) and in future online applications (right).

Already existing solutions (e.g. RealityServer) can handle the high system requirements of interactive realistic real-time modeling. These techniques could be used for interactive online experiments to get general threshold values of indicators and use these for setting trade-offs in stakeholder workshops with experts. The variety of web application is high, so the integration of the models in game engines is also conceivable (Bishop 2011), which run on nearly all mobile devices and operation systems. This flexibility offers also a high rate of return and the interviewees get an interactive user interface with navigation and indicator setting possibilities online.

Current technical possibilities offer multiple options for an operationalization of qualitative factors like landscape aesthetics and identity. Although concepts of how to develop the supporting tools already exist, the lack of operable interfaces makes their implementation difficult. All methods of the modules in the presented workflow are rather sophisticated. The challenge is to design the interfaces between the modules in order to let the workflow run smoothly. Then, the resulting tool can really improve participative planning processes and potentially provide suitable means to also taken into account urban identity.

"Dream" Regional Planning – "Real" Estate Development Based on Shopping Center Developments as Examples of "Real" Re-Mixing

Evelyn Susanne Ernst

(Dipl.-Ing. Evelyn Susanne Ernst: Regional Planner & Real Estate Developer; 1070 Vienna/Austria, Wimbergergasse 14/1/15, evelyn.ernst@aon.at)

1 ABSTRACT

The task of a regional planner was, is and will be to keep dreaming of an imaginary ideal future – and to prepare concepts and plans by harmonizing different uses to get the surroundings as close as possible to the dream.

The task of a real estate developer is to look for needles in the haystacks of plots and projects – and to identify successful property opportunities for reaching a profit target.

The interdisciplinary methods and manifold theories of regional and urban planning have undergone scientific research and practical evaluation "for an eternity", whereas real estate development started shy attempts at first theories and new project development standards not even 20 years ago. These were mainly postulated by economists, who didn`t (yet) have as a basis a comprehensive knowledge of planning responsibilities with their entanglements of environmental, historical, technical, social, legal, political and many other aspects of forward-looking planning.

Both disciplines are still in most respects separated not only by different points of view, but also by educations, frameworks, theories, processes, strategies, terminologies, etc. Indeed they need to improve their mutual understanding, as planners have the major knowledge of realistic project opportunities, and real estate developers have the financial resources to realize the dreams in due time.

I will describe some of the gaps between planners and developers that need to be closed to make the planners` dream of Re-mixing the Cities REAL - as the name REAL CORP 2012 implies.

2 INTRODUCTION

Isn`t it remarkable that REAL estate developers do not attend or present at the REAL CORP Conference? But I can reassure you that regional and urban planners do not usually visit real estate conferences either. Endless examples show that without a sound knowledge of real estate development urban and regional planning remains a faraway dream. And vice versa: real estate developers need a better understanding of the stringent complexity of regulations and regional politics.

Do we need real estate developers when we have succeeded without them for ages?

Aren`t proposals as well as designs and solutions safe in the hands of architects?

The reason we need them:

is comparable to why we are already used to the (additional) expertise of regional and urban planners in any architectural process. The complexity of requirements is rising sharply, regulations and laws are getting more and more challenging and this calls for ever increasing expertise. Due to globalisation, the complexity of projects, as well as the requirements from investors to construction companies, are increasing relatively even in less-favourable areas. Financing and commercialisation are examined according to international banking and feasibility standards even for small projects, and commercial tenants are already used to comparing their contracts with frame contracts and rental studies of "big players" even when their demands are not comparable in that regard ...

So the answer is:

Yes, we need real estate developers at least for commercial, industrial and hotel projects, retirement homes, healthcare facilities, and last but not least for mixed use project developments, due to the growing demands of our society.

… and an additional answer is:

The solution to the far-reaching misunderstandings of planners and developers is to analyse, explain and work together on solutions to harmonise the different points of view. And to accept that regional and urban

planners have as their responsibilities the "eternal" consequences for society, but real estate developers take their decisions according to economic calculations for the investment period.

In recent years a few (postgraduate) programmes have been started to offer education combining both disciplines, but in most European countries there is still no "real estate development" education at the university level as there are just few scientific investigations and assessments.

3 INTERDEPENDENCE OF REGIONAL PLANNING AND REAL ESTATE DEVELOPMENT

Everyone involved in planning procedures knows that the basis of regional and urban concepts and plans are collections of more or less practically useful planning theories and many legal and technical preconditions.

But these regional planning instruments theoretically summarize, in advance, project possibilities which are not clearly defined until specific plots are examined in details by real estate developers who usually investigate different variants during an initial real estate development process with respect to their economic potential.

It would be advantageous if these initial feasibility studies from real estate development were already also based on the legal and technical constraints according to all available planning instruments.

Unfortunately many examples of project ideas still show that in the opinion of developers, especially regarding large-scale projects, planners and "serving" politicians are expected to adapt regional planning instruments to develop ideas as quickly as possible – time for investors runs very fast.

3.1 Excursus: regional and urban planning

Different political cultures produce very different kinds of planning and this is not just valid in the comparison of different continents or countries, but also for any region, project or involved decision maker, and especially for the political decisions of the permitting process.

Planning theory is not a universal theory, and we must constantly reinterpret what we do in the light of our own experiences is another fundamental piece of Prof. John Friedmann (Prof. em. University of British Columbia, Canada), based on his over 60 years of theoretical and practical experience, and who is at the age of 86 still recognised in specialist circles worldwide as one of the leading academics in the field of planning culture and planning theory.

The driving forces behind regional and urban planning are in particular:

- public authorities (regional planning laws / infrastructure requirements)
- land owners (transactions to market / own use / specific projects)
- regional and urban planners
- political decision makers

and just to mention the main professions who are entitled by governments to regional and urban planning:

- regional and urban planners (technical education)
- architects (technical education)
- cooperation with social, technical, legal, demographic and other experts

But as mere technicians are accepted officially to lead a planning process, the involvement and question "Who are the planners" is an ongoing discourse. In this respect I shall quote once more without comment John Friedmann: professionals with a tertiary degree in the field? Architects specializing in urban design? The city engineer?Housing experts?Public officials who occupy positions in municipal planning offices? And should we distinguish city planners from, say transportation or environmental planners? Are social planners in or out? What about planners who are not engaged in drawing any sort of plan (strategic or otherwise) but are involved in the resolution of conflicts about urban issues of one kind or another? Do certain lawyers qualify, even though they have no planning degree? And what of city managers? … we also loose ourselves in another part of the labyrinth, whenever we ask about the "planning process" ...

3.2 Excursus: real estate development

Real estate development is the motor of the estate economy, which provides the market with new products in the form of new buildings and reactivation of existing buildings . It provides according to most experts, the idea-location-capital triangle to a real estate development project.

The driving forces behind real estate development are in particular:

- investors (private / institutional)
- (large) construction companies
- real estate development companies
- real estate agencies
- public authorities (incl. public private partnerships)

and 3 main types of developers, depending on their type of involvement:

(1) trader developer (market / investors / funds – trading profit))

(2) investor developer (own portfolio / property – rental profit)

(3) service developer (counselling / advice - fee)

Depending on these different driving forces behind the profession "developer" the professional background of these developers includes a wide range from economists, lawyers, politicians to other (self-made) experts, but astonishingly few architects and other planners.

The reason might be that technicians are not just different personalities with other professional expectations but rather that they are poorly educated in the necessary complex economies.

I would, however, like to emphasize once more from another point of view the different real estate development approach to projects by giving some examples of typical methods which are not, or at least not in detail, considered by planners during regional planning procedures:

- location analysis
- market and competition analysis
- user requirements programme
- cost-utility analysis / feasibility analysis
- capital budgeting
- valuation of real property / performance measurement
- market placement / public relations
- property management

3.3 Different approaches and perspectives of RP and RED

The following short descriptions are intended to highlight the cross-sectoral perspectives that are of key significance for the development and evaluation of individual projects.

Regional planning is decided primarily by politics with the objective of sustainable use of land and infrastructure, with a lack of short term instruments and money for realisation.

Real estate development is initiated primarily based on market forecasts with the objective of an appropriate return on investment either from development of a defined area or the need for an area/building for a defined use.

(1) regional planning (RP) - "eternal" / future generations

- focus: development for the benefit of a region – POLITICS
- framework: + political + legal + technical requirements

(2) real estate development (RED) - "20 years" / investment period

- focus: return on investment (RoI) of a specific project – MARKET

- framework: + economic + legal + technical requirements

Comparison of Principles

Real Estate Developments		Regional Planning
1 project	**basic**	region
return on investment	**focus**	regional benefit
market development	**success**	regional development
economic calculations	**theories**	multiple planning theories
investment period (e.g. 20 y)	**time frame**	eternity (life cycle of buildings)
investors	**final decision**	politicians

4 EXAMPLE: SHOPPING CENTER DEVELOPMENT

"Shopping Center" doesn`t need any explanation, does it?

Is shopping center development similar to other challenges of real estate development?

Starting with the 1st "no"-answer:

Even though America is said to be the homeland of "shopping centers", they are unknown there as they are called "shopping malls" and in British English it is "shopping centres" - therefore it depends on the authors preference to a country or continent which terminology is found in the names of the centers/centres/malls or in literature.

Also the respective definition of size is not regulated, so in Austria the minimum size for a shopping center is 4,000 sqm or more than 10 shops plus 2 anchors, or more than 20 outlets whereas the international minimum starts at 10,000 sqm – but these are no official accepted regulations either.

Architect Victor Gruen, who was born in Austria but worked from 1938 onwards mostly in America as an urban and regional planner, is quoted by many experts as "father of shopping centers" but criticised in a speech 1978 London "Americans for perverting his ideas …and proclaimed "I refuse to pay alimony for those bastard development" and he claimed that their [developers] motives had changed ...present day developers, Gruen lamented, only look at the bottom line. The developer were new anonymous real estate entrepreneurs ... promotors and speculators who just want to make a fast buck". So the initiative for his development of shopping malls was to offer a kind of meeting place with shops, social infrastructure, restaurants, with a mall construction as protection from the weather. Cars and parking "deserts" were not a big issue that time and Victor Gruen kept fighting against the influence of individual mobilization or what the politicians, planner, and developers made out of it: tree or cars? cars!

… and to continue with the 2nd "no"-answer:

The development of a shopping center is not comparable for a developer with other development projects, in respect of their far reaching consequences and specialised knowledge with high complexity which is shared within mostly international "inner cercles" of investors, tenants, planners, statisticians, construction companies, center managers, etc. using a specialised range of key figures.

Retail developments, and especially shopping centers, are perfect examples to demonstrate the tip of the iceberg in regards of the interdependence regional planning and real estate development, as they see themselves in terms of

- highly specialised knowledge
- high economic drive
- high total retail turnovers
- high turnover per deal size
- international developers
- international investors

- increasing shopping center percentage to other retail
- increasing investment of cross border compared to local purchasers
- high employment opportunities
- high tax revenue
- good political reputation
- good monumental reputation – as long as the architecture is respectable

but according to my own experience as well as official statistics there are some other factors such as

- few serious players in the market
- high economic risk
- high impacts on regions
- high percentage of cancelled and postponed developments
- high number of unprofessional "wannabe developers"
- high risk of reusability when a center has seen already better days ...

After the real estate crises in 2008 the economic power of retail and shopping center development in Europe reached € 37.2 billion in 2011, with a revival in high value deals and of international buyers . Therefore the economic drive of profit calculations for specific locations versus best possible use of land, technical and social infrastructure continues to challenge urban and regional planning.

The first year after the 2008 crises, forecasts were somewhere between "hope" and "hell", but the total retail investment turnover in Europe had recovered already to € 36.2 billion in 2010 , for some experts an unexpectedly high level.

Nevertheless, the figures for developments which were stopped / postponed / new in 2010 showed the confusion in the market and the challenge for regional planners who had to deal (or not to deal, that`s the question?) e.g. in Romania, a country not known for high purchasing power of its 19 million inhabitants and 370 km of motorways, with 86 shopping center projects, of which 35 were stopped, 48 postponed and 3 new.

Another key figure demonstrated in the year 2010 – therefore 2 years after the crisis – is the comparison of projected and existing leasable areas in shopping centers per 100 inhabitants.

Hungary is one of the EU countries which pushed itself 2012 in a deep financial crisis, but nevertheless was already in 2010 at a high level with 24 sqm existing leasable area per 100 inhabitants (see e.g. Switzerland with 28 sqm) and additional projects up to nearly 50 sqm (see Switzerland existing + projected 37 sqm in total). With these high dreams of developing the country, Hungary was on the way to becoming the second best-equipped country in Europe.

At least according to statisticians the "winner" 2010 was Estonia with a total of 59 sqm (43 sqm existing, 16 under development) per100 inhabitants.

As a comparison, well developed Austria was in 3rd place with a total of 38 sqm (32 sqm existing).

Last but not least, Bulgaria as an example of the challenges which regional planners and developers are facing, where shoppers had 10 sqm leasable area / 100 inhabitants and an additional 10 sqm were planned.

As a final example Turkey with its 8 sqm existing leasable in shopping centers per 100 inhabitants, and including projects under development a total of 11 sqm,. And this country is, in comparison to many other countries full of development dreams, expected to have a promising development of the economy due to the demographic numbers with 50 % younger than 29 years.

5 CONCLUSION

Nomen est omen:

REGIONAL planning needs to act as the PRINCIPAL in long term REGIONAL development, whereas

REALestate development has to take as the AGENT for short term REALisation measures.

Regional planners are not used to profit calculations and "feasibility studies" and real estate developers are not willing "to get rejected by butterflies on a wild meadow or a mistrust in their traffic concept".

The challenge for urban and regional planning is to find

theoretical as well as political and practical answers for the key question:

"how can regional planning on the basis of sustainable use of land and infrastructure

support and ensure real estate developments of shopping centers for a reasonable retail policy?"

To realize project visions and concepts – from either regional planners or real estate developers – in due time there is, besides the mutual understanding and knowledge an unconditional need for clear objectives from politicians and planners regarding zoning and prioritisation, including instruments supporting realisations, especially for developments with high profit expectations such as commercial, industrial, and hotel projects, retirement homes, healthcare facilities, and the supreme discipline of mixed use project developments,

Comprehensive knowledge of both disciplines is the basis

for making sweet dreams of sustainable developments come true

in due time and

combining quality with profitability

… and never to forget:

to save enough money for subsequent projects!

3-Plus der Initiierung und Umsetzung smarter Mobilitätslösungen: Die Gunst der Stunde nutzen!

Martin Berger, Ulrich Bergmann, Markus Frewein, Mario Platzer

(Dr. Martin Berger, verkehrplus, 8020 Graz, Elisabethinergasse 27a, martin.berger@verkehrplus.at)

1 ABSTRACT

Smarte Mobilitätslösungen (Carsharing 3G, Fahrradverleihsysteme, E-Mobilität und organisierter Sammelverkehr), die von Entwicklungen im Bereich der mobilen Technologien stark profitieren, besitzen das Potenzial sowohl zum Klima- und Umweltschutz beizutragen als auch die Mobilitätschancen der Bevölkerung zu verbessern. Eine wesentliche Schlüsselfrage lautet daher: Wie lassen sich smarte Mobilitätslösungen in der Praxis besser imitieren und letztlich umsetzen? Ausschlaggebend dafür sind eine Vielzahl unterschiedlicher Einflüsse, die von der Gesetzeslage, Fördersituation, Innovations- und Mobilitätskultur vor Ort über die Eigenschaften smarter Mobilitätslösungen hinsichtlich Akzeptanz und CO_2-Reduktionspotenzial bis hin zu den Akteuren mit ihren Netzwerken reichen. Ausgehend von theoretischen Ansätzen aus der Politikfeld- (z.B. Multiple-Stream Ansatz und dem Policy-Cycle) und Sozialforschung (Sozialen Netzwerkanalyse) wird die formulierte Schlüsselfrage aus unterschiedlichen Perspektiven mit den Methoden der Delphi-Befragung, der Sozialen Netzwerkanalyse und der Expertenbefragung empirisch analysiert, um umfassende Hinweise für die Initiierung und Umsetzung smarter Mobilitätslösungen zu erhalten. Entscheidend sind letztlich sich öffnende Gelegenheitsfenster: Wenn gleichzeitig mehrere fördernde Einflussfaktoren vorhanden sind, dann steigen die Chancen für eine erfolgreiche Implementierung enorm. Dazu zählen robuste Netzwerke und gut vernetzte Schlüsselpersonen, die das Projekt unterstützen, staatliche Förderungen und eine ausgeprägte Innovations- und Mobilitätskultur vor Ort sowie smarte Mobilitätslösungen mit CO_2-Reduktionspotenzial, die von der Bevölkerung akzeptiert und genutzt werden.

2 EINLEITUNG

2.1 Ausgangslage und Zielstellung

Anspruch und Realität einer nachhaltigen Mobilität klaffen immer noch auseinander. Trotz ambitionierter verkehrs- und klimapolitischer Leitvorstellungen, Ziele und Programme (z.B. CEC 2005, Klimastrategie 2010) wird immer mehr statt weniger Pkw gefahren. So verschiebt sich der Verkehrsmarkt nach wie vor zugunsten des Pkw-Verkehrs, wie eine zunehmende Pkw-Verkehrsleistung (Anstieg von 79,2 Mrd. auf 101,4 Mrd. Personenkilometer (+ 28 % von 1990 bis 2009) (Anderl et al. 2010) und ein steigender Motorisierungsgrad[1] (+5 % von 2005 (504 Pkw/1000Ew.) bis 2010 (530 Pkw/1000Ew.)) zeigen. Entsprechend trägt der Verkehrssektor mit einem Anteil von 27 % und 21,9 Mio. t CO_2-Äquivalente (2009) maßgeblich zu den österreichischen Treibhausgasemissionen bei. Bislang wurden die in der Klimastrategie 2010 formulierten Reduktionsziele von ca. 2,8 Mio. t CO_2-Äquivalente (2009) verfehlt (Anderl et al. 2010). Ob und inwieweit diese Ziele zukünftig erreicht werden, hängt insbesondere davon ab, wie multimodales Verkehrsverhalten in der Bevölkerung durch eine stärkere Verbreitung von smarten Mobilitätslösungen und der nahtlosen Vernetzung mit dem bisherigen Angebotsspektrum des Umweltverbunds forciert werden kann.

Smarte Mobilitätslösungen profitieren dabei von technologischen Entwicklungen der digitalen Welt: Smartphones mit mobilem Internet, Ortungsfunktionalität und Touchscreen, deren Verbreitung in der Gesellschaft rasant fortschreitet, vereinfachen das Informieren, Organisieren, Reservieren und Bezahlen. Somit rückt „Mobility-on-Demand“ immer näher. Smarte Mobilitätslösungen gelten als innovativ, intelligent, effizient und attraktiv, wobei im Folgenden Carsharing 3G, Fahrradverleihsysteme, E-Mobilität und organisierter Sammelverkehr thematisiert werden.

Obgleich smarte Mobilitätslösungen das Potenzial haben CO_2 zu reduzieren, weniger Lärm zu verursachen, weniger Fläche zu beanspruchen etc. und die Mobilitätschancen in der Bevölkerung zu verbessern, bleiben diese bislang eher Nischenprodukte. Daher gilt es die komplexen verkehrspolitischen Mechanismen sowie Einflüsse, die sich fördernd oder hemmend auf die Initiierung und Umsetzung smarter Mobilitätslösungen in

[1] Quelle: http://www.statistik.at/web_de/services/wirtschaftsatlas_oesterreich/verkehr/index.html (Zugriff: 25.02.2012)

der Praxis auswirken, zu identifizieren. Es werden gegliedert nach drei Einflussbereichen folgende Fragestellungen beantwortet:

Smarte Mobilitätslösung	**Beschreibung**
CarSharing 3G (3. Generation)	CarSharing ist eine organisierte, gemeinsame Verwendung von Pkw durch mehrere Nutzer. Gegen ein zeit- und/oder entfernungsabhängiges Entgelt erhält der Nutzer ein CarSharingfahrzeug, welches vom Anbieter unterhalten, gepflegt und repariert wird. Die 3. Generation des CarSharings zielt auf eine stärkere Flexibilisierung durch eine Spontannutzung („Instant Access“) und „One-Way-Fähigkeit“ ab.
organisierter Sammelverkehr	Sammelverkehre zielen auf eine bessere Auslastung von Pkw-Fahrten durch Mitfahren ab. Dazu zählen beispielsweise spontane, privat organisierte Fahrgemeinschaften, Shuttledienste und auch die Nutzung von bestehenden Kapazitäten im Taxiverkehr zu Zeiten eines geringen bzw. nicht vorhandenen ÖV-Angebotes. Aktuell existieren dynamische Ridesharingsysteme, welche mit Social Media Plattformen kombiniert sind. Durch Echtzeitinformationen mittels Internet und Standortbestimmungen (GPS) wird „On-Demand“ Service möglich.
Fahrradverleih-Systeme	Öffentlich zugängliche Fahrräder lassen sich unentgeltlich oder gegen Verleihgebühr temporär nutzen. Es wird ein bestimmtes Gebiet abgedeckt und das Angebot ist 24 Stunden am Tag mit geringem Aufwand zugänglich. Die letzte Generation zeichnet sich durch ein erweitertes Angebot mit Pedelecs aus, ist multimodal verknüpft insbesondere mit dem ÖV, basiert auf Informationstechnologien und die teilautomatisierte Fahrradausleihe erfolgt per Telefon, per Chipkarte, Internet oder Smartphone. Zusätzlich besteht die Möglichkeit Fahrräder an verschiedenen Orten auszuleihen und rückzugeben („One-Way-Fähigkeit“).
E-Mobilität mit Organisations-system	Betreiberunternehmen (z.B. Stromanbieter, Automobilhersteller) bieten Batteriefahrzeuge, Hybridfahrzeuge und/oder von Brennstoffzellen angetriebene Fahrzeuge an. Mögliche Geschäftsmodelle der Mobilitätsanbieter für E-Auto, E-Bike, Pedelec, E-Roller, E-Moped, E-Motorrad, Segway etc. sind Fahrzeugverkauf, Fahrzeugleasing, Fahrzeugverkauf und Batterieleasing, CarSharing etc.

Tabelle 1: Smarte Mobilitätslösungen.

Smarte Mobilitäts¬lösungen

- Welche Verbreitungschance haben die einzelnen smarten Mobilitätslösungen?
- Welche CO_2-Wirksamkeit sind durch die smarte Mobilitätslösungen zu erreichen?
- Welche Zielgruppen zeigen eine Affinität zu welchen smarten Mobilitätslösungen?

Initiierungs- und Umsetzungs¬prozess

- Welche Rahmenbedingungen (rechtliche und finanzielle) hemmen oder forcieren die Initiierung und Umsetzung smarter Mobilitätslösungen?
- Inwiefern hat die Struktur vor Ort (Siedlungs-, Wirtschafts-, Bevölkerungsstruktur, Innovations- und Mobilitätskultur) eine Auswirkung auf die Initiierung und Umsetzung smarter Mobilitätslösungen?

Soziale Netzwerke und Akteure

- Welche Rolle haben Schlüsselfiguren (Förderer, „Provider“, „Gatekeeper“ etc.) und wer sind diese?
- Wie gut sind Personen aus unterschiedlichen Institutionen z.B. Verwaltung, Politik, Verkehrs-betrieben etc. vernetzt?
- Wie lässt sich die Netzwerkstruktur charakterisieren? Was zeichnet optimale Netzwerke aus, wenn es um die Umsetzung und Verbreitung smarter Mobilitätslösungen geht?

3 STAND DER WISSENSCHAFT

Smarte Mobilitätslösungen zu initiieren und umzusetzen ist aufgrund ihres Innovationscharakters eine große Herausforderung. Aufgrund ihrer Umsetzungskomplexität sind diese als sogenannte „Wicked Problems" (Rittel und Webber 1973) einzuordnen, wobei eine Reihe von Besonderheiten eine Rolle spielen: Machtpolitische Verhältnisse, die verkehrspolitische Entscheidungen beeinflussen, eine hohe soziale Komplexität mit einer Vielzahl unterschiedlicher Akteure, Zielvorstellungen und Lösungsvorschläge, spezifische lokale bzw. regionale Problemlagen und Potenziale etc. Für ein besseres Verstehen dieser vielschichtigen, miteinander verwobenen Zusammenhänge, wird daher ein umfassender analytischer Erklärungsansatz verfolgt. Während der aus der Organisationstheorie stammende Multiple-Streams-Ansatz

(Kingdon 1984, Rüb 2009) drei unterschiedliche Ströme mit (i) Problemwahrnehmung, (ii) Lösungsansätzen und (iii) politischen Machtverhältnissen sowie die von einer günstigen Situation geprägten Gelegenheitsfenster („window of opportunity“) als Erkärungsmodell für politisches Handeln thematisiert, untersucht die Soziale Netzwerkanalyse (Jansen 2006) Beziehungen von Akteuren. Das Konzept des sozialen Netzwerkes basiert auf der Austauschtheorie, die den sozialen Alltag von Menschen durch einen wechselseitigen Austausch von Leistungen („Reziprozitätsprinzip“) beschreibt (Schubert et al. 2001: 13). Menschen können dabei nicht unabhängig voneinander betrachtet werden, sondern es ist vielmehr von einer ständigen gegenseitigen Beeinflussung durch Andere auszugehen (Widmer und Troeger 2005). Hingegen beschreibt das Modell des Policy-Cycles den politischen Entscheidungsprozess in mehreren Stadien (Howlett et al. 2009, Jann und Wegrich 2009) und dient hauptsächlich der analytischen Strukturierung des Initiierungs- und Umsetzungsprozesses. Die dargelegten Ansätze bilden den theoretische Rahmen der eigenen Untersuchung, um der hohen Komplexität verkehrspolitischer Initiierungs- und Umsetzungsprozesse besser gerecht zu werden.

Zu smarten Mobilitätslösungen liegen eine Reihe von Studien vor, die unterschiedliche Aspekte thematisieren: Systembeschreibungen (z.B. Monheim et al. 2011), Chancen und Hemmnisse der Umsetzung (Frick et al. 2003, Beckmann et al. 2005), Akzeptanz und Mobilitätsverhalten von Nutzer (Knie et al. 2012; Bundesamt für Energie 2006), Umwelteffekte (Firnkorn und Müller 2011) etc. Bislang eher wenig betrachtet sind die Prozesse der konkreten Umsetzung, wobei die Studie von Beckmann et al. (2005) hierzu einige wesentliche Anhaltspunkte liefert. Es wird dargelegt, dass das Zusammenwirken einer Vielzahl von fördernden Faktoren aus den Bereichen Akteure und Kommunikation, Art der Maßnahmen und Rahmenbedingungen in einer spezifische Situationen für ein Gelingen entscheidend sind. Weniger die Art der Maßnahme sondern stärker die beteiligten Akteure sind dabei bedeutsam. Eine vertiefende quantitative Analyse von verkehrspolitischen Akteurskonstellation mit der bereits in anderen Teildisziplinen der Sozialforschung stark präsenten Sozialen Netzwerkanalyse ist bislang in diesem Zusammenhang nicht erfolgt. Beispielsweise beschränkt sich Schreiner (2003) in seinen Ausführungen auf die Akteursgruppen Verwaltung, Ingenieurbüros und Wissenschaft und diskutiert deren Beziehungen innerhalb und zwischen den Akteursgruppen.

4 METHODIK

Für eine umfassende und systematische Analyse des Initiierungs- und Umsetzungsprozesses smarter Mobilitätslösungen wurde eine Delphi-Befragung (Häder und Häder 2004, Rowe und Wright 1999), eine Prozessanalyse mittels leitfadengestützten Experteninterviews (Mieg und Näf 2005) und eine Soziale Netzwerkanalyse (Jansen 2006) realisiert. Tabelle 2 beschreibt die einzelnen Methoden anhand unterschiedlicher Kriterien. Im Gegensatz zu quantitativen Befragungen der Sozialforschung zählen Experteninterviews aufgrund der kleinen Anzahl an Befragten und aufgrund der Offenheit der Fragen zu den qualitativen Methoden der Datenerhebung (Mieg und Näf 2005).

	Delphi-Befragung	**Experteninterviews**	**Soziale Netzwerkanalyse**
Untersuchungs-gegenstand	Beurteilung smarter Mobilitätslösungen	Analyse Initiierung- und Umsetzungsprozess	Analyse von Netzwerkstruktur, Gruppenbeziehungen und Schlüsselpersonen
Forschungs-ansatz	quantitativ (Häufigkeitsverteilung, Mittelwerte)	qualitativ (Zitate, Bestätigung oder Ablehnung von Arbeitshypothesen, Nennungen)	quantitativ (Netzwerkvisualisierung und Kennwerte)
Methoden-charakteristika	zweistufige und reflexive Befragung	prozessorientierte Inhaltsanalyse des Interviews	gegenseitige Beeinflussung und Austausch von Wissen, Ressourcen etc.
Datenerhebung	postalisch und per E-Mail versendeter Fragebogen	telefonisches, leitfadenorientiertes Interview	telefonische Befragung
Stichprobe	35 internationale Experten/-innen	18 beteiligte Personen an konkreten Umsetzungen	34 Akteure mit Bezug zum Thema Mobilität in der Region
Untersuchungs-raum	europaweit	österreichweit	Obersteiermark-West

Tabelle 2: Methodik.

5 ERGEBNISSE

Nachfolgend dargestellte empirische Ergebnisse zeigen erstens das Potenzial smarter Mobilitätslösungen auf Basis einer Delphi-Befragung, zweitens deren Initiierungs- und Umsetzungsprozess nachgezeichnet mit Experteninterviews und drittens die Bedeutsamkeit von Netzwerken und Akteuren analysiert und visualisiert mit der Sozialen Netzwerkanalyse.

5.1 Potenziale smarter Mobilitätslösungen

Verbreitungschance und CO_2-Wirksamkeit

Eine hohe Verbreitungschance existiert unter der Voraussetzung, dass Verkehrsteilnehmer smarte Mobilitätslösungen kennen, akzeptieren und letztlich nutzen. Ebenso ist die CO_2-Wirksamkeit von Interesse.

Abbildung 1 zeigt eine kombinierte Betrachtung dieser beiden Faktoren.[2] Laut der Expertinnen und Experten der Delphi Befragung weisen Fahrradverleihsysteme und die organisierte E-Mobilität sowohl eine hohe CO_2-Wirksamkeit als auch eine große Verbreitungschancen auf, was optimal ist. Hinsichtlich der CO_2-Wirksamkeit stimmen Carsharing 3G und der organisierte Sammelverkehr überein, jedoch hat letztere Mobilitätslösung die geringste Verbreitungschance.

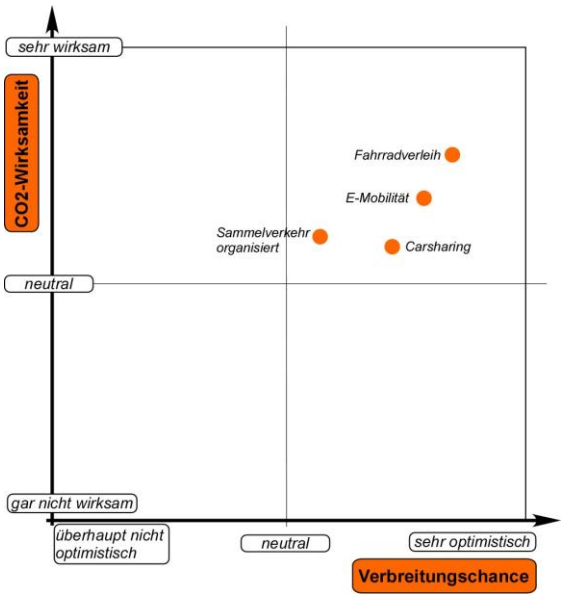

Abbildung 1: Verbreitungschance und CO_2-Wirksamkeit von smarten Mobilitätslösungen (Delphi Befragung n=35, Quelle: verkehrplus).

Entwicklungstrend und Nutzungspräferenzen zukünftiger Zielgruppen

Untersuchungen (z.B. Bamberg et al. 2000) zeigen, dass eine zielgruppenspezifische Ausrichtung und Anpassung von verkehrlichen Maßnahmen - hierzu zählen auch smarte Mobilitätslösungen - zur Steigerung der Akzeptanz sinnvoll sind. Für die Zielgruppenanalyse werden Mobilitätstypen aus einer Untersuchung von Hunecke und Haustein (2007) zugrunde gelegt, bei denen die Einstellungen der Verkehrsteilnehmer wesentliches Klassifizierungsmerkmal sind. Aus Tabelle 3 geht als Expertenurteil der Delphi-Befragung hervor, sowohl wie sich die Entwicklungstendenz der unterschiedlichen Mobilitätstypen in den nächsten 20 Jahren verändert als auch wie hoch der zukünftige Nutzeranteil für die jeweiligen Mobilitätslösungen prognostiziert wird. Es wird von den Experten abgeschätzt, dass vor allem die Anteile der Mobilitätstypen „selbstbestimmte Mobile“, „umweltsensibilisierte ÖV-Fans“ und „wetterresistenten Rad-Fans“ zukünftig steigen. Diese Mobilitätsgruppen sind eher multimodal unterwegs und zeichnen sich durch eine Affinität gegenüber smarten Mobilitätslösungen aus. Im Gegensatz dazu liegt die Einschätzung der Nutzung von smarten Mobilitätslösungen durch die Gruppen „Pkw-Individualisten“ und „ÖV-distanzierte Zwangsmobile“

[2] Als Antwortkategorien standen bei der Frage nach der Verbreitungschance „überhaupt nicht optimistisch“, „nicht optimistisch“, „neutral“, „optimistisch“ und „sehr optimistisch“ und bei der CO2-Wirksamkeit „gar nicht wirksam“, „wenig wirksam“, „neutral“, „wirksam“ und „sehr wirksam“ zur Auswahl.

deutlich niedriger. Zu beachten ist, dass die Bevölkerungsanteile dieser Zielgruppen zukünftig abnehmen, wie die Experteneinschätzung zeigt.

	Prognostizierte Nutzungspräferenzen smarter Mobilitätslösungen				
	Selbstbestimmte-Mobile	**Umwelt-sensibilisierte ÖV-Fans**	**Wetterresistente Rad-Fans**	**Pkw-Individualisten**	**ÖV-distanzierte Zwangsmobile**
Sammelverkehr	32%	35%	13%	8%	12%
CarSharing	35%	28%	14%	11%	12%
Fahrradverleih	32%	28%	23%	7%	10%
E-Mobilität	28%	25%	15%	18%	14%
Einschätzung Entwicklungstrend der Mobilitätstypen[3]	**+4%**	**+3%**	**+1%**	**-3%**	**-4%**

Tabelle 3: Einschätzung Entwicklungstrend der Mobilitätstypen in den nächsten 20 Jahren sowie deren Nutzungsverteilung (Delphi Befragung n=35, Quelle: verkehrplus).

5.2 Rahmenbedingungen und Strukturen vor Ort

Finanzierung und staatliche Förderungen

Eine Grundvoraussetzung für die Initiierung und Umsetzung von smarten Mobilitätslösungen ist die Verfügbarkeit von finanziellen Mitteln. Fast drei Viertel der 18 Fallbeispiele profitieren dabei von einer finanziellen Förderung (Abb. 2, links). Der Einfluss dieser wird durchweg als positiv beurteilt (Abb. 3, Mitte). Bei differenzierter Betrachtung von geförderten oder nicht geförderten Projekten fällt auf, dass im letzteren Fall die finanzielle Lage wesentlich schlechter beurteilt wird, so dass gerade dann staatliche Förderungen das Risiko senken (Abb. 3, rechts), die sowohl für Investitionen als auch den laufenden Betrieb verwendet werden. Aktuell werden vorwiegend E-Mobilitätsprojekte und Fahrradverleihsysteme gefördert. Geringer fällt die Förderquote für CarSharing und den organisierten Sammelverkehr aus (Raithofer 2011).

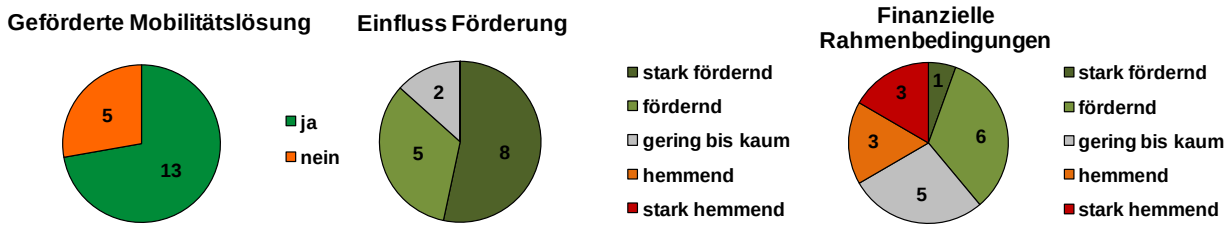

Abbildung 2: Anzahl der geförderten Mobilitätslösungen [li.], Einfluss von Förderungen auf die Initiierung und Umsetzung [mi.] und allgemeine finanzielle Situation (Prozessanalyse n=18, Quelle: verkehrplus).

Öffnungs- und Experimentierklausel

Sowohl Experimentier- als auch Öffnungsklauseln (Maaß 2001) dienen der Aufhebung von Standardregelungen (z.B. Stellplatzverordnungen, Kraftfahrliniengesetz). Durch die legale Möglichkeit von bestehenden „starren" Regeln abzuweichen, können smarte Mobilitätslösung flexibel umgesetzt werden. Beispielsweise schaffen befristete Ausnahmegenehmigungen den erforderlichen Spielraum.

In fast der Hälfte der Fälle existieren zu starre Gesetze, Regelungen oder Verordnungen (Abb. 3, links). Dementsprechend empfinden ca. 1/3 der Befragten die rechtliche Lage als hemmend (Abb. 3, rechts). Experimentier- als auch Öffnungsklauseln werden als Möglichkeit gesehen Rahmenbedingungen zu schaffen, die auf die jeweilige smarte Mobilitätslösung abgestimmt sind und somit die Initiierung und Umsetzung fördern (Abb. 3, Mitte).

[3] In Anlehnung an Hunecke und Haustein (2007) sind die einzelnen einstellungsbasierten Mobilitätstypen aktuell mit je 20 % gleichverteilt.

Abbildung 3: „Starre“ Rechtslage [li.], Einfluss von Öffnungs-/Experimentierklauseln auf die Initiierung und Umsetzung [mi.] und Wahrnehmung der allgemeinen rechtlichen Situation [re.] (Prozessanalyse n=18, Quelle: verkehrplus)

Strukturen vor Ort

Smarte Mobilitätslösungen müssen zu den Strukturen vor Ort (z.B. Tourismus als maßgebender Wirtschaftsfaktor, Streusiedlungsstruktur, Überalterung der regionalen Bevölkerung) passen, damit diese optimal funktionieren. So wird in fast allen Fällen die hohe Bedeutung der Strukturen vor Ort bestätigt (Abb. 4, links). In 12 von 15 Fällen fördern z.B. der Tourismus, ein hoher Anteil an ÖV-„captives“ (Pendler, Schüler, ältere und einkommensschwächere Personen) die Initiierung und Umsetzung smarter Mobilitätslösungen (Abb. 4 Mitte). Gleiches gilt für eine ausgeprägte Innovations- und Mobilitätskultur (z. B. offene Akteure, hohes Umweltbewusstsein, viele realisierte Vorreiterprojekte) (Abb. 4, rechts), die den Rahmen für neue Ideen und innovative Ansätze schafft.

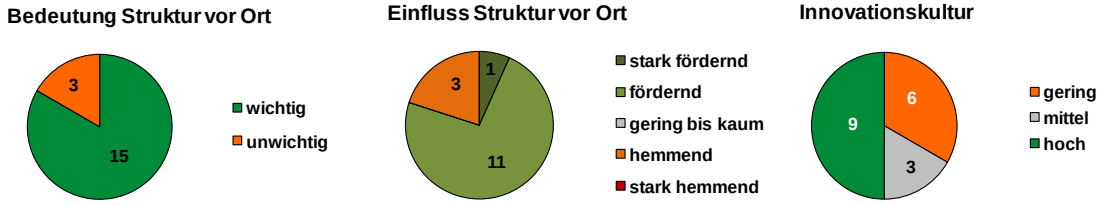

Abbildung 4: Regionale Eigenheiten [li.], deren Einfluss auf die Umsetzung [mi.] und Ausprägung der regionalen Innovationskultur [re.] (Prozessanalyse n=18, Quelle: verkehrplus)

5.3 Soziale Netzwerke

Soziale Netzwerke verbinden Menschen und sind deren soziales Kapital. Zu den relevanten Akteuren der Beispielregion Obersteiermark-West zählen Bürgermeister, Landtagsabgeordnete, Gemeinderäte, Unternehmer, Taxibetreiber, Busunternehmer, Interessenvertreter, Verwaltungsmitarbeiter etc. Über das soziale Netzwerk knüpfen Personen formelle oder informelle Kontakte. Außerdem lassen sich Informationen und Wissen leichter und schneller austauschen, wenn stabile Verbindungen zu Anderen bestehen. Je besser bedeutsame Akteure einer Region vernetzt sind, desto günstiger sind die Voraussetzungen für Innovationen und die Umsetzung smarter Mobilitätslösungen.

Identifikation von Schlüsselpersonen

Für die Netzwerkbildung sind Schlüsselpersonen mit vielen Beziehungen zu anderen und/oder einer strategisch wichtigen Netzwerkposition von besonderer Bedeutung. Schlüsselpersonen können unterschiedliche Rollen einnehmen: Einerseits fungieren sie als „Aushängeschilder” und tragen dabei zu einem Wandel der Innovations- und Mobilitätskultur bei, erzeugen ein positives mediales Echo (Marketing), sind Vorbilder etc. Ihre Mitarbeit wirkt sich z.B. positiv auf die Entschlossenheit und Motivation anderer Akteure aus. Andererseits sind Personen als Vermittler einer Idee und/oder deren Umsetzung (Provider, Kümmerer etc.) relevant. Besonders wichtig ist dabei die Fähigkeit von Personen – den sogenannten „Gatekeepern“ – den Kontakt zur Peripherie des Netzwerkes mit unterschiedlichen Institutionen zu halten (Abb. 5 links). Schlüsselpersonen stammen vor allem aus der Politik und regionalen Organisationen (Abb. 5, rechts).

Günstige Netzwerkstruktur für die Initiierung und Umsetzung

Das Potenzial einer Region für smarte Mobilitätslösungen hängt stark von der Struktur des sozialen Netzwerkes ab (Katzmair 2010). Beispielhaft lässt sich das Netzwerk der Obersteiermark-West folgendermaßen charakterisieren:

- Homogenes und stabiles Zentrum: Zentral gelegene Akteure kommen vorwiegend aus regionalen Organisationen und der Politik. Der sehr häufige Kontakt („strong ties“) und die vorhanden Dreiecksbeziehungen zwischen Menschen aus diesen beiden Personengruppen steigern die Stabilität und letztlich das Vertrauen (Abb. 5, links).
- Vielfältige Peripherie: Die vorhandene Diversität und Heterogenität in den Randbereichen des Netzwerkes führen zu einem vermehrten Angebot an unterschiedlichen Ressourcen, Wissen und Informationen im Netzwerk. Hierbei handelt es sich im Speziellen um Akteure aus den Bereichen Ausbildung, Tourismus und Verwaltung aber auch regionalen Verkehrsunternehmen. Diese eher fachspezifischen und dezentral gelegenen Subgruppen sind eher lose über „Dyaden“-Beziehungen („weak ties“) miteinander vernetzt (Abb. 5, rechts).
- Effektive Vernetzung zwischen Zentrum und Peripherie: Innerhalb des Gesamtnetzwerkes bestehen keine auffälligen Lücken oder Redundanzen. D.h. es fallen beim Wissensaustausch zwischen der innovationsfreudigen Peripherie und dem stabilen Zentrum nur geringe Transaktionskosten an. Durch das Zusammenspiel unterschiedlicher Wissens- und Erfahrungsquellen steigt die Wahrscheinlichkeit der Umsetzung und Verbreitung von smarten Mobilitätslösungen.

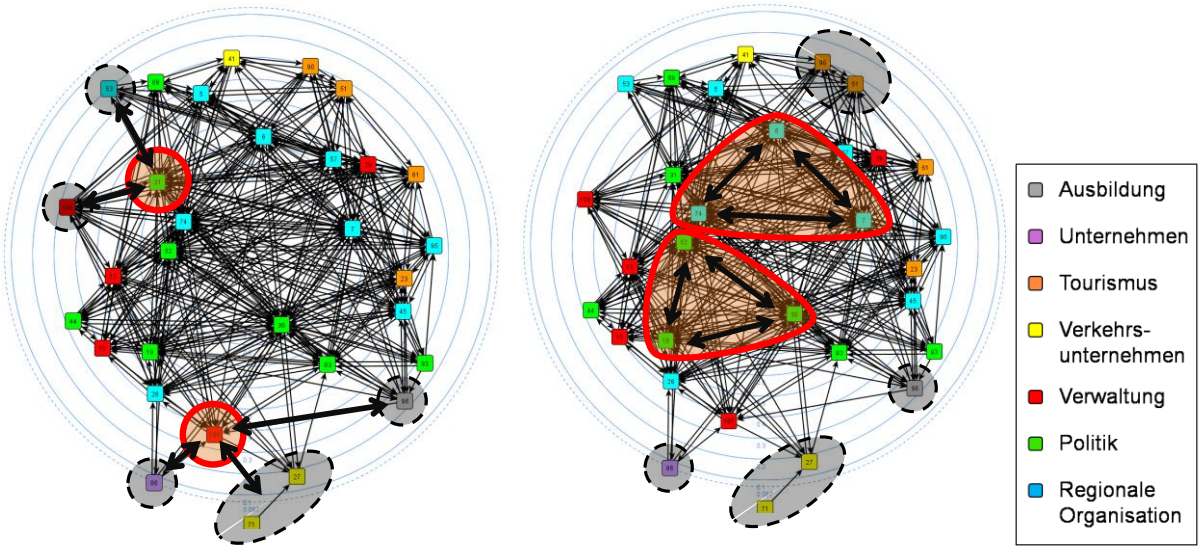

Abbildung 5: Netzwerk „Häufigkeit Kontakt“ der Obersteiermark-West: Maklerpositionen im Netzwerk [li.] und Zentrum und Peripherie [re.] (Netzwerkanalyse n=34, Quelle: verkehrplus).

5.4 3-Plus der Umsetzung - Gelegenheitsfenster: „Nutze die Gunst der Stunde!“

Insgesamt zeigen die empirischen Ergebnisse, dass weniger einzelne Faktoren für die Initiierung und Umsetzung von smarten Mobilitätslösungen verantwortlich sind, als vielmehr sogenannte Gelegenheitsfenster („windows of opportunity“), d.h. ein gleichzeitiges Auftreten vieler miteinander verwobener Einflüsse (Abb. 6 rechts oben). Gelegenheitsfenster für die Implementierung smarter Mobilitätslösungen öffnen sich durch vorhersehbare (z.B. Machtverschiebungen infolge zu Ende gehender Legislaturperiode, Neuwahlen und Verfolgung spezifischer Parteiprogramme etc.) oder zufällige Ereignisse (z. B. Katastrophen), die kurzfristig als äußere Impulse Veränderungen ermöglichen.

Wenn zeitgleich günstige Voraussetzungen bei

- den Rahmenbedingungen mit Förderungen sowie einer existierenden Innovations- und Mobilitätskultur vor Ort (vgl. Kap. 5.2),
- den Eigenschaften smarter Mobilitätslösungen mit einem hohen Potenzial zur CO_2-Ersparnis und einer hohen Akzeptanz in der Bevölkerung (vgl. Kap. 5.1) und
- den Akteuren, Netzwerken und Kommunikation mit einer robusten, dezentralen Vernetzung und Schlüsselfiguren als Katalysatoren, Gatekeepern etc. (vgl. Kap. 5.3)

vorhanden sind, dann steigen die Chancen für eine erfolgreiche Initiierung und Umsetzung von smarten Mobilitätslösungen (Abb. 6, rechts unten). Daher gilt es, Gelegenheitsfenster für die Initiierung und Umsetzung smarter Mobilitätslösungen zu erkennen und die Chance im „richtigen Moment" zu ergreifen.

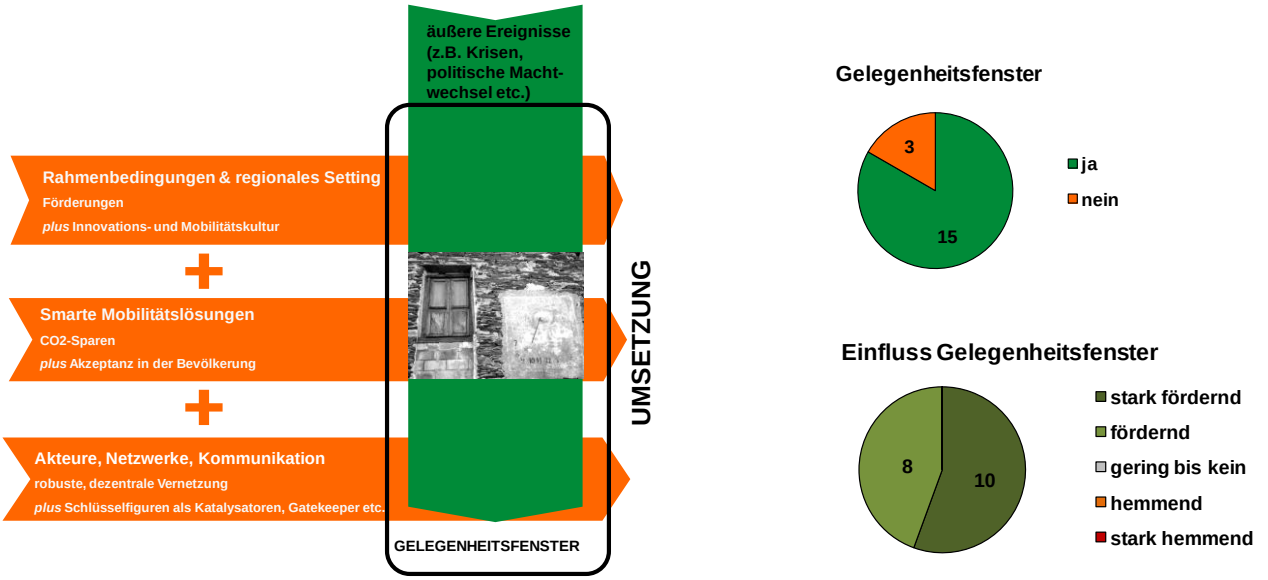

Abbildung 6: 3-Plus der Umsetzung [links] und Auftreten von Gelegenheitsfenster [re. oben] und deren Einfluss auf die Initiierung und Umsetzung [re. unten] (Prozessanalyse n=18, Quelle: verkehrplus).

6 ZUSAMMENFASSUNG UND AUSBLICK

Die Initiierung und Umsetzung smarter Mobilitätslösungen bleibt immer einzelfallbezogen und hängt von einer Vielzahl von fördernden und hemmenden Faktoren ab (Abb. 7). Somit dienen die dargestellten Ergebnisse als Anhaltspunkte für flexible Umsetzungsstrategien, wobei es gilt, die spezifische Situation zu begreifen und zu berücksichtigen.

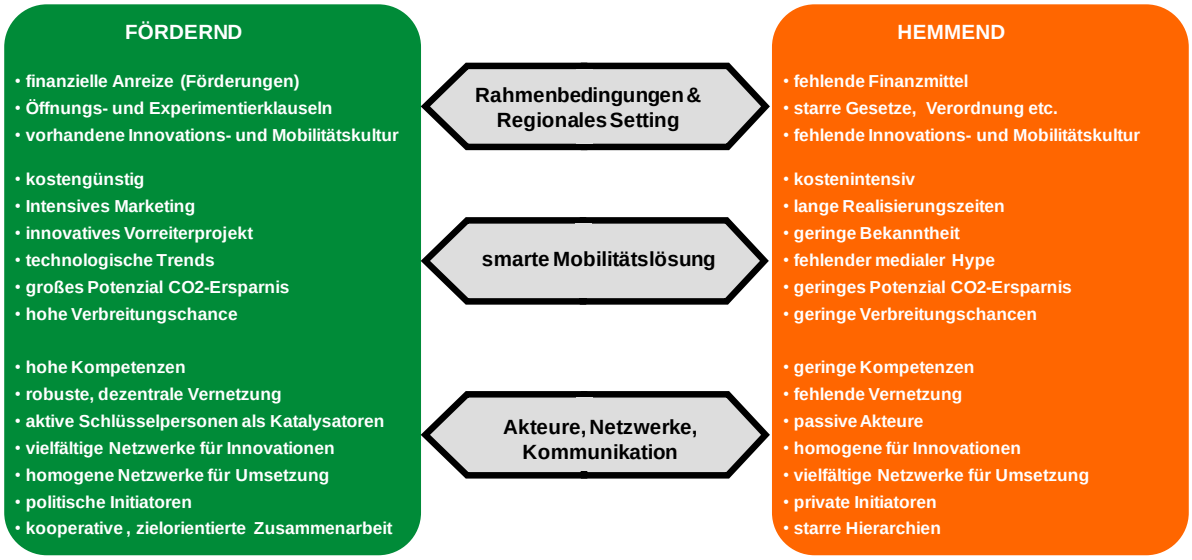

Abbildung 7: Fördernde und hemmende Einflussfaktoren bei der Initiierung und Umsetzung smarter Mobilitätslösungen (Quelle: verkehrplus).

Um den komplexen Initiierungs- und Umsetzungsprozess smarter Mobilitätslösungen besser nachzuskizzieren, bilden Ansätze aus der Politikfeldforschung mit dem Multiple-Stream-Ansatz und dem Policy-Cycle sowie aus der Sozialforschung mit der Sozialen Netzwerkanalyse die theoretische Grundlage der empirischen Analysen.

Aus unterschiedlicher Perspektive werden empirische Befunde zusammengetragen, die in ein umfassendes Erklärungsmodell in Analogie zum Multiple-Stream-Ansatz münden. Integriert betrachtet werden sowohl der Kontext der drei Ströme mit (i) Rahmenbedingungen, (ii) Eigenschaften der smarten Mobilitätslösung sowie

(iii) Akteure, Netzwerke und Kommunikation als auch die Situation mit dem Gelegenheitsfenster: Die Gunst der Stunde nutzen!

6.1 Handlungsempfehlungen

Derzeit stehen viele smarte Mobilitätslösungen an der Schwelle zum Breiteneinsatz. In dieser Phase sind Initiierungs- und Umsetzungswissen von besonderer Bedeutung. Einige wesentliche Handlungs¬empfehlungen lauten:

- Globale Trends als Katalysator smarter Mobilitätslösungen nutzen: Beispielsweise kommen als Katalysatoren ein steigendes Umweltbewusstsein („CO_2 sparen“, globale Klimaerwärmung, Ressourcenverknappung und –verteuerung etc.), das Prinzip „Teilen statt besitzen“ (z.B. CarSharing) und die rasante Weiterentwicklung neuer Schlüsseltechnologien (z.B. Smartphones, Internet etc.) in Frage.
- Bekanntheit von smarten Mobilitätslösung steigern: Gezielt symbolisch-emotionales Marketing (Hunecke et al. 2007) betreiben und mediale Hypes initiieren, um Emotionen zu aktivieren und neue Symbole (Erlebnis, Status etc.) für smarte Mobilitätslösungen zu schaffen, ist folgerichtig.
- Wirkungen von smarter Mobilitätslösungen systematisch kontrollieren: Wirkungskontrollen überprüfen mit empirischen Erhebungsmethoden, ob die mit der smarten Mobilitätslösung beabsichtigten Effekte (z.B CO_2-Reduktion) objektiv erreicht wurden. Dadurch wird die Qualität der Mobilitätslösungen verbessert, Lerneffekte induziert, Transparenz gegenüber der Öffentlichkeit hergestellt und Erfolg sichtbar gemacht.
- Staatliche Förderungen gewähren: Förderungen senken das finanzielle Risiko; folglich steigt der Anreiz smarte Mobilitätslösungen zu implementieren.
- Leuchturmprojekte initiieren: Vorreiterprojekte stellen besonders innovative smarte Mobilitätslösungen dar, über die nur geringe Erfahrungswerte über Umsetzung und Betrieb vorliegen und als „Blaupause“ für Nachahmerprojekte dienen können.
- Verstärktes Augenmerk auf Regionen richten: Smarte Mobilitätslösungen müssen eine kritische Masse an Nutzern überwinden, um zu funktionieren, effizient betrieben werden zu können und CO_2 zu sparen. Hierzu bieten Regionen als größere Einheiten ein entsprechendes Marktpotenzial.

6.2 Forschungsbedarf

Empirisch fundierte Wissensgrundlagen für die Initiierung und Umsetzung smarter Mobilitätslösungen sind zu erweitern. Folgender Forschungsbedarf besteht:

- Überprüfung und Erweiterung des entwickelten Analyserahmens: Der aus der Politikfeldforschung abgeleitete Erklärungsansatz des Multiple-Stream Ansatzes für den Initiierungs- und Umsetzungsprozesses sollte verfeinert und an weiteren empirischen Beispielen - insbesondere mit höheren Fallzahlen - auf seine Tauglichkeit überprüft werden. Erst dadurch lassen sich Ursache-Wirkungs-Zusammenhänge zwischen Erfolgsfaktoren bzw. Hemmnissen und erfolgreichen bzw. gescheiterten Implementierungen smarter Mobilitätslösungen tiefgründig aufarbeiten. Durch die Berücksichtigung vieler sich wechselseitig beeinflussender Einflüsse entsteht ein realistischeres Bild der Initiierungs- und Umsetzungssituation. Dafür ist ein Theorie- und Methodentransfer aus der Sozial- und Politikwissenschaft adäquat.
- Stärkere Fokussierung auf die Beziehungen zwischen Menschen: Da Akteure und ihre Netzwerke die Initiierung und Umsetzung smarter Mobilitätslösungen maßgeblich beeinflussen, sind vermehrte Forschungsarbeiten mit der Sozialen Netzwerkanalyse in diesem Anwendungskontext sinnvoll. Nur so gelingst es, wertvolle Einsichten in das komplexe Beziehungsgeflecht der Menschen zu erhalten und somit neues Umsetzungswissen zu generieren. Insbesondere stellt sich die Frage, wie die aufwändige und komplexe Soziale Netzwerkanalyse durch Vereinfachungen stärker in Praxis diffundiert werden kann.
- Lernen aus gescheiterten Projekten: Meist werden bei der Analyse von Fallbeispielen für den Aufbau von Umsetzungswissen für Maßnahmen ausschließlich typische Erfolgsfälle und weniger Misserfolgsfälle, die möglicherweise sogar ein besseres Lernen ermöglichen, betrachtet.

7 DANKSAGUNG

Der Aufsatz beruht auf Erkenntnissen des Forschungsprojektes ImMoReg „Implementierung innovativer, klimafreundlicher Mobilitätslösungen für Regionen“ der Programmlinie Neue Energien 2020 - 2. Ausschreibung und wurde durch den Klima- und Energiefonds des Bundes gefördert.

1 ABSTRACT

Im Zuge der Schaffung nachhaltiger, nutzungsgemischter Stadtstrukturen im Sinne der europäischen Stadt haben ganzheitliche Strategien sowie das abgestimmte Handeln aller am Stadtentwicklungsprozess beteiligten Akteure in den vergangenen Jahren an Bedeutung gewonnen. Den daraus resultierenden Anforderungen muss insbesondere auf der Ebene der Stadtplanung im Sinne der baulich-räumlichen Ordnung der Stadt entsprochen werden. Zwar wurden bereits eine Vielzahl erfolgreicher Strategien entwickelt und in der stadtplanerischen Praxis verankert, dennoch werden auch weiterhin Strategien und Instrumente etabliert werden müssen, mit denen unter effizientem Ressourceneinsatz Entscheidungen ermöglicht werden, die den zunehmend komplexen Anforderungen gerecht werden.

Eine zentrale Rolle zur Qualifizierung der Stadtplanung vor dem Hintergrund der sich wandelnden Rahmenbedingungen und den zukünftigen Herausforderungen kommt dem Einsatz von Informations- und Kommunikationssystemen zu. Einhergehend mit den rasanten technologischen Entwicklungen der Methoden und Techniken zur Visualisierung und Simulation räumlicher Fragestellungen ergibt sich eine nahezu unüberschaubare Menge an neuen Einsatzmöglichkeiten im Rahmen der Stadtplanung. Hierbei ist es von wesentlicher Bedeutung, die neuen Technologien und Anwendungen hinsichtlich ihrer Relevanz für das stadtplanerische Handeln zu untersuchen und Anforderungen zu definieren, die zum optimalen Einsatz sowie zur zielgerichteten Weiterentwicklung bestehender Methoden und Anwendungen beitragen können.

Exemplarisch für die rasanten Entwicklungen steht die zunehmende Bedeutung der dritten Dimension, insbesondere im Rahmen digitaler 3D-Stadtmodelle, zur Darstellung stadtplanerischer Fragestellungen sowie zur Simulation urbaner Prozesse. Hinsichtlich ihrer Bedeutung für die Stadtplanung stellen digitale 3D-Stadtmodelle in erster Linie ein wichtiges Instrument zur Kommunikation, Diskussion und Vermarktung räumlicher Planungen dar. Gleichzeitig bilden sie durch die Möglichkeiten zur statischen oder dynamischen Darstellung räumlicher Zusammenhänge und Wechselwirkungen ein wertvolles Analysetool. Vor diesem Hintergrund erfüllen Stadtmodelle auch im Rahmen des Entwerfens unter komplexen Rahmenbedingungen wichtige Funktionen bei der Erstellung und Überprüfung planerischer Alternativen.

Ziel des Tagungsbeitrages ist es, neue Anwendungsfelder von 3D-Stadtmodellen als Instrumente zur direkten Darstellung von Geodaten im dreidimensionalen Kontext zu identifizieren sowie Ansätze zur Etablierung von 3D-Stadtmodellen als eigenständige Kommunikations-, Entscheidungsunterstützungs- und Planungsinstrumente aufzuzeigen.

2 AUF DEM WEG ZU NACHHALTIGEN, NUTZUNGSGEMISCHTEN STADTSTRUKTUREN

2.1 Rahmenbedingungen der Stadtentwicklung

Die Entwicklung der Städte Europas wird aktuell und zukünftig von tiefgreifenden demografischen, ökonomischen und gesellschaftlichen Umwälzungen bestimmt sein. Neben knapper werdenden finanziellen Ressourcen und politischen Handlungsspielräumen stellt im Zuge des Umgangs mit besagten Umwälzungen insbesondere das gewachsene Bewusstsein gegenüber den hochkomplexen Wirkungszusammenhängen und teilweise gegenläufigen Prozessen, unter denen die Transformation der Städte stattfindet, die Planenden vor große Herausforderungen. Es muss nach neuen Wegen gesucht werden, auf denen unter effizientem Ressourceneinsatz rationelle Entscheidungen ermöglicht werden, die allen Aspekten der Stadtentwicklung Rechnung tragen und den komplexen Anforderungen gerecht werden.

Hierbei werden vor allem Ansätze der integrierten Stadtentwicklungspolitik eine zunehmend wichtige Rolle spielen, in deren Rahmen bestehende stadtplanerische und städtebauliche Aufgaben und Instrumente mit denen anderer raumrelevanter Politiken verknüpft werden sowie unter Einbeziehung aller am Stadtentwicklungsprozess beteiligten Akteure koordiniert werden (BMVBS [2007a]; S.2).

Die wachsende Bedeutung ganzheitlicher Strategien zum Schutz, zur Stärkung sowie zur Weiterentwicklung der europäischen Städte hat durch die ‚Leipzig Charta zur nachhaltigen europäischen Stadt', die im Rahmen eines informellen Treffens der für Stadtentwicklung zuständigen Minister aller EU-Mitgliedsstaaten im Mai 2007 in Leipzig verabschiedet wurde, ebenfalls Eingang in die europäische Politik gefunden. Neben der Forderung zur Erarbeitung gemeinsamer Grundsätze und Strategien zählen die besondere Berücksichtigung von benachteiligten Stadtquartieren im gesamtstädtischen Kontext sowie die Forderung, die Ansätze einer integrierten Stadtentwicklungspolitik stärker zu nutzen, zu den zentralen inhaltlichen Aussagen der ‚Leipzig Charta' (Ebenda). Zur Fortsetzung und konkreten Ausgestaltung des mit der ‚Leipzig Charta' auf europäischer Ebene begonnen Dialogs soll das ebenfalls im Jahr 2007 durch das Bundesministerium für Verkehr, Bau- und Stadtentwicklung veröffentlichte Memorandum ‚Auf dem Weg zu einer nationalen Stadtentwicklungspolitik' beitragen. Ausgehend vom Leitbild der europäischen Stadt sollen im Rahmen der nationalen Stadtentwicklungspolitik neue Strategien und Instrumente für gerechte, kooperative, nachhaltige und schöne Städte erarbeitet werden (BMVBS [2008]).

2.2 Planerische Herausforderungen im Rahmen der Schaffung nutzungsgemischter Stadtstrukturen

In Umsetzung der vorangegangen beschriebenen integrierten Ansätzen steht die Stadtplanung großen Herausforderungen gegenüber. Diese liegen einerseits in der Notwendigkeit zur Verknüpfung stadtplanerischer Aufgaben und Instrumente mit denen anderer raumrelevanter Politiken sowie andererseits in der Notwendigkeit zur Einbindung und Koordination der weiteren Akteure. Somit steht zum einen die Etablierung kooperativer Strategien der Stadtplanung im Vordergrund, mit deren Hilfe zum raumverträglichen und zukunftsfähigen Ausgleich der unterschiedlichen Ansprüche und Interessen beigetragen werden kann. Zum anderen kommt der Stadtplanung die Aufgabe zu, unter Berücksichtigung der vielfältigen Ansprüche an den Raum Entwicklungsmöglichkeiten mit dem Ziel eines schlüssigen und möglichst konfliktfreien zukünftigen Zustandes vorwegzunehmen und so zu verknüpfen, dass sie eine zielführende und belastbare Grundlage zur weiteren Entwicklung der städtischen Bereiche bilden.

Bezogen auf die Herausforderung zur Schaffung nutzungsgemischter Stadtstrukturen im Sinne der nahahltigen europäischen Stadt muss die Stadtplanung nach Wegen suchen, anhand derer beispielsweise den anhaltenden Entdichtungs- und Ausdünnungsprozessen sowie den damit einhergehenden Tendenzen zur weiteren Funktionstrennung (Jessen [2007]; S.57) in den Städten begegnet werden kann. Dies kann durch die Schaffung von Entwicklungsmöglichkeiten für Nutzungen geschehen, die beispielsweise aufgrund von bodenpreisbedingten Monostrukturierungsprozessen aus Kernstadtbereichen verdrängt wurden. Die Entwicklungspotentiale müssen durch das „Zusammenführen von Wohnen, Arbeit, Handel, Bildung, Freizeit und ÖPNV" (Kiepe [2007]; S.4) zur Herausbildung mischgenutzter Bereiche im Sinne der europäischen Stadt genutzt werden. Ein wesentliches Ziel bei der Etablierung nutzungsgemischter Stadtstrukturen ist hierbei in der Reduzierung der Verkehrsbelastungen durch den MIV in den Kernstädten. Die nutzungsgemischte Stadt muss durch stadtverträgliche Verkehrs- und Mobilitätskonzepte unter „Aufwertung des Fuß- und Radverkehrs und die verstärkte Förderung des ÖPNV" (Ebenda) unterstützt werden.

Die zentrale planerische Aufgabe liegt somit im Erhalt und in der Wiederherstellung von Multifunktionalität insbesondere in den Bereichen der Kernstädte, wobei vor dem Hintergrund der demographischen und sozialen Rahmenbedingungen insbesondere den Bedürfnissen älterer Menschen sowie der Bevölkerungsgruppen mit Migrationshintergrund Rechnung getragen werden muss (Ebenda).

„Was für eine Nutzungsmischung ist anzustreben, um die Integration von Ausländern und älteren Menschen in unser gesellschaftliches Leben zu ermöglichen? Welche bauliche Dichte ist angemessen, um gegenseitige Beeinträchtigungen zu vermeiden, aber eine zunehmende Zersiedelung der Landschaft zu verhindern" (Bielefeld/ El Khouli [2007]; S.34). Diese und andere Fragen gilt es sich zu stellen. Die nachfolgende Abbildung abstrahiert das Ziel einer kleinteiligen Nutzungsmischung.

Abb. 1: Nutzungsmischung im Städtebau (eigene Darstellung nach: Breuer/ Müller/ Wiegandt [2000]; S.8)

Potentiale zur Entwicklung und Etablierung neuer baulich-räumlicher Strukturen mit einem hohen Grad an Nutzungsmischung bieten sich hierbei im Rahmen der Reaktivierung von Brachflächen im Bestand, wie ehemaligen Bahnflächen oder Militärstandorten, bei Stadterweiterungen sowie bei der Stadterneuerung. In Folge einer höheren Nutzungsmischung kann den gegenwärtigen Entdichtungsprozessen entgegengewirkt werden, wodurch wiederum den Forderungen nach einem urbanen Zentrum, einer multifunktionalen Stadtstruktur und einer höheren Effizienz der Siedlungsstrukturen entsprochen werden kann. SIEDENTOP et al. geben allerdings zu bedenken, dass „von einem Sättigungspunkt ausgegangen werden [kann], oberhalb dessen keine weiteren Einsparungen an Ressourcen (z.B. Baustoffe, Energie, Kosten) pro Einheit Nutzfläche oder Haushalt mehr erzielt werden können“ (Siedentop et al. [2007]; 107). Auch gilt es die im Zuge einer Nutzungsverdichtung zunehmenden Konflikte mit nutzerbezogenen Präferenzen im Rahmen der Planung zu berücksichtigen (Ebenda).

Der diesem Handeln zugrundeliegende Anspruch der Stadtplanung, die gesamtstädtische Entwicklung im Sinne integrierter Strategien in räumlicher, ökonomischer und gesellschaftlicher Hinsicht zu steuern, setzt hierbei ein umfassendes Wissen über den zu planenden Raum, die darin stattfindenden ökonomischen und gesellschaftlichen Prozesse sowie deren Wirkungszusammenhänge voraus. Vor diesem Hintergrund muss nach Wegen gesucht werden, anhand derer die Entscheidungsfindung im Rahmen komplexer stadtplanerischer Fragestellungen unterstützt und qualifiziert werden kann.

3 COMPUTERBASIERTE VISUALISIERUNG UND SIMULATION IN DER STADTPLANUNG

3.1 Entscheidungsunterstützung in der Stadtplanung

Spricht man angesichts der sich wandelnden Rahmenbedingungen und den Herausforderungen bei der Schaffung nutzungsgemischter Stadtstrukturen von Unterstützung und Qualifizierung der Entscheidungsfindung, so spielt der Einsatz von Informations- und Kommunikationssystemen eine zunehmend tragende Rolle.

Während in diesem Zusammenhang die kommunikationstechnischen Anwendungsmöglichkeiten auf der prozessualen Seite, beispielsweise durch den ergänzenden Einsatz des Internets in Planungs- und Beteiligungsverfahren der Bauleitplanung (Steinebach/ Müller [2006]; S.7), zum Einsatz kommen, greift auf der materiellen Seite der Planverfahren die informationstechnische Komponente (Engelke [2002]; S.183). Letztere bietet vielfältige Möglichkeiten zur computergestützten Verarbeitung und Aufbereitung komplexer Datengrundlagen zur Qualifizierung der Planungsgrundlagen, zur zielgerichteten Bewertung und Abwägung aller relevanten Ansprüche und Bedürfnisse an den städtischen Raum sowie zur Abschätzung der möglichen Auswirkungen geplanter Maßnahmen.

Basierend auf den genannten Möglichkeiten lassen sich zwei grundsätzliche Ebenen identifizieren, unter denen die Entscheidungsfindung angesichts der komplexen stadtplanerischen Fragestellungen durch den Einsatz von EDV-Anwendungen unterstützt werden kann. Eine der besagten Ebenen ergibt sich aus den vielfältigen technischen Möglichkeiten zur Sammlung und Archivierung umfassender Datenbestände. Diese ermöglichen im Rahmen der Dokumentennavigation sowohl die zielführende Aufbereitung als auch die strukturierte Vorhaltung und kontinuierliche Aktualisierung aller für den Entscheidungsprozess notwendigen Informationen. Somit erlauben die EDV-Systeme den „schnellen Zugriff auf planungsrelevante Informationen im Sinne einer Hilfe und Unterstützung der planenden Instanzen“ (Pflueger [2000]; S.21) und dienen dadurch im Wesentlichen der „Planungsvorbereitung durch die Bereitstellung von raumbezogener

Information und raumbezogenen Analyseergebnissen“ (Schwarz-von Raumer [1999]; S.57). Die zweite Ebene zur Unterstützung der Entscheidungsfindung bildet sowohl die Möglichkeiten zur Analyse und Bewertung der zur Verfügung stehenden Daten als auch zur Simulation zukünftiger Entwicklungen. Zum einen lassen sich hiermit neue raumbezogene Daten durch die Verknüpfung von raum- und prozessbezogenen Daten gewinnen, deren Analyse und vergleichende Bewertung von Alternativen das Treffen planerischer Entscheidungen unmittelbar unterstützt. Zum anderen können durch die Simulation möglicher zukünftiger Zustände die Konsequenzen planerischen Handelns bereits im Vorfeld abgeschätzt werden und erlauben das Treffen von Entscheidungen im Sinne von hinreichend begründeten ‚Wenn- Dann‘-Aussagen.

Ausgehend von seinen Ursprüngen in den späten 1950er- Jahren fand in den darauf folgenden Jahrzehnten weltweit eine hochdynamische Entwicklung statt, die sowohl durch den rasanten technischen Fortschritt als auch durch zahlreiche Entwicklungssprünge und -brüche in gesellschaftlicher und fachlicher Hinsicht gekennzeichnet war. Basierend auf SAUBERER und KIAS (Sauberer [1984])/ Kias [1990]; S.119ff.) sowie unter Weiterführung der von ihnen definierten Phasen lässt sich die Entwicklung des EDV-Einsatzes in fünf wesentliche Adaptionsphasen unterteilen:

- die „Pionierphase“,
- die „Euphoriephase“,
- die „Realismusphase“,
- die „GIS-Phase“,
- die „Netz-Phase“.

Letzgenannte Phase fand in den letzten Jahren unter intensiver Fortentwicklung und weitgehender Etablierung von Netzwerktechnologien statt. „Die Vernetzung von Computern und einzelnen Arbeitsstationen erlaubt Formen der elektronischen Kommunikation, die ein ortsungebundenes und kooperatives Arbeiten auf verschiedenen Ebenen unterstützen“ (Pflueger [2000]; S.39). Die Verfügbarkeit von leistungsfähigen Netzwerken ermöglichte somit sowohl den Zugriff auf verteilte Datenbanken und deren Verknüpfung untereinander als auch die Nutzung und den gegenseitigen Austausch der zur Verfügung stehenden verteilten Daten und Methoden. Allem voran das Internet, dass sich durch die Verknüpfung von lokalen bis internationalen Computernetzwerken zu einem globalen Netzwerk entwickelte und im Zuge umfassender Privatisierungs- und Kommerzialisierungstendenzen seit Ende der 1990er-Jahre zu einem Massenmedium zur Kommunikation sowie zum Austausch von Informationen und Daten geworden war, begann in der Planung eine wesentliche Rolle zu spielen.

Zusammenfassend bildeten sich hierbei durch die neuen Möglichkeiten der Informations- und Kommunikationstechnologien nach PFLUEGER (Ebenda; S.37f.) fünf inhaltliche Schwerpunkte für den Einsatz in der Stadtplanung heraus:

- Optimierung von Planungsinformationssystemen durch verbessertes Daten- und Informationsmanagement.
- Neue Wege zur Projektsteuerung und zum verbesserten Controlling im Pla¬nungsprozess.
- Entwicklung und Bereitstellung offener, benutzerdefinierter Plattformen für entwurfsorientierte CAD- und GIS-Systeme.
- Das Internet als Medium für neue Formen und Strategien der Öffentlichkeits¬arbeit sowie der Partizipation.
- Weiterentwicklung computerbasierter Visualisierungs- und Simulationsformen im gesamten Planungsprozess.

Insbesondere die Nutzung computerbasierter Visualisierungen und Simulationen zur Darstellung räumlicher Sachverhalte sowie zur Vorwegnahme möglicher Entwicklungen leistet einen wichtigen Beitrag zur Qualifizierung des stadtplanerischen Handelns im Zuge der Schaffung nachhaltiger, nutzungsgemischter Stadtstrukturen.

3.2 Visualisierungen und Simulationen räumlicher Prozesse

Bezogen auf die Stadtplanung kommen visuelle Darstellungen auf zwei grundlegenden Ebenen zum Einsatz. Zum einen unterstützen sie das gezielte Erfassen, Analysieren und Verstehen der im stadtplanerischen Kontext relevanten Rahmenbedingungen, Prozesse und Wechselwirkungen. Visualisierungen leisten somit bereits im Vorfeld der eigentlichen Planung einen wichtigen Beitrag zur Sichtbarmachung und zum Verständnis räumlicher Situationen und Prozesse, aus dem sich planerische Maßnahmen zum Erreichen eines angestrebten zukünftigen Zustandes ableiten lassen. Zum anderen dient die visuelle Darstellung der eigentlichen Planungen sowohl der Überprüfung als auch der Erläuterung und Veranschaulichung möglicher zukünftiger Entwicklungszustände. Vor diesem Hintergrund sind Visualisierungen wie kein anderes Medium dazu geeignet, räumliche Planungen zwischen den am Planungsprozess beteiligten Akteuren sowie gegenüber der Öffentlichkeit zu kommunizieren.

Zusammenfassend kommt Visualisierungen im Kontext der Stadtplanung somit die Rolle eines zentralen Informations- und Kommunikationsmediums zu, welches sowohl die visuelle Abbildung quantitativer und qualitativer Raumeigenschaften und -zusammenhänge (Planungsnetzwerk geo-Innovation [2010]; S.2) als auch die umfassende Veranschaulichung der daraus resultierenden Planungen und ihrer Auswirkungen zum Gegenstand hat.

Über die visuelle Darstellung räumlicher Sachverhalte und möglicher Entwicklungszustände hinaus ermöglicht der EDV-Einsatz in der Stadtplanung die Simulation räumlicher Prozesse und somit das „Nachbilden eines dynamischen Prozesses in einem System mit Hilfe eines experimentierfähigen Modells, um zu Erkenntnissen zu gelangen, die auf die Wirklichkeit übertragbar sind“ (VDI-Richtlinie 3633 [1992]), Hieraus lassen sich die wesentlichen Aufgaben ablesen, die eine Simulation erfüllen muss. Diese liegen in der Beschreibung des Verhaltens von Systemen, in der Ableitung von Theorien und Hypothesen sowie letztendlich in der Vorhersage des zukünftigen Verhaltens dieser Systeme auch unter veränderten Rahmenbedingungen. Der Faktor Zeit spielt im Rahmen der Simulation in zweierlei Hinsicht eine wesentliche Rolle. Zum einen sollen aktuelle oder zukünftige Zustände zu vorab definierten Zeitpunkten in Form von Momentaufnahmen simuliert werden, zum anderen gilt es, dynamische Prozesse in ihrem zeitlichen Ablauf zu simulieren und diese Prozesse über bestimmte Zeitspannen hinweg nachzuahmen. Die Qualität der durchgeführten Simulationen und somit der auf diesen basierenden Erkenntnisse und Entscheidungen hängt dabei in hohem Maße von den hinterlegten Modellen sowie der Richtigkeit, Aktualität und Vollständigkeit der zugrundeliegenden Datensätze ab, anhand derer die Simulationen durchgeführt worden sind.

Angesichts rasanter und vielfältiger technischer Entwicklungen haben sich in den vergangenen Jahren unzählige neue Möglichkeiten und potentielle Einsatzfelder für Visualisierungen und Simulationen herausgebildet. Diese neuen Möglichkeiten haben bisher nur sehr eingeschränkt Eingang in die Planungspraxis gefunden, da die Planungswissenschaft nicht mit den tatsächlichen Entwicklungen mitgehalten hat und die technischen Neuerungen bislang lediglich auf experimenteller Ebene betrachtet.

Vor diesem Hintergrund stehen sowohl die Suche nach klar definierten Anwendungsfeldern im Kontext der Stadtplanung als auch die darauf aufbauende zielgerichtete technische Weiterentwicklung der bestehenden Anwendungen der Visualisierung und Simulation im Fokus der weiteren Untersuchung. Hierbei gilt es aktuelle Forschungsfelder und Entwicklungsrichtungen zu berücksichtigen und im Weiteren hinsichtlich ihrer Potentiale zur Qualifizierung der Stadtplanung mit ihren spezifischen Charakteristika und Aufgabenfeldern zu analysieren.

Gleichzeitig bildet der effektive und zielführende Einsatz der aus den rasanten Entwicklungen, insbesondere der letzten Jahre, hervorgegangenen vielfältigen Technologien und Anwendungen eine der aktuell größten Herausforderungen. Die nahezu unüberschaubare Menge an neuen Einsatzfeldern, wie sie sich beispielsweise durch weiterentwickelte CAD- und GI- Systeme, 3D-Stadtmodelle und Web Mapping-Tools bis hin zu den Möglichkeiten, die sich im Rahmen der so genannten ‚Neogeographie‘ (Eisnor [2006]) ergeben, bieten vielfältige Qualifizierungsmöglichkeiten für die gesamte Stadtplanung. Hierbei ist es zunächst von großer Bedeutung, diese neuen Technologien und Anwendungen kritisch auf ihre planungsrelevanten Einsatzmöglichkeiten hin zu analysieren und daraus Bedürfnisse abzuleiten (Berchtold/ Krass in: SRL [2007]; S.8), die den optimalen Einsatz und zielgerichtete Weiterentwicklung bestehender

Methoden und Anwendungen zur Darstellung der komplexen Rahmenbedingungen sowie zur Simulation räumlicher Prozesse und zukünftiger Entwicklungszustände ermöglichen.

4 3D- STADTMODELLE ZUR VISUALISIERUNG UND SIMULATION URBANER PROZESSE

4.1 Potentiale und Einsatzfelder von 3D-Stadtmodellen

Exemplarisch für die Weiterentwicklung im Bereich der Geografischen Informationssysteme steht die zunehmende Bedeutung der dritten Dimension bei der Darstellung räumlicher Sachverhalte und Planungen (Kleinschmit [2010]; S.190).

Während sich die Möglichkeiten zur dreidimensionalen Darstellung von zweidimensional erstellten Inhalten bereits sehr früh zum Standardrepertoire der CAD- und GI-Systeme entwickelten und hier, je nach Visualisierungszweck und eingesetzter Software, Planungen unter Ausnutzung der Vorteile dreidimensionaler Darstellungen in abstrakter bis hin zu fotorealistischer Weise abgebildet werden können, kommt 3D-Stadtmodellen in diesem Zusammenhang eine zunehmend bedeutende Rolle zu.

Neben den Vorteilen digitaler Visualisierungen sowie den generellen Potentialen dreidimensionaler Visualisierungen zeichnen sich digitale 3D-Stadtmodelle gegenüber physischen Modellen in erster Linie durch ihre hohe Flexibilität aus.

- Schnelle Modifizier- und Erweiterbarkeit bei gleichzeitiger hoher räumlicher und grafischer Genauigkeit,
- freie Wahl des Blickwinkels und Erlebbarkeit der Stadtstrukturen mittels festgelegter Animationspfade oder der freien ‚Begehung',
- vielfältige Möglichkeiten zur Veröffentlichung und Verteilung beispielsweise über das Internet
- sowie Möglichkeiten zur Integration raumbezogener Datenbanken und Anwendungen zur Simulation räumlicher Prozesse

stellen hierbei einige der mit der Nutzung von 3D-Stadtmodellen verbundenen Potentiale dar.

Eine wegweisende Entwicklung für die zunehmende Etablierung und vielfältige Nutzung von virtuellen 3D-Stadtmodellen war hierbei die Etablierung des ‚CityGML' -Standards zur Erstellung und Editierung der Modelle sowie zum Aufbau der zugrundeliegenden Datenbanken (www.opengeospatial.org; Zugriff: 12.11.2011). Im Jahre 2008 wurde ‚City-GML' durch das ‚Open Geospatial Consortium' (OGC) als internationaler Standard definiert (Ebenda). Im Rahmen der hiermit verbundenen Vorschriften zur Modellierung und zum Aufbau der 3D-Stadtmodelle wurden unter anderem verschiedene Modellierungsebenen festgelegt. Gemäß ihrer Detaillierungsgrade unterscheidet man hierbei fünf ‚LODs – Levels of Detail', die sich wie folgt kategorisieren lassen (Slingsby/ Raper [2008]; S.51):

- LOD 0 in Form von digitalen Geländemodellen, die auf regionaler Ebene zum Einsatz kommen und je nach Einsatzzweck um Texturen und Orthofotos ergänzt werden,
- LOD 1 zur Abbildung von Stadt- und Baustrukturen durch die Extrusion von flächen- oder gebäudescharfen Kubaturen aus dem Geländemodell,
- LOD 2 als die Ergänzung der Gebäudekubaturen um Dachformen, sowie gegebenenfalls prägende Anbauten und grobe Texturen
- LOD 3 visualisiert Einzelgebäude oder Gebäudegruppen inklusive umfassender architektonischer Details und stellt somit ein klassisches Architekturmodell dar,
- LOD 4 ergänzt als Innenraummodell das Architekturmodell um Aussagen zur inneren Organisation der Gebäude und ihrer Gestaltung.

Hinsichtlich ihrer Bedeutung für die Stadtplanung stellen digitale 3D-Stadtmodelle in erster Linie ein wichtiges Instrument zur Kommunikation, Diskussion und Vermarktung räumlicher Planungen dar. Anhand der dreidimensionalen Visualisierung der gegebenen räumlichen Rahmenbedingungen als auch des geplanten zukünftigen Zustandes kann allen am Planungsprozess beteiligten Akteuren ein sehr guter Eindruck der tatsächlichen Wirkung einer Planung vermittelt werden.

Abb. 2: 3D-Stadtmodell mit Texturen als Zusatzinformation am Beispiel Londons (www.bp.blogspot.com; Zugriff: 18.03.2011)

Gleichzeitig bilden sie durch die Möglichkeiten zur statischen oder dynamischen Darstellung räumlicher Zusammenhänge und Wechselwirkungen ein wertvolles Analysetool, beispielsweise im Rahmen von Simulationen zur Schadstoffausbreitung oder zur Simulation der möglichen Auswirkungen einer Planung bereits im Vorfeld. Vor diesem Hintergrund erfüllen Stadtmodelle auch im Rahmen des Entwerfens unter komplexen Rahmenbedingungen wichtige Funktionen bei der Erstellung und Überprüfung planerischer Alternativen.

4.2 Hemmnisse hinsichtlich des Einsatzes von 3D-Stadtmodellen

Trotz weitreichenden technologischen und methodischen Entwicklungen in den vergangenen Jahren steht der Einsatz von 3D-Stadtmodellen in der Stadtplanung noch großen Hemmnissen gegenüber, die im Wesentlichen folgende Bereiche umfassen:

- hohe Kosten im Rahmen der Datenbeschaffung, des Kaufs der zum Einsatz notwendigen Hard- und Softwareausstattung sowie zur Schulung der Mitarbeiter (Kleinschmitt [2010]; S.187),
- eingeschränkte Interoperabilität sowohl zwischen den unterschiedlichen Systemen und Anwendungen der Visualisierung und Simulation als auch der zugrundeliegenden Datensätze,
- fehlende Standards bezüglich Verwaltung, Herausgabe und Kosten planungsrelevanter Daten,
- vorhandene Softwarearchitekturen erfordern zeitintensive Einarbeitung, da ihre Handhabung in der Regel nicht intuitiven Handlungsweisen folgt (Hagen et al. [2006]),
- anhaltende Dominanz zweidimensionaler Anzeigemedien trotz wachsender Bedeutung dreidimensionaler Visualisierungstechniken (Wietzel [2007]; S.241),
- fehlende Transparenz und Verständlichkeit komplexer Simulationen versus geringe Praxisrelevanz zu stark vereinfachter Simulationsmodelle und
- mangelnde Flexibilität und Modularität bestehender Stadtmodelle.

Gleichzeitig bildet der effektive und zielführende Einsatz der aus den Entwicklungen der vergangenen Jahre hervorgegangenen vielfältigen neuen Technologien und Anwendungen eine der aktuell größten Herausforderungen auch im Rahmen der Nutzung von 3D-Stadtmodellen. Die nahezu unüberschaubare Menge an neuen Einsatzfeldern, wie sie sich beispielsweise durch weiterentwickelte CAD- und GI- Systeme, und Web-Mapping-Tools bis hin zu den Möglichkeiten, die sich im Rahmen der so genannten ‚Neogeographie' (Eisnor [2006]) ergeben, ermöglichen vielfältige neue Einsatzfelder, die es in die bestehenden 3D-Modelle zu integrieren gilt. Hierbei ist es zunächst von großer Bedeutung, diese neuen Technologien und Anwendungen kritisch auf ihre planungsrelevanten Einsatzmöglichkeiten hin zu analysieren und daraus Bedürfnisse abzuleiten (Berchtold/ Krass in: SRL [2007]; S.8), die den optimalen Einsatz und zielgerichtete Weiterentwicklung bestehender Modelle ermöglichen.

In ihrer Gesamtheit lassen sich diese Hemmnisse am Besten in der großen Diskrepanz zwischen dem Stand von Technik und Wissenschaft sowie dem eigentlichen Einsatz in der Planungspraxis beobachten. Bei letzterem stehen Faktoren wie unklare Einsatzfelder, geringe Transparenz und Nachvollziehbarkeit sowie zahlreiche technische Hürden dem umfassenden Eingang in das Planungshandeln entgegen.

4.3 Ansätze zur Qualifizierung von 3D-Stadtmodellen

Um den vorangegangen aufgeführten Hemmnissen, denen der zielgerichtete Einsatz von digitalen 3D-Stadtmodellen aktuell gegenübersteht, effektiv begegnen zu können, bedarf es neben der rein technischen Auseinandersetzung mit den gegebenen Einschränkungen in zahlreichen Fällen auch der interdisziplinären Forschung unter intensiver Beteiligung der Planungswissenschaften.

Hierin spiegeln sich die zwei Ebenen wieder, unter denen die Qualifizierung von 3D-Stadtmodellen erfolgen muss. Während sich die erste Ebene in methodischer und inhaltlicher Hinsicht mit den Anforderungen der Stadtplanung an das zielgerichtete und effektive Arbeiten mit 3D-Stadtmodellen auseinandersetzt, steht auf der zweiten ebene die Auseinandersetzung mit den bestehenden technischen Möglichkeiten zur Visualisierung räumlicher Sachverhalte und zur Simulation städtischer Prozesse mittels 3D-Stadtmodellen im Fordergrund.

4.3.1 Inhaltliche Ebene

Bezogen auf das Ziel der Schaffung nutzungsgemischter Stadtstrukturen im Sinne der nachhaltigen europäischen Stadt müssen seitens der Stadtplanung Anwendungsfelder für 3D-Stadtmodelle sowie daraus resultierende Anforderungen definiert werden, anhand derer zielführend und effektiv bestmögliche Informations- und Entscheidungsgrundlagen geschaffen werden können. Angesichts der besonderen Herausforderungen der Planung im Bestand müssen hierbei vielfältige, teilweise gegenläufige Entwicklungstrends in die integrierte Betrachtung miteinbezogen und der bestmögliche Ausgleich der Ansprüche an den städtischen Raum sichergestellt werden. 3D-Stadtmodellen kommt hierbei die Aufgabe zu, die Bestimmungsfaktoren der räumlichen Entwicklung zielgerichtet darzustellen und mögliche räumliche Entwicklungen zu simulieren. Besagte Bestimmungsfaktoren reichen hierbei von äußeren Bestimmungsfaktoren wie ökonomischen, gesellschaftlichen, demographischen und rechtlichen Rahmenbedingungen sowie übergeordneten Planungszielen bis hin zu lokalen Bestimmungsfaktoren beispielsweise der Bau-, Raum-, Verkehrs-, Akteurs- und Sozialstrukturen.

Zur Identifikation weiterer Anforderungen zur zielgerichteten Weiterentwicklungen der Methoden und Anwendungen der Visualisierung und Simulation ist die Planungswissenschaft gefordert, unter Beteiligung der Informatik und weiterer relevanter Disziplinen, vertiefende Erkenntnisse, beispielsweise auch aus den Bereichen der ‚Human-Computer-Interaction' oder der Wahrnehmungspsychologie, zu gewinnen.

4.3.2 Technische Ebene

Hinsichtlich der Möglichkeiten zur Weiterentwicklung der 3D-Stadtmodelle gilt es, diese als eigenständige Kommunikations-, Entscheidungsunterstützungs- und Planungsinstrumente herauszubilden. In Ergänzung ihres ursprünglichen Einsatzzweckes zur reinen Abbildung räumlicher Sachverhalte und Planungen können sie hierbei zunehmend auch als Datenbanken zur georeferenzierten Speicherung großer Datenmengen sowie als Instrumente zu deren direkten, thematisch differenzierten Darstellung im dreidimensionalen Kontext Einsatz finden. Darüber hinausgehend haben sich, insbesondere im Zusammenhang mit den Entwicklungen des ‚Web 2.0', dynamische 3D-Stadtmodelle etabliert, die neben der Integration von statischen GIS-Funktionalitäten auch die Durchführung von raumbezogenen Simulationen erlauben.

Diese Entwicklungen ermöglichen der Stadtplanung neben der Visualisierung räumlicher Rahmenbedingungen und möglicher Entwicklungszustände auch die Simulation dynamischer Prozesse im dreidimensionalen Kontext. Gleichzeitig muss gewährleistet sein, dass der stadtplanerisch Entwerfende in der Anwendungsumgebung eines 3D-Stadtmodells stufenlos zwischen unterschiedlichen räumlichen Ebenen sowie verschiedenen Detaillierungsgraden wechseln und somit in optimaler Weise beispielsweise die stadträumlichen Konsequenzen seiner Planung analysieren und beurteilen kann. „Mit dem starren Sandkastenblick aus der Distanz ist es vorbei. Die Stadtentwerfer zoomen heute locker in die spezifische Situation des geographischen, wirtschaftlichen, soziologischen oder kulturellen Terrains hinein – und von da zur Gesamtschau zurück" (Hanimann [2009]; S.3).

Weiterhin müssen die Entwicklungsrichtungen im Bereich der Visualisierung durch die neuen Möglichkeiten zur weitreichenden Vernetzung und Interaktion, wie beispielsweise durch das ‚World Wide Web', gesehen werden. Diese Entwicklungsrichtungen umfassen:

- die kontinuierliche Weiterentwicklung von ‚Web 2.0'-Anwendungen hinsichtlich ihrer Möglichkeiten zur Visualisierung raumbezogener Informationen,
- die Identifizierung von Anwendungsfeldern im Zuge der Herausbildung des ‚Semantic Web',
- den Einsatz von ‚Web Mapping'-Diensten zur Analyse raumbezogener Informationen, beispielsweise durch die Integration von GIS-Funktionalitäten,
- die Nutzung der Möglichkeiten zur ortsungebundenen Kommunikation und Interaktion in Verbindung mit Anwendungen der ‚Neogeografie' zur Verortung und Echtzeitvisualisierung räumlicher Informationen,
- die Etablierung neuer interaktiver und kollaborativer Elemente der ‚Augmented Reality' und der ‚Virtual Reality' zur Visualisierung raumbezogener Daten und Informationen.

Eine daraus resultierende Anforderung an 3D-Stadtmodelle ist somit in ihrer Flexibilität zu sehen. Hierbei darf Flexibilität nicht im Sinne von ‚anything goes', sondern vielmehr als die Definition von fixen und flexiblen Elementen (Christiaanse [n.b.]; S.1) gesehen werden, die auf ihre wesentlichen Inhalte reduziert sind und sich gleichzeitig flexibel erweitern und hinsichtlich ihrer Eigenschaften modifizieren lassen.

Zur Gewährleistung der geforderten Flexibilität ist eine weitere wesentliche Anforderung in der weitestmöglichen Standardisierung und Interoperabilität zu sehen. Diese Forderung umfasst sowohl die zur Verfügung stehenden raumrelevanten Daten als auch die integrierten Möglichkeiten der Visualisierung und Simulation. Bezogen auf die Datengrundlagen steht die Schaffung einheitlicher Geodateninfrastrukturen sowie die Etablierung von Standards bezüglich Verwaltung, Herausgabe und Kosten planungsrelevanter Daten im Fokus. Bezüglich der Anwendungen stellen die Etablierung von Schnittstellen sowie die Integration unterschiedlicher Anwendungen innerhalb eines Systems die Schwerpunkte dar. Als Beispiel für eine derartige Anwendung kann ein 3D-Stadtmodell gesehen werden, dass um GIS-Funktionalitäten oder Simulationsprogramme ergänzt wurde.

5 FAZIT

Vor dem Hintergrund der Bewältigung des demografischen, ökonomischen und gesellschaftlichen Wandels sowie dem Ziel der Schaffung nachhaltiger, nutzungsgemischter Stadtstrukturen steht die Stadtplanung vielfältigen Herausforderungen gegenüber. Es müssen Strategien und Instrumente etabliert werden, anhand dener unter effizientem Ressourceneinsatz Entscheidungen ermöglicht werden, die den zunehmend komplexen Anforderungen gerecht werden.

Hierbei kommt insbesondere dem Einsatz computerbasierter Visualisierungen und Simulationen zur Darstellung räumlicher Sachverhalte sowie zur Vorwegnahme möglicher Entwicklungen wesentliche Bedeutung bei der Qualifizierung stadtplanerischen Handelns zu. Ein zentrales Instrument ist hierbei in 3D-Stadtmodellen zu sehen, die es als eigenständige Kommunikations-, Entscheidungsunterstützungs- und Planungsinstrumente zu etablieren gilt.

Wesentliche Anforderungen hinsichtlich des zukünftigen Einsatzes von 3D-Stadtmodellen zur Visualisierung und Simulation räumlicher Prozesse sind in der Gewährleistung größtmöglicher Flexibilität sowie der weitestmöglichen Schaffung einheitlicher Standards zu sehen. Die Fortführung der Suche nach Einsatzfeldern und Qualifikationsmöglichkeiten muss hierbei Gegenstand interdisziplinärer Forschung sein.

Ecological Problems of Motor Transport of Azerbaijan

Piriyev Yakub Maksim oglu, Gozalov Sulhaddin Kamal oglu

(Piriyev Yakub Maksim oglu, dean of faculty of transportation of Azerbaijan University of Architecture and Construction, Ph.D., Associate Professor)
(Gozalov Sulhaddin Kamal oglu, head chair of «Automobile Transportation» of Azerbaijan Technical University, Ph.D., Associate Professor)

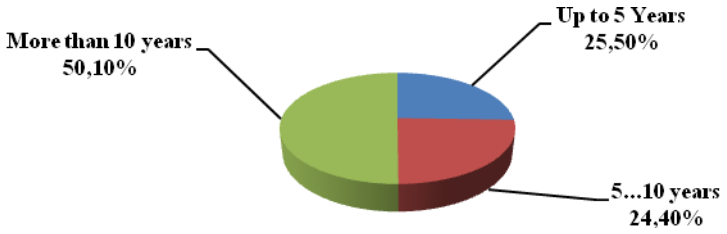
Automobile transport is one of the leading and the most complex means in the transport system of Azerbaijan.

Over the past decade the motor transport has been developing at faster pace relative to other transport modes and sectors of economy (Table 1). This has been provided by its objective advantages supplemented by significant progress in the field of road construction and construction of motor vehicles. It should be noted that the number of cars per 1000 people was 55 in 2000 while in 2011 it was about 115. Currently, the number of car park of the Azerbaijan Republic is more than one million units.

Years	2003	2004	2005	2006	2007	2008	2009	2010	2011
Number of automobiles, unit.									
Azerbaijan	511 460	554 031	612 069	690 012	773318	860 047	925 866	982 553	1030079

Table 1

Car park of the country is relatively old (as shown in the following diagram) and the average age is about 10 years, where about 20% of the car park is being exploited for more than 15 years, and part of that car park has been completely worn out and should be disposed off.



Age structure of the car park of the Azerbaijan

The process of motorization had a significant influence on the rapid development of the economy and social sphere. However, one of the main problems in the motorization of the country are the environmental problems, similar to all developed countries. Motorization in the Republic leads to intense pollution of the environment.

The actual total mass of emissions can be determined by the expression:

$$M = \sum_{i=1}^{n} m_{i.n} \cdot K_{i.m.c} \cdot A_i \cdot L_{i.q};$$

where:

$m_{i.n}$-the regulatory allowable weight of i harmful emissions:

$K_{i.m.c}$-Coefficient taking into account the influence of technical conditions of the vehicle for the weight of i harmful emissions:

A_i-The number of the vehicles of type i:

$L_{i.q}$-The average annual mileage of the vehicles of type i

According to the calculations the total annual amount of emissions of the car park of Azerbaijan Republic (with good technical condition of vehicles) is about one million tons. Of these, about 600 tons of carbon monoxide (CO), 240 tons of hydrocarbon (CH), 85 tons of nitrogen oxides (NOx), 25 tons of soot and 0.05 tons of lead.

In conditions of rapid growth of the car park other problems rise related to the complexity of the situation in organisation of transportation safety in the field of road safety. As a result, road accident rate also increases.

Analysis of accident statistics (Fig. 1) shows that the majority of them are directly or indirectly related to the intensity or tightness of transport movement.

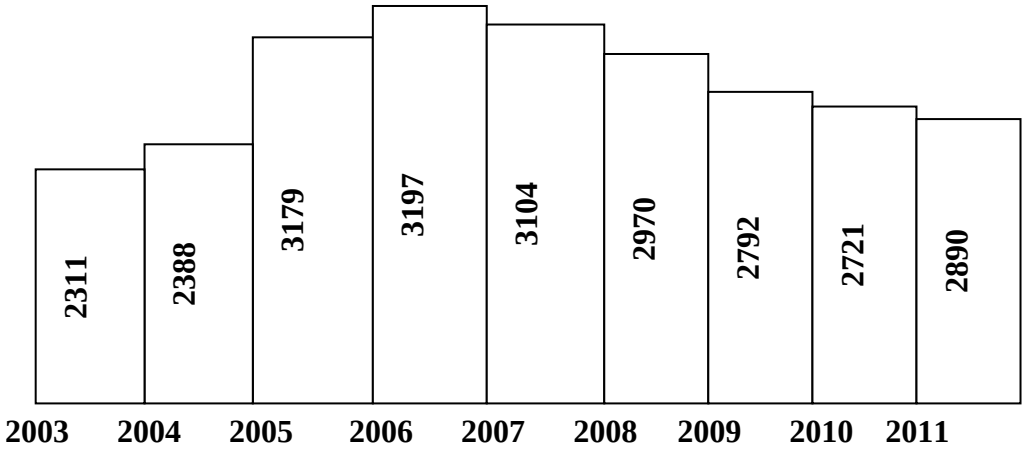


Fig.1. Dynamics of road traffic accident change in Azerbaijan

In addition, one of the main negative aspects is the uneven distribution of the car park around the regions of the country, which is typical for most of CIS countries. That is why, a complex situation regarding the environmental safety and organization of road safety has particularly emerged in Baku. Rapid growth of private car park should also be considered as one of the main reasons for this situation along with unsatisfactory road conditions. Currently, about 60% of the vehicles are located in Baku. It should be noted that the statistics do not consider the number of cars whose drivers are temporarily working and living in Baku without official registration. The accumulation of the main part of the car park in Baku creates huge problems, both in terms of traffic safety (occurrence of traffic jams), and urban air pollution. Proportion of the road transport vehicles in the total amount of pollutants' emissions into the atmosphere by all man-made sources is up to 75%, and the noise impact on the city's population is 85-90%. The greatest harm from air pollution is effecting people. International experience suggests that the biggest concern in this context usually causes such pollutants of the urban environment as lead and fine aerosols. These pollutants result from the use of leaded gasoline.

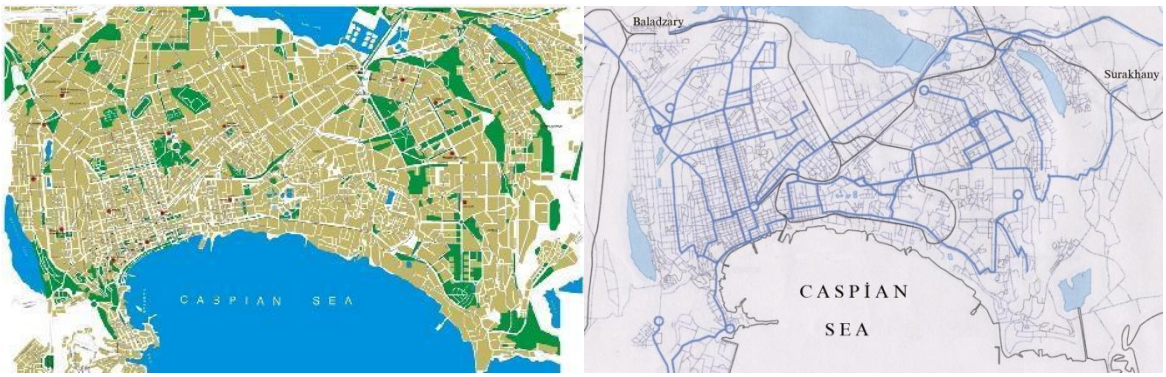

Fig. 2. Scheme of street road network of Baku

One of the main problems of the process of motorization in the Republic is a growing discrepancy between the rate of growth of motorization and the demand for transportion to the rate of development of roads. It would be enough to compare the growth dynamics of cars and roads in the city of Baku for the last 9 years (Table). As can be seen from the table (data from the State Committee on Statistics of Azerbaijan Republic),

the total number of vehicles for the period rose by more than 3.0 times, whereas the total length of the roads increased only by about 16.0%.

Number of Automobiles, units.									
City Baku	205 072	249 857	295 862	363 918	427 083	502 369	549 511	598 132	638 649
Roads, km									
City Baku	1923	1963	2018	2087	2113	2138	2173	2198	2223

Table 2

Baku is an acient city with its formed architecture layout and a complex scheme of the road network (Fig. 2). A part of the city (the old part of town and "Icheri Sheher") was built on a rectangular pattern layout of the road network, another part of the microregions on a neighborhood scheme, and some parts are based on a free style. So this in its turn makes the optimal functioning of the traffic flow and operation of the services and facilities that are responsible for the organization and regulation of traffic even more complicated. The total length of road network suitable for car traffic in Baku city is about 2173 km. Given the above data the most simple and approximate calculations show that for normal traffic conditions (at the level of street and road load of Z = 0.4 ... 0.6) that there is a need for 3550 km of single-lane streets more(which is 1775 km of two-lane or 888 km of four-lane streets).

For constrained motion, these values would be about 1056 km of single-lane or 528 km of two-lane, or 264 km of four-lane streets respectively. Whereas the number of visitors, parked cars and the coefficient of getting to the line which was equal to 0.7 were also taken into account. According to the calculations it is clearly seen that the traffic is particularly busy on the main highways of Baku, especially around the central parts, additionally almost blocked or completely blocked during the “peak” hours. It is impossible to improve the movement on the roads by usual organizational and management methods, which contributes to traffic accidents, increase of emissions and noise pollution, increase in the delay of passengers and cargo transfer.

Different methods are being used in order to change the traffic situation and thus improve the ecological situation in Baku. The most typical of which are the following:

- parking management system (paid parking, parking restrictions);
- development of the public transport network (construction of new subway stations, increasing the length of public transport routes);
- construction of new multi-storey interchanges, tunnels, express highways, construction of new highways;
- restricted access of vehicles to certain areas of the city (the introduction of residential and pedestrian areas, prohibition or restriction of movement of freight transport).

Fig. 3.Transport infrastructure of Baku city

All these methods and tools used in practice do not respond flexibily enough to the traffic conditions and do not provide radical solutions to environmental problems of road transport.

In order to improve traffic management and to provide significant changes in the environmental impact of road transport in Baku the center of intellectual control of transport processes (cictp) has been introduced for explotation in December 2011. This is a comprehensive system of information support and management on land road transport based on the use of modern information and telecommunication technologies and management practices.

Fig. 4. Centre for Intelectual Controle of Transportation Process in Baku

The introduction of the center of intelligent management of traffic processes allows to reduce delays in traffic, travel time and decrease the volume of harmful emissions.

In general, in order to reduce the harmful effects of road transport on the environment of Azerbaijan and to provide the rational management of environmental activities he following must be done:

- The organization of effective management of environmental activities through targeted program planning;
- A gradual upgrade of the age and structure of the car park of the republic:

- Improvement of existing industrial and technological base for the control of technical condition and maintenance of vehicles:
- Creating an effective system of environmental control and monitoring using a network of stationary and mobile monitoring stations, as well as points of control of environmental parameters of vehicles;
- A combination of legal and economic methods of environmental management in transportation;
- The use of mandatory certification on environmental standards for vehicles, fuel, equipment, technology, etc:
- Development of a system of environmental training and retraining of transport specialists.

In order to implement these areas enormous work is being done to improve and technically upgrade the entire transportat system of Azerbaijan in recent years.

Effects Comparison of Tools to Control the Traffic Demand as an Instrument of Urban Environmental and Climate Policy

Dietrich Leihs

(Dipl.-Ing. (FH) Dietrich Leihs, MAS, Kapsch TrafficCom AG, Am Europlatz 2, 1120 Vienna, dietrich.leihs@kapsch.net)

1 ABSTRACT

The Clean Air Directive did not aim to traffic emissions only, but one of the consequences were more than 160 Low Emission Zones throughout Europe, regulating the traffic from polluter cars in urban areas. Most of the Low Emission Zones are drive bans for vehicles with high PM emissions, some are charged zones. Both variants proved to be in a position to change traveler behaviour, though charged zones tend to be more flexible than drive ban zones as people have more time to adopt, more people can be affected, the zones can be substantially larger and the scheme can be tightened more sensitive. Assuming that the instrument of Low Emission Zones might be applied to carbon emissions as well leaves nearly no option but charged zones due to these reasons. As a consequence, the charging scheme is crucial in order to help reducing carbon emissions. Basically two different charging principles are discussed in Europe: conventional cordon prizing and mileage based pricing. With cordon pricing, the charge gets due when passing the zone boundaries, while with mileage based pricing, the charge increases with the distance traveled. So obviously, mileage based pricing is more suitable as it follows the polluter-pays-principle while cordon pricing seems to be insensitive to this. By applying traffic models and demand elasticity models it is possible to determine the achievable benefit of both; comparing this benefit to the system cost leads to the cost-benefit-analysis of both principles. An example is given in this paper.

2 BACKGROUND

The citizens' request for healthy and livable city centers as well as legal regulations like the EU Ambient Air Quality directive [1] effect communalities to take action in order to reduce air pollutants immissions. This directive fixes the threshold values for important pollutants like SO2, NOX, particle matter, etc. Any European citizen can claim for proper measures to be taken by the regional government. Communalities are reacting; in Europe some 160 low emission zones were set up, more will follow.

3 INTRODUCING LOW EMISSION ZONES

According to the Low Emissions Zones Network [2], Low Emission Zones (LEZs) are areas where polluting vehicles are restricted from entering. This means that polluter vehicles are banned or have to pay a charge. The emissions that are aimed to be reduced by LEZs are mainly particle matter and sometimes nitrogen dioxide.

The existing ~160 European LEZs can be classified into the following categories:

	Drive ban	***Charge***
All Vehicles	e.g. German LEZ	Milan Ecopass
Heavy Goods Vehicles (HGV)	e.g. Netherland LEZ	e.g. London LEZ

Table 1: Categories of Low Emission Zones

The experience on these categories can be summed up as follows:

- All vehicles drive bans: The ban affects the whole vehicle fleet (private + commercial) by pollution class sensitively excluding from entering the zone.
- HGV Drive bans: Commercial vehicles are pollution class sensitively excluded from entering the zone.
- HGV charge: Commercial vehicles have to pay a charge according to the pollution class when entering the zone.
- All vehicles charge: All vehicles are subject to a pollution sensitive charge when entering the zone

3.1 Effects of Drive Bans

Drive bans are immediately effective from the first day on; hence this is the fastest way to reduce traffic pollution - if the driver's compliance is enforced.

However, drive bans make necessary a sudden behavioral change like using public transport instead of the private cars or investing into modern or green cars. Frequently, due to the financial burden, certain sections of the population are disadvantaged in adopting properly; such are low income groups, families with many children, economically inactive households, handicapped people and small scale enterprises. A typical vehicle distribution according to the pollution class is shown in Fig. 1.

As vehicles that fail the access criteria become practically worthless, debates are regularly picked up about governmental overriding of private rights. These debates completely overlay the debate about the ecological reasons and the necessity for behavioral changes. In addition, exemptions from the drive ban as well as long transitional periods are set to smooth the deployment, indeed compromising the fact of a rapid pollution reduction, counting on the natural renewal of the vehicle fleet. Applied to the general public, driving bans are very likely to miss the target of sustainably setting minds and changing mobility habits; although applied to the commercial segment (HGV), pollution reductions are achievable: Being electronically enforced, the HGV specific LEZs in The Netherlands caused a significant higher share of less polluting Euro-4 and Euro-5 vehicles within the zone than outside, resulting in a concentration reduction of -0.2 ... -1.1 µg/m³ for NO2 and -0.1 ... -0.6 µg/m³ for PM10 [2].

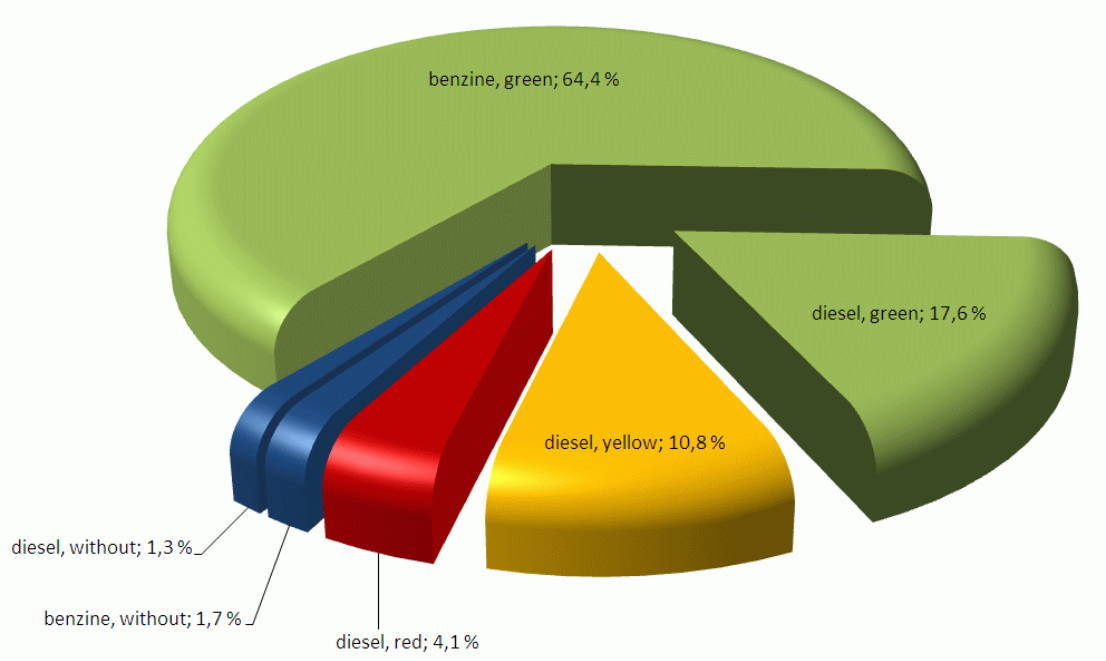

Fig. 1: Typical distribution of passenger cars in a city of ~100.000 inhabitants that is categorizing vehicles according to the PM10 pollution class; the class is depicted with coloured stickers (green for less polluting vehicles, yellow for the mid range, red for heavily polluting vehicles, no sticker in case the vehicle is too old for categorizing); vehicles are excluded from entering the zone according to the sticker color (name of the city is known to the author, source: web-based vehicle registration statistics of the city).

It is noteworthy that the driving bans are static, i.e. 7 x 24, during working hours, etc. Though, particle matter and other emissions and immissions heavily depend on dynamic influence factors like the weather situation or the traffic situation, particularly congestion [5]. Most of all, PM immissions vary seasonally. During summer, the near-ground air gets heated up and rises; wind distributes the particle matter over a larger area, consequentially the pollution in the city is reduced. During winter though, the near-ground air stays where it is and particle matter concentrates with on-going traffic. Additional PM sources are house fires and winter road sand. If precipitation stays out, the air is not cleaned. The immissions thresholds may be exceeded even without any traffic contribution. At the other hand, if the weather is favorable, traffic eventually does not lead to an exceeding of the thresholds. In the first case the driving ban is reasonable, in the second case the driving ban comes to nothing. Particularly the second argument is taken up by lobby groups and gets part of the public discussion, knowing that there are other traffic related emissions like CO2 that are not covered by the driving ban.

3.2 Effects of Charged Low Emission Zones

Charging at the other hand promises a smoother but more sustainable behavioral change as the affected population is not completely excluded from entering the city; people may adopt according to the individual

capabilities and needs. The London LEZ for instance with its nearly 1500 km² aims at the commercial segment [11]; namely HGV have to pay a day pass ticket of 200£ (100£ for vans and minibuses) depending on their pollution class. The result was that fleets were reorganized; in the meantime, a near 100% compliance with the appointed minimum emission class is recognized. Concerning CO2, there may be some small benefits through newer and more fuel-efficient vehicles being introduced into the fleet as a result of the scheme, but the zone does not specifically target CO2 emissions.

On the other hand, charging can be applied to private cars as well: With the "Ecopass" program, the Italian city of Milan charges according to a Euro emission class model [7]. Vehicles with the worst pollution class have to pay a day pass ticket for 10€, other, less polluting vehicles have to pay 2€ or 5€; the most modern vehicles including GPL fuelled vehicles have free access to the zone. The polluter cars were reduced by -56.7% in the first year of operation. Pollution could be reduced quickly; the effects are measurable even outside the zone. Finally, CO2 was reduced by 9% [8]. Secondary effects like reduced congestion and less parking pressure were measurable.

3.3 From LEZ to L-GHG

LEZ with drive bans are hardly an option to be used as a Low Greenhouse Gas Zone because drive bans are digital: Vehicles are excluded or they may enter. Long transition periods would be needed, the political consensus would end up with transition phases that are close to the natural fleet renewal, probably foiling the Commission's White Paper on Transport target of halving the GHG emissions from private car use in cities until 2030 [3]. Considering the experience with conventional LEZ, charged schemes obviously seem to be the better choice.

By analyzing the existing charged LEZs, a traffic cut can be observed; hence GHG is reduced accordingly as shown above. On the long run LEZs produce a shift from old cars to new – compliant – cars. Concerning CO2, there are some small benefits through newer and more fuel-efficient vehicles being introduced into the fleet as a result of the scheme, but no zone specifically targets CO2 emissions. Consequentially, the CO2 reduction first of all comes from the fleet renewal but will increase again according to general traffic increases. This can be demonstrated in the city of Milan, where the daily traffic volume in the zone was cut from 98 thousand to 87 thousand vehicles (see Fig. 2). The scheme encourages the usage of less polluting modern vehicles – and they are entering; People change from older cars to newer ones, but they do not sustainably change their behavior. The vehicles have less polluting engines, though the scheme helps less with congestion [4], bringing the well known increased fuel consumption due to stop-and-go operation and particle matter emissions due to tire and break abrasion – being emitted even by electric vehicles. At the same time, the revenues collected diminish, threatening the ability to keep the system in operation.

Though, is there a hint that a conventional charged LEZ can be turned into a Low GHG zone? By analyzing the time period shortly after introducing the scheme, two behavioral changes are recognizable [6]:

(1) The polluter cars were reduced by -56.7% in the first year of operation. This was a less sustainable achievement as many of those cars are being substituted by less polluting Euro 4&5 vehicles that are not subject to charging.

(2) Car traffic dropped by 5 million vehicles in the first year of operation – at the same time, 35 million additional rides took place in public transport. The local public transport operator increased the rolling stock capacity prior to the introduction.

The lessons learned from the Ecopass program are the following:

The paying for pollution principle is in a position to encourage behavioral changes. people use more public transport instead of (polluting) private cars or renew the fleet in a significant dimension;

The sustainability of behavioral changes depends on the applied scheme; Making GHG emissions part of the scheme allows selectively decarbonising cities;

A prerequisite of introducing such a scheme is the consensual decision making as well as the public consultancy in order to generate knowledge and acceptance.

4 COMPARING CORDON CHARGING TO MILEAGE-BASED CHARGING

Access regulation turns out to be a strong instrument to change traveler behaviour towards a smaller footprint. Applying driving bans for not complying vehicles is simply not feasible, as too many people would be excluded; apart of that, the zones need to be large in order to achieve a substantial effect. So the remaining option is charged zones, accompanied by information & education and a balanced mix of complementary measures. The decision making process of charged zones though covers two crucial questions:

Which measure or scheme can achieve the desired effect while polluter-pays-principle is kept in a fair and transparent way?

Is the cost-benefit-ratio positive?

4.1 Effects comparison of cordon pricing and mileage-based pricing

With cordon pricing, a flat fee is charged when accessing the zone. In contrary, a mileage based charge is up to the distance driven within the zone. How can the two schemes be compared?

The cost model of Prof. Rémy Prod'homme [9] from the University Paris XII offers a possibility to assess the effects of such measures. His model can be applied to any given area; the road usage q can be measured in vehicle*km. It considers the demand for the use of the roads as a function of the unit cost of using the road. The most important element of this unit cost is the cost of the time needed to drive one km. Furthermore it considers the individual cost i(q), which could be considered a supply curve; this is the per-km cost borne by a motorist. And finally he considers the social cost s(q) created by a vehicle as a function road usage. This social cost is equal to the individual cost plus the cost of the additional time spent by all other vehicles because one extra vehicle is on the road. It is given by $s(q) = i(q) + i'(q)*q$. According to the model, the individual optimum is where the individual cost curve intersects with the demand curve; the social optimum is where the social cost curve intersects with the demand curve. A congestion charge increases the individual cost and shifts the intersection points towards less traffic.

Table 2 shows the model parameters that are used for comparing a cordon pricing to a mileage pricing, the model represents a city of 500,000 – 700.000 inhabitants:

Traffic category	Share [%]	Daily traffic count	Average km in the zone	1000 veh*km in the zone
Traffic within the zone	10	41,894	4	168
Short distance traffic with origin/destination in the zone	40	167,577	4	670
Long distance traffic with origin/destination in the zone	40	167,577	4	670
Through traffic	10	41,894	4	168

Table 2: Synthetic traffic model for assessing the effects of urban road user charge

It is worth mentioning, that the above numbers highly influence the shape of the cost curves in Fig. 3. For instance, if the average km in the zone increases, the cost curves get more flat because the same traffic is distributed on longer stretches of road ("less congestion"); if the charges are increased, the cost curves go up. Two charge variants are set:

A cordon charge of € 1,00 for every access/exit

A mileage charge of € 0,15 per km.

The demand curve is typical and is taken from the London Congestion Charge [10]. The effects of these variants are shown in the figure below.

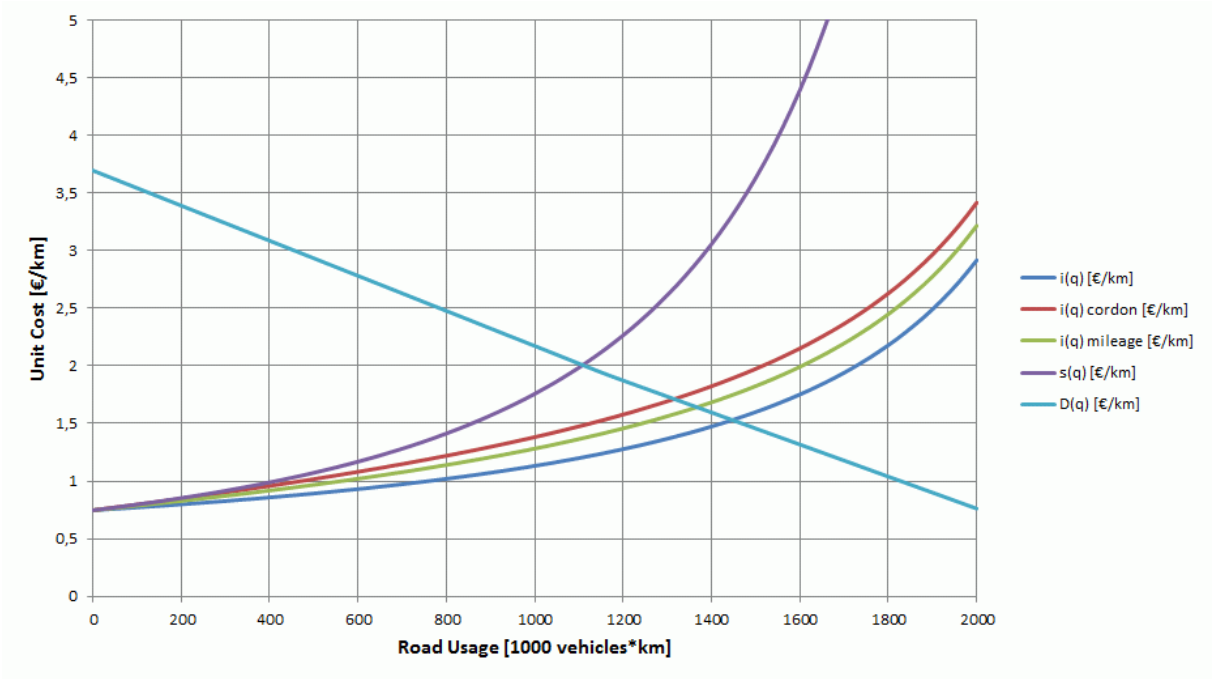

Fig. 3: Effects of urban road user charging on the traffic; individual cost rise with increasing traffic due to higher travel times, consequentially the demand declines with higher traffic; i(q) … individual cost; i(q) cordon … individual cost with cordon charging; i(q) mileage … individual cost with mileage based charging; s(q) … social cost; D(q) … demand curve; Lw … social loss due to congestion without any measure; Lm … social loss due to congestion with mileage based charging; Lc … social loss due to congestion with cordon pricing.

The social loss due to congestion without the charge is Lw; in this example this loss is € 573 mn per year. This loss can be reduced due to the charge variants to Lm (€ 370 mn per year) or Lc (€ 339 mn per year) respectively. The social gain due to the measure is Lw-Lm in the case of mileage based charging (€ 203 mn per year) or Lw-Lc. In the case of cordon charging (€ 233 mn per year). By increasing the charges, the intersection points of the respective individual cost curves (i(q) cordon and i(q) mileage) with the demand curve D(q) would move left towards the social optimum, showing the traffic reducing effects of the charge.

4.2 Cost benefit comparison

In addition to the above parameters, 100 access sites and 700.000 registered users are assumed; in the cordon variant, each access site registers every vehicle passage; for simplicity, in the mileage based charging variant, each access site serves as an enforcement site, verifying that the obliged vehicles carry a working on-board unit. On the basis of state-of-the-art industry cost, the following comparison is given in Table 3:

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

	Cordon pricing	***Mileage pricing***
Technology	DSRC on-board units for frequent drivers (30%); standard ANPR registering	GNSS on-board units for all vehicles; GPRS communication to central
Capital expenditures [€]	27 mn.	123 mn.
operating expenditures [€/y]	9 mn.	93 mn.
Social gain [€/y]	233 mn.	203 mn.

Table 3: Synthetic traffic model for assessing the effects of urban road user charge

The most significant reason for the high capital expenditures with mileage pricing is the significant higher GNSS on-board unit price for all registered users. The reason for the high operating expenditures with mileage based pricing is the communication cost for all GNSS on-board units.

5 CONCLUSION

In Europe, Low Emission Zones were the response to the Clean Air Directive that limits the maximum threshold levels of air pollutants immissions. Most of the European Low Emission Zones are pure driving ban zones aiming on PM10 emissions only. Some Low Emission Zones are charged zones, which turn out to be a little more flexible. When bringing carbon emissions into the access criterion, there is nearly no choice than deploying charged zones, but still the open question is to apply a simple cordon scheme or a mileage based pricing that follows the polluter-pays-principle at best.

By applyin demand elasticity models, the proper scheme and charge can be determined in order to achieve the desired traffic reduction and carbon reduction. The outcome of this assessment is the social benefit of the measure. This benefit is facing the deployment and operating cost for the scheme, giving a decision support for choosing the right measure.

1 ABSTRACT

Today the urban spaces and attendance of people in public spaces are very problematic and urban planners discuss about it very much.

At a glance if we review the history of urban planning, we can see that after industrial revolution and rapid growth of cities and after some solutions that urban planner thought about it, the appearance of cities changed. During these changes the attendance of citizens was changed too. By the theory of zoning that modernist urban planners suggested as "Aten charter" in 1933, the city was divided to three zones for working, recreation and living and circulation. So the importance of human spaces and urban spaces was reduced and increasing of automobiles became other factor for making urban spaces more unsuitable for people.

2 HISTORY OF URBAN PLANNING IN THE WORLD AND IRAN

2.1 Theories of urban planners after nineteenth centuries

In developing countries that most of urban planning decisions followed from the European theoreticians, their cities changed as well. Urban spaces became to some ugly and dangerous spaces for attending pedestrian and citizens and this situation have been trying till now.

In Europe and other developed countries after facing with these negative affects in their cities, some activities were launched to solve this problem in urban spaces. Some urban spaces were altered or designed to attract people and to have the ability of attendance of citizens in them.

One of the theoreticians that had noticeable theories was "Kamillo sitte", he pointed to the importance of attendace of people in city and urban spaces should be seen as "a place of social interaction" and he mentioned why new urbanism couldn't create attractive and memorable spaces and cities.

There were some other theoreticians such as "Pugin", "Ruskin", "Moris" who also recommended to review the history and returning to aesthetics of the past and there were also some body like Jean Jacobs who emphesized the attendance of people in public spaces and enriching social relationships. [1]

2.2 Principals of traditional urban spaces in Iran

In historical urban planning of Iran, there were some valuable principles which haven't been continued by our contemporary urban planning and these urban spaces have been changed to some unvalued spaces which were just allocated to automobile.

Our traditional urban spaces had some principles which include:

(1) The priciple of juncture of urban elements and houses:

In the old cities of Iran residential units have been jointed to each other with central courtyard and create a united complex. The arrangement and the orientation of all of the elements of houses were obeyed from "modularity" and "order", so there was harmony in city.

(2) The priciple of contrast spaces:

Contrast spaces are some spaces which have different width and length and height. The worth of contrarst spaces is that it can mitigate the monotony of the space.

(3) The priciple of encompassing the space:

Encompassing the space is the first principle of traditional spaces in Iran. This principle is common in all old cities. In Iran, traditional urban spaces are surrounded by arcades and colonnades to create a symmetrical and balanced space.

[1] CHOAY, Francoise

(4) Inner space and outer spaces:

Traditional urban desgining was involved with "outer" spaces which include public spaces such as squares and streets and "inner" spaces that include inner courtyards within the houses.

The concept of both inner and outer space is equal except in their scales.

Inner courtyards in houses are surrounded by rooms and outer spaces are encompassed by mosque, public bath, houses and some other buildings.

(5) The priciple of perception of spaces:

A traditional urban designer had a good perception of the meaning of "space" and "mass". He believed that the city is a combination of "mass" and "space".

(6) The priciple of composition:

In a traditional city, we had a harmonized composition so that it created a unity of forms.

In old cities we can find a composition by integrating different elements, and this composition showed a strong identity.

(7) The principle of territory:

We can identify three different spaces in traditional cities: 1- private space such as courtyards 2- semi-private or semi-public space such as a deadend street or a "Hashti"[2] .3- public spaces like streets and squares.

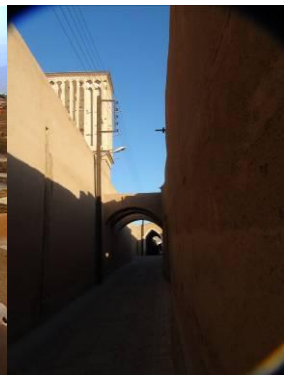
(8) The priciple of proportion and scale:

Proportion means the ratio of dimesions of a space. If we use correct and human proportion in space, it will create a sense of relaxation in people.

Scale is the relation between the sizes of a space with other spaces and Human scale is good relation between the sizes of a space with the size of human beings.

In traditional urban spaces we could find a good proportion and human scale in their spaces. In Iran in the regions with hot and dry climate, there are some norrow streets that get shade most of the time, but inspite of its small width people can feel comfort because of the color of walls which are covered by thatch.

The roofscape of Yazd city



streets which covers with thatch

Naghsh jahan square

Ganjali khan square

[2] Hashti was a semi-private space that was located in the entrance of teraditional houses for rapid and informal meeting.

As it was mentioned, most of the traditional urban spaces of Iran expect few of them were destroyed during the renovation of streets and erecting highways and new regions.

Of course few spaces which have been remained from the past show the magnificence and power of traditional urban planning such as Naghsh Jahan square and Ganjalikhan square.

2.3 Tekiyeh and Hoseyniyeh and Moharam ceremony

One type of spaces which were very important in our traditional urban spaces was Tekiyeh or Hoseyniyeh. These spaces have reserved their importance till now. Tekiyeh or Hoseyniyeh were used mostly for howling ceremony in the month of "Moharam". People howl for their third martyred leader (Imam Hossein) by holding special ceremony, they cry and beat on their chest.

Howling in Moharam - Ashoora

The ceremony of these days is one of the most important ceremonies between Shiite Muslims that people try to hold this ceremony in the best way.

Shah Vali Hoseyniyeh in Taft city

In the past the space for holding this ceremony was identified clearly in traditional cities and now we can't see these spaces in contemporary cities of Iran like past time. Nowadays just some streets and squares are allocated to this ceremony and they are not suitable for it.

Intrupting the traffic of vehicles with parade of howlers

Of course some Tekiyehs have been remained from the past that are still so magnificent and can envelop this social activity such as Amir Chaghmag square in Yazd city and Shah Vali Tekiyeh in Taft city.[3]

2.4 Some recommends for designing Hoseyniyehs and Tekiyehs

In designing the surrounded spaces we sould respect two aspects:

(1) The principle of juncture and relation between urban spaces in the centre of district should be concerned in the other word designed space should be one of the compotent of exist spatial organization in city.

(2) Each urban space should be formed by needs and activities of its citizens. However in general we can mention some recommends for Tekiyeh and Hoseyniyeh as follows:

- In designing Tekiyeh and Hoseyniyeh we should notice the aspect of spatial relation of this element wih other urban elements.
- In designing Tekiyeh and Hoseyniyeh spaces should be surrounded simply and proportionately.
- It should be avoided to convert Tekiyeh and Hoseyniyeh to vehicle access squares.
- Every intrupt in old and historical spaces such as Tekiyeh and Hoseyniyeh should be under surveillance of authorities and axperts. [4]

3 RECENT SITUATION OF URBAN SPACES IN IRAN

Urban spaces of Iran have lost their property as a social space. Our urban spaces such as streets and squares don't present any attraction to attract pedestrian. If some body is seen in this space, it is because of an obligation not for their wish. Most of our streets and square are full of automobile without suitable furniture or attractive function to absorb people and so cities don't have enough civic vitality and most of times they seem ugly, unusable and bore.

Toopkhaneh square in Tehran without any attraction for attendance of people

3.1 Some renovation activities to enrich urban spaces in Iran

Actually pedestrianization and respecting principles in designing historical urban spaces have been launched in Iran but there is still a long distance to ideal situation. Some activities have been done in several cities in Iran during recent years.

For example in centre of Tehran (capital of Iran) some commercial streets were allocated to pedestrian and it caused to increase safty and value in these streets.

Pedestrianization in centre of Tehran (Bazar region)

[4] TAVASOLI, Mahmood

4 CONCLUSION :HOPES AND CHALENGES

By some alteration in urban planning of Iran and suitable execution, we can lead cities to a more human manner that other countries recommend to do it too. We should convert our contemporary city to an attractive and memorable city which shows a strong identity.

It is clear that these changes in cities of Iran need a lot of cost and time but at first we should start it with proper legislation in urban designing and giving priority to the attendance of people than automobile. In this case we should emphasize on some legislation that are related to this case and persuade to execute these laws until we could make a prosperous and vivid city.

For example for Moharam ceremony we need some suitable spaces that like past time peolpe can hold their ceremony in the best manner.

We should revive our Tekiyehs and Hoseyniyehs to be adaptable for this important social activity.

Indeed by restoring these spaces we will enrich one of our important cultural elements to be presented in the world.

At the end I repeat that in designing urban spaces especially in historical districts we should define the principles of their combinations, proportions, scales and forms of buildings and issue some codes about them. Followimg these codes will lead us to a richer space with a storng identity that of course could be more adaptable with social activities and huminty.

Amir Chakhmag Hoseyniyeh in Yazd city

1 ABSTRACT

This paper has investigated the environmental challenges faced by Peri urban settlements in the Lagos Megacity. An intense study of the Isheri, Ibafo and Sagamu Interchange areas along the Lagos Ibadan Expressway axis was done. Socio economic characteristics, housing and environmental conditions as well as rural urban linkages were done to determine the flow of interaction between the settlements and the Lagos Metropolis. Data collection was by the administration of structured questionnaires. 46,113 and 191 were administered on household heads in Isheri, Ibafo and Sagamu Interchange areas respectively. survey was by systematic random sampling. The study revealed a high level of interaction between the settlements and the Lagos Megacity as over 60 % of respondents working in Lagos. The study also revealed that land value, rental value had increase since 2005 when the highest rate of influx was observed. However environmental problems in the area of infrastructure and security were observed. The paper concluded by suggesting strategies for mitigating identified challenges and these include the introduction of participatory planning mechanisms as well as the enforcement of development control.

2 INTRODUCTION

According to OECD (1979:) the impacts of economic growth and physical expansion of the urban area are not confined within urban boundaries; they reach into much wider areas surrounding urban centres, creating so-called urban areas, urban fringe areas, or peri-urban areas. As such, the peri-urban area can be defined as the meeting of urban and rural activities. While the peri-urban area retains the characteristics of the rural area, changes take place with respect to physical configuration, economic activities, social relationships and so forth. This meeting of different systems creates both opportunities and problems, which have significant impact on the environment and people's livelihoods. Lagos has grown from predominantly farming and fishing villages to highly urbanized settlements. With a population of over 10 million people on a built up area of 17500ha, it is regarded as a mega city (Mabogunje, 2002). Lagos with its high migration rate and even higher population rate has grown in an amoebic fashion into surrounding rural areas, hence the proliferation of peri-urban settlements adjacent to Lagos

This study appraises the nature and environmental challenges of peri-urban settlements along the Lagos Ibadan Axis of the Lagos Megacity, and considers in detail, the environmental conditions, socio-economic activities as well as the linkages Lagos Megacity.

3 URBAN-RURAL LINKAGES AND FLOWS

At the broad theoretical level, it is suggested that there are economic, social, political and ideological linkages between urban and rural places. These find their physical expression in measurable flows of people, money and budgetary allocation. These flows are also associated with interactions between people, places and objects, but do not in themselves actually embody those interactions (Unwin,1989). This system proposes four kinds of linkages (i.e. economic, social, political and ideological) and many more flows that are derived from them.

Firman (1996) identified, four levels of interactions occur with major cities and they are

(1) the peri-urban regions: those areas surrounding the cities within a daily commuting distance from the core and characterised by high interaction with it;

(2) the agricultural regions, often lying along the corridors connecting a large city core to smaller town centres;

(3) densely populated rural regions;

(4) sparsely populated frontier regions

The Research team of the Development Planning Unit, University College London (2000) while attempting to characterise the features of the peri-urban interface and the related environmental problems posited that population size, population density in built up areas, infrastructural characteristics, administrative boundaries and predominant economic activities are the main variables that distinguish rural from urban. The peri-urban interface constitutes an uneasy phenomenon, usually characterised by either the loss of rural aspects (loss of fertile soil, agricultural land, natural landscape etc) or the lack of urban attributes (low density, lack of accessibility, lack of services and infrastructure etc) Attempts to conceptualise this new development landscape range from the emphasis on rural-urban linkages as footloose processes rapidly transforming territories, to the notion of the peri urban as a term qualifying areas with mixed rural and urban features. (Dayaratne, 2003). According to Firman (1996), the administrative integration of surrounding rural areas into the jurisdiction of the urban settlements is a pragmatic way of eliminating unnecessary conflicts in a highly integrated rural-urban territory.

Douglass (1998) proposed a new paradigm of networking settlements that integrates the realities and the potential of rural-urban linkages in the process of regional development policy formulation: Rather than trying to make a single large city into an omnibus centre for a vast region, the network concept is based on a clustering of many settlements, each with its own specialisation and localised hinterland relationships. His supposition is that even from the point of view of growth centres, an integrated network of dynamic centres is more likely to counterbalance a big city than some artificially boosted growth centre. (Douglass, 1998)

Dayaratne, (2003) on the transformations of the peri urban areas, averred that peri-urban areas are undergoing major transformations. Large numbers of urban residents, pushed out by high housing costs in the city, look for cheap accommodations in the peri-urban areas. The poorer, informal-sector workers move/rent often overcrowded temporary shack/rooms hurriedly built. Squatting is predomint, while numerous forms of slums and shanties emerge,. At the same time residents of peri-urban settlements usually are employed in the city, while traditional agriculture gives way to new forms of production aimed are fulfilling the urban dweller's need for fresh vegetables.

Rakodi, (1998) sees the peri-urban interface as a dynamic zone both spatially and structurally. Spatially it is the transition zone between fully urbanised land in cities and areas in predominantly agricultural use. It is characterised by mixed land uses and indeterminate inner and outer boundaries, and typically is split between a numbers of administrative areas. The land area which can be characterised as peri-urban shifts over time as cities expand.

It is also a zone of rapid economic and social structural change, characterised by pressures on natural resources, changing labour market opportunities and changing patterns of land use.

Rakodi further recognised the complexities of building a spatial framework around what is essentially an amorphous and mobile site for the interaction of various social, economic and cultural processes and inter-linkages between the rural and the urban, stressing the relationship between urban and the immediate rural areas being the result of a process over time.

DFID (1998) defines the peri-urban interface as characterised by strong urban influences, easy access to markets, services and other inputs, ready supplies of labour, but relative shortages of land and risks from pollution and urban growth. The concept of the peri-urban settlement is one referring to an area where urban and rural development processes meet, mix and inter-react on the edge of the cities. It is often not a discrete area, but rather a diffuse territory identified by combinations of features and phenomena, generated largely by activities within the urban zone proper; hence the development of a peri-urban area is an inevitable consequence of urbanisation and as cities in developing countries continue to grow, the peri-urban area moves outward in waves (DFID, 1998). In addition to their spatial characterisation, peri-urban settlements are conceptualised as squatter settlements, illegal areas, areas of high population growth due to rural migration (and natural growth), low priority areas in terms of urban planning, areas with diverse socio-cultural composition and low income, socio-economic situation (World Bank, 1999, UNICEF, 1999). These approaches may be classified according to the set of variables they choose to emphasize: physical attributes, such as proximity to the city and poor infrastructure; socio-economic variables; or urban-rural flows (of people, energy, goods). Adell, (1999); Allen, (1999) and Jenkins (2003).

Scant research exists on the phenomenon of peri-urban settlements in Nigeria. In a study on the impact of the spatial growth of Ibadan on its surrounding hinterland, Areola (1994) focused on the resource processes and the environmental impact of the growth. The findings of the study focused less on the problems of the growth as it affects the city itself but more on the problems generated in the city region, (Areola 1994). The study concluded that full understanding of the economic and environmental effects of Ibadan city's growth and spatial expansion can be gained only through detailed studies of the region (Areola 1994). Salau (2006) revealed an earlier research by Maconachie and Binns (2003) on people-environment relationships at the rural-urban interface of Kano, Northern Nigeria in which they identified socio-economic and cultural factors as the most significant forces shaping the process of peri-urban change in the city.

Jaiyebo, (2003) avers that there is a death of information on the peri-urban interface in Nigeria, and the rates of city expansion and migration to the city fringes are not adequately documented. Studies which made reference to peri-urban settlements include those of Mabogunje (1968), LASG (2004), Odumosu (2004), CPMS (2005), FGN(2006) Gandy, M (2006) MPPUD (2005),and Salau, T.I. (2006). However, they all made reference to this phenomenon in the context of the growth and development of the Lagos Metropolis. hence this paper is of utmost importance, as it investigates these settlements and identifies the challenges faced as well as the potentials for growth and development and ultimate integration with the Lagos Megacity.

4 CONTEXT OF THE RESEARCH

The spatial growth of Lagos Metropolis has gone beyond the physical boundaries of Lagos State and spilled over at many points into adjoining Ogun State. The Lagos Metropolis is located along the narrow coastal plain of the Bight of Benin. The metropolis, an estimated 300 square kilometres, is a group of islands endowed with creeks and a lagoon. The city began in the fifteenth century as a Portuguese trading post exporting ivory, peppers, and slaves, and has overflowed its natural boundaries of about 3.8 sq. km in 1881 to a huge metropolis of over 1,183 sq. km in 2002 (Oyesiku, 2002), and a diversity of activities, functions and reflections have gradually spread over a larger territorial area as the metropolitan area. According to Odumosu (2004), the spectacular pattern of urban development of Lagos has seen the mainland segment of the Metropolis expand across shanty towns like Agege, Egbeda, Idimu, Ajegunle, Ketu, Bariga, and Ejigbo-Ikotun.

The resulting Lagos Megacity region includes the continuously expanding area comprising for the moment all of the 20 local government areas of Lagos State and the emerging urban, rural communities and peri urban settlements comprising of various geographic areas that have developed at different time in close linkage to the Lagos metropolitan area, Spatial expansion of the metropolitan Lagos has extended outwards annexing nearby settlements along the southwest end of Ojo-Badagry Expressway, the south east axis along the Lekki Epe corridor, the north east axis along Ikorodu corridor, Alimosho-Igando-Iba-Lasu corridor north west of Metropolitan Lagos and the Lagos-Ibadan axis north of Metropolitan Lagos.

Since metropolitan Lagos is practically saturated, growth had being outwards to the peri urban settlements, the regions with the potential for expansion; strong interconnection with the Lagos Megacity, strong local growth for informal activities for the local and urban population. The corridors along the Lagos-Ogun State borders have been experiencing the highest pressure as the Metropolitan Lagos spills over to them. Otta, Ibafo/Mowe, Ojodu/Akute, and Ogijo areas are already under heavy and intense pressure of physical growth with very few indicators of real development. (Lagos Mega city Report 2006) . this study therefore investigates the Lagos Ibadan Peri Urban axis located in this zone.

The peri urban settlements of the Lagos Ibadan Axis is located on between Latitude 60 44' North and Longitude 30 25' East'' of Isheri North and Latitude 60 54' North and Longitude 30 7' East'' of the Sagamu interchange. In aerial distance, Lagos Ibadan Axis of the Expressway is about 32 kilometres between the Isheri North end of Lagos State and the Sagamu Interchange of the Expressway in Ogun State. The peri urban settlements of the Lagos Ibadan Axis are strategically located nodal settlements along the Lagos - Ibadan Expressway absolving the spillover population from the Lagos Megacity.

The Lagos Ibadan Peri Urban settlements are a cluster of small settlements along the axial of the Lagos Ibadan Expressway. The Lagos Ibadan Expressway is a unimode transportation route that links Lagos with other parts of Nigeria via the Sagamu-Ore Expressway. The Expressway also serves as connecting distributaries to major towns and roads that converge along its axis. The street pattern of the Expressway is

decidedly radial, with Ibafo peri urban area street pattern taking shape along its traditional core, while the newer areas of Isheri and Sagamu Interchange portray deliberate mix up of land use activities without recourse to planning standards.

Lagos Ibadan corridor has grown strongly in its physical extent along Lagos - Ibadan Expressway which runs in a north-west direction from Metropolitan Lagos towards Ibadan along the state boundary with Ogun State and extends to a distance of about 32 kilometres terminating at the Sagamu Interchange. The physical extent of the towns and settlements runs in a linear fashion along the Expressway extending inwards to some few kilometres from the Expressway.

The physical development of Lagos Ibadan corridor is further reinforced by various religious institutions that have taken over the corridor in recent years; and are major flash Point for seasonal traffic congestion. They include the Redemption Camp at Mowe, Mountain of Fire Ministry Camp at Km 12, Deeper Life Ministry at Km 15, and NASFAT site at km 16. Other major land uses are those of various private universities, Cargo Airport at Sagamu Interchange, residential estates such as the Gateway Village, Riverview, Havillah, Sparklite Estates, Paradise City and others. The peri urban settlements have similar land use with slight variations along the population pattern. All of them of course provide residential land use. A very high percentage, 86 %, has farmland cultivated by peasant subsistence farmers. These are the two predominant uses of the land. 28 % have social facilities such as schools, police posts and institutions that complement residential land use. Only a few, 12.3 %, have any commercial activities and these are mainly retail shops. The bigger settlements have markets and petrol filling stations. (CPMS, 2005). Only six have any industries at all, and these include textile industries in Ibafo, feed mill in Orimerunmu, cocoa processing industry in Warewa Araromi, and several cottage industries in Mowe, Loburo, Ofada and other smaller settlements.Major development axes are at Mowe, Ibafo, Ofada and the Redeem camp, where intensive development activities extend from the Expressway inwards to a distance of about 2.5 kilometres. Table 1 below highlights the key characteristics of the zone.

Peri Urban Zone Characteristics	**PERI URBAN ZONES ACTIVITIES**
Peri Urban Zone	Sagamu Interchange: 50 %; Ibafo: 30 %; Isheri: 20 %
Dominant Settlements	Mowe; Ibafo; Ofada
Population Estimate (2003)	21,740
Land Area	450 km2
Degree of Land Use	Minimal < 10 %
Topography	Low and gentle 5 – 25 m
Main Access	Lagos-Ibadan Expressway
Roads & Highways	No Road Network; Transit Corridor
Water Supply	No Water Supply System
Economic Infrastructures	Rudimentary
Social Infrastructures	Rudimentary

Table 1: Characteristics of the Lagos Ibadan Peri Urban Zones Source: CPMS (2003) Ogun State Conceptual Regional Plan (2004 - 2025) Main Report

Eighty two settlements have been identified in this zone (CPMS, 2005) of which more than 70 % are hamlet of less than 100 persons. Another 20 % have population of between 1000 and 2500 each. The six dominant settlements are Ofada, Abaren, Orimerunmu and Arepo with population sizes in the range of 2,500 to 5,000; and Mowe and Ibafo with populations greater than 10,000. (CPMS 2003).

The study area comprises three major areas

Isheri Area constitutes a substantial portion of the first OPIC acquisition; occupants in the area include the cattle and ram dealers on the bank of the Ogun River, Sparklite Estate, a private developer housing effort, the Isheri community to the east of the expressway and the OPIC head office. At its northern fringe are the settlements of Arepo and Warewa. This portion of the corridor is low-lying on both sides of the expressway.

Ibafo Area This area is dominated by Ibafo, a town on both sides of the expressway, with several other settlements including Araromi, Magboro Akeran and Magboro Sofolarin. The area also contains three religious settlements, MFM, Deeper Life and NASFAT with their potential to create large flash traffic. The centre of Ibafo is approximately at 13.5 kilometres from the State boundary with Lagos State, and it extends

for about 3 kilometres along the expressway. It is elliptical in shape, tapering off from the 3 kilometres along the expressway to less than 100 metres wide two kilometres away on both sides of the expressway.

Sagamu Interchange Area is made up of the gateway city to the north of Ibafo, starting from Mowe and extending to the Sagamu Interchange. The dominant existing settlement is Mowe, which has grown to merge with Loburo and Pakuro. Others are Ofada, Orimerunmu, Abaren and Asese. Major settlements include the Redemption Camp and CETEP University There is projected to be about 26,500 Mowe today occupies an area of about 11 square kilometres, estimated from digital images. About 90 % of this land area is west of the expressway, and it extends about 3 kilometres inwards. Its extent along the expressway is about 3.5 kilometres starting at about kilometre 20 to 23.5 from the State boundary with Lagos State. The major catalyst for the development of Mowe is the siting of the Redemption Camp in a nearby settlement of Loburo.

5 RESEARCH METHODOLOGY

Lagos Ibadan Peri Urban Axis was purposively selected for this research because of its distinct geographic attribute of linking Lagos to the rest of Nigeria. The study area was delineated on the basis of its linear form of settlements along the Lagos Ibadan Expressway with scattered residential quarters for the purpose of questionnaire administration.

Data collection was by systematic random sampling. Data was collected on the socio-economic characteristics of residents, physical and infrastructural facilities as well as their interaction with the Lagos Metropolis. A sample size of 5 % of the sample frame of the estimated 6840 buildings (CPMS 2005) along the Lagos-Ibadan Axis was selected. 350 questionnaires were administered on household heads in 19 of the 82 settlements that make up the axis. 46, 113 and 191 household heads were sampled in Isheri, Ibafo and Sagamu Interchange Areas respectively. Data analysis was by both simple descriptive statistics as well as parametric analysis.

5.1 Socio-Economic Characteristics of the Respondents

The population is a relatively young one with about 71.1 % aged between 20 and 40 years old. 7.7 % of the respondents are less than 20 years of age, while those between 41 to 60 years make up 18 % of the population. Those above 60 years of age are 9 %. The pattern of the age distribution is similar across the three zones, this may largely due to the fact that the axis is a transitory zone for working age men, unable to afford the cost of living in the Megacity.

The survey also revealed that the male population was 93.5 %, 54.9 % and 39.8 % in Isheri, Ibafo and Sagamu Interchange areas respectively. a significant proportion of the respondents are single; 43.5 %, 41.6 % and 48.2 % in Isheri, Ibafo and the Sagami Interchange areasn respectively, while there are more married people in Ibafo and Sagamu Interchange areas (46.9 % and 45 %). Only about 26.1 % of the respondents in Isheri are married. The differeing figures in gender and marital status in Isheri may be attributed to the Cattle Market which is a sector dominated by men.

The Lagos Ibadan Peri Urban Zones is largely made up of Nigerian nationalities (86.3 %) comprising of various tribes such as the Yoruba speaking people of the Ijebu, Awori, Egba, Yewa, and Egun extraction; the Igbo, Hausa, Isokos, Urhobos, Calaber, and Ijaw. The nationalities fro the West African Coast is about 11.4 % of the respondents, while 2.3 % of the populations are from other African Countries. Educational level is a key determinant for measuring standard of living in the study area. The study carried out revealed that 26.0 % of the total respondents are literate by United Nations standards, having completed a minimum of secondary education. 34.8 %, 32.7 % and 19.9 % have secondary education in the Isheri area, Ibafo area and the Sagamu Interchange respectively, the high level of literacy across the three zones is attributable to its proximity to the Lagos Megacity.

The survey of occupational status of the respondents revealed that 26.6 % are Government employee and self self-employed respectively while the unemployed and retired accounts for 22.6 % and 3.4 % respectively. However, a breakdown of the occupational status of the three peri urban zones revealed that trading, civil service and students/apprentice are the most common activities, representing 15.1 %, 29.4 % and 21.4 % in that order, while 6.9 % are engaged in teaching, 5.4 % in farming, 10 % are artisans, 9.4 % are factory workers, and 2.3 % are retirees. In all the peri urban zones, the majority of the respondents are civil servants

followed by students and apprentice while trading activities was high in Ibafo and Sagamu. While majority of the respondents (26.6 %) are earning less than N10,000 per month, those who are earning between N10,000 and N20,000 are 26.6 % and 25.4 % are earning between N20,001 and N40,000. 3.1 % earn between N40,001 and N60,000, 5.7 % are earning between N80,001 and N100,000. those who claimed to earn above N100,000 per month are 3.5 % of the respondents. Interestingly, mode income per month was less than N10,00 for Isheri and Sagamu Interchange areas, and between N20,000 and N40,000 in Ibafo. 16 % of the respondents in Ibafo area earn over N100,000 monthly. and It could be deciphered from all these that a larger proportion (62 %) of the respondents earn less than N20, 000 per month.

5.2 Housing and Environmental Profile of the Study Area

Majority of the houses in the study area were built between 2000 and 2010. The period that recorded the highest rate of building was between 6 to 10 years, which recorded almost half of the total buildings surveyed. This is followed by the period between 0-5 years recording a total of 17.1 % of the total number of buildings. A study of the pattern of growth within the three peri urban zones shows that majority of the new building construction has been more concentrated around the Isheri-Ibafo areas, which adjoins the Lagos Megacity. Housing types in the study area are small rooming house types (28.6 %). The detached type of houses, 1.7 % and compound houses 27.1 %, while block of flats accounted for 25.1 %. The dominance of the rooming type is explained by the rapid growth of the Lagos Megacity in to the adjoining peri urban settlements by low income earners and the adaptable nature of its design. It is easier to build and less costly to adapt for higher returns. It is also easier to let out to the various sizes of households.

Residential areas in the peri urban zones differ according to the areas, but, the emerging trend is the acquisition of large tracks of land for the construction of housing estates. Major housing projects are Gateway Estates Riverview Estates, Havillah Estates and Sparklite Estates. Residential use in the peri urban zone covers 50.9 % of the total land area

Squatting is widespread across the study area, especially in Isheri. The study also revealed that 30 % of the respondents were landlords, while 39.7 % were tenants. Interestingly 25.1 % were squatters. In Isheri area, about 50 % of the buildings were were occupied by their owners, while 32.6 % were squatters. In Ibafo, 29.2 % are owner occupier, while rented apartments made up 27.4 % and squatters were 15.9 %. 46.6 % of respondents in the Sagamu Interchange areas were rented, 30.7 % were owner-occupiers, while 22 % are squatters. Average number of rooms for exclusive household use is 2 in Ibafo area, 3 in Isheri and Sagamu Interchange areas respectively.

Household wastes generated in the study area are mostly mixed use related wastes such as cartons, papers, foodstuffs, animal waste, and other related commercial and household wasete. Wastes generated in the area are disposed by incineration (15.3 %), 6.9 % in manure piles, 26.6.5 % are thrown into canals and drains, while those collected by garbage operators accounted for 22.6 %. A look at the house waste disposal pattern of the peri urban zones shows a similar pattern for the areas; as disposals through landfills and incineration is the most common means of disposing waste, also, garbage collectors and indiscriminate disposal in to canals and drainage channels are also common.

The peri urban zone is fed primarily by the Lagos – Ibadan expressway with no significant tee-off between the Berger Junction at Isheri and the Sagamu Interchange. About 58 % of the settlements have access by road, and 20 % indeed have tarred roads. However, the dominant mode of transport is the commercial motor cycle locally known as Okada. Only Mowe and Ofada have roadside drains. In the Isheri-Ibafo area, there are a few feeder roads, mainly serving rural communities and some OPIC estates. Most of these roads are earth roads, but a few were designed and constructed by OPIC. All of them have no defined road junctions at intersections with the expressway, which. Developments along the peri urban settlements are therefore very difficult to access. Trailers park along the road at Ibafo constituting serious hazard to high speed vehicles and visual unpleasantness. In the Sagamu Interchange area, there are much fewer feeder roads feeding the expressway, reflecting the limited development in the area. There is, however, an old network of roads connecting Ofada, Mowe and Pakuro and linking with the Papalanto – Sagamu Junction Road. There are other earth tracks in the area linking the villages.

5.3 Linkages of the Study Area to the Lagos Megacity

61.1 % of all respondents work within the Lagos Megacity. 27.7 % work within the peri urban axis while only 9.7 % work in Ogun State. They travel to Lagos mostly by public buses (63.1 %) or private cars (31.1 %). Outside of work, 23.4 % visit Lagos at least twice weekly for social engagements and cultural interactions, while 17.1 % to buy goods.

62.6 % of the respondents are of the opinion that land value has grown with the increasing influx of workers within the city to the peri urban zones. House rent in the Isheri zone was considered to have increased 100 %, Ibafo 38.9 % and Sagamu Interchange by 62.6 % in the period between 2005 and 2010.

54.3 % of the respondents in consider the Lagos Ibadan Expressway to exert a positive impact on their settlement. Reasons adduced include accessibility, increase land value and commercial returns. Those who consider the location of the Expressway as exerting a negative impact gave traffic congestion and accidents, noise, security and influx of strangers as their reasons.

It was discovered that in between 2005 and 2010, when the highest growth rates occurred in the axis, basic infrastructure and social amenities generally worsened. The respondents attributed the situation to the influx of people as well as the settlements still being adjudged rural when their populations had far exceeded rural limits.

Indices	Improved	Worsened	No Change observed
Electricity	33.4 %	59.1 %	6.9 %
Water Supply	43.1 %	46.6 %	9.4 %
Security	31.4 %	55.1 %	12.6 %
Cost of Travel	8.6 %	62.0 %	28.6 %
Traffic Flow	9.1 %	78 %	11.1 %
Land Value	32.3 %	37.1 %	30.0 %
Rent Value	36.9 %	48.6 %	14.0 %
Crime	38.0 %	42.3 %	16.3 %
Pollution	34.0 %	46.6 %	17.7 %

Table 2: Changes in Peri Urban Growth Indices

Generally, majority the respondents believed land value has increased consequent upon the proximity of the Lagos Megacity. Also believed to have increased are such indices as house rent (62.6 %), traffic intensity (69.4 %), population growth (76.6 %), housing density (60.3 %), urban spatial growth rate (64.9 %), crime rate (66 %), and environmental problems (60.9 %). urban sprawl is the only stable activity, while land availability has reduced considerably (51.4 %) occasioned by the different types of development taking place in the peri urban zones as shown in table 3 below

Indices	Increased	Reduced	Stable
Land Value	55.7 %	36.9 %	3.4 %
House Rent	62.6 %	30 %	4 %
Traffic Intensity	69.4 %	13.1 %	13.7 %
Population Growth	76.6 %	19.7 %	0.3 %
Housing Density	60.3 %	30.3 %	6.0 %
Urban Growth Rate	64.9 %	21.1 %	10.6 %
Crime Rate	66.0 %	19.1 %	11.4 %
Urban Sprawl	39.1 %	47.4 %	9.1 %
Land Availability	25.7 %	17.7 %	51.4 %
Environmental Problems	60.9 %	15.1 %	17.1 %

Table 3: Changes in Environmental Indices in the Study Area

In order to determine the intensity of interaction between the Lagos Megacity and the Peri urban settlements, the gravity model was adopted

The formula for calculating the gravitation flow of one settlement from the other is:

The Gravity Model = $\frac{\text{Population}^1 \text{ x Population}^2}{\text{Distance}^2}$

Where:

D^2= the distance between the settlements

P^1= population of Lagos Megacity

P^2= population of Lagos Ibadan Peri Urban settlements

	Distance between the Settlements	Population of Lagos Megacity	Population of Settlement	Force of attraction
Isheri	10,000m	9,3000,000	4,700	437.1
Ibafo	18,000m	9,3000,000	10,000	287.04
Sagamu Interchange	32,000m	9,3000,000	10,800	98.06

Table 4 below outlines the level of intensity

From the foregoing, the force of attractions is stronger at the Isheri peri urban zone. One may therefore say that the expected interaction between the Lagos Megacity Region and the Peri Urban Settlements increases as the product of the populations of the two (PiPj) increases, and it decrease as the distance between the Megacity and the settlemetn (dij) increases. As shown from the calculations above, the attraction between the Lagos Megacity regions and Isheri peri urban zone (437.1) increases as its approaches Ibafo and decreases as it approaches the Sagamu Interchange

6 DISCUSSION

This paper has examined issues relating to the peri-urban settlements along the Lagos Ibadan axis of the Lagos Megacity. The objectives of the study are to determine extent and character of peri-urban settlements of the Lagos Megacity and the relationships that exist between the peri-urban settlements and the Lagos Megacity region looking at the social and economic interactions between them

The rapid growth of the Lagos Ibadan Expressway peri urban settlements and its reflection on the environmental quality of life of the residents has been found to have been largely influenced by its close proximity to the Lagos Megacity and this situation has created a number of environmental effects on the peri urban settlements. Majority (92.3 %) of the respondents believed the town has experienced some changes as a result of the proximity,

An easily notable effect of the Lagos Megacity on the peri urban settlements is the phenomenal increase in the population of the Lagos Ibadan Peri urban settlements over time due to massive relocation of residents from the Lagos Megacity. Study of the trends of population growth pattern of the Lagos Megacity and that of the Lagos Ibadan Peri urban settlements shows direct positive correlation. This research found out that about 76.6 % of the people in the Lagos Ibadan Peri urban settlements moved in from Lagos and about 89.8 % of this group moved in less than 10 years ago. Factors such as cheaper land, cheaper rent, social engagements and cultural interactions, political affiliations nearness to Lagos and nearness to work place were identified as reasons for moving to the Lagos Ibadan Peri urban settlements.

There is intense interaction between the Lagos Megacity and the Lagos Ibadan Peri urban settlements. The spatial pull of Lagos reaches peri urban axis of the Lagos Ibadan Expressway and a dominant commuting pattern between them exists with great implications for the entire Peri urban settlements. A large number of people living in the Peri urban settlements were found to be working in Lagos and commuting to Lagos on daily basis. This study found that about 96.3 % of the respondents commute to Lagos on daily basis and about 64 % of this group do so for employment purpose only.

Traffic situation in the Lagos Ibadan peri urban zones was generally considered by the respondents to be worse accounting for about 78 % of the total respondents the traffic intensity shows that there is an increase in the capacity of the traffic; proximity to the Lagos Megacity was adduced by the respondents for the increase.

Another effects of the Lagos proximity on the peri urban settlements is the increase on house rent and land values. The value of land and house rent in the Lagos Ibadan peri urban settlements has risen sharply especially between the last 10 and 15 years.

The study of land and housing development pattern in the Lagos Ibadan peri urban settlements axis shows that land value has increase by (55.7 %) in the peri urban zones, which relates directly with upsurge in its population resulting from the spillover of the Lagos Megacity. Majority of the developments in the peri urban zones are located along the axial of the Lagos Ibadan Expressway, most of which are done without necessary planning approvals.

Due to the outward and uncoordinated growth of the Lagos Megacity, and the unplanned settlements along the peri urban corridors of the Lagos Ibadan Expressway with the attendant land use conflicts, there is the threat of growing environmental problems. The use of contiguous land between the Lagos Megacity and the Lagos Ibadan Expressway peri urban settlements consequent upon the conurbation process has important ramifications for the environmental management of the zones. The use of land is basic to all human activities and as population increases the intensity of activity becomes accelerated with consequent effects on the uses of land. It therefore implies that activities in the Lagos Megacity have spilled-over into the adjoining peri urban settlements. The issue of land use spill-over between the Lagos Megacity and peri urban settlements has become a problem within the last many years with the rapid increases in developmental activities especially residential and religious settlements that have led to the erosion of the character and integrity of the Lagos Ibadan Expressway. The attendant effects are high land values, high traffic intensity and hold-ups.

The development of these religious settlements and the corresponding residential development all have their implications and ramifications in terms of infrastructures, environmental pollution, farmlands and agric lands, social services, economic base, that brings about an undue pressure and burden on the peri urban settlements resulting in the lopsided use of land and created by the over-spill of the Lagos Megacity into the peri urban zones.

As the Lagos Ibadan peri urban settlements grows in spatial dimensions as a result of the forces exerted by the Lagos Megacity, most of the development occurring along the axis of the peri urban settlements are largely mixed use residential, commercial, institutional use in nature, but, the spate of speed of this developments activities has outstripped environmental management process necessary for proper development and planning of the peri urban zones.

This situation is such that there are developments activities going on at a fast rate with a very low rate of infrastructural provision and environmental management.

Majority of the Lagos Ibadan peri urban settlements residents are of the opinion that the proximity of the Lagos Megacity has definite effects on environmental quality of the peri urban settlements, especially in the areas of pollution, environmental sanitation, water quality, housing, traffic, and crime rate. The study revealed that basic infrastructure as well as security and traffic have generally worsened with the influx of people into the area

This study has shown that the growth potential of any particular settlement is inversely proportional to its distance from the Lagos Megacity. Settlements that are in close proximity to the Lagos Megacity have a higher propensity to grow demographically and spatially than those that are far from such centres. This explains the phenomenal growth and expansion of the Lagos Ibadan peri urban settlements due to its close proximity to the Lagos Megacity. The attraction between the Lagos Megacity region and Isheri peri urban zone increases as its approaches Ibafo and decreases as it approaches the Sagamu Interchange. The expected interaction between the Lagos Megacity Region and the Lagos Ibadan Expressway Peri Urban Settlements increases as the product of the populations of the two increases, and it decrease as the distance between them increases.

7 CONCLUSION

This study has revealed the environmental issues of peri urban settlements along the Lagos Ibadan Axis of the Lagos Megacity. The major elements that were considered are the need for a positive approach to peri urban development in development planning; the need for effective governance of the peri urban settlements of the Lagos Megacity; environmental management of the peri urban settlements and the coordination of development proposals and Implementation mechanisms for infrastructure, housing and land supply in the peri urban zones. The many socio-economic and environmental problems currently found in the peri urban settlements of the Lagos Megacity make it imperative that efforts are made to define the parameters for environmental management and sustainable patterns of peri urban management.

The issues concerning planning, infrastructure, housing, land supply environmental sanitation, traffic management and community participation need to be addressed in an integrated manner through a division of responsibilities between the state and local governments. Activity centres in the peri urban settlements should be identified and redesigned to create rooms for offices, supermarkets, small-scale industrial centres, restaurants, entertainment centres and other urban amenities. These centres should receive the full attention of the Physical Planning Departments of the Lagos and Ogun State Governments and representatives of the Lagos Chamber of Commerce and industries as well as of the Nigerian Economic Summit Group to relocate or establish new employment generating enterprises in the peri urban settlements.

Curtailing the further spread of incompatible and illegal developments within the peri urban settlements is an issue of considerable importance. Anticipating such development by realistic zoning and facilitating the quick and easy access to well laid-out and, if possible, serviced plots of land by individuals or estate developer can be important strategy in this regard.

Apart from the problem of solid waste and generally poor environmental sanitation, the Lagos Megacity Region peri urban settlements suffers from water and air pollution due to the poor waste disposal facilities, traffic intensity along the Expressway, discharges of cattle waste from the operators of the Kara Cattle Market and Slaughter Slab greatly impair the quality of water in the Ogun River. Citizens in the peri urban settlements must be mandated by the local governments to maintain clean and sanitary environment and every household must own refuse dust-bin for their waste materials. The Lagos and Ogun State Governments should relocate and merge many of the existing public centres such as markets, motor parks, bus terminals, abattoirs and re-develop with adequate infrastructural facilities.

A participatory planning strategy which seeks to involve the residents themselves in determining their management of their environment, their needs in terms of the priority infrastructure and services required their willingness to contribute to the cost of providing such facilities and their engagement in poverty-reduction activities to improve on their social, economic and political situation need to be put in place in the peri urban settlements.

1 ABSTRACT

In 2010, Babolsar (a city in the northern Iran) with a population of about 47927 residence, consumes 14500 Kg meat per day approximately. The results of the current situation of slaughterhouse in Babolsar indicate that this location is inappropriate which in those required principals, standards and criteria for location selection were ignored and revelation of the adverse environmental effects would be predicted in the near future. In this study using a variety of data such as the distance from legal limits of the city, the distance of road communication, The potential for agricultural and construction, the distance of urban infrastructure, the distance of earthquake faults, the distance of surface water, wind aspects, pedology plan, hypsometric, vegetation ,geology and… .

These parameters in special models "fuzzy logic" are composed and selected the best location among different alternatives and different plans were sugested.

2 INTRODUCTION

Not only do Uncontrolled population growth, Urban development, The advent of new technology, The resulting changes in habits and consumption patterns and furthermore Restrictions on the use of natural resources cause a Variety of complex problems in our quality of life but they pose also social, economical and ultimately environmental issues. Growing urban population of Iran and also creating new population centers, policy and performance evaluation and many different urban operations based on Master plan and comprehensive national plans (land use planning) indicate the strongly requirements of planning for municipal slaughterhouse with the specialty of the scientific and correct locating. Continuing the traditional practice of slaughterhouses has posed a devastating effect on our environment, the quality of the public health and the residence in particular. It is widely admitted that the functional system of Iran's slaughterhouses acts based on traditional principles. This matter when would be harsh that its destructive effects on the other current urban systems, particularly ecological system are considered. One of the important research steps along with the planning for the slaughterhouses is locating factors and finding a suitable place of their settlement. Several criteria are involved in order to find the suitable location of slaughterhouse that they have their particular importance and make restriction on the choices either. Final goal of these criteria is to find a location that will pose minimal adverse environmental effects on the surrounding natural environment. Contamination of underground water resources and the soil pollution can be considered as an illustration. Researchers have been conduct that the population of Babolsar has been grown over the recent decades. For instance, in 1966 the average of the population was around 12016 which rose to 18810 in 1976 and 30200 in 1986. This city had 40630 residence approximately in 1996 (a village that is called Miandasht near to Babolsar has a population around 1986 which added to 38644 in terms of integration in this field). Growth rate for the period between1976-1986 was %4.8. Thus the population had a decrease around %3 between 1986-1996 and in 1999 was around 42738. It is also for Bbolsar in 2010, 47927 – growth rate: %2.15, in 2016, 66135n - growth rate: %2.5, in 2026, 84658 - growth rate: %2.5 would be predictable. With an assumed constant for meat consumption, Per capita consumption was 0.12 kilograms in 2010 per day, so that residence daily consumed 5500 kilograms of meat. In the other words based on the latest statistics, each person consumes 0.12 kilograms meat for their daily use that is equal with 43.8 kilograms annually.

According to the table1, Babolsar with a population around 47927 is considered in the category between 30001-50000 so the required area is 0.38 square meter per person or in another word this city needed a capacity around 18212 m² in 2010. But due to consideration of a Twenty-year planning horizon up to 2026 for this research thus, we should concentrate on the category between 50001-100000 that is 0.35 m² per person. As a result the required area for the infrastructure is 29630 m² (3 Hectare approximately). First

location of the Babolsar Slaughterhouse is located on the eastern part of the city. But it seems the current location neither has the standards for its space (7655 m²) based on the above table, nor has the qualified environmental status. Moreover, not only its destructive environmental effects appears now but also its negative impact will be seen in the near future and the sustainable development of the eastern part of this city is confronting a crisis. Locating the current situation of slaughterhouse in Proximity of the Shazdeh-rood river, putting in the city limits, being in the spatial and physical development of the city, local Prevailing winds that contain urbanscape pollution, uncontrolled population growth and the requirement of a wider space in order to prepare meat supply residents and the lack of responsiveness of the current landfill in the near future. The purpose of this study is selection an appropriate location or locations to optimize for Babolsar slaughterhouse which is based on natural and artificial information by the using of geographic information systems. During this study diffirent environmental variables by the using of fuzzy logic technique integrate and combine, then an appropriate location will be selected.

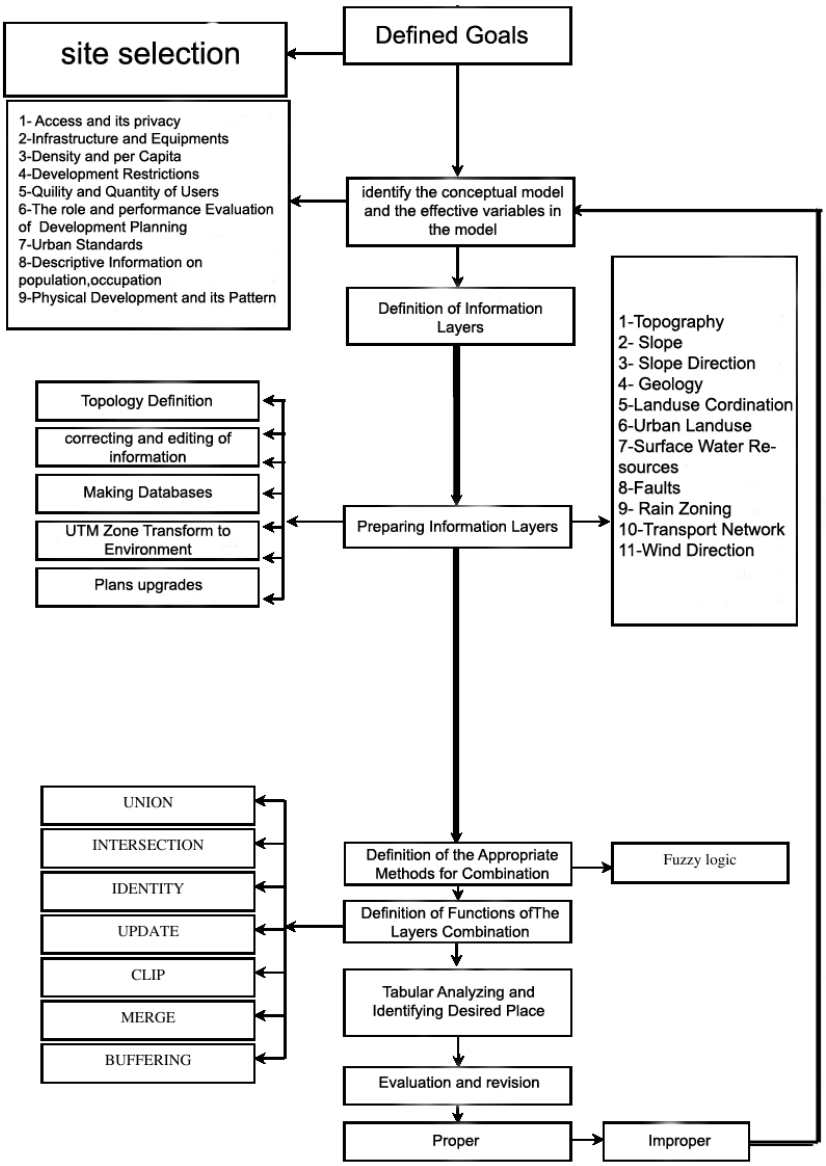
Population of city	Requierd area for each person (m²)
More than 10000 persons	0.86
From 10001 to 20000 persons	0.55
From 20001 to 30000 persons	0.48
From 30001 to 50000 persons	0.38
From 50001 to 100000 persons	0.35
More than 100000 persons	0.18

Table1: Required area for the infrastructure of Slaughterhouse based on population.

3 LITERATURE REVIEW

Finding an adequate location for urban infrastructure is one of the important subjects in Urban development planning. To express the importance of this subject for instance, management and finding a location for urban infrastructure accurately such as landfills, industrial slaughterhouses in some important provinces or states in Canada and The U.S like Quebec, Chattanooga, Washington, Massachusetts are considered as one of the main pillars of sustainable development and American planning association (APA) take it in to account as one of the significant goals for long-term and short-term plans of some states such as Chattanooga, Washington, Massachusetts, California, Seattle in order to reach to a stability in the 21st century.(Krizek et al,1996) Hendrix and Buckly in a study with the title of ‘’use of GIS for selection of sites for land application of sewage waste’’ in Vermont state in 1992, a 210-hectare area evaluated in the cases of physical and economical indicators such as appropriate soil, the depth of main rock, the land use, surface and underground water, zoning height…and they reconnoitered suitable places around an area which is called Mad.(Hendrix et al, 1992) the task of livestock slaughters and its pollution and dealing with this issue has a long experience. For instance, in an article with the title of “The use of water in its regulation in Medieval Siena” by Kucher, the waste water and the pollution from livestock slaughtered in Siena in the Medieval are discussed. He says contaminated water was caused a conflict between Butchers' guild and municipality, because the municipality claimed that the residual water from slaughter was caused the water pollution and as a result fountain contamination and it was believed the location of slaughterhouse must be transferred to somewhere outside of the city. He also mentioned to ancient water supply system of Yazd (a city in the middle part of Iran) that consumption and re-use of water could be considered as a symbol for developing and developed countries (Kucher, 2005). Shanmugan a scientist from Bangladesh has done a research based on the experience of ” GIS-MIS-GPS” for the realization of management of municipal facilities for the local environment and Bengal. In this research various aspects have been covered such as, requirements, methodology, development process for three systems “GIS-MIS-GPS”. The main part of this research is to deduce how the selected systems in each period of urban planning. In Iran finding the location for slaughterhouses has frequently done in the basis of urban master plan. But it is noticeable that the environmental points of view in this matter are not completely clear and it is specified just based on one or some limit indicators. In the seventh century AH, Ibne Okhveh is mentioned in the 16th article of municipal regulations about livestock slaughter that is incumbent upon the certain agent to prevent the butchers of slaughter in front of their shops due to side walk’s contamination which is absolutely forbidden and that

causes outbreaks. Thus, they must slaughter inside the slaughterhouse and moreover butchers are not be able to hang the slices of meat outside of their shops, because they can collision with people and making a mess. In the other part of this article he says, all the butchers are obliged by the agent to salt their work tables in order to prevent infections by the parasites due to high temperature, furthermore, they should cover them by a straw and some heavy dishes in terms of prevention of dogs licking and also protect of insects' entrance. In a research with title of criteria and standards of industries settlement the environment organization classifies the slaughterhouses as highly polluting industries and assigns criteria for finding the appropriate location but just concentrate on dos and don'ts in particular(Habibi, 2005).. In volume 9th of mayor Green series by Saeeid nia, the slaughterhouse discussion is proposed as a section of urban facilities and is mentioned some criteria for finding their location (saeeid nia, 1999). In 1995, in a research with title of placement mathematical model for poultry slaughterhouses in Shahed investment Company by Nouri is explained about select the optimal location, preparation and capacity estimation. He used the transportation model in this research and to maximize profits by the consideration of checking the cost and revenue (Nouri, 1995).



4 METHODS, MODELLING AND RESEARCH DATA

In the process of positioning the appropriate lands, conceptual model and effective variables in model such as access and its privacy, infrastructure and equipment, production, consumption, recycling... identifying and after the definition of the levels of information such as topography, geological slop, geology, barriers to the development, fault, rural communication network, surface water…, preparing these Layers in terms of topology definition, correcting and editing, upgrade…have done and after definition, the appropriate methods of Identify the composition and functions of layer composition in terms of union, intersection,

clipping, buffering, merge, update…in order to combining layers have been performed and after an analyze the database Table is merged, appropriate location has been identified and evaluated. The algorithm of the below indicates the method.

5 VARIOUS MODELS OF INFORMATION INTEGRATION IN ORDER TO SITE SELECTION

One of the most significant capability of GIS which introduces it as a special and exclusive system is site selection, data integration capability in terms of modeling and determination of land suitability by valuation of the land area. Due to the integration and combination of norms, the best place to establish the optimal centers and places would be chosen. There are several ways in order to combination the criterias. The most important are:

(1) Boolean Logic

(2) Index Overlay

(3) Probability Logic

(4) Coefficient of Correlation

(5) Artificial Neural Networks

(6) Fuzzy Logic

Fuzzy was first introduced by Iranian professor Asgar Lotfi Zadeh, professor of Brekly University – USA to implement in uncertainty condition. This theory is able to provide several of phenomena, variables and the ground to deduction, control and decision making in uncertainty condition.

One of critical levels in tradition Site Selection analysis which it's hypothesizes, assured accuracy of fully unreal incoming data. In a comprehensive analysis, is too hard and sometimes impossible to provide accurate numeric data required by traditional methods base on Boolean algebra. For an example, for a particular activity it's possible to have a natural partitioning border between proper and non-proper regions, but in many cases of description cases about location conditions, they do not have natural cut offs determined threshold limit. In the common approach to a threshold limit, for example in a manner which defined that an acceptable site should be located in 1 KM from the river. But such a threshold limit is not natural. Why a site in 0.99km from the river will be acceptable, and a site located at 1.01km from the river will be placed in an acceptable class? Usually there a kind of ambiguity and lace of explicitly in such conditions. In addition usual methods always assume that criteria weights are given in a numeric form, which provide a preference from the most important to most unimportant of Site Selection standards. So, related discussion to ambiguity, doubt and inaccuracy should find a solution in Site Selection problems, which this may work well with Fuzzy set theories and Fuzzy logic (Rajabi et al. ,2009).

6 ANALYZING AND ASSESMENT OF THE BABOLSAR SLAUGHTERHOUSE LOCATION

The Babolsar slaughterhouse was created around 30 years ago and is situated in near the Shazdeh Roud Bridge, Beheshti Street. Municipality of Babolsar has run it during these years. Waste, or possibly sick livestock which produce daily, are burnt by a particular machine and the wastes are carried by waste transporting car. The slaughterhouse is divided in to 2rooms for cattle and sheep slaughter, bath, guard room, veterinary chamber, rest room for slaughterers. The compound is 9980 m^2 and the infrastructure is 695 m^2.

Current location of the Babolsar slaughterhouse is situated in the western legal limits of the city. The different environmental plans of this area express that the current location cannot satisfy scientific criteria for site selecting and it does not consider some problems such as pollution of surface water and groundwater, aesthetic tasks conflict, community(utilization conflict), economy(property and land prices) and neglect of tourist attractions due to its proximity with Shazde Roud river.

The coordinate of Babolsar slaughterhouse's current location in the UTM system is X=649471.09 and Y=4063138.20 which is quite unfavorable environmentally. The most significant reasons are:

(1) Wind diagram based on climate data indicates that the wins blow to the city from the north-west direction mainly and obviously the site selection of the slaughterhouse should not be on the way of prevailing winds, while the current situation is situated on this way.

(2) This current location is located in the legal limits of the city while based on master plan of Babolsar the legal distance form a large slaughterhouse to a town border is around 6 Km, for a middle size one is 3 Km and for small ones is considered 2 Km.

(3) Air pollution and the odor of it especially in the warm seasons pose an unpleasant effect on the tourism and public health and safety of surrounding places are under threat.

Fig. 1: Current location of the Babolsar slaughterhouse.

7 SITE SELECTION CRITERIA FOR THE BABOLSAR SLAUGHTERHOUSE

For site selecting of a slaughterhouse there are not any fixed and defined standards but for the most of variables used in this study, reliable reasons can be find that due to environmental constraints and potential of each area checking back of that criteria is a top priority. In order to find an appropriate landfill as a preliminary and initial instruction, following articles could be followed:

7.1 Location relative to the city

The site location should be place out of the city limits. Moreover site selecting must not be on the way of the city development.

7.2 Distance to the city

The legal distance form a large slaughterhouse to a town border is around 6 Km, for a middle size one is 3 Km and for small ones is considered 2 Km.

7.3 The position in relation to communication roads

The site should be located near to one of the arterial roads or a byroad link to the arterial road. In cities that are located on the railway track, it is more accurate to choose a place for slaughterhouse near the railway and if it possible create a branch line to be observed.

7.4 Slope

It should be constructed in an area lower than the city level in order to prevent the spread of contamination.

7.5 Prevailing wind

It must not situate on the way of prevailing wind.

7.6 Required water

It should be constructed in an area which in the required water can be accessible. Due to high consumption of water, tap water is not recommended. In this task drilling deep or semi-deep wells are favorable

7.7 Geometric shape of the area

It should be selected as rectangular shape because the infrastructure of slaughterhouse is situated longitudinally.

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

7.8 Wastewater treatment

The site should be positioned in order to prepared wastewater treatment and outgo as well. Thus, the following points are recommended in order to achieve this purpose: For a city with sewage system, the site should be selected on a place that the slaughterhouse wastewater does not flow in to sewer. When a city does not have sewage system and the slaughterhouse is situated somewhere near a river, after treatment of the slaughterhouse's wastewater, the harmless excess water could be directed in to the river. If there is no a river, the slaughterhouse's wastewater should refined after ensuring that the remaining water to be disposed in to adjacent lands in terms of agricultural use

7.9 Location of polluting industries

Slaughterhouse should not be exposed to pollution from industrial operations, dust, smoke, ash…

7.10 Watercourse

The land of a slaughterhouse should be away from the watercourse and it has an ability to have a durable foundation and columniation.

7.11 Farmers and nomads

Site selection should be in a place which is on the way of nomads but this criterion is important in areas where livestock passes specifically.

7.12 Access to electricity network

In the terms of the requirement of a slaughterhouse to electricity, site selection must be located in a place that the power grid is legally permissible. In large slaughterhouses the required electricity could be prepared by the use of a generator instead of power network but it is not recommended except in emergencies.

It should be noted that some measures such as slope, aspect, rainfall, distance from the historical and cultural monuments due to being non-functional do not consider in this study. For instance, the slop is rarely bigger than 0.5%, so it is not different for the slope direction and the rainfall is almost equal for this area.

According to the given the parameters, Site selection in the eastern Babolsar does not seem appropriate. Thus, reselecting for the slaughterhouse is a priority. On the other hand, physical planning for the urban development in terms of urban, regional and national levels must seek new geographic area that qualify for the creation of new cities, towns, infrastructure locating… or define urban development.

In this research a range of 20 km radius around the legal limits of the city is considered which includes 15 natural and artificial layers. By the use of different methods such as fuzzy logic these layers were combined and by the terms and conditions, prioritizing or in another words weighting the desired location for municipal solid waste landfill for at least 20yeras in the future in three prioritizations will prepare.

As mentioned that for the first time the fuzzy logic theory was expressed by Dr. Asgar Lotfizadeh UC Berkeley professor for the conditions of uncertainty. For reasoning, control and decision making under uncertainty this theory is able to define the mathematical formulation for a host of inaccurate and vague data, variables and systems. Accordingly, for the fifteen-fold layers of this study, membership degree of variables can be defined:

The distance of artificial objects (urban infrastructure, slaughterhouse, gas station, aviculture…) =

$$\int_0^{600} 1/x + \int_{600}^{2700} 2700 - \left(\frac{x}{2400}\right) + \int_{2700}^{\infty} 0/x$$

The minimum distance: 600m

The maximum distance: 2700m

Class number: 7

Data Domain: 300m

First class: 2700-300/2400=1

Second class: 2700-600/2400=0.87

Third class: 2700-900/2400=0.75

For all the layers this operation has done and it's weighting results with its plans present. Then, by the use of overlapping functions, these layers with their membership degrees are combined together and after the calculation of the total weight belong to the final map and classified them in to different classes, 3 sites are selected and defined. It should be noted that the proposed area consists of 32000 Polygon integrating layers is selected and presented. The most important characteristics these three sites are:

- The vegetation cover is low.
- Average distance from water sources is 570m
- Average distance of artificial objects (urban infrastructure, slaughterhouse, gas station, aviculture,…) is 1100m
- Average altitude is -21m
- Windward is low-intensity
- Appropriate for construction
- inappropriate for cultivation
- The lands have the potential for construction
- The lands do not have the potential for cultivation
- The soil type is coastal, gravel, sand and shelly geologically
- In terms of urban development compare with the other areas, construction will not be found
- The field has a saline soil and drainage problems are recognizable
- Average distance to Babolsar is 6000m
- Average distance for all 3 sites to communication roads is 550m
- Average distance to the legal limits of Babolsar is 8100m
- Average distance to the major faults around the city is 1200m

8 CONCLUSION

Babolsars urban development has been consequence from two main phenomenon, rural-urban continuum and natural growth of urban population. As an illustration, the growth from 18810 in 1976 to 47921 in 2010 it is clear to everyone that the urban management system in a critical condition and is far from ideal situation. This task is more tangible when the slaughterhouse site selecting was done based on criteria and standards. It means that the current location of slaughterhouse has not constructed based on scientific, technical criteria and appropriate planning. Assuming continuation of current urban meat consumption, 14.5Ton daily and 5296Ton annually, the requirement of accurate and efficient site locating should be a top priority.

The initial location of Babolsar slaughterhouse is situated in the south part of the city. But based on the mentioned criteria, this location is not required the sufficient standards in case of its area in particular (7655m²). Furthermore, it has an inappropriate environmental situation and not only its environmental pollution has emerged now, but also it will pose a devastating effect on the environment in the near future and sustainable development of the eastern city is facing a crisis. The proximity of the location to the Shazdeh Roud, being in the legal limited area of the city, locating in the urban physical development, being on the way of prevailing winds that cause landscape pollution, sharp increase in urban population, the requirement for a larger area in order to produce more meat for the residence and end of useful life of the current landfill in the near future, all the requirements for finding a new location have made it an absolute necessity.

The current site selecting has not considered the environmental parameters such as being away from earthquake faults, agricultural land, human settlements, suitable soil, urban physical development, wind direction, surface water, geology…and it indicates tangible kind of poor urban and regional management which threatens the future sustainability of the area. On the other hand, the future of the city is creating based on growing urbanization, the urban area formation, settlement of refugees….Defining plans and project in terms of guiding and controlling development for urban area which leads to compromise damages to biological resources and improving the tourism around the Shazdeh Roud. So, protection of valuable

environmental zones around the city, including the current place of slaughterhouse and sufficient site selecting with a less harm effects on environment and sustainable development are of significant requirements.

Combining artificial and natural data by the use of fuzzy logic and implement it in GIS can be practical not only for Babolsar, but also for the other regions of this country. Three areas which have been positioned in this research will satisfy all the requirements in this case for 20 years. The city requirements will satisfy due to its placement in an average radius around 6Km even up to 100 years in the future. The coordination is: the first priority, X=645019.31, Y=4058183.39 the second priority, X=654592.23, Y=4059100.06 the third priority, X=642790.14, Y=4056579.22.

1 ABSTRACT

This study discusses the urban flood prevention spatial planning by utilizing the spatial analysis technique to investigate urban environmental feature and different urban flood issues happened in different location while facing the complicated coexistent relationship between urban flood. Typhoon Morakot in Tainan will be the case study. This study utilizes the Geographically Weighted Regression (GWR) to explore the variables of urban environment. The outcome may serve as basis for establishing future land-use indicators and as decision-making reference for concerned government agencies.

Key Words: Urban Flood, Geographically Weighted Regression , Land use plan

2 INTRODUCTION

In 2005, the World Bank issued Natural Disaster Hotspots – A Global Risk Analysis which indicted that Taiwan may be the most vulnerable to natural hazards place on earth, with 73 percent of population exposed to three or more hazards. Urban flood is a major compound disaster world-wide that causes serious loss to economic activities and impacts on urban activities severely. This study focuses on establishing flood index to explore the variables of urban environment that was considered as one of the most important aspects in regional flood-risk management.

Flood is among the most severe risks on human lives and properties, and has become more frequent and severe along with local economical development. As the Taiwan's city has been compact rapidly and more stress is put on the land to support the increased population. In turn, floods that once occurred infrequently during pre-development periods have now become more frequent and more severe due to the transformation of the watershed from rural to urban land uses and urbaniziation phenomenon is one of the main research topics in the last decade. A comprehensive plan addressing flood hazard management is therefore, necessary. This plan should combine land use strategies for each zone with the careful consideration of certain structural controls. This can be achieved by the minimal disruption of natural environments. These strategies could serve as basic components in a comprehensive flood management plan in Taiwan.

Therefore, the important issue is integrating spatial analysis technique to investigate urban environmental feature and different compound disaster issues happened in different location with complicated coexistent relationship between urban and disaster. The GWR Model was a popular method that applied to modify the flood problem (Brunsdon et al., 1996; Fotheringham et al., 1998; Platt, 2004; Zhang et al., 2004; 2005; Kupfer and Farris, 2007). Although this approach can incorporate more factors as the predictors and improve the statistical significance of the fitting model, it also increases the difficulty of date collecting for predictors to predict the damage in the future. Since flood damage is affected by many factors, some multiple regression models to incorporate such factors were also proposed.

This paper begins by reviewing pertinent literature regarding spatial pattern in assessing urban flood. Next, a GIS flood grade system integrates into the research to enhance the effectiveness and precision of measurements. Thus, the aim of this study is to establish the flood for flood shape area by using the smallest possible number of independent variables, while considering the spatial variation and solving the problem of spatial autocorrelation in residuals.

3 METHOD

The following equation expresses the relationship of the flood spatial autocorrelation, geographically weighted regression, and data from study area:

3.1 Spatial Autocorrelation

Similar objects in proximity to one another are positively spatially auto correlated, and vice versa, zero autocorrelation occurs when attributes are distributed independently in space. Moran's I, as expressed in equation 4, 5.

$$I(d) = \sum_{i} \sum_{l} w_{il} z_i z_l / S_0 m_2 \quad (1)$$

Where

$$S_0 = \sum_{i} \sum_{l} w_{il}, \quad m_2 = \sum_{i} z_i^2 / I, \quad z_i = x_i - \bar{x} \quad (2)$$

A weight matrix has elements representing the connections in a set of spatial unit . The may assume any value, but in this paper we shall confine ourselves to a binary weight matrix consisting of ones (connected) and zeros (not connected). The diagonal elements of are zero. The variable is mapped onto the spatial units. The spatial autocorrelation analysis coefficient, Moran's I, is is the value of equity for each zone. i =1,2,. . ., I .

3.2 Geographically Weighted Regression

If the residual has spatial autocorrelation, then GWR can be utilised to modify the OLS regression to solve the problem (Brunsdon et al., 1996; Fotheringham et al., 1998; Platt, 2004; Zhang et al., 2004; 2005; Kupfer and Farris, 2007; Chang, 2008). If the spatially varied characteristics in flood are taken into account, equation 6 can be modified as:

$$y_i = b_0(\mathrm{u_i},\mathrm{v_i}) + \sum_{k=1}^{n} b_k(u_i, v_i) \cdot X_{ik} + \varepsilon_i \quad (3)$$

where: y_i is the flood of point i; x_i is the flood shape area of point i ; u_i, v_i is the coordinates of the $\boldsymbol{i}$ point in space; b_0 (u_i, v_i), b_k (u_i, v_i) is the realization of the continuous function at point $\boldsymbol{i}$; ε_1 is the residual of point (u_i, v_i).

3.3 Data and study area

Located in the southeastern corner of Eurasia Taiwan sits in the middle of the Western Pacific festoon of islands. It faces the East China Sea to the north (600 km from the Ryukyu archipelago), the Bashi Channel to the south (350 km from the Philippines), the Taiwan Strait to the west (averaging 200 km from the Chinese mainland), and the Pacific Ocean to the east. Situated at the western rim of the Pacific Basin, the island plays an important role as an East Asian crossroad.These study area Tainan is the forth-grade city in Taiwan, but it's the oldest city which has abundant cultural heritage, as the cultural style presented. The methodology will now be described in greater detail, taking as an example its pilot application for Tainan in Taiwan, which is a town in which there is present risk from flood hazard. The extent of the flooding suffered by the inhabitants of Tainan in 2009 is illustrated in Fig. 2.

Fig. 2. Tainan, Taiwan, in the floods of Auguster 2009(source: http://www.flickr.com/photos/kyo4890x115/3807860280/)

4 RESULTS

4.1 Explore spatial data analysis of flood area

This paper through a cases studies in where natural hazard happened areas and the analysis used the data from Tainan in 2009. The method integrates GIS techniques, spatial autocorrelation analysis (SAA) and local indicators of spatial association (LISA) to analyze the process of disaster scale and decision making is guided by examination which may vary from large regions. The disasters mapping of locations with significant LISA statistics, together with an indication of the type of local spatial association as given by the quadrants in the Moran scatter plot, provide the basis for a substantive interpretation of spatial clusters or spatial outliers. Show in figure 3.

Flood Area	A	B	C	D	E
Explore spatial data analysis					
Fig.3 The SAA and LISA analysis

The result of the SAA analysis on Tainan the value of Moran's I is positive 0.52, and refers to the random and independent distribution in region. LISA provides information on the relative important of four types of spatial association: (1) high–high, high values (above the mean) associated with high risk values such as A, B D areas; (2) low–low, low values (below the mean) associated with low risk values; (3) low–high, low values associated with high risk values; and (4) high–low, high values associated with low risk values. In the future, the land use planning suggests strengthening prevention such as Yong Kang district, Sinying district and Madou district.

4.2 GWR model

The GWR model results were more closely examined in this study to develop fur¬ther knowledge for later use in modifying the traditional OLS regression model. The regression result is shown in Table 2.

Effective Number of Parameters	Correlation Coefficient (r)	Coefficient of Determination (r^2)	Adjusted r-square (r^2 Adj)	P-valu
7.39	0.33	0.109	0.109	0.046(*p<0.05)

TABLE 2 Global regression parameter estimates (nis37)

The coefficient of determination is 0.109 while the residuals plot is shown as in Fig. 2. The application of GWR model improved the increased from 0.36, demonstrating that GWR provides a better interpreting ability than OLS. As shown in Fig. 4, the histogram of intercept estimates displays three obvious groups. Figure 6 depicts the spatial distribution of these three groups. There is a significant clustered pattern indicating that basic flood shape area increase gradually from west to southwest corner in the study region shown in fig.5. These parameter estimates indicate the change of the flood with the flood shape area, and are increased gradually from west to northwest in the study area.

4.3 Land use and flood analysis

The analyses of land using and flood herein cover comparisons of area size and land using category in Tainan City. In addition to interpreting the results of previous analyses of land using and flood in broad views, we predict that land using under limited control resources has some impacts to the flood.

Flood	Land Using Category	Total area(ha)	Number	Mean	S. dev.
High	Agriculture	1,254.6	729	1.72	5.61
	Building Area	1,40.2	1,290	0.10	0.71
	Green Space and Park	9.9	30	0.33	0.63
Medium	Agriculture	5,572.6	7,680	0.72	2.49
	Building Area	1,017	9,223	0.11	0.66
	Green Space and Park	4,549.7	193	0.23	0.76
Low	Agriculture	514.9	1,324	0.38	1.67
	Building Area	713.9	7,296	0.09	0.58
	Green Space and Park	128.5	233	0.55	1.25

TABLE 3 The descriptive statistic of flood

In Tainan City, 1,254.6 hectares of agriculture area were damaged because of high flood. Green space and park were not enough to absorptive capacity in the high flood area over 9.9 hectares. The highest capacity which green space and park can be absorptive in the Medium flood area is about 5,572.6 hectares. In the past, land use and flood analyses have been used to represent the size qualities of land use category. The land use and flood are affected by population, land using construction, and local differences. The construction of land using is often related to the geographic environment and urban development that mainly influences urban flood intensity.

5 CONCLUSTION

The paper proposed an approach that not only uses the smallest numbers of explained variables to establish the flood functions for flood shape area, but also solves the problem in traditional regression models by overlooking the spatial variations with flooding loss characteristics.

The introduction of the GWR model improved the coefficient of determination from 0.36 in the original OLS to 0.109. The GWR model corrects the spatial autocorrelation problems in residuals with some drawbacks still. It produces a different set of estimates for the regression parameters at each sample points. On the other hand, the results of flood and land use analyses indicate the three level risk of flood within land using situation, taken the urban flood characteristics of spatial pattern into consideration to improve green space and urban park area, and land using capacity that supplements urban environment safety and sustainable development.

Fill in the Blanks: Challenging the Modernism, Satisfying the Users' Needs?

Aleksandra Djukic, Aleksandra Stupar

(Dr Aleksandra Djukic, Assistant Professor, University of Belgrade, Faculty of Architecture, Bulevar kralja Aleksandra 73/2, 11000 Belgrade, adjukic@afrodita.rcub.bg.ac.rs)

1 ABSTRACT

The contemporary transformations, caused by frictions between local and global forces, have to provide comprehensive answers to numerous questions – from urban efficiency, environmental challenges, social (in)equality, to urban history, identity and future sustainability. However, the processes which shape our environment sometimes do not respond to actual needs of users, creating a gap between ambitious visions of professionals and politicians and our everyday life patterns.

Considering all recent challenges the paper will analyze the case of New Belgrade and its current urban metamorphosis which has an impact on the character of open public spaces. The focus of the research will be Block 21, which was built during the 1970s and 1980s, after the national architectural competition. Following the guidelines of the Master plan it was conceived as a mono-functional residential block, but its reconstruction, conducted in two phases (during the 1990s and 2000s), instigated some typological changes. New functions were added (for ex. commercial and office spaces), as well as new residential structures, which were quite different from existing ones. Open community spaces were also transposed to another type, different in size, function, pattern of communication and accessibility.

Following the thesis that successful public spaces should be responsive to the needs of their users, the paper will present a research which has been done on needs and conflicts in open space. Based on a survey and interviews of end users, along with observation and behavior mapping of activities, this paper should provide answers on how recent changes of Block 21 meet users' needs and to what extent they collide with the original modernist outline.

2 INTRODUCTION

The iconic modernist structures of New Belgrade have always been a symbol and a testimony of all ideological shifts in Yugoslav and Serbian society. More then 60 years of its urban existence has brought numerous adjustment and changes in its economic, social and functional structure, but its rigid and over-scaled urban matrix has mostly remained untouched. However, during the 1990s the process of a specific urban reconstruction started, tackling the sensitive issues of modernist architectural legacy, challenging the purity of original conception and introducing some new patterns of behavior and urban needs.

Since then, open public spaces in New Belgrade have been influenced by socio-economic turbulence on local and global level and included into an inevitable transformation of urban tissue. Their identity and role in everyday life of the local community have been redefined, tracing a new path for emerging models of urban life. The scale, as well as the spatial and functional concepts of these spaces have been questioned and exposed to professional criticism, while the upgrading and adjustment to contemporary demands and standards have become an imperative of further development of New Belgrade.

The old framework has been tested and modified, the questions of environmental quality have been raised, but the reality of open public spaces still has to be synchronized with identified needs of users. Therefore, the research presented in this paper underlines the importance of several important factors which have to be considered in every process of regeneration and renewal in order to provide a flexible and satisfying urban setting. The increased speed of global flows certainly requires immediate solutions, but they should provide a long-term sustainability and not just another instant remedy with numerous contraindications.

3 BEING MODERN?

3.1 The origin

After the end of the WWII, New Belgrade was conceived as a new administrative center of the state, reflecting ideological and technological aspirations of the recently established socialist society. Its unique

position in the topology of Belgrade enabled its total modern design based on a grid which followed ideas of Le Corbusier (Fig. 1).

Composed of nine mega-blocks the new urban space provided mainly residential and administrative activities, without necessary adjustments to the real needs of inhabitants. The public space of urban blocks was not articulated enough, which caused its inappropriate and uncontrolled use. Since the first generation of inhabitants came mostly from rural areas, they 'cultivated' this space in their own way – creating a semi-rural ambiance of gardens and small orchards around new buildings. Simultaneously, a traditional places for social interaction – streets and squares – were substituted with over-sized communal spaces which only stimulated alienation of potential users. However, there were some additional problems detected during the 1970s and 1980s such as a high density of mega-blocks, height of the buildings, quality of construction, monotony of urban blocks, lack of user-friendly public spaces and lack of facilities and services (Zivković, 1975).

Figure 1: Belgrade vs. New Belgrade – competitive scales and design.

3.2 Facing the changes

The 21st century has brought significant changes in the physical and functional structure of New Belgrade. The density has increased, new commercial activities have been introduced and it has become one of the major construction sites in Belgrade. The original typology of mega-blocks has been modified with new buildings positioned along the existing boulevards and the previous character of public spaces has been changed. Nowadays, the open modernist mono-functional assemblies are upgraded into a mixed-use development but some green spaces disappeared under hundreds of thousands of new square meters. Considering the number of inhabitants (about 300.000), their new social structure, a new profile of space users/consumers and their contemporary needs, it was necessary to focus attention to the quality of open/public spaces. Therefore, during the last decade, a process of revitalization and rehabilitation has started, (re)shaping the existing urban environment and inserting some new facilities (Figure 2).

Figure 2. New structures – mixed-use development, built during the last decade.

Various planning documents (from the Master plan of Belgrade 2021, district regulation plans and municipality programs) certainly provide a good foundation for action, but a survey about real users' needs had not been conducted before the beginning of the rehabilitation process. Therefore, this paper will present findings of a research done in 2011 which could guide some future interventions in the public space of New Belgrade mega-blocks, define updated requirements/standards and influence a process of evaluation – due to newly established criteria.

4 TOWARDS A NEW SOCIAL INTERACTION

4.1 Selecting the research polygon

The conducted part of research was limited to a selected case study - Block 21, representing one of the oldest mega-blocks in the Municipality of New Belgrade (Fig.3).

The main idea was to create recommendations for rehabilitation of public spaces which would be adjusted to the needs of all users and would be able to achieve a new level of general attractiveness and utilization. There were two basic research scopes – related to urban hardware (physical qualities of open urban spaces) and software (needs of users, especially within mega-blocks and their public spaces).

It was also important to distinguish two main groups of inhabitants, according to their place of origin, unique urban identity and attitude towards the surrounding. The first one consists of young people born in New Belgrade, with strong preferences toward the existing urban environment. The second one represents newcomers (from other towns or rural areas) who have (had) difficulties to adjust to a different scale and spatial concept, as well as to accept new habits. Consequently, the first group totally identifies with their residential background and the second group denies an imposed spatial framework, consciously or unconsciously fighting against its rules and limitations (Savic, 2000). However, in order to define total scale of users'needs, to determine a set of quality standards and to conduct comprehensive process of evaluation of public spaces, both groups were considered.

Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

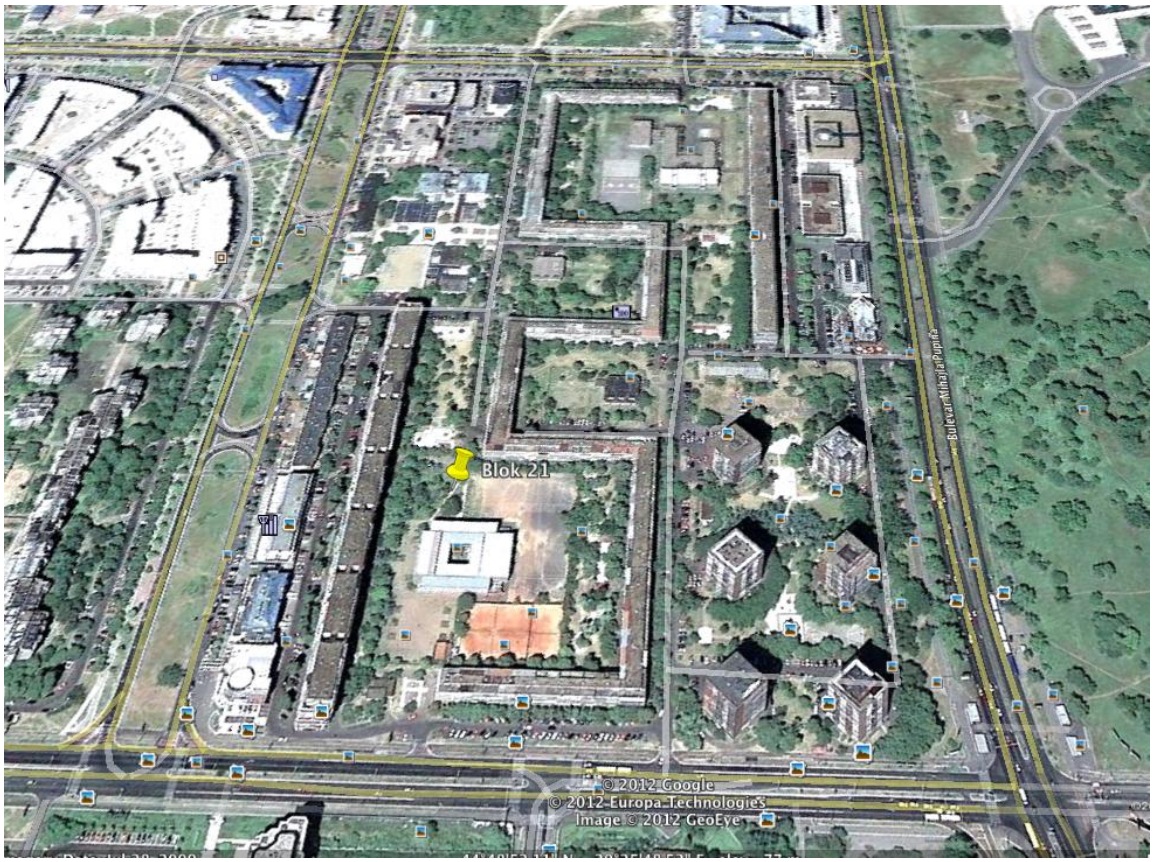

Figure 3: Block 21

The analysis of physical qualities of open spaces was enabled through a method of direct population survey which included 200 inhabitants of New Belgrade. The socio-demographic structure of the group was similar to the structure of the inhabitants, both in the Municipality of New Belgrade and Block 21, while the survey covered 2% of residents of Block 21 (Fig. 4).

The questionnaire was structured around five sections/thematic entities i.e. elements of mental maps defined by Kevin Lynch (1960) – paths, edges, districts, nodes and landmarks. The outcome of the survey revealed that the urbanscape(s) of New Belgrade and Block 21 have a potential to become local centers/focal points of social interaction, easily recognizable by their inhabitants.

The second part of the research, which underlined specific urban needs, provided an evaluation of open public spaces in Block 21. The survey was based on six main criteria, reflecting current state of the built environment and emphasizing issues of safety, equipment, accessibility, comfort, capacity and diversity of urban activities.

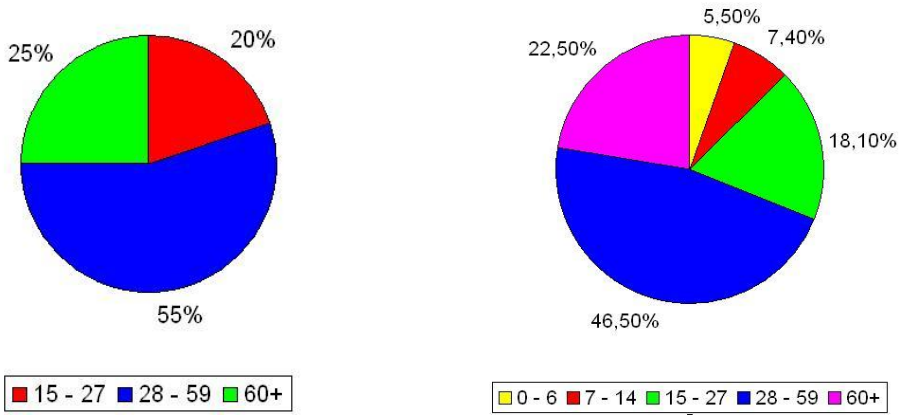

Figure 4: 4a/The age structure of the selected group of respondents vs. 4b/The age structure of population of New Belgrade.

4.2 Mapping the perception

The first part of the research was based on everyday observations of urban environment of Block 21 and the already mentioned basic elements - paths, edges, districts, nodes and landmarks. Analyzing the role and significance of paths/directions in the selected mega-block it was evident that the most important directions are Mihajlo Pupin Boulevard, Zoran Djindjic Boulevard and Milentija Popovica street. These corridors, which are essential parts of the rigid modernist grid, either connect or represent the tangent lines to the main landmark of New Belgrade - Business center Usce (Fig. 5).

Figure 5 The urban landmark - Business center Usce.

The next part of the questionnaire was related to identification and role of edges, which, according to Lynch, represent linear elements of urban space and act as boundaries or gaps (Jordan, 2003). The survey showed that some of the main paths/directions are also perceived as spatial boundaries (due to very intensive traffic), but some other streets (for ex. Proleterske solidarnosti str.) are identified as gaps in the continuity of urban space.

The role of the next spatial element – district – was analyzed on two levels: external and internal. The first one is related to the possible presence of landmark(s) which could be noticed from a distance, while the second one describes the uniqueness and specific atmosphere of an urban area. According to the survey, block 21 has three distinctive districts/areas – the assembly of six high-rise residential buildings (called 'Six Soldiers') (Figure 6), the area outlined with a long residential building in a meander-like form and the recently built area along Zoran Djindjic Boulevard. Furthermore, the respondents identified several nodes – as important points of arrival or departure within the block. Some of them are related to recreational activities (the inner courtyard of a high school and children playground) and to an interesting mixture of social interaction/entertainment and food and grocery shopping (open green market and McDonald's restaurant).

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

Figure 6. The district landmark - "Six soldiers".

The most important landmark and a focal point which directs movement (and different activities) is the business and shopping center Usce (Figure 5). It is in a close proximity of the selected block 21 but it also represents both local and city landmark. However, there are some other buildings which are identified as landmarks - due to their height, form, urban role or materialization (for ex. hotel Hyatt, Sava Center, '6 soldiers' and Arena) but their perception and visual significance are mostly related to local/New Belgrade scale.

4.3 Evaluating the public space

The second part of the research was oriented toward the open public spaces of block 21. They were analyzed and evaluated according to a matrix composed of six basic aspects/criteria which provided information about safety, accessibility, legibility, comfort, attractiveness and livability of the block (Fig. 7). The method of survey was used again and it gave an insight into actual needs of users. The results indicated that one of the main problems is subjective feeling of unsafety (mostly during the night), which is cased by insufficient public lighting and over-scaled public space. Furthermore, the respondents criticized some elements of the environmental comfort, especially during the summer (67%). The lack of green spaces was emphasized (98%), as well as the insufficient capacity of existing parking and garage places (92%). However, the maintenance of green public spaces was perceived ambiguously because 58% of respondents have a positive opinion about its general quality. It is also interesting to underline some other needs – for ex. to separate facilities by different groups of users (58%) or to increase the capacity and variety of sports facilities (42%).

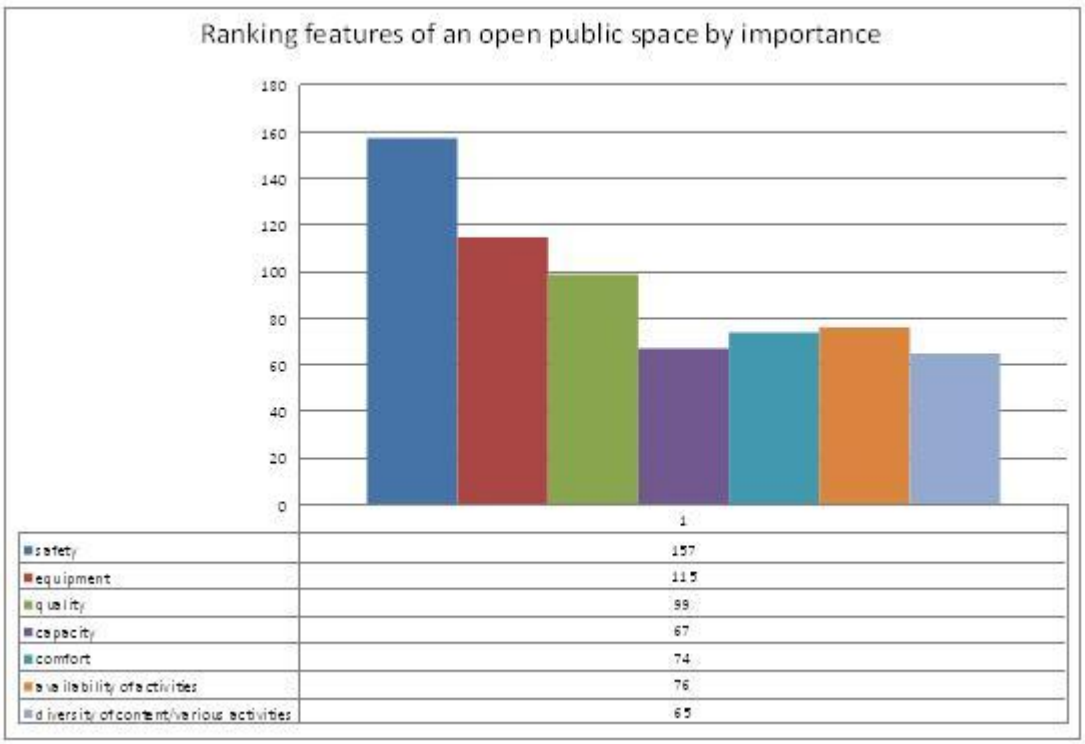

Figure 7: The results of evaluation.

According to the presented results (Fig. 8) the general opinion of inhabitants is not so positive. The majority of them think that the open public spaces of block 21 do not fulfill some of the selected criteria – safety (more than 80%), equipment and general quality of pavement and facilities (50%-60%), accessibility and comfort (37%) and livability (i.e. capacity and diverse of activities) - 30%. These identified problems should be used as initial points for further improvement of open spaces and according to them a list of priorities related to revitalization and redesign should be created (Fig. 9) – for ex. designing more children playgrounds (66%), increasing the number of parking lots (60%), increasing the number and quality of green spaces and improving the quality of the public space equipment/urban mobiliary (54%). However, the issues of accessibility and inclusive design were not so important for the current users (45%), as well as the introduction of new activities in the block (37%).

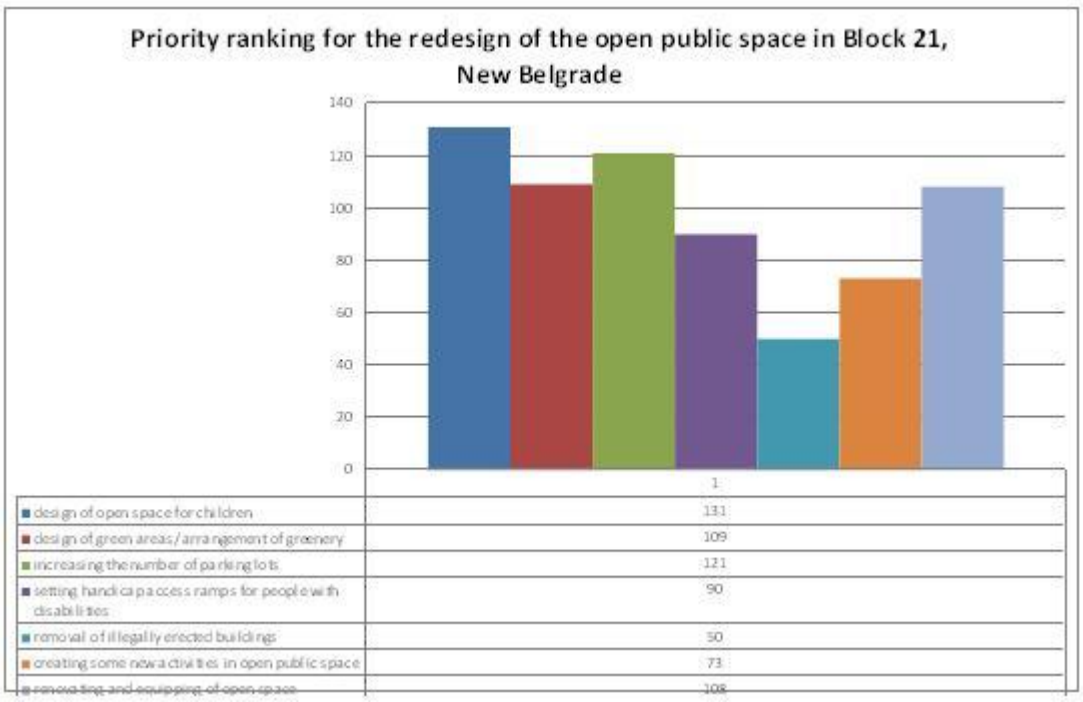

Figure 9. The survey results - evaluation of priorities for redesign of open public spaces.

4.4 Environmental challenges

The block 21 was built in the early 1970's and the buildings were designed without consideration of energy demands and consumption (Krstic-Furudzic, Djukic, 2007). Almost 90% of building stock was residential, with a few public buildings built in the late 1970's (kindergarten, elementary school, high school and district center). Before the regeneration, at the beginning of the 21st century, the block was mono-functional, with low density and large open spaces between buildings, but with good access to public transportation (the distance from buildings to bus and train stops is less than 500m).

After the reconstruction, block 21 became multifunctional, with commercial and business activities, which cut the number of journeys by car per day (everyday shopping, going to bank or etc.). New bicycle lines provide "green way of transport" (Djukic, Vukmirovic, 2011). With new development, spacing between buildings is reduced, density is increased and a better climate comfort is provided – especially during hot summers or cold and windy winter days.

Finally, in order to insure future sustainability of public spaces, it is necessary to apply some new elements of urban design - for ex. intensive greenery and flat green roofs wherever possible, water scenes, covering of open spaces with pergola, tent and vegetation which allow shade in the summer and solar radiation in the winter, the use of non-slip materials which decrease heat radiation during the summer and the improvement of visual identity of open spaces.

5 CONCLUSION: IMPROVING THE QUALITY

The research conducted in block 21 in New Belgrade indicates that recent processes of regeneration in mega-block have influenced some changes in public spaces within urban blocks, although with different effects. According to the data provided by the survey, the perception of paths/directions and edges/boundaries is clear, the existing landmarks are sufficient and easily readable and recognizable, but the position of nodes and their connections are not highly graded by the users. Furthermore, the evaluation of the open public spaces in the block, which was based on six selected criteria, opens some questions and traces new directions for the future planning/design process. The important design parameters are identified, the hierarchy of users' needs and detected problems is established and the issues of safety and overall environmental quality are emphasized. The redesign of children playgrounds, as well as the increased number of parking lots are underlined as the highest priority.

The identified problems and challenges could present an important input for every plan and action in public space. They reflect real needs of different groups of users, provide data for basic guidelines, define types and

scales of physical and functional transformations and influence the selection of planning instruments and tools. The research described in this paper highlights the importance of continuous adjustments and upgrading of public spaces, especially in a specific urban environment which is exposed to contemporary currents and trends, but also to some degree restricted by its rigid matrix and previous ideological labels. Therefore, the comprehensive process of urban regeneration of New Belgrade should also be one of strategic aims which trace further urban revival of this area. The Master Plan of Belgrade 2021 also emphasizes some priorities related to this issue – from the recovery of damaged urbanity, redesign and modernization of public spaces and their equipment, construction of a new and recognizable urban identity to the permanent education of inhabitants oriented towards the understanding of numerous benefits driven by urban renewal and regeneration.

Obviously, the period of transition demands integral approach which combines physical, functional, social and environmental solutions, raising the responsibilities for both citizens and city governments. Open public spaces in mega-blocks have always had a problem of scale and critical mass, but intensification of certain activities (especially recreation and leisure) could provide a necessary magnet on a local level, which should reinforce their role as gathering points. Additionally, the upgrading of spatial elements and their modernization in accordance with the demands of contemporary culture should enable a new, attractive setting for urban life and induce a re-symbolization of old patterns and structures. Establishing balance between needs of users and expected (and planned) sustainability of public spaces is not an easy task, but a high level of adaptability should be required and included in all plans and projects.

Geographic Views on Regional Planning and Development of Bosnia and Herzegovina

Rahman Nurkovic

(Rahman Nurkovic, Associate Professor, University of Sarajevo, , Faculty of Natural Sciences, Department of GeographyZmaja od Bosne 33, 71 000 Sarajevo, Bosnia and Herzegovina, rahmannurkovic@hotmail.com)

1 ABSTRACT

Geographic views on regional planning as an indicator of differences in regional development of Bosnia and Herzegovina are studied in the paper. In this regard, economic development, socio-economic transformation and regional development in Bosnia and Herzegovina have been considered. With evaluation of relevant parameters, ranking of developmental centres according to order of development has been performed, and typology of regional development of macroregions was built. The expressed differences in development were completed by corresponding structural characteristics of the observed spatial units.

2 INTRODUCTION

Over the past few decades in the world, problems of regional planning and development became evident. They are discussed at national, continental and world level. Regi¬onal developmental problems particularly gained in importance in Europe as a consequence of integration processes within the European Union. General socio-economic development of Bosnia and Herzegovina as a factor of regional development at the beginning of 1990s has been marked by several important events, which reflected intensly on its regional development.

Regional planning has geographic, temporal, functional and institutional outspread. Temporal outspread originates from orientation of planning to the future. From the past it takes the elements and factors that are of fundamental importance for analysing the existing conditions of the future development, respectively for determining the potential and desired changes, and the ways to them (Friedman, 1987).

Spatial planning deals with the issues of spatial setting the development based on a significant cognition that the space has limited abilities for development and growth setting, not on its general hinderances. It would be very uncertain if spatial planning separated, respectively, moved from developmental interests. In contemporary regional economic development of Bosnia and Herzegovina the greatest disputes are related to natural and social factors of spatial planning and regional development. Regardless these differences, it is quite certain that natural components of the space largely define the economic system of many contemporary societies and economic spaces, accordingly the regional development of Bosnia and Herzegovina as well.

Connection between space and regional development should be observed in the dialectical unity. There is no influence of space on development without its retroactivity on the space itself. Thus, space appears at the same time as factor, but also as the object of development. Namely, it is known that development affects essentially the condition and quality of natural space components. That influence reflects in the level of economic development of single activities in Bosnia and Herzegovina. .

3 REGIONAL DEVELOPMENTAL DIFFERENCES

Regionally, developmental differences are the problem of the whole world (Lorber 2003). Despite the efforts toward more balanced regional development, differences are increasing to a certain extent in more developed countries as well, and exertion gets one of the major issues of today's world. The European countries are also differently developed, and developmental differences between different regions are even more expressed.

Although regional developmental differences are dependant on a series of factors, natural condition, geographic position, political causes and inherited economic conditions are regarded as major ones. The mentioned factors are the determining factors in economic and regional development of Bosnia and Herzegovina in the regional aspect. As a rule, regional development is a product of the number of factors. In Bosnia and Herzegovina, in cities, suburbanized areas, and other suburbian settlements and industrial settlements, even 95% of all jobs are present. On the other hand, less developed areas cannot follow such development and leg behind.

The European Commision presented its vision of regional development through spatial plans in Bosnia and Herzegovina, on the basis of five regions, as follows: Sarajevo economic region (about thirty municipalities),

Northeast Bosnia (about forty municipalities), Northwest Bosnia (about thirty municipalities), Central Bosnia (about twenty municipalities) and Southeast Bosnia (about thirty municipalities). Sarajevo city is a regional and economic centre of the economic region of Sarajevo, a centre of Norteast Bosnia is in Tuzla, of Central Bosnia in Zenica, of Southeast Bosnia in Mostar and of Northwest Bosnia in Banja Luka.

With regard to size of territory of Bosnia and Herzegovina, population density, communicativeness of space, level of economic development and distribution of larger urban centres, it has been estimated that optimum spatial size of one macroregion ranges between 10 to 15 thousand km2. With such size of one macroregion the average maximum distance of marginal parts of one macroregion from its centre would range bewteen 56 to 69 km. It is being aimed therewith that the maximum distance of marginal areas from the basic centre be up to 100 km and only in situations when altenative divisons are not possible, that distance would be somewhat more than 100 km (Nurković 2005).

The objective of the European Union regional policy tends to a decrease in regional developmental differences. This includes a provision of financial resources for development of the less developed countries and the border areas within the programme „INTERREG“, which is intended for support of economic participation among the regions.

Such allocated financial aid would contribute structurally to weak border areas, improving living conditions in a province, assisting in putting an end to problems during integration of the countries into EU, and contribute economically to other participations and connecting with both sides.

With spreading the economic participation and assistance in the border areas, strong globalization influences are always in the fisrt plan, which primarily use cheap raw materials, market, undamaged natural environment, available space, localities for recreation, cheap labour force in industrial facilities and in cross-border employment etc (Christensen 1985).

There is much of such cross-border participation in different forms on the border between Bosnia and Herzegovina and Croatia: in 2001, about 14.000 inhabitants of Bosnia and Herzegovina travelled for work to Croatia, Serbia and Montenegro on daily basis, thereof about 8.000 to Croatia and about 6.000 to Serbia and Montenegro. Such participation and connecting means a determining overall expansion, not only economic expansion of the centres of power to the border and other regions and their influence on economic and regional development. This is particularly important for tourism, which is the most dominant in border regions (Pak 2003).

With regard to natural, social and economic factors, differently developed border regions of Bosnia and Herzegovina are classified into three groups:

- Border areas with a high level of urbanisation and a cross-border connection of the population and economy, eg. between Brčko and Gunja;
- The second group is represented by the border areas between Serbia and Montenegro, which are very far from larger developmental centres or, simply said, those areas that border with the less developed border areas in both neighboring countries;
- The third group comprises the border areas on Croatian-Hungarian border, which include, to a larger extent, traditionally less developed areas. (Osmanković, 2001).

Bosnia and Herzegovina belongs to mountainous European countries. In particular, its border areas are dominantly hilly. Since the relief definitely affects the population, traffic passability and a series of other developmental elements, it affects for the most part the development of border areas. So, dominatly mountainous border area at the farthest border of Bosnia and Herzegovina and Croatia is divided on several different parts with the broad valleys in Bosanska krajina, wide open against the closer million agglomerations of Zagreb and Belgrade. In every place the border areas on Bosnia and Herzegovina-Croatia border are mixed. c

Problems with which the planners from Bosnia and Herzegovina encountered seem to be similar to those in other countries. Most of the problems have been solved in a similar manner as in other countries, but the errors in planning and implementation of the plans were not avoided as it has been expected. The urbanised population in the whole period has had rather high growth rates.The achieved level of urbanisation in 2011 (according to criterion by which inhabitants of settlements bigger than 2.000 inhabitants are regarded as

urbanised) of 49,5% indicates that Bosnia and Herzegovina lined up to the countries having medium urbanisation level.

The highest growth of the number of settlements was achieved in a group of the settlements with 2.000-10.000 inhabitants, and the highest demographic growth had the settlements in group of 50.000 -100.000 inhabitants. Spatial arrangement of the settlemets with more than 2.000 inhabitants, respectively 10.000 inhabitants, with basic road infrastructure and directions of concentration of population and activities is seen on Map 1. Some sociologic researches indicate that in such rapid quantitative changes of the size of cities one should seek also a significant incapability of adjusting the settled population to urban conditions, intolerance, agressiveness and alike. Many pople see it as the urban-rural conflict.

In expert works of Vresk, Nurković and Rebernik, urban geographers and planners, the German geographer Auerbach, who indicated to certain dependence between the size and number of the cities in the region even at the beginning of the 20th century, is often applied for analysis of hierarchic dimension of the urban systems. In the simplest form of the rank-size rule it is expected to have a city in series of cities in the country or the region, which are distributed by size, respectively the number of inhabitants of the largest city is divided by ordinal numeral of that city. It can be demonstrated by the formula: $Pk = \frac{P1}{k}$ with P1 the largest city and Pk a city with ordinal numeral k.

Table 1, of 15 selected cities in Bosnia and Herzegovina, based on application of the rank-size rule, indicates that Sarajevo is the largest city, and the next group of cities is a group of approximately equal cities (Fig.1). Frequency distributions of cities according to the rank-size rule have shown that the population of Bosnia and Herzegovina prefers living in larger cities. From the aspect of industrialisation and urbanisation, it is a consequence of deagrarisation and demand for jobs in secondary, tertiary and quaternary activities in the city.

City	Population		Position		Real order	Population
	1981	1991	1981	1991	-	2010
Sarajevo	448.519	527.049	1	1	1	750.000

4 BASIC DIRECTIONS OF DEVELOPMENT OF SPATIAL PLANNING IN BOSNIA AND HERZGOVINA

Upon creating the Spatial Plan of Bosnia and Herzegovina a very broad process of preparation of spatial plans of municipalities has been open, and a certain number of spatial plans of special areas were performed. Preparation of spatial plans of municipalities was based mainly on methodology and experiences gained on the preparation of the spatial plan of Bosnia and Herzegovina. For these needs no particular researches were done. The basic approach at the preparation of municipal plans was based on polycentric development, respectively on development of secondary municipal centres and centres of cummunity of villages, as well as on decrease of the present process of population concentration in the municipal centres.

Orientation was also on the protection of agricultural and forest soil, sources of drinking water and valuable natural and hystorical areas. Spatial plans of the municipalities became a very significant instrument of protection and arrangement of space, although they had some defficiencies such as imprecise data bases, insufficient knowledge of local circumstances by planners, insufficient inclusion of local communities in plan preparation and alike (Nurković 2003).

Demands for integration with EU emphasize the problems of preservation and further development of national identity, as well as the requirements that are in sense of competitiveness placed by urban system of Europe (Černe 2005). Urban areas of Bosnia and Herzegovina will integrate into the urban network of Europe (Euro-regions) through regional cooperation, by forming the network of urban centres and by development of multimodal transport corridors.

It is estimated that this concept corresponds to a new urbanisation process, which is characteristic of polycentric urbanised regional space, strong communication corridors, regional division of work, as well as various privileges related to living environment. Ideas of understanding the new conurbations as competitive parts of the European urban system may be applied on already formed agglomerations of Bihać, Banja Luka, Tuzla, Zenica, Sarajevo and Mostar. The area of Sarajevo should be treated as a metropolitan region, which will be formed as one of significant urban centres of southeast Europe.

For urban continuity and cultural iden¬tity of Bosnia and Herzegovina historical inheritance has a particular importance, so it is indispensable to provide its renewal and inclusion into the development, as part of the European cultural inheritance. With spatial plan of Bosnia and Herzegovina the planned area of natural values (about 16% of area of Bosnia and Herzegovina) should be protected by special plans (spatial plans of special areas) and included into natural inheritance of Europe and the world (UNESCO). Cities of Bosnia and Herzegovina have great importance as developmental centres and generators of development, which

makes them nodal points in area planning, and regional development and regional development on the whole.

It is necessary to organize institutions for spatial planning and regional development on regional level (Klemenčić 2005). At the state level it is obvious that a research also needs to be organised through an adequate institute for spatial planning. Economic and interdisciplinary researches of regional inequalities have shown that they are mostly a result of economic reasons (general economic policy, employment and pricing policy, balance of payments etc.), and other factors such as natural-geographic conditions, historical inheritage, traffic-geographic possibilities etc.

It is important to say that an explanation for the mentioned regional inequalities in Bosnia and Herzegovina is found mainly in traffic-geographic separation of some areas in relation to nationalor broader regional centre. That problem of separation, in essence, is reduced to a question of traffic accessibility. It can be said that, unlike more accessible regions of Bosnia and Herzegovina, regarding a kind and number of traffic connections, time of travelling and travel expenses, less accessible regions separated, burdened with serious developmental difficulties.

In the mentioned research of regional development and regional inequalities application of model centre-periphery represents a significant methodologic innovation. Bosnia and Herzegovina is faced with a problem of regional inequalities. They were particularly expressed in the past twenty years, which caused implementation of adequate policy of re-gional development. These inequlities were intensified due to war cirumstances after 1990 and need to be considered in the future as well. However, within its territory Bosnia and Herzegovina has a core region and peripheral and undeveloped regions as well. Therefore, certain considerations of relation centre –periphery, on the basis of traffic role, respectively traffic accessibility, may serve as a foundation for realising the issues of regional development of Bosnia and Herzegovina.

5 CONCLUSION

In contemporary regional economic development of Bosnia and Herzegovina the biggest disputes are related to natural and social factors of spatial planning and regional development. Regardless these differences, it is quite certain that natural components of space largely determine the economic system of many contemporary societies and economic spaces, and accordingly the regional development of Bosnia and Herzegovina as well. Connection between space and regional dvelopment should be observed in the dialectical unity. This is also proved by experience of Bosnia and Herzegovina and involvement of the international community in the regional development and forming the regions in Bosnia and Herzegovina.

Recommendations for Bosnia and Herzegovina from the European Union, on the basis of knowledge of quality spatial plans and national characteristics, and additionaly by realising different succesful examples, would be oriented toward the regional development. It seems that all potentials of adequate regionalisations and regional development have not been fully recognized yet. The authors from Bosnia and Herzegovina have recognized four, respectively five basic macroregions in the area of Bosnia and Herzegovina with centres in Sarajevo, Mostar, Zenica, Tuzla and Banjaluka. These regions have scientific, expert, empirical, historical and every other foundation.

Geschlechterverhältnisse und Mobilität–Welchen Beitrag leisten Mobilitätserhebungen?

Mechtild Stiewe, Juliane Krause

1 ABSTRACT

Mobilität ist eingebettet in bestehende Geschlechterverhältnisse unserer Gesellschaft, wobei sowohl das biologische als auch das soziale Geschlecht (sex/gender) von Bedeutung sind. Die Genderperspektive in der Mobilitätsforschung zu berücksichtigen bedeutet, sie durch geschlechtsspezifische Datenerhebungen und –auswertungen zu thematisieren. Es wurde ein erweiterter Genderbegriff im Zusammenhang mit Mobilitätsuntersuchungen entwickelt und darauf aufbauend die Erhebungsdesigns der großen Mobilitätserhebungen in Deutschland analysiert. Festgestellt werden konnte, dass in den verschiedenen Erhebungen Genderaspekte wie beispielsweise Betreuung, Pflege und Begleitung von Kindern und Angehörigen zwar erfasst werden, diese in den Analysen und Veröffentlichungen bislang jedoch nur wenig Berücksichtigung finden. Vor diesem Hintergrund werden insbesondere die Daten zur Mobilität in Deutschland (MID 2008) im Sinne des Gender Mainstreaming ausgewertet.

2 PROBLEMAUFRISS

Mobilität und Verkehrshandeln sind eingebettet in bestehende gesellschaftliche Strukturen und Geschlechterverhältnisse unserer Gesellschaft. Tägliche Wege zur Arbeit, zum Einkaufen, die Begleitung von Kindern oder alten Menschen bestimmen unseren Alltag. Es sind immer Frauen und Männer, Kinder und Ältere, Mobilitätseingeschränkte, Menschen mit Migrationshintergrund, die diese Wege zurücklegen, also Menschen mit einem biologischen (sex) und einem sozialen Geschlecht (gender).

Die Berücksichtigung der Genderperspektive in der Mobilitätsforschung bedeutet einerseits Geschlechterverhältnisse zu thematisieren (geschlechtsspezifische Datenerhebungen und -auswertungen), andererseits gilt es, einen Perspektivenwechsel vorzunehmen und die Blicke zu schärfen auf unterschiedliche Lebenslagen, Lebensstile und Strategien zur Alltagsbewältigung, die sich nicht mehr ausschließlich am biologischen Geschlecht bzw. den tradierten Rollenzuschreibungen festmachen.

Zur Erhebung des Verkehrsverhaltens werden in der Verkehrsplanung Mobilitätserhebungen (Beobachtungen oder Befragungen) durchgeführt, wobei Befragungen zusätzlich zum individuellen Verkehrsverhalten auch Bestimmungsgründe und subjektive Motive des Verhaltens erfassen lassen. Mobilitäts- und Verkehrserhebungen liefern Informationen zur Soziodemografie von Personen und Haushalten sowie deren Wege (z. B. Führerscheinbesitz, Pkw-Verfügbarkeit, Wegezweck und Verkehrsmittelnutzung).

Mobilitätserhebungen in Form von Haushaltsbefragungen in Kommunen und Regionen orientieren sich häufig am so genannten „Kontiv-Design“ (Haushaltsbogen, Personenbogen, Wegeprotokolle). Das (biologische) Geschlecht wird bei allen großen Studien sowie bei kommunalen Mobilitätserhebungen, ebenso wie Genderaspekte (z. B. Betreuung, Pflege und Begleitung von Kindern und Angehörigen) in der Regel zwar erfasst, in den Auswertungen, Analysen und Veröffentlichungen finden diese Aspekte bislang nur unzureichend Berücksichtigung.

Hier gilt es, Kriterien für gendersensible Mobilitätserhebungen zu entwickeln sowie Hinweise zur Modifikation und Ergänzung der traditionellen Erhebungsdesigns und ihrer Auswertung und Interpretation zu entwickeln. Dies mit dem Ziel, letztendlich zu mehr Geschlechtergerechtigkeit in der Mobilitätsforschung beizutragen.

Eine erfolgreiche Umsetzung von Gender Mainstreaming im Verkehrsbereich ist besonders in einer Zeit der immer weiteren Differenzierung von Haushaltsstrukturen und Lebensstilen ein Qualitätsmerkmal von Planung und Politik und bei der Entwicklung konkreter Handlungsansätze unverzichtbar.

3 BEGRIFFE UND INDIKATOREN MIT GENDERBEZUG

3.1 Gender

Gender - das bedeutet, nicht stereotyp "die Frauen" oder auch "die Männer" in den Blick zu nehmen, sondern Menschen in ihrer Unterschiedlichkeit und Vielfalt zu berücksichtigen. Niemand ist nur männlich oder nur weiblich, aber wir leben in einer Welt, die maßgeblich durch die Zuweisung von Geschlechterrollen geprägt ist. Durch die Verwendung des Begriffs „Gender“ oder „soziales Geschlecht“ werden die Geschlechter und deren Verhältnisse zueinander stärker in den Blick gerückt, es werden die sozialen Unterschiede oder Rollen beschrieben, die Frauen und Männer in Abhängigkeit ihrer sozialen Situation bzw. Lebenssituation in unserer Gesellschaft haben.

Der Begriff Gender ...

... verweist auf die ökonomischen, sozialen und kulturellen Zuschreibungen und Chancen die damit verbunden sind, männlich oder weiblich zu sein. In fast allen Gesellschaften unterscheiden sich Männer und Frauen im Hinblick auf ihre Aktivitäten, im Zugang zu und Kontrolle über Ressourcen und auf die Teilhabe an Entscheidungsprozessen. Die Geschlechterdefinition – was es heißt, männlich oder weiblich zu sein – variiert zwischen den Kulturen und ändert sich mit der Zeit. (Quelle: Leitfaden EU Gender Mainstreaming 2005 / EQUAL Program)

3.2 Gender Mainstreaming

Gender Mainstreaming verfolgt das Ziel der Geschlechtergerechtigkeit und bedeutet, bei allen Planungen und Entscheidungen, Verordnungen oder Gesetzen von Anfang an daran zu denken, dass sie sich unterschiedlich auf Frauen und Männer auswirken könnten, da es keine geschlechts-neutrale Wirklichkeit gibt.

Die Genderperspektive besagt, dass Frauen und Männer, aber auch Kinder/Jugendliche, Mobilitätseingeschränkte, Ältere, Menschen mit Migrationshintergrund in der Gesellschaft unterschiedliche Lebensbedingungen und Chancen vorfinden. Sie alle entwickeln aufgrund geschlechtsspezifischer, sozialer bzw. ethnisch-kultureller Sozialisation und unterschiedler Lebenssituationen spezifische Interessen und Bedürfnisse. Sie sind von gesellschaftlichen Prozessen und deren Auswirkungen unterschiedlich betroffen.

Der so erweiterte Genderbegriff bezieht die genannten Gendergruppen mit ein, wobei jeweils noch nach Geschlecht und Alter differenziert werden sollte. Der erweiterte Genderbegriff umfasst auch die baulich-räumlichen Strukturen, das heißt die Betrachtung der Siedlungsstruktur. Die Lebensverhältnisse der Bevölkerung variieren nicht nur in Abhängigkeit vom regionalen Kontext, sondern zusätzlich nach dem Geschlecht, d. h. die Situation von Frauen und Männern unterscheidet sich zwischen Kernstädten, Umlandkreisen, ländlichen Kreisen und/oder dem ländlichen Raum (unterschiedliche Verfügbarkeit von Öffentlichen Verkehrsmitteln, unterschiedliche Vielfalt und Nähe von Infrastruktureinrichtungen, Entfernung der Orte des täglichen Lebens).

3.3 Indikatoren mit Genderbezug [1]

Indikatoren zeigen etwas an, Ausgangspunkt der Erstellung von Indikatoren ist ausdrücklich oder implizit die Definition eines Ziels, in dessen Richtung sich die Wirklichkeit verändern soll. Die Entwicklung von Indikatorensystemen ist somit nicht wertfrei.

Bei Indikatorensystemen mit Genderbezug im internationalen Kontext ist Verkehr bzw. Mobilität (noch) kein Thema, im nationalen Kontext gibt es erste Ansätze, von Bedeutung sind hier der Gender-Index und der bundesweite Gleichstellungsatlas.

Jedes Jahr veröffentlicht das Entwicklungsprogramm der Vereinten Nationen (UNDP) den Bericht über die menschliche Entwicklung. Dabei wird jährlich der Index für menschliche Entwicklung berechnet, bekannt unter der Abkürzung HDI (Human Development Index). Darüber hinaus seit 1995 der geschlechterbezogene Entwicklungsindex (gender-related development Index), kurz GDI [2] . Auf nationaler Ebene sind in erster

[1] Vgl. ausführlicher KRAUSE, 2011.

[2] Seiner Bedeutung liegen dieselben Variablen zugrunde wie der des HDI. Der Gender Empowerment Measure (GEM). „Empowerment“ (oder Ermächtigung) steht für die Stärkung der Rolle der Frauen und die Förderung der Teilhabe an politischen und gesellschaftlichen Entscheidungsprozessen.

Linie die zahlreichen Indikatorensysteme zum Themenfeld „Nachhaltigkeit“ zu nennen. Diese sollen helfen, notwendige Prozesse hin zu einer nachhaltigen Entwicklung zu steuern, Grundlage ist die Agenda 21.

Die Nationale Nachhaltigkeitsstrategie „Perspektiven für Deutschland: Unsere Strategie für eine nachhaltige Entwicklung“ legt 21 Indikatorenbereiche vor (Stand Fortschrittsbericht 2008). Diese Indikatoren sind vier Bereichen zugeordnet. Im Bereich Lebensqualität ist der Indikatorenbereich „Mobilität“ mit dem Nachhaltigkeitspostulat „Mobilität sichern – Umwelt schonen“ jedoch lediglich durch Indikatoren wie Güter- bzw. Personentransportintensität oder Anteil des Schienenverkehrs an der Güterbeförderungsleistung dargestellt.

Der Gender-Index [3] ist ein Instrument, welches die Chancengleichheit oder auch -ungleichheit zwischen den Geschlechtern indizieren, darstellen und zwischen den Regionen vergleichbar machen soll. Er ist das erste bundesweite Messinstrument zum regionalen Vergleich der Gleichstellung von Frauen und Männern. Für 19 Indikatoren aus den Bereichen Ausbildung, Erwerbsleben und Partizipation werden die relativen Abweichungen der Indikatorenausprägung für Frauen und für Männer berechnet. Der Gender-Index ist der Mittelwert dieser 19 relativen Geschlechterdifferenzen [4]. Gestützt auf das räumliche Informationssystem, die Laufende Raumbeobachtung des BBSR, werden erstmals bundesweit flächendeckend, systematisch und umfassend die regionalen Lebensverhältnisse von Frauen und von Männern in diesen drei Bereichen Ausbildung, Erwerbsleben und Partizipation bewertend im Gender-Index zusammengefasst. Ziel ist es, den komplexen Sachverhalt der Gendergerechtigkeit sichtbar zu machen und dadurch die zentralen Handlungsfelder für mehr Chancengleichheit in den verschiedenen Regionen zu veranschaulichen (vgl. www.gender-index.de). Mobilität und Verkehr sind jedoch (bislang) kein Thema.

Der Atlas zur Gleichstellung von Frauen und Männern in Deutschland (Gleichstellungsatlas) ist eine erste Standortbestimmung der Gleichstellungssituation nach Bundesländern anhand von 30 Indikatoren. Interessant für die Untersuchungsfragestellung ist die Kategorie Lebenswelt mit den beiden Indikatoren „Ältere Menschen in Einpersonenhaushalten“ und „Lebenserwartung“. Bei beiden Indikatoren zeigen sich deutliche geschlechtsspezifische Unterschiede (BMFSFJ, 2009).

Die regelmäßige Berücksichtigung zentraler Kenngrößen aus dem Mobilitätsbereich – wie beispielsweise die (geschlechtsspezifische) Betrachtung der Wegezwecke oder die Erreichbarkeit unterschiedlicher Ziele – könnte dazu beitragen, die Chancengleichheit bzw. geschlechtsspezifische Unterschiede aufgrund gesellschaftlicher Rahmenbedingungen, Einstellungen und Gewohnheiten aufzuzeigen. Eine gute Datengrundlage bieten die regelmäßigen Erhebungen zum Mobilitätsverhalten der Bevölkerung.

4 LANDESWEITE EHEBUNGEN ZUM MOBILITÄTSVERHALTEN

Die drei bundesweiten Erhebungen zum Verkehrsverhalten der Bevölkerung in Deutschland sind Mobilität in Deutschland (MID), Mobilität in Städten (SrV) sowie das Deutsche Mobilitätspanel (MOP). Diese Erhebungen dienen auch als empirische (Kalibrierungs)Grundlagen für Verkehrsmodelle und damit auch gesamtstädtischen oder regionalen Verkehrsplanungen.

Mobilität in Deutschland (MID) ist die bundesweite Haushaltsbefragung [5] zum Verkehrsverhalten. Hierbei werden die außerhäuslichen Aktivitäten und Wege aller im Haushalt lebenden Personen von ausgewählten Stichprobenhaushalten in einem bestimmten Stichtag mittels eines standardisierten Fragebogens erfasst. Die erste bundesweite, umfassende Erhebung des Verkehrsverhaltens der Bevölkerung wurde 1976 im Rahmen der KONTIV – Kontinuierliche Erhebung zum Verkehrsverhalten durchgeführt, diese wurde mit jeweils ähnlichem Design in den Jahren 1982 und 1989 wiederholt. Im Jahr 2002 erfolgte die Untersuchung erstmals als gesamtdeutsches Projekt unter dem Namen Mobilität in Deutschland (MiD). Im Rahmen von MiD 2008

[3] www.gender-index.de

[4] Die Formel zur Berechnung des Gender-Index lehnt sich dem schwedischen Jäm-Index (auch als Gender Equality Index bezeichnet) an. Statistische Tests unterstützen den Gender-Index als geeignetes Messinstrument der regionalen Gleichstellung von Frauen und Männern.

[5] Bei Haushaltsbefragungen zum Verkehrsverhalten werden die außerhäuslichen Aktivitäten und Wege aller im Haushalt lebenden Personen von ausgewählten Stichprobenhaushalten in der Regel an einem Stichtag mittels eines standardisierten Fragebogens erfasst. Im Regelfall werden Daten und Informationen zum werktäglichen und sonntäglichen Verkehrsverhalten erhoben. Die Erhebungseinheit ist der Haushalt, d. h. die Befragungsunterlagen werden an die Haushaltsadresse für alle Haushaltsmitglieder verschickt. Untersuchungseinheit ist die individuelle Person.

erfolgt eine Stichtagserhebung über 12 Monate in 25.000 Haushalten mit 62.000 Personen. Im Rahmen von regionalen Aufstockungen sind weitere Gemeinden hinzugekommen. Bei der Auswertung werden die BBR-Siedlungstypen berücksichtigt (vgl. MEYER/ MILBERT et al., 2007). Im Gegensatz zur MiD 2002 ist in der MiD 2008 die Staatsangehörigkeit (Bezug zu Migrationshintergrund) nicht mehr erfragt worden.

Das System repräsentativer Verkehrsbefragungen (SrV) erhebt Daten zur Alltagsmobilität von Personen auf der Grundlage von Haushaltsbefragungen in Städten. Das SrV wurde an der TU Dresden zur Gewinnung von Daten zum städtischen Personenverkehr in der DDR entwickelt. Die erste der als Haushaltsbefragung durchgeführten Erhebungen hat 1972 stattgefunden. Im Rahmen der SrV werden Daten für so genannte mittlere Werktage (Dienstag bis Donnerstag) erhoben Die SrV-Ergebnisse werden sowohl für jede beteiligte Stadt (Stichprobenumfang pro Stadt mindestens 1.000 Personen) als auch abstrahiert für verschiedene Stadtgrößen ausgewertet. Auftraggeber sind Kommunen, Länder sowie Verkehrsunternehmen. Der Untersuchungsraum des SrV 2008 umfasst 76 Städte, Gemeinden und Verwaltungsgemeinschaften auf dem Gebiet der Bundesrepublik Deutschland.

Das Deutsche Mobilitätspanel (MOP) ist eine als Panel angelegte Längsschnittstudie zum Mobilitätsverhalten. Die Personen derselben Haushalte werden über insgesamt drei Jahre hinweg einmal pro Jahr zu ihrem Mobilitätsverhalten befragt. Jeweils im Herbst werden die Teilnehmenden gebeten, eine Woche lang ein Wegetagebuch zu führen. Befragt werden alle Haushaltsmitglieder ab einem Alter von 10 Jahren. Die Stichprobe besteht jährlich aus ca. 1.500 Personen (750 Haushalte), von denen zwei Drittel „Wiederholer“ der Befragung sind, das andere Drittel wird neu für das Panel angeworben.

Bislang werden explizit „Genderfragen“ in der Mobilitätsforschung kaum angesprochen. Zwar gibt es eine Reihe von Studien, die immer wieder belegen, dass sich Frauen und Männer außer Haus unterschiedlich bewegen (Verkehrsmittelnutzung, Wegezwecke etc.). So werden Indikatoren wie Pkw-Verfügbarkeit, Führerscheinbesitz, Verkehrsmittelwahl und Wegezwecke geschlechtsspezifisch und häufig auch nach Altersgruppen ausgewertet. Eine Differenzierung zwischen sex und gender ist bislang jedoch kaum zu finden.

Im Kontext dieser Untersuchung wird im Schwerpunkt auf die bundesweite Mobilitätserhebung Mobilität in Deutschland (MID) eingegangen.

5 GENDERASPEKTE IN DER MID

Voraussetzung für eine Chancengleichheit ist - unabhängig vom Geschlecht – eine soziale Teilhabe am gesellschaftlichen Leben. Diese wird wesentlich auch durch die Mobilitätsmöglichkeiten bestimmt; wichtig ist eine gute Erreichbarkeit von Wohn- und Arbeitsorten, Versorgungs-, Bildungs- und Kultureinrichtungen. Dass Frauen und Männer unterschiedlich mobil sind, zeigt sich in allen Lebensphasen. Nur eine gender-differenzierte Analyse des Verkehrsverhaltens zeigt ein realistisches Bild der gesellschaftlichen, sozialen und räumlichen Rahmenbedingungen für Mobilität. (vgl. STIEWE/ KELP-SIEKMANN, 2010)

5.1 Referenzgruppen als Grundlage für eine gendergerechte Auswertung

Bei der Bildung von Referenzgruppen (so genannte Gendergruppen, z. B. Ältere Menschen, Alleinlebende, Mobilitätseingeschränkte, Menschen in Familienhaushalten, Menschen mit Migrationshintergrund) wird davon ausgegangen, dass bei diesen Gruppen das Mobilitäts- bzw. Verkehrsverhalten aufgrund bestimmter Rahmenbedingungen und ähnlicher Bedürfnisse „verhaltenshomogen“ ist. Der Begriff Referenzgruppen wurde aus den Bezeichnungen Lebensphase (MiD), Lebensstile/Mobilitätsstile und Haushaltstypen (MiD), verkehrssoziologische Personengruppen (SrV) sowie Untersuchungen zum Verkehrsverhalten verhaltenshomogener Gruppen bzw. zur Lebenssituation bzw. zum Mobilitätsverhalten von Frauen abgeleitet. Gebräuchliche Kriterien zur Bildung dieser Gruppen sind die Berufstätigkeit (Stellung im Erwerbsprozess), die Stellung im Beruf, das Geschlecht, das Alter, die Pkw-Verfügbarkeit, die Anwesenheit von Kindern im Haushalt (vgl. HOLZ-RAU, 1990).

Im Rahmen des Projektes wurden anhand einer umfassenden Literaturrecherche bedeutende Indikatoren zur Bildung von Referenzgruppen aus der Genderperspektive und Bezug zum Mobilitätsverhalten ermittelt (Abb. 1). Als zentrale Faktoren zur Bestimmung des Mobilitätsverhaltens von Gendergruppen haben sich die soziale Situation (Single, alleinerziehend, Partner/in), die Erwerbstätigkeit und das Vorhandensein von Kindern im Haushalt (Versorgungsarbeit, Begleitmobilität) herauskristallisiert. Weitere bedeutende

Indikatoren sind Alter, Geschlecht, Lebensphase, Haushaltstyp, ökonomischer Status, PKW-Verfügbarkeit, Regionstyp [6].

Fig. 1: Indikatoren zur Bildung der Referenzgruppen

Als Ergebnis lassen sich folgende Referenzgruppen mit Genderbezug ableiten: Kinder und Jugendliche,

Menschen mit Migrationshintergrund, Mobilitätseingeschränkte Personen, Menschen in bestimmten Lebenssituationen; Alleinerziehende, Ältere Menschen, Alleinlebende.

Bei der nachstehenden Betrachtung wird aus den Daten der MID 2008 als erster Schritt das Mobilitätsverhalten der Referenzgruppe „Menschen in bestimmten Lebenssituationen“ analysiert: Alleinerziehende (1 Erwachsene/r und mind. 1 Kind unter 18 Jahren) , Einpersonenhaushalte (Menschen bis einschl. 64 Jahre), Familienhaushalte (2 Erwachsene und mind. 1 Kind unter 18 Jahren), Ältere Menschen (ab 65 Jahre), wobei jeweils nach Geschlecht differenziert wird.

Die Gruppe der Alleinerziehenden zeichnet sich durch einen sehr hohen Frauenanteil (88%) aus, der Altersdurchschnitt liegt hier bei 42,2 Jahren. Über ein Viertel (26%) der Haushalte in dieser Gruppe besitzt kein Auto. Die Gruppe der Älteren Menschen sticht mit einem Frauenanteil von 55% heraus, was sich durch die höhere Lebenserwartung von Frauen erklärt. Auffällig an dieser Gruppe ist, dass auch hier knapp ein Viertel keinen Pkw besitzt. Familienhaushalte dagegen sind nur zu 2,4% ohne Auto, 38% der Haushalte besitzen ein Auto, 50% besitzen zwei Pkw. Mit 40,0 Jahren haben Personen aus Familienhaushalten den niedrigsten Altersdurchschnitt unter den Referenzgruppen. Die Alleinlebenden haben - die Gruppe der Älteren Menschen ab 65 Jahren ausgeklammert – mit 46,6 Jahren den höchsten Altersdurchschnitt. Bei Betrachtung der Altersgruppen fällt auf, dass sich 58% der männlichen Alleinlebenden in den Altersklassen 30 bis 59 konzentrieren, während bei den Frauen über alle Altersgruppen eine relativ ausgeglichene Verteilung zu beobachten ist, sich jedoch im Vergleich zu den Männern in der Altersklasse 60 bis 64 deutlich mehr Frauen befinden. In dieser Gruppe liegt der Anteil der Haushalte, die kein Fahrzeug besitzen bei 29%.

6 UNTERSCHIEDE IM VERKEHRSHANDELN EINIGE ERGEBNISSE AUS DER MID

Im Hinblick auf Unterschiede in der Lebenssituation der Geschlechter, der Ethnie, der Herkunft und der Sozialisation ist zwar in vielen Bereichen eine Tendenz zur Angleichung erkennbar. Dennoch sind Frauen nach wie vor in vielen gesellschaftlichen Bereichen strukturell benachteiligt u. a. hinsichtlich Einkommen, Arbeitsbedingungen oder Vermögen. Zudem sind sie, unabhängig von der Berufstätigkeit, immer noch mehrheitlich zuständig für den Hauptteil der Reproduktionsarbeit (Kindererziehung, Pflege von Angehörigen, Haushaltsführung, etc.). Zur Erfüllung dieser Aufgaben legen sie zusätzliche Wege zurück, sind anders mobil (mehr zu Fuß und mit öffentlichen Verkehrsmitteln) und heben sich somit vom durchschnittlichen Mobilitätsverhalten der Männer ab.

[6] Die siedlungsstrukturelle Typisierung des BBSR gliedert Deutschland in drei Regionstypen und neun Kreistypen) nach den Merkmalen Bevölkerungsdichte sowie der Größe und zentralörtlichen Funktion der Kernstädte der Regionen (MEYER/ MILBERT et al., 2007).

So legen statistisch betrachtet beispielsweise berufstätige Mütter in Deutschland 4,3 Wege pro Tag zurück; im Gesamtdurchschnitt werden in Deutschland 3,4 Wege pro Tag zurückgelegt (MiD 2008). Eine Zunahme der Berufstätigkeit von Frauen – insbesondere von Müttern – führt nicht jedoch zu Gleichheit, sondern zur Doppelbelastung der Frauen bei eher gleichbleibenden Verhältnissen für die Männer. Im Alter bis 30 Jahre hingegen gibt es – betrachtet man nur das Geschlecht, unabhängig von der Lebenssituation – keine signifikanten Unterschiede.

Im Folgenden werden einige ausgewählte Ergebnisse der Auswertung der MiD vorgestellt; berücksichtigt wurden dabei alle Personen ab 18 Jahren.

6.1 Führerscheinbesitz

Eine zentrale Kenngröße der Mobilitätsvoraussetzung ist der Führerscheinbesitz. Insgesamt verfügen 93% der Männer und 83% der Frauen über einen Führerschein. In den letzten Jahren ist der Anteil der Personen, die einen Führerschein besitzen kontinuierlich gewachsen. Betrachtet man die steigenden Führerscheinzahlen jedoch altersgruppenspezifisch, so ist bei den jungen Erwachsenen ein leicht rückläufiger Trend zu erkennen; 87% der Frauen und 85% der Männer besitzen einen Führerschein, dies ist auch die einzige Altersgruppe in der der Anteil der Personen, die einen Führerschein besitzen bei den Frauen größer ist als bei den Männern. Insgesamt holen Frauen in allen Altersklassen beim Führerscheinbesitz auf, dennoch verfügen in der Altersgruppe über 74-Jährigen nur 49% über einen Führerschein.

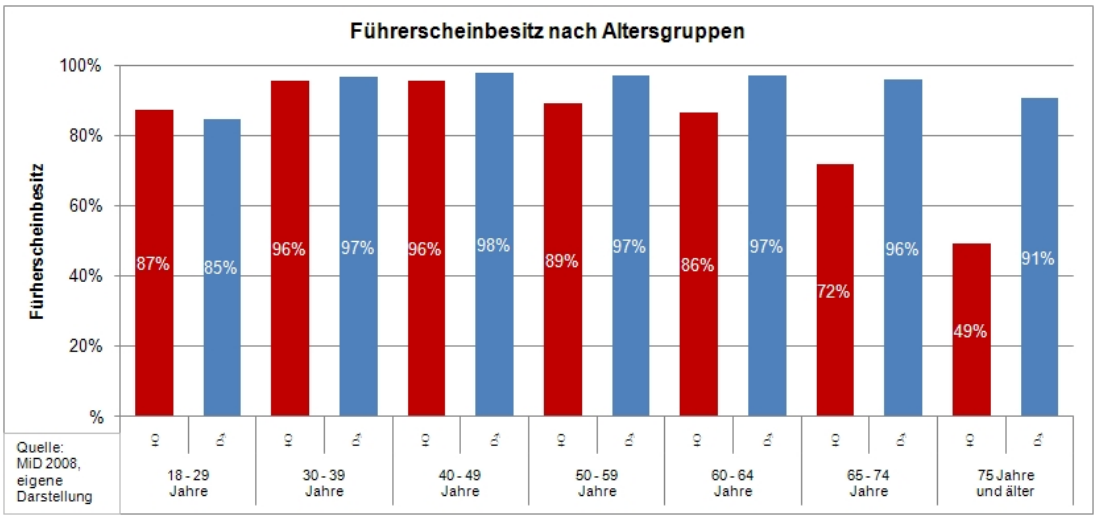

Fig. 2: Führerscheinbesitz nach Altersgruppen

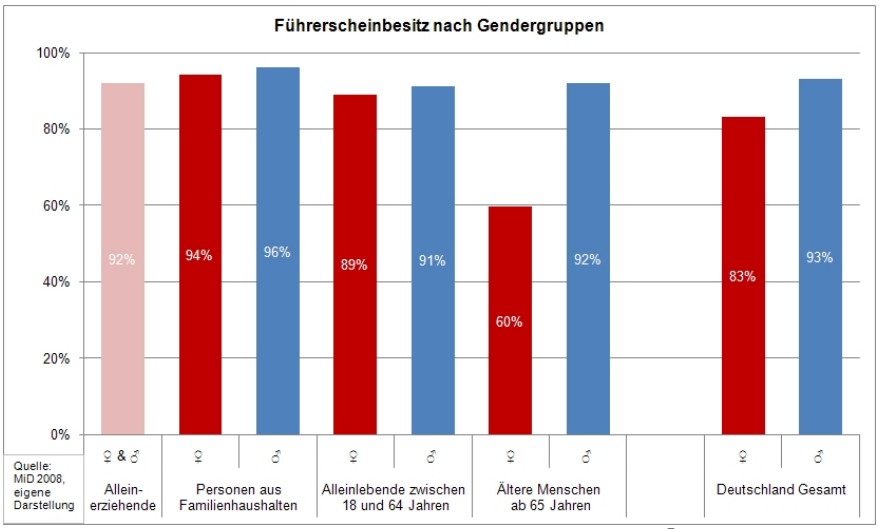

Fig. 3: Führerscheinbesitz nach Gendergruppen [7]

[7] Zwischen der Gruppe der Älteren Menschen und der Alleinerziehenden (=7 Fälle)sowie zwischen den Älteren Menschen und den Personen aus Familienhaushalten (=210 Fälle) ergaben sich Überschneidungen. Die betroffenen Fälle wurden der Gruppe der Älteren Menschen zugeordnet.

Unterschiede im Führerscheinbesitz zeigen sich auch ganz deutlich in Abhängigkeit der Lebenssituation. In Familienhaushalten ist der Führerscheinbesitz sowohl bei den Männern als auch bei den Frauen am höchsten. Auch die Alleinerziehenden [8] (88% Frauen) verfügen zu 92 % - und damit überdurchschnittlich häufig - über einen Führerschein.

6.2 Pkw-Verfügbarkeit

Entscheidend neben dem Führerscheinbesitz ist für das Mobilitätsverhalten die Pkw-Verfügbarkeit. Junge Frauen haben zwar häufiger einen Führerschein als Männer in der gleichen Altersgruppe, können aber seltener über einen Pkw verfügen. Insgesamt geben 83% der Männer aber nur 72% der Frauen an, jederzeit über einen Pkw verfügen zu können. Dass der Führerscheinbesitz nicht mit der Pkw-Verfügbarkeit einhergeht zeigt sich insbesondere in der Gruppe der jungen Erwachsenen. Über alle Altersgruppen können Männer eher über einen Pkw verfügen als Frauen. Wenn Frauen über ein Auto verfügen können, sind sie häufig aber nicht Besitzerin des „verfügbaren Pkw“; dies erklärt sich dadurch, dass der Fahrzeughalter – insbesondere des Erstwagen – häufig der Mann ist. Es ist zu vermuten, dass Frauen immer noch häufiger auf die Pkw-Nutzung verzichten müssen, wenn mehr Personen mit Führerschein im Haushalt leben als Pkw vorhanden sind.

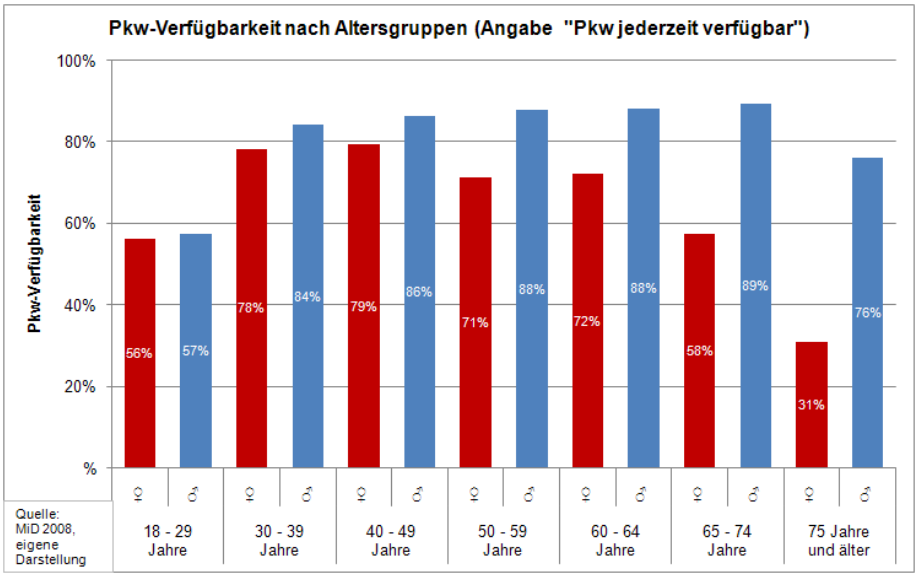

Fig. 4: Pkw-Verfügbarkeit nach Altersgruppen

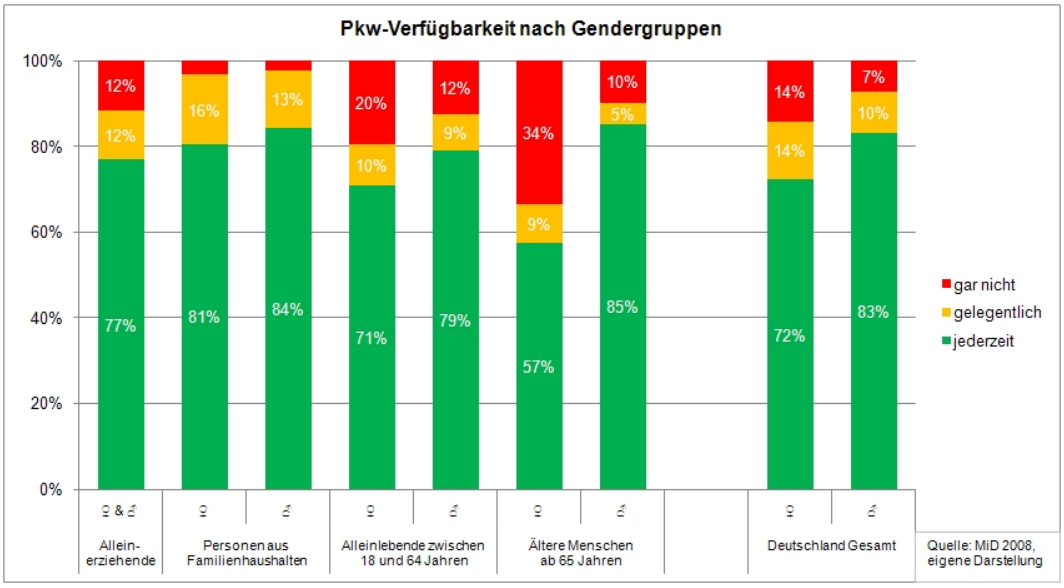

Fig. 5: Pkw-Verfügbakeit nach Gendergruppen

[8] Da der Anteil der Männer bei den Alleinerziehenden nur 12 % (=54 Befragte) beträgt, wurde auf eine geschlechterdifferenzierte Darstellung an dieser Stelle verzichtet.

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

Bezieht man das Einkommen mit in die Betrachtung ein, so wird deutlich, dass weit über die Hälfte der Haushalte mit geringem Haushaltseinkommen keinen Pkw besitzt und auch nicht darüber verfügen kann. Hierbei handelt sich vor allem um Rentnerhaushalte und Haushalte ohne Kinder. Eine Ausnahme stellen die Alleinerziehenden dar, sie verfügen trotz geringen Einkommens häufiger über einen Pkw, wohl auch um die vielfältigen Mobilitätsbedürfnisse und -zwänge realisieren zu können. Es zeigt sich also, dass uneingeschränkte Zugang zum Pkw längst nicht die Regel ist sondern es in Bezug auf das Alter und die jeweilige Lebenssituation durchaus Unterschiede gibt.

6.3 Verkehrsmittelnutzung

Frauen legen deutlich mehr Wege zu Fuß zurück als Männer; dies zeigt sich über alle Altersgruppen und auch in den verschiedenen Lebenssituationen. Bei der Nutzung der Öffentlichen Verkehrsmittel ist über alle Wege betrachtet kaum ein Unterschied zwischen den Geschlechtern festzustellen; lediglich die älteren Frauen nutzen öffentliche Verkehrsmittel deutlich häufiger als die Männer, was auch auf die fehlenden Führerscheine zurückzuführen ist. Die meisten Wege mit dem Pkw werden von Männern aus Familienhaushalten zurückgelegt. Insgesamt lässt sich sagen, dass Auto bis ins Alter hinein das am häufigsten genutzte Verkehrsmittel ist und das Unterwegssein bei den Männern eher durch die Autonutzung geprägt ist als bei den Frauen. Bestimmt wird die Autonutzung in hohem Maße auch die Pkw-Verfügbarkeit; steht ein Pkw zur Verfügung, wird dieser auch genutzt.

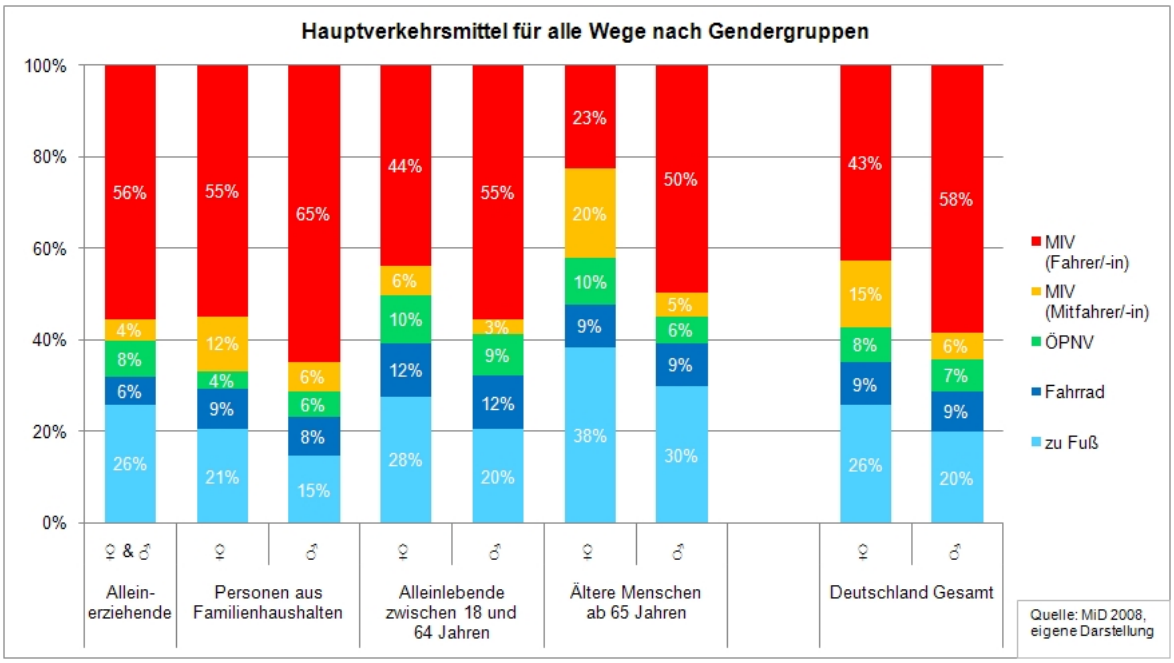

Fig. 6: Modal Split nach Gendergruppen

6.4 Wegezwecke

Während sich die Anzahl der Wege zwischen Frauen und Männern insgesamt nur wenig unterscheidet, zeigen sich im Hinblick auf die Wegezwecke deutliche Unterschiede zwischen den Geschlechtern und der Lebenssituation – auch das Alter spielt hier einen entscheidende Rolle. So ist der Anteil der Begleitwege bei Alleinerziehenden und Frauen aus Familienhaushalten mit 18% bzw. 20% deutlich größer als in den anderen Gruppen. Auch der Anteil der Einkaufswege ist mit 23% bei den Frauen aus den Familienhaushalten deutlich höher als der der Männer (15%). Gleichzeitig ist der Anteil der Arbeitswege und der dienstlichen Wege deutlich geringer als bei den Männern derselben Gruppe. Dies deutet auf eine traditionelle Arbeitsteilung hin. Der Wegezweck Freizeit hat den geringsten Anteil in der Gruppe der Frauen aus Familienhaushalten mit 26% und bei den Alleinerziehenden mit 28% aller Wege.

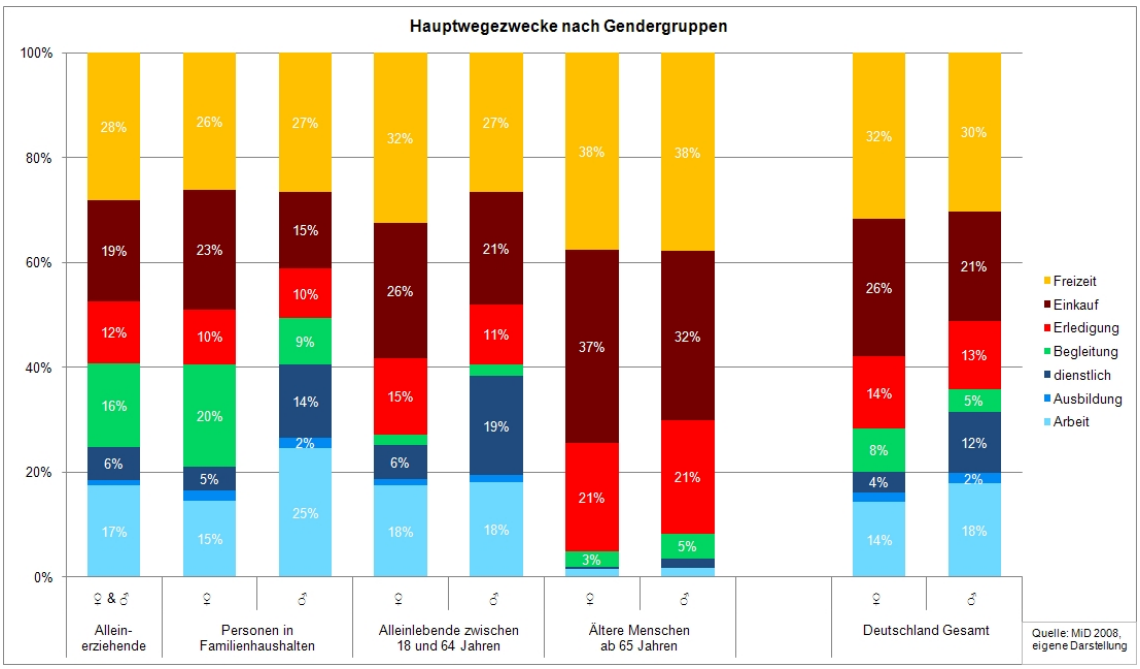

Fig. 7: Hauptwegezwecke nach Gendergruppen

6.5 Wegenanzahl, Unterwegszeiten und Distanzen

Bei den zentralen Mobilitätskenngrößen „Mobil am Stichtag“, Wegeanzahl, tägliche Unterwegszeit und zurückgelegter Distanz zeigen sich zwischen den Referenzgruppen deutliche Unterschiede. Zwar unterscheidet sich die Zahl der täglich zurückgelegten Wege zwischen Männern und Frauen insgesamt kaum, doch zeigen sich je nach Lebenssituation deutliche Unterschiede. So legen Alleinerziehende mit 4,2 Wegen pro Tag die größte Anzahl zurück; ältere Frauen hingegen legen nur 2,6 Wege zurück. 95,5% der Alleinerziehenden waren am Stichtag unterwegs, sie weisen mit knapp 100 Minuten am Tag auch die größte Unterwegszeit auf. Die durchschnittliche Wegelänge ist dabei mit gut 10 km dabei deutlich kürzer als die der Männer aus Familienhaushalten, die durchschnittlich 16 km pro Weg zurücklegen. Der Alltag der Alleinerziehenden, aber auch der Frauen aus Familienhaushalten ist durch eine Vielzahl an Versorgungs- und Begleitwegen geprägt, die häufig zu Fuß zurückgelegt werden und mit einem entsprechenden Zeitaufwand einhergehen. Die geringste Mobilitätsquote weisen die älteren Frauen auf; 20 % von ihnen waren am Stichtag gar nicht unterwegs, sie legen durchschnittlich 2,6 Wege am Tag zurück und sind ca. 64 Minuten unterwegs. Ein Großteil der Wege wird von ihnen zu Fuß zurückgelegt.

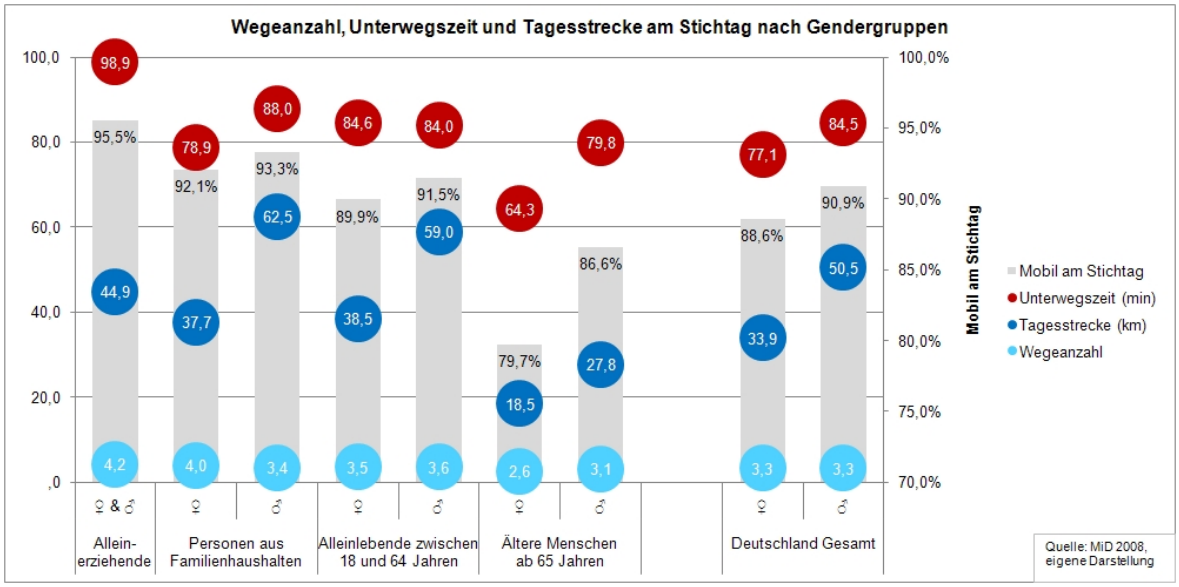

Fig. 8: Wegeanzahl, Unterwegszeit und Tagesstrecke am Stichtag sowie Anteil mobiler Personen nach Gendergruppen

7 FAZIT

Die Analyse der Erhebungsdesigns großer Mobilitätserhebungen hat gezeigt, dass in verschiedenen Erhebungen durchaus Genderaspekte erfasst werden, diese in den Auswertungen und Veröffentlichungen bislang nur in geringem Maße thematisiert werden.

Auswertungen der vorliegenden Daten zeigen, dass Unterschiede in den Mobilitätsvoraussetzungen sowie im Verkehrshandeln zwischen den Geschlechtern vorliegen.

Es sind also immer noch Maßnahmen notwendig, die Gerechtigkeit zwischen den Geschlechtern herzustellen, eine zentrale Voraussetzung ist es aber zunächst den Status quo sichtbar zu machen und die vorliegenden Erhebungsdaten im Sinne des Gender Mainstreaming auszuwerten.

Geschlechtergerechtigkeit lässt sich aber auch nicht ohne Berücksichtigung von Migrationsaspekten herstellen. Mit Gender Mainstreaming wird damit der Blick einerseits auf diese strukturellen Unterschiede gelenkt, andererseits aber auch für die unterschiedlichen Bedürfnisse, Interessen und Anforderungen auch innerhalb der Gruppen (in Abhängigkeit von der Lebenssituation) der Männer und Frauen geschärft. Damit geraten z.B. die soziale Lage, das Alter aber auch der ethnische Hintergrund in den Blickpunkt. Dies setzt jedoch voraus, dass entsprechende Daten auch erhoben werden. So gibt es beispielsweise bislang nur wenig Kenntnis (und kaum Daten) über das Mobilitätsverhalten von Menschen mit Migrationshintergrund. Erste Hinweise kann hierzu das aktuelle Forschungsprojekt des ILS „Mobilität von Menschen mit Migrationshintergrund und soziale Benachteiligung durch ungleiche Mobilitätschancen liefern“.

Auch wenn Bund, Länder und Kommunen zur Umsetzung des Gender Mainstreaming und damit auch zu einem Gender-Monitoring verpflichtet sind, zeigt sich, dass gerade im Mobilitätsbereicht wenige Genderindikatoren und im Sinne des Gender Mainstreaming analysierte Daten vorliegen.

Die bundesweiten Verkehrserhebungen wie MiD, SRV und MOP aber auch die auf kommunaler oder Kreisebene durchgeführten Mobilitätserhebungen bieten jedoch bereits eine gute geschlechterdifferenzierte Datengrundlage für ein Gender-Monitoring, die es auch in der Planungspraxis zu nutzen gilt.

1 ABSTRACT

Städte und Dörfer in Deutschland müssen die sich aus gesamtgesellschaftlichen Entwicklungen ergebenden Probleme, wie Alterung und Schrumpfung der Bevölkerung, sozialer Wandel sowie abnehmende öffentliche Mittel, bewältigen. Dies betrifft auch das sich zunehmend wandelnde Sportverhalten mit einer geänderten Nachfragesituation und wirkt sich auf die Sportorganisation und die Sporträume im kommunalen Wirkungskreis aus. Die sich daraus ergebenden notwendigen Anpassungsstrategien und Maßnahmen stellen die Städte und Dörfer vor neue Herausforderungen.

Sport und Bewegung leisten einen wichtigen gesellschaftlichen Beitrag, der sich vor allem in den Bereichen Gesundheit, Soziales, Ökonomie und Ökologie widerspiegelt. Sport kann damit als integrativer Bestandteil der kommunalen Daseinsvorsorge verstanden werden. Der sich vollziehende Wandel sollte von den Kommunen als Chance begriffen werden, die Sportentwicklung als wesentlichen Faktor der nachhaltigen Ortsentwicklung zu verstehen und aktiv zu gestalten. Aufgrund der hohen Raumwirksamkeit von Sport und Bewegung betrifft dies vor allem auch die Stadtplanung, die diesen Bereich zunehmend in ihre konzeptionellen Ansätze integrieren sollte.

Der Beitrag „Gesunde Kommune – Chancen für eine nachhaltige Stadtentwicklung durch Sport und Bewegung“ analysiert die Zusammenhänge zwischen Raum und Sport sowie die aktuellen Entwicklungstendenzen von Sport und Bewegung und deren räumliche Auswirkungen. Vor dem Hintergrund des strukturellen, gesellschaftlichen und demographischen Wandels werden Konsequenzen für eine nachhaltige Ortsentwicklung abgeleitet und zukünftige neue Lösungsansätze für die Raumentwicklung zur Stabilisierung und Stärkung der Sport- und Bewegungsangebote zur Diskussion gestellt. Als Grundlage dienen die Ergebnisse aus Projektphase 1 des im Jahr 2011 von der Entwicklungsagentur Rheinland-Pfalz e.V. beauftragten und vom Lehrstuhl Stadtplanung in Kooperation mit dem Lehrgebiet Sportwissenschaft der TU Kaiserslautern begonnenen Forschungsprojektes „Gesunde Kommune – Sport und Bewegung als Faktor der Stadt- und Raumentwicklung“. Im Rahmen des Projektes wurde dazu eine Bevölkerungsbefragung in sechs Untersuchungsgemeinden in Rheinland-Pfalz durchgeführt.

2 AUSGANGSSITUATION

Gesellschaftliche Veränderungen (vgl. dazu Abschnitt 5.1 und 5.2) erzeugen wesentliche Auswirkungen auf das Sportverhalten der Bevölkerung, die sich auch maßgeblich auf die Nachfragesituation im Bereich von Sport und Bewegung niederschlagen. Neben der weiteren Ausdifferenzierung der Nachfrage nach „klassischen“ Sportarten (Fußball, Handball, etc.) nehmen informelle, selbstorganisierte Formen (Joggen, Nordic Walking, etc.) von Sport und Bewegung zu.

Dabei haben Sport und Bewegung – neben der sozialen Funktion – im Siedlungsbild als sichtbare bauliche Anlagen hohe Bedeutung. Zu nennen sind nicht nur „klassische“ Sportstätten, sondern zunehmend auch „Ermöglichungsräume“ für Sport und Bewegung, die aufgrund ihrer multifunktionalen Nutzbarkeit zum freien Sporttreiben anregen. Für die Kommunen stellt sich aufgrund den Anforderungen des Wandels und der Tatsache, dass Stadt- und Sportentwicklung in der Vergangenheit häufig getrennt voneinander betrachtet wurden, die Aufgabe, eine integrierte Planung dieser Flächen und Räume zu betreiben, um nachhaltige, nutzungsgemischte Stadt- und Ortsstrukturen zu schaffen.

Da die Chancen von Sport und Bewegung als Beitrag zur Bewältigung des Wandels bislang kaum öffentlich wahrgenommen und diskutiert werden, soll der vorliegende Artikel auch dazu beitragen, für diese Thematik in der (Fach-)Öffentlichkeit zu sensibilisieren.

3 BEDEUTUNG VON SPORT UND BEWEGUNG

Neben gesundheitlichen und sozialen Leistungen haben Sport und Bewegung ökonomische und ökologische Effekte (vgl. Abb. 1). Somit leisten Sport und Bewegung unterschiedliche Beiträge im räumlichen, sozialen und gesundheitlichen Bezug.

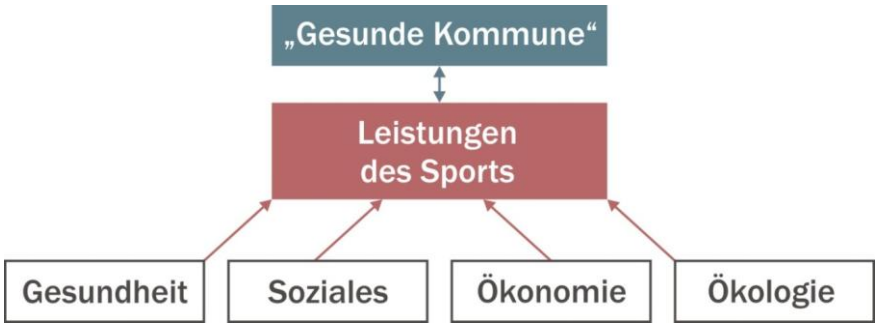

Abb. 1: Leistungen des Sports (eigene Darstellung).

3.1 Gesundheit

Untersuchungen belegen, dass u.a. durch Bewegungsmangel gesundheitliche Beeinträchtigungen, wie Übergewicht, Haltungsschäden und Gefäßkrankheiten, in der Bevölkerung auftreten können. Im Umkehrschluss können Sport und Bewegung zu einem gesunden Lebenstil des Einzelnen sowie der gesamten Gesellschaft beitragen. Besondere Bedeutung erlangen Sport und Bewegung dabei in den Altersgruppen der Älteren sowie der Kinder und Jugendlichen. Aufgrund der Alterung der Bevölkerung kommt dem Sport eine wesentliche Rolle zu, da die Ausübung von Bewegung und körperlichem Training zur (dauerhaften) körperlichen und geistigen Leistungsfähigkeit beiträgt und gleichzeitig den Erhalt einer selbständigen Lebensführung und Gemeinschaft im Alter fördert. [1] Vor dem Hintergrund des medial bestimmten Freizeitverhaltens (Fernsehen, Internet) von Kindern und Jugendlichen und dem daraus resultierenden Mangel an Bewegung gewinnen sportliche Aktivitäten in dieser Altersgruppe ebenfalls zunehmend an Bedeutung und können präventiv dazu beitragen, langfristige körperliche und geistige Entwicklungsprobleme zu verhindern. [2] Neben positiven Auswirkungen auf die körperliche Gesundheit in allen Altersgruppen leisten Sport und Bewegung auch einen erheblichen positiven Beitrag zur psychischen Gesundheit, beispielsweise durch die Minimierung von Angstzuständen und Depressionen sowie eine insgesamt verbesserte Stressregulation und Stimmung.[3]

3.2 Soziales

Sport und Bewegung bewirken verschiedene soziale Effekte, die sich u.a. in der Integrationsfunktion niederschlägt: „Sport eröffnet die Möglichkeit, die soziale Distanz zwischen Personen zu verringern, indem er Gefühle wie Gemeinschaft, Kameradschaft, Zugehörigkeit und Gleichheit von Personen aus unterschiedlichen sozialen Schichten oder verschiedener ethnischer Herkunft vermittelt.“ [4] Somit können sich durch die Ausübung von Sport und Bewegung soziale Kontakte ergeben, die zu einer intensiven Kommunikation, Kontaktpflege und sozialer Anerkennung auch außerhalb des Sports führen und bis in den sozialen Nahbereich ausstrahlen können. „Grundlage für die Kommunikation ist das gemeinsame Tun bzw. das gemeinsame Erleben des Sports.“ [5] Zudem können durch die Teilnahme an sportlichen Betätigungen soziale Spannungen und Aggressionen – gerade auch im Wohnungsnahbereich – abgebaut werden. [6] Das führt auch dazu, dass Sport- und Bewegungsangebote als Mittel in der Drogen- und Kriminalitätsprävention

[6] Vgl. a.a.O., S. 25.

eingesetzt werden. Daneben können die Durchführung von sportlichen Veranstaltungen und die Existenz erfolgreicher Sportvereine in einer Region als identitätsstiftende Merkmale für die lokale und regionale Bevölkerung gelten, die bestehende strukturelle Defizite, wie z.B. eine hohe Arbeitslosenquote, zumindest ansatzweise überstrahlen können. [7] Somit lässt sich festhalten, dass das Motiv, Sport und Bewegung auszuüben, meist nicht nur durch gesundheitliche Aspekte bestimmt wird, sondern, dass „Sport (…) häufig nur Mittel zum Zweck (ist), um Eingang in bestimmte Gemeinschaften zu finden und sich in sozialen Beziehungen zu integrieren." [8]

3.3 Ökonomie

Ökonomische Effekte durch den Sport sind in ihrer vollständigen Bandbreite schwer zu erfassen; genaue Aussagen über monetäre Auswirkungen sind nur begrenzt zu treffen. Es ist aber davon auszugehen, dass Sport und Bewegung direkte wirtschaftliche Effekte auslösen und einen bedeutenden Wirtschaftszweig darstellen. [9] Auf der kommunalen Ebene sind die Durchführung von Sportveranstaltungen [10] mit zahlreichen Folgeeffekten, aber auch der Sporttourismus [11] zu nennen. Aufgrund eines beobachtbaren steigenden Gesundheits- und Körperbewusstseins in der Bevölkerung ist auch weiterhin von dynamisch wachsenden Beschäftigungs- und sonstigen ökonomischen Effekten in diesem Wirtschaftszweig auszugehen. [12]

3.4 Ökologie

Sport und Bewegung haben auch Auswirkungen im Themenbereich Ökologie, allerdings weniger offensichtlich als in den vorher genannten Dimensionen. Zwar können „klassische" Sportstätten und für sportliche Betätigungen genutzte Freiräume einen Beitrag zur Durchmischung und Durchgrünung der Siedlungsstruktur leisten und stellen nicht selten ein wichtiges Gestaltungselement dar, welches auch positive Auswirkungen auf die Siedlungsökologie (Lebensraum für einheimische Tiere und Pflanzen, etc.) haben kann. Andererseits führt der Bau und Betrieb von Sportstätten (Landschaftsverbrauch, Flächenversiegelung) sowie die Nutzung des anlagen- sowie naturgebundenen Raums durch körperliche Aktivitäten immer auch zu einer Beeinträchtigung von Natur und Landschaft, die durch eine zunehmende Mobilität zur Anreise zu den Sportstätten oder -räumen noch verstärkt werden kann. [13] Bei einer maßvollen Ausgestaltung der sport- und bewegungsfreundlichen Aktivitäten ist es jedoch möglich, solche negativen Wirkungen zu minimieren.

4 RAUMWIRKSAMKEIT UND -BEDEUTSAMKEIT VON SPORT UND BEWEGUNG

Im Unterschied zu anderen gesundheitsfördernden Maßnahmen (z.B. gesunde Ernährung, Verzicht auf Genussmittel) sind Sport und Bewegung raumbedeutsame Faktoren der individuellen Gesundheit. Sport und Bewegung werden in bestimmten Räumen ausgeübt – die Auswahl des Raumes erfolgt dabei nach

[12] Vgl. a.a.O., S. 18.

[13] Vgl. dazu u.a.: Gans, Paul; Horn; Michael; Zemann, Christian (2003): Sportgroßveranstaltungen – ökonomische, ökologische und soziale Wirkungen, Ein Bewertungsverfahren zur Entscheidungsvorbereitung und Erfolgskontrolle, Schriftenreihe des Bundesinstituts für Sportwissenschaft, Band 112, Bonn, Schorndorf.

verschiedenen Kriterien (beispielsweise nach der Organisation des Sporttreibens – vereinsgebunden oder selbstorganisiert, der ausgeübten Sportart, den persönlichen Interessen der sportlich aktiven Personen sowie der Jahreszeit).

Generell kann dabei zwischen normierten Sportstätten (z.B. Sporthallen, -plätze, Schwimmbäder), die sich i.d.R. in öffentlicher bzw. vereinsbezogener Trägerschaft befinden, Ermöglichungsräumen für Sport und Bewegung (z.B. öffentliche Flächen wie Plätze, Straßen, Parks und Wiesen, aber auch private Räume wie Wohnung, Garten) sowie kommerziell betriebenen Sportstätten (z.B. Fitnessstudios, Yogaschulen) unterschieden werden. Die Ausweisung und Gestaltung von normierten Sportstätten und Ermöglichungsräumen sind durch planerische Maßnahmen steuerbar. Je nach Größe der Kommune, den Finanzierungsmöglichkeiten sowie der Anzahl der sporttreibenden Bevölkerung bestehen jedoch Unterschiede hinsichtlich der Anzahl und Ausstattung der normierten Sportstätten. Um eine gute Erreichbarkeit der Sportstätten für alle Bevölkerungsteile zu ermöglichen, sollten sich die Sportstätten im Idealfall dezentral an gut zugänglichen Standorten im Siedlungskörper einer Kommune befinden. Dennoch ist bei größeren Distanzen oftmals der Rückgriff auf den motorisierten Individualverkehr bzw. den öffentlichen Personennahverkehr notwendig. Durch ihre Lage im direkten Wohnumfeld bieten Ermöglichungsräume eine schnelle, (barrierefreie) Erreichbarkeit zu Fuß oder per Fahrrad, was gerade für mobilitätseingeschränktere Bevölkerungsteile (Kinder und Jugendliche, Ältere) für die Ausübung von Sport und Bewegung maßgeblich ist. Somit tragen ein vielseitig nutzbares Wohnumfeld aus Grün- und Freiflächen, das zur freien Ausübung von Sport und Bewegung anregt, sowie das Vorhandensein normierter Sportstätten im räumlichen Bezug auch entscheidend zur Attraktivität eines Wohnstandortes sowie der Vermeidung der Nutzung des motorisierten Freizeitindividualverkehrs durch die Bevölkerung bei.

5 SPORT UND BEWEGUNG IM WANDEL

5.1 Auswirkungen des demographischen Wandels auf Sport und Bewegung

Die sich zukünftig verstärkende Alterung und Schrumpfung der Bevölkerung in Deutschland und in den einzelnen Bundesländern stellen neue Herausforderungen für das Sport- und Bewegungsangebot dar. So ist einerseits damit zu rechnen, dass sich mittel- bis langfristig die Anzahl (vereinsgebundener) Sporttreibender verringert und andererseits eine alternde Gesellschaft zu einer Verschiebung der Nachfrage nach bestimmten Sport- und Bewegungsangeboten führen kann.

Für das im Südwesten Deutschlands gelegene und in weiten Teilen ländlich, d.h. durch eine geringe Bevölkerungs- und Siedlungsdichte, geprägte Bundesland Rheinland-Pfalz, wird laut Bevölkerungsvorausberechnung [14] des Statistischen Landesamtes nach der „mittleren Variante“ für den Zeitraum von 2006 bis 2020 ein Rückgang der Bevölkerung um ca. 128.000 Personen (-3,2 %) auf rund 3,9 Mio. Einwohner sowie bis zum Jahr 2050 ein Rückgang der Bevölkerung um ca. 603.000 Personen (-14,9 %) auf rund 3,45 Mio. Einwohner vorausberechnet. Bis 2020 wird nach Erhebungen des Statistischen Landesamtes gleichzeitig mit einem erheblichen Rückgang der Anzahl der Sportvereinsmitglieder zu rechnen sein (Rückgang von rund 20.000 Mitglieder im Organisationsbereich des Sportbundes Pfalz). Bis 2050 wird sich diese Entwicklung allein in der Region Rheinpfalz (Rückgang um ca. 42.800 Mitglieder) und in der Region Westpfalz (Rückgang um ca. 48.300 Mitglieder) im Vergleich zu den Mitgliedszahlen im Jahr 2006 (beide Regionen: 537.837 Mitglieder) massiv verstärken. [15] Untersuchungen belegen, dass schon jetzt rund 45 % der Vereine in Deutschland vom demographischen Wandel betroffen sind (Rheinland-Pfalz: 40,2 %). 1,7 % aller deutschen Sportvereine sind demnach durch die demographische Entwicklung in ihrer Existenz bedroht, in Rheinland-Pfalz betrifft dies 0,8 % der Sportvereine. [16]

[14] Eigene Berechnungen auf Grundlage von: Statistisches Landesamt Rheinland-Pfalz (2007): Rheinland-Pfalz 2050, zweite regionalisierte Bevölkerungsvorausberechnung (Basisjahr 2006), statistische Analysen Nr. 7, 2007, Bad Ems, S. 134.

[15] Vgl. Statistisches Landesamt Rheinland-Pfalz (Hrsg.) (2006): Bevölkerungsentwicklung in der Vorder- und der Westpfalz, Vortrag von Dr. Ludwig Böckmann anlässlich der Vortragsreihe „Zukunftsbausteine“ des Sportbundes Pfalz am 18. September 2008 in Kaiserslautern.

[16] Vgl. Breuer, Christoph et al (2006): Sportentwicklungsbericht 2005/ 2006 – Analyse zur Situation des Sports in Deutschland, Sportvereine und demographischer Wandel, Köln, S. 6 und 12.

Neben der quantitativen Nachfrage nach Sport- und Bewegungsangeboten wird sich aufgrund des demographischen Wandels zukünftig verstärkt die qualitative Nachfrage verschieben, da nicht nur der prozentuale, sondern auch der absolute Anteil der Senioren in den Sportvereinen erkennbar ansteigen wird. So ist beispielsweise schon für den Zeitraum 1986 bis 2006 im Organisationsbereich des Sportbundes Pfalz ein erheblicher Anstieg des Anteils der Senioren (ab 61 Jahren) als organisierte Sportvereinsmitglieder feststellbar (1986: über 25.500, 1996: über 50.000, 2006: knapp 84.000). [17]

Der demographische Wandel hat somit aktuell und zukünftig tiefgreifende Veränderungen in der Sportlandschaft zur Folge, auf welche zunächst die Sportvereine durch Anpassung der Sportangebotsstruktur, damit einhergehend auch die Gemeinden in Bezug auf das räumliche Angebot reagieren müssen.

5.2 Auswirkungen der Individualisierung und Pluralisierung der Gesellschaft auf Sport und Bewegung

Die Individualisierung der Gesellschaft (Selbstbestimmung und Emanzipation) sowie die Pluralisierung der Lebensstile (Ausdifferenzierung und Vervielfältigung der Lebensformen) führen im Bereich von Sport und Bewegung zu einer stark veränderten Nachfragesituation. Damit einher gehen gesunkene Arbeitszeiten, ein höher Anspruch in der Freizeitgestaltung bei gleichzeitiger Flexibilität und erhöhter Mobilität des Einzelnen. Dadurch ist eine stärkere Differenzierung der Nachfrage nach bestimmten Sportangeboten zu beobachten; individuelle Angebote gewinnen an Bedeutung. Sichtbar wird dies u.a. in der seit einigen Jahrzehnten feststellbaren Ausdifferenzierung der Sportlandschaft. Während in den 1960er Jahren nur etwa 30 verschiedene Sportarten gezählt wurden, waren es Anfang des 21. Jahrhunderts bereits rund 240. [18] Gleichzeitig steigt die Anzahl der Sportvereine in Deutschland und Rheinland-Pfalz langsam an: Während 1990 5.688 Sportvereine in Rheinland-Pfalz existierten, stieg diese Zahl bis zum Jahr 2008 auf 6.298 Vereine an. [19] Zudem differenziert sich das Angebot an verschiedenen Trend- und Nischensportarten immer stärker aus.

Die Organisationen des Sports, hauptsächlich die Sportbünde und -vereine, stehen somit, ähnlich wie bei den Anpassungen im demographischen Wandel, vor der Herausforderung, ein entsprechendes Sportangebot zu schaffen und dies an die aktuellen und zukünftigen Bedürfnisse anzupassen. Ebenso wichtig ist es aber in diesem Zusammenhang, entsprechende und dauerhaft finanzierbare Infrastrukturen sowie an sich veränderndende Bedürfnisse angepasste Sportstätten in die querschnittsorientierte Stadt- und Ortsplanung einzubeziehen.

5.3 Auswirkungen der Finanzkrise der öffentlichen Haushalte auf Sport und Bewegung

Die angespannte Haushaltslage vieler Kommunen und öffentlicher Träger als hauptsächlicher Betreiber von Sportanlagen hat erhebliche Auswirkungen auf die Situation von Sport und Bewegung. So ist absehbar, dass Investitionen in Planung, Bau und Betrieb (inkl. Sanierung) von Sportstätten zurückgehen werden. Auch der organisierte Sport selbst, insbesondere die Sportvereine, werden Kürzungen der Fördermittel hinnehmen müssen. Dadurch wird es den Vereinen zunehmend erschwert, ihre organisatorische und bauliche Infrastruktur dauerhaft aufrechtzuerhalten. Ebenso werden sich Kommunen und Sportvereine durch die zunehmende Konkurrenz von privatwirtschaftlichen Anbietern im Bereich von Sport und Bewegung auf neue Organisations-, Entwicklungs- und Betreibermodelle einstellen müssen.

6 STATUS QUO AUF KOMMUNALER EBENE

6.1 Forschungsprojekt „Gesunde Kommune – Sport und Bewegung als Faktor der Stadt- und Raumentwicklung“

Das Forschungsprojekt „Gesunde Kommune“, das im Jahr 2011 vom Lehrstuhl Stadtplanung, Prof. Dr.-Ing. Gerhard Steinebach, in Kooperation mit dem Lehrgebiet Sportwissenschaft, Prof. Dr. Arne Güllich, der TU

Kaiserslautern im Auftrag der Entwicklungsagentur Rheinland-Pfalz e.V. begonnen wurde, hat aktuelle Fragen von Sport und Bewegung in Rheinland-Pfalz, deren Bedeutung für „gesunde Kommunen“ [20] sowie die Konsequenzen für die Stadt- und Ortsplanung behandelt. Ausgangspunkt der Überlegungen für das Projekt war die These, dass Sport und Bewegung gezielt für die Raumentwicklung genutzt werden sollten, um zur Bewältigung des strukturellen, gesellschaftlichen und demographischen Wandels neuartige Konzepte und Lösungsansätze entwickeln zu können.

Auf der Grundlage der erhobenen Ausgangssituation wurden die aktuelle Situation und Veränderungen sowohl in demographischer und räumlich-struktureller Hinsicht als auch von Sport und Bewegung in unterschiedlich großen und strukturierten Untersuchungsgemeinden [21] in Rheinland-Pfalz erfasst und analysiert. Mithilfe einer empirischen Grundlagenerhebung (Bevölkerungsbefragung, Expertengespräche mit kommunalen Vertretern) zu verschiedenen Themenkomplexen (Sportverhalten und -organisation, Mobilität, baulich-räumliche Situation/ Ökologie und Soziales), welche sowohl die aktuellen als auch in Teilen die retrospektiven Sport- und Bewegungsaktivitäten der Bevölkerung abbildete, konnte eine Analyse der qualitativen und quantitativen Sportnachfrage in den Untersuchungsräumen durchgeführt werden. Nachfolgend werden dazu ausgesuchte Befragungsergebnisse aus Projektphase 1 vorgestellt.

6.2 Ergebnisse des Forschungsprojektes

Für das Projekt wurden insgesamt 7.000 Fragebogen in den Untersuchungsgemeinden verteilt, davon wurden 578 beantwortet. Die Rücklaufquote beläuft sich demnach auf rund 8,3 %. Aufgelistet nach der Gemeindegröße stellen sich die Rücklaufquoten folgendermaßen dar: kleinere Kommunen (Ortsgemeinde Steinbach/ Donnersberg, Ortsgemeinde Höheinöd, Landkreis Cochem-Zell [22]) 10,2 %, mittlere Kommunen (Stadt Landstuhl, Stadt Cochem) 4,9 % und große Kommunen (Stadt Kaiserslautern) 9,2 %.

Zur Ermittlung des Grades der sportlichen Aktivität der Bevölkerung in den Untersuchungsgemeinden wurde die Frage gestellt, ob innerhalb der vergangenen zwölf Monaten aktiv Sport und Bewgeung getrieben wurde. Hierbei gaben 73 % an, im Laufe des vergangenen Jahres Sport ausgeübt zu haben. Bei Betrachung des Ergebnisses differenziert nach den jeweiligen Größenkategorien der Untersuchungsgemeinden, ergeben sich nur geringe Abweichungen: So beträgt der Anteil an sportlich Aktiven in den großen und kleinen Kommunen 72 %, während diese Quote in den mittleren Kommunen über dem Durchschnitt bei 79 % liegt.

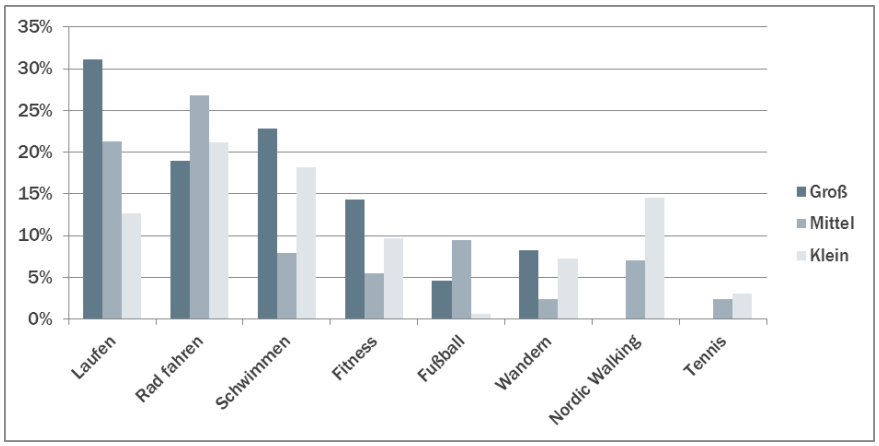

Abb. 2: Ausgeübte Sportarten im Sommer unterschieden nach großen, mittleren und kleinen Kommunen (eigene Darstellung).

[20] Im Rahmen des FuE-Projektes verdeutlichte dabei der Begriff „gesunde Kommune“ die Bedeutung von Sport und Bewegung im Raum und umfasst das weitreichende Verständnis der Leistungen von Sport und Bewegung in den Bereichen Gesundheit, Soziales, Ökonomie und Ökologie (vgl. dazu auch Abschnitt 3).

[21] Folgende Untersuchungsgemeinden wurden im Rahmen des Projektes betrachtet:

- Stadt Kaiserslautern (99.275 Einwohner, Stand: 31. Dezember 2010),
- Stadt Landstuhl (8.599 Einwohner, Stand: 31. Dezember 2010),
- Stadt Cochem (4.940 Eiwnohner, Stand: 31. Dezember 2010),
- Landkreis Cochem-Zell (63.884 Einwohner, Stand: 31. Dezember 2010),
- Ortsgemeinde Steinbach/ Donnersberg (786 Eiwnohner, Stand: 31. Dezember 2010) und
- Ortsgemeinde Höheinöd (1.205 Einwohner, Stand: 31. Dezember 2010).

[22] Da sich der Landkreis Cochem-Zell aus einer Vielzahl kleinerer Kommunen zusammensetzt, wird diese Gebietseinheit den kleinen Kommunen zugeordnet.

Neben Laufen (32 %) und Radfahren (22 %) zählt Schwimmen (16 %) zu den am häufigsten ausgeübten Sportarten im Sommer, wobei deutliche Unterschiede zwischen den Gemeindegrößen zu beobachten sind: Während Laufen und Schwimmen bei den Bewohnern der großen Kommunen einen hohen Stellenwert einnehmen, ist das Interesse an der Sportart Laufen in den kleinen Gemeinden geringer (13 %). Im Gegensatz dazu ist die Ausübung von Nordic Walking in den kleinen Kommunen am größten (15 %) (vgl. Abb. 2). Im Winter bevorzugen die Befragten Sportarten wie Fitness (23 %), Laufen (22 %) und Nordic Walking (12 %). Laufen ist somit sowohl im Sommer als auch im Winter eine beliebte Sportart. Auch kann festgestellt werden, dass im Sommer hauptsächlich Outdoor-Sportarten ausgeübt werden, währenddessen m Winter dem Indoor-Fitnesstraining mit 23 % der Nennungen eine wichtige Rolle zukommt.

Gefragt nach der Motivation zur Ausübung von Sport und Bewegung werden gesundheitliche Gründe genannt (25 %), das Erleben von Spaß und Freude (24 %) sowie das Bedürfnis nach Naturerlebnis (16 %). Auch das Pflegen von sozialen Kontakten und Ablenkung vom Alltag werden häufig von den Befragten angegeben. Der Leistungs- /Wettkampfgedanke steht hingegen nur bei 6 % der Befragten im Vordergrund. Die herausragende Bedeutung des Sporttreibens für das gesellschaftliche Zusammenleben in den Kommunen wird bei der Herausbildung von Freundschaften durch gemeinsames Sporttreiben deutlich: Über alle Altersgruppen hinweg zeigt sich, dass durch die Ausübung von Sport und Bewegung Freundschaften entstehen können (vgl. Abb. 3).

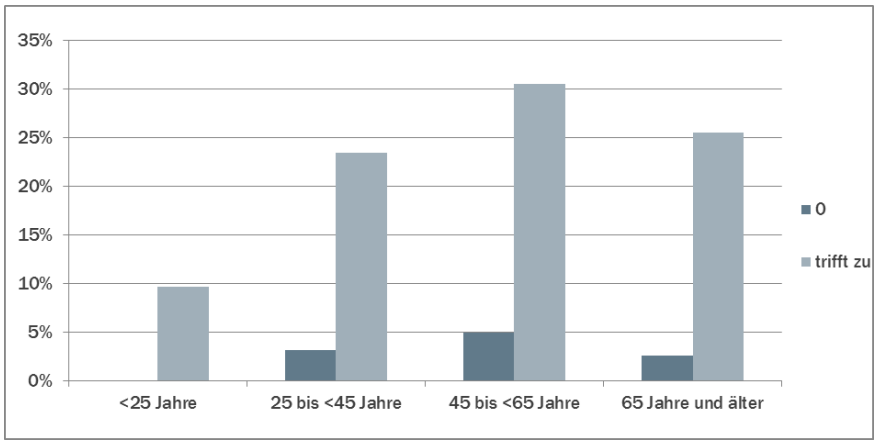

Abb. 3: Ergaben sich aus den von Ihnen betriebenen Sport- und sonstigen Freizeitaktivitäten Auswirkungen auf Ihr alltägliches Sozialleben im Sinne von Freundschaften? (eigene Darstellung)

Insgesamt 53 % der Befragten gaben bei der Frage nach der Organisationsform des Sports an, dass sie Sport entweder ausschließlich oder teilweise vereinsgebunden ausüben (17 % lediglich Ausübung von Sport im Verein, 36 % Ausübung von Sport im Verein sowie selbstorganisiert). Demgegenüber steht ein Anteil von 47 %, der nur selbstorganisierten Sport betreibt. Bei Betrachtung der einzelnen Größenkategorien der Untersuchungsgemeinden ergeben sich einige Unterschiede: Während mehr als die Hälfte der Befragten aus den großen Kommunen den Sport ausschließlich selbst organisieren, tun dies nur rund 42 % der sportlich Aktiven in den mittleren Kommunen. Letztere sind hingegen anteilig häufiger sowohl im Verein als auch selbst organisiert aktiv. Die Befragten in den Großstädten treiben im Vergleich am seltensten ausschließlich im Verein Sport. Zudem fällt auf, dass die aktuell nicht mehr aktiven Sportler früher deutlich häufiger in Vereinen Sport getrieben haben, als das bei den aktiven Sportlern der Fall ist. Damit ist eine höhere Bedeutung des Vereinssports in der Vergangenheit feststellbar und unterstreicht den zunehmenden Trend zur Individualisierung des Sporttreibens. Zusätzlich wurde die Frage nach passiver Mitgliedschaft in Sportvereinen gestellt. Dabei ist die Mehrheit der Mitglieder in einem Sportverein über alle Gemeindegrößen hinweg auch in diesem sportlich aktiv (77 %). Während rund 32 % der Befragten in kleinen Kommunen Mitglieder eines Sportvereins sind ohne selbst in diesem sportlich aktiv zu sein, sind dies in größeren Gemeinden nur ca. 16 %. Somit kann auf eine größere Bedeutung und Verbundenheit mit den Sportvereinen in kleinen Kommunen geschlossen werden.

Differenziert nach Sommer und Winter werden von den Befragten eine Vielzahl unterschiedlicher Sportstätten und -anlagen als Orte des Sporttreibens angegeben. Im Sommer werden hauptsächlich „andere Sportstätten“ (33 %) und von den „klassischen“ Sportstätten v.a. Sporthallen (19 %), Freibäder (14 %) sowie Sportplätze (10 %) genutzt. Insbesondere die Befragten der großen Gemeinden nutzen individuelle Orte zur

Sportausübung (40 %). Im Winter sind die Befragten sogar noch differenzierter hinsichtlich der Wahl der Sportstätte (44 % „andere Sportstätten“). Danach folgen die witterungsunabhängige Sporthalle und das Hallenbad mit jeweils 17 % sowie der Sportplatz mit 6 %. Auch im Winter nutzen hauptsächlich die Bewohner der großen Kommunen individuelle Sportstätten (rund 55 % „andere Sportstätten“).

Befragt nach der Lage des Orts der Sportausübung zum Wohnort geben 42 % der Befragten an, dass sie ihre am häufigsten ausgeübte Sportart im Sommer in ihrem unmittelbaren Wohnumfeld ausüben, während 20 % den Wohnort verlassen. Im Winter sind die Befragten hinsichtlich der Sportausübung weniger mobil als im Sommer: Knapp die Hälfte (46 %) treibt den ausgeübten Sport am Wohnort. Obwohl ein Großteil der Befragten ihren Sport am Wohnort ausüben, stellt der Pkw im Sommer das wichtigste Verkehrsmittel dar, um die jeweilige Sportstätte bzw. den Ermöglichungsraum für Sport und Bewegung zu erreichen. Gerade die Bewohner der mittelgroßen Gemeinden nutzen den Pkw zu diesem Zweck. Am zweithäufigsten gehen die Befragten zu Fuß zum Sport, am dritthäufigsten wird das Fahrrad genutzt (vgl. Abb. 4). Eine noch häufigere Nutzung des Pkws zum Erreichen der Sportstätte ist im Winter feststellbar, während witterungsbedingt das zu Fuß gehen sowie das Fahrradfahren an Bedeutung verlieren.

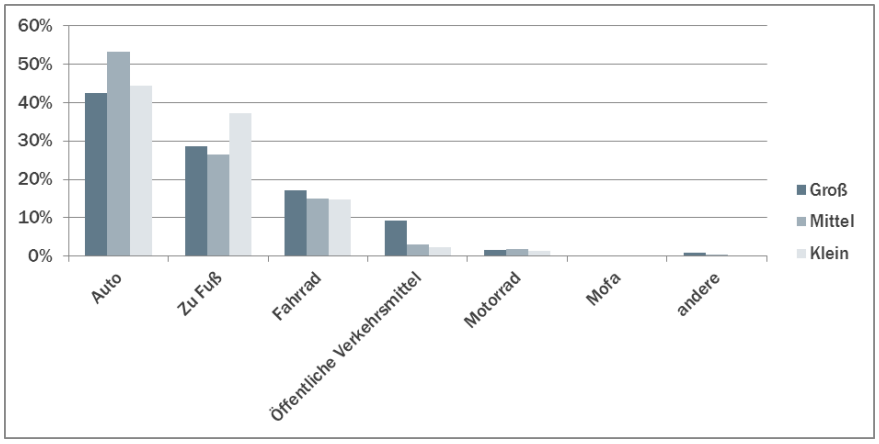

Abb. 4: Mit welchen Verkehrsmitteln erreichen Sie den Ort Ihrer sportlichen Aktivitäten in der Regel im Sommer? (eigene Darstellung)

Bezogen auf die Zufriedenheit mit dem Sportangebot der ortsansässigen Sportvereine äußerte sich die überwiegende Mehrheit der Befragten positiv (zufrieden: 55 %, sehr zufrieden 8 %). Nur 10 % gaben an, (sehr) unzufrieden zu sein. Insbesondere die Befragten aus den großen Kommunen sind zufrieden mit dem Sportangebot der ansässigen Sportvereine – hierbei kann vermutet werden, dass dies auf die größere Angebotsvielfalt in den großen Gemeinden zurückzuführen ist. Auch ist der Großteil der Befragten mit der Häufigkeit und der Spannbreite der Sportangebote überwiegend zufrieden. Lediglich bei den altersgruppenspezifischen Sportmöglichkeiten sehen insbesondere die Befragten in den mittleren und kleinen Kommunen Verbesserungsmöglichkeiten. Die Anzahl der Sportmöglichkeiten (Sporthallen, Sportplätze, Parkanlagen, etc.) im eigenen Ort wird von den Befragten in den einzelnen Gemeinden mehrheitlich (sehr) positiv eingeschätzt. Auch mit der Ausstattung der Sportmöglichkeiten im Wohnort sind die Befragten zufrieden, lediglich weniger als 15 % sehen Verbesserungsbedarf.

7 AUSBLICK UND ANPASSUNGSSTRATEGIEN

7.1 Zukünftige Rolle von Sport und Bewegung in der Stadt- und Raumentwicklung

Sport und Bewegung kommen bei der Schaffung nachhaltiger, nutzungsgemischter Stadt- und Ortsstrukturen eine hohe Bedeutung zu. Die Änderung der quantitativen und qualitativen Nachfrage nach organisierten und informellen Sport- und Bewegungsangeboten hat erhebliche räumliche Auswirkungen auf regionaler und kommunaler Ebene. Um ein der Nachfrage angepasstes Angebot für die Bevölkerung sichern zu können, bedarf es planerischer Konzepte und politischer Entscheidungen. Da Sport und Bewegung sehr unterschiedliche Bevölkerungsgruppen und sehr viele Menschen erreichen, kann damit ein wichtiger Beitrag zur kommunalen Entwicklung geleistet werden. Vom zukünftigen Handeln der Gemeinden und der sonstigen Planungsträger wird es abhängen, den Sport in die querschnittsorientierte räumliche Gesamtplanung zu integrieren und damit auch zur Bewältigung eigener Aufgaben zu qualifizieren.

7.2 Anpassungsstrategien und Handlungsempfehlungen

Aus den Ergebnissen der empirischen Grundlagenerhebung des Projektes „Gesunde Kommune“ wurden Strategieansätze und Handlungsempfehlungen zur bedarfsgerechten Anpassung der Sportinfrastrukturen an die sich ändernden Rahmenbedingungen sowie zur Schaffung von Ermöglichungsräumen für Sport und Bewegung auf verschiedenen Ebenen (Land, Region, Kommune) formuliert.

Ein wesentliches Aufgabenfeld bildet die Qualifizierung öffentlicher Räume zu multifunktional nutzbaren Standorten sowohl für informelle als auch vereinsgebundene Sport- und Bewegungsmöglichkeiten. Neben der Anpassung bestehender öffentlicher Räume ist die Um- und Neunutzung von Baulücken, Brachflächen oder Leerständen erforderlich. Um im Sinne „gesunder Kommunen“ Städte und Gemeinden baulich-räumlich weiterzuentwickeln, ist weiterhin eine funktionale Verknüpfung der „klassischen“ Sportstätten und -räume untereinander sowie mit unterschiedlichen Ermöglichungsräumen für Sport und Bewegung zu empfehlen. Die Schaffung dezentraler, wohnungsnaher Sport- und Bewegungsangebote durch Bestandsentwicklung und Nachverdichtung kann auch dazu beitragen, neue Grün-, Freiraum- und Erholungsangebote im unmittelbaren Wohnumfeld der Bevölkerung zu schaffen und stellt einen wichtigen Baustein auf dem Weg zu nachhaltigen Stadt- und Dorfstrukturen sowie zur Bewältigung der Herausforderungen des Stadtumbaus dar.

Wegen der sich ändernden Nachfrage nach Sport- und Bewegungsangeboten sowie der sich wandelnden Motive für das Sporttreiben sollten die normierten Sportstätten angepasst und bestehende Normen novelliert werden. Dabei sollten die Sportstätten weniger auf ihre Tauglichkeit für Wettkämpfe und den Leistungssport bewertet als vielmehr zur Eignung für die Sportausübung nach den Zielen der Gesundheitsvorsorge und der Freude an Sport und Bewegung verändert werden. Im Sinne demographie- und sozialgerechter Planung sollten gleichzeitig Strategien zur Mehrfachnutzung von Sportstätten durch möglichst breite Nutzergruppen sowie zur Vernetzung mit sonstigen Einrichtungen der sozialen Infrastruktur konzipiert werden.

Bei einer Neugestaltung der Sportstätten sollten auch die Möglichkeiten der Informations- und Kommunikationstechnologien verstärkt einfließen, um beispielsweise durch ein Monitoringsystem die tatsächlichen sportbezogenen Defizite und die Wirkungen im Raum zu erfassen.

Im Weiteren wird empfohlen, den Begriff „gesunde Kommune“ zu einem Markenzeichen weiterzuentwickeln und mit einem integrierten Entwicklungskonzept zu verbinden. Dazu gehören auch neue Formen der Kooperation mit denen Akteure aus den Bereichen Sport, Stadtplanung, Soziales und Umwelt – auch über die Kommunalgrenzen hinweg – dezentrale Strukturen stärken und institutionalisieren können.

Die im Projektjahr 2011 erarbeiteten Anpassungsstrategien und Handlungsempfehlungen für die Sportstättenplanung und die räumliche Planung sollen nun in einer weiteren Projektphase im Jahr 2012 in der rheinland-pfälzischen Praxis erprobt, auf ihre Wirksamkeit hin eruiert und ggf. angepasst werden.

GIS for Urban Environmental Management Plan: Making it through the Crisis

Piyali Bandyopadhyay

(Piyali Bandyopadhyay, Project Scientist, Central Pollution Control Board, Delhi, Flat no 437 GH/13 Paschim Vihar, Delhi-110063, India, bandyo.piyali@gmail.com)

1 ABSTRACT

Ever increasing population on urban areas is the biggest concern in developing countries. With the increase in population and related activities, the demand for supportive services viz. transportation, water supply, drainage/sewerage, garbage collection and disposal etc. that are essential is far exceeding the supply of these services. Each developmental activity includes a land use and these land uses are likely to have impact on the environment. The environmentally relevant land uses are trade and industry, housing construction, transport facilities, utilities, refuse/hazardous waste and wastewater installations, quarrying/mining, power generation, recreation and tourism etc. While taking up developmental activities, the assimilative capacities of the environment to air or water or land pollution are rarely considered. Also, due to lack of proper land use controls, the developmental activities tend to be haphazard and uncontrolled thus leading to over use, congestion, poor land use compatibility etc. The environmental pollution problems in urban areas are becoming complex and are creating high risk environment. The solutions of pollution control in individual sectors viz. transport, industry etc. are not entirely solving the problems.

Conventionally, the environmental pollution problems are solved by introducing environmental management techniques such as control of pollution at source. Like the various causes of air pollution are particulate matter (e.g settling chambers, inertial separators, wet scrubbers spray scrubbers, fabric filters and electrostatic precipitators etc), gaseous emissions , fugitive emissions, odour and noise. These measures are proving to be inadequate because of the complexity associated with the urban dynamics. In large urban agglomerations, the problems cannot merely be solved by pollution control measures only.The consequences of neglecting environmental factors in planning are severe. They are felt as deterioration of the natural systems and likewise the socio-economic living conditions. The environmental problems of concern and increased environmental risks.

There is a need for safer, healthier and sustainable cities. The cause of the pollution problems is to be identified and solutions provided for short-term mitigation measures and long-term prevention measures. For this to be possible is for better understanding of the problems, collective efforts and improved approaches/techniques in planning practice. This may be done through environmental planning by preparing environmental management plans by using modern techniques. This includes mapping the characteristics and environmental profile of an urban area and to identify the environmental pollution hot spots; preparing an environmental management plan that includes rehabilitation and mitigation measures; and recommend guidelines for environmentally compatible land use planning.

Geographic Information System (GIS) is a technique which makes series of maps with one outcome. The comprehensive environmental management plan requires a series of maps to understand the area and to identify the trends to make way out the solution. GIS technique helps to prepare from reference map or base map to other theme maps which charecterise the urban area including land use, drainage, topography etc in one hand and specific environmental quality assessment like air pollution potential at source (domestic, industrial, traffic) in different grids (of 1 km X 1 km), water pollution potential, land pollution potential, garbage/solid waste/hazardous waste pollution potential area in other hand. This mapping technique is able to produce all the environmental hot spots due to air pollution, water pollution, solid waste disposal, land use incompatibility etc. and the sources for the same identified. Urban environmental magement plan includes mitigation measures and abatement infrastructure and land use controls of an urban premise. The areas of incompatible land uses could be easily identified through overlay analysis in GIS and accordingly planned for shifting either of the source or the receiver to make resilient city. The paper desribes the process how GIS can be used for pollution abatement and environmental management measure for making Sustainable City.

2 INTRODUCTION

Three fold increase of population in urban centres in India makes uncontrollable demand for basic needs. The demand for supportive services i.e water, electricity, solid waste disposal, drainage/sewerage line is

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

accelarating day by day which is beyond the capacity of area services. This demand is not confined not only in one pklace but through spillover population forms new area as urban sprwal. This development activity has certain positive as well as negative environmental impact on landuse. The environmentally relevant land uses are mainly trade and industry, housing construction, transport facilities, utilities, refuse/hazardous waste and wastewater installations, quarrying/mining, power generation, recreation and tourism etc. While taking up developmental activities, the assimilative capacities of the base environment i.e. air or water or land pollution are rarely considered. Due to malpractice land use zonation and controls all the developmental activities tend to be haphazard and uncontrolled thus leading to congestion or over use or poor land use compatibility. The environmental pollution problems in urban areas are becoming complex and are creating high risk environment. Pollution abatement control for individual sectors for as an example Transportation or industry etc. are not entirely solving the problems.

According to 2011 census of India the total population of India is 1,210,193,422. The annual growth of population is 1.8%. The total urban population of India is 377,105,760 which is about 31.16% of the total population of India. The urban population of India has the annual growth rate of about 3.21%. As per 2011 India has 7935 town. The no of town grow over 2800 for last 10 years. The urbanization in India mainly is due rural to urban migration of population. The fast growth of urban population impose pressure on urban infrastructure, land, natural resource. The Indian cities are getting suffocated every day due to influx of population.

Sustainable city is the dream of every planner. The concept of sustainable city is thoroughly interconnected with environmental protection and economic development. The sustainable city can be defined as one which is able to support the basic need of the people along with the necessary infrastructure of civic amenities, health and medical care, housing, education, transportation, employment, good governance etc. The fundamental Characteristics of a sustainable city are as follows:

- Adequate governance set up which can meet the need of the population and ensure civic responsibilities, community participation, a sense of identity, transparency and equity in local institution.
- Planned housing system with sufficient infrastructural facility like local market school, medical facility, facility towards waste disposal etc.
- An appropriate transport system acts as the nervous system for any habitation it has also effect on the environment.
- Environmental consideration in the planning and effective environmental infrastructure for environmental monitoring and pollution control.

The success of sustainable city is entirely dependent upon monitoring and management of various aspects of urban and city life practically which is impossible without dynamic information system.

3 NEED OF THE STUDY

There is a need for safer, healthier and sustainable cities. The cause of pollution is to be identified and solutions provided for short term mitigation measures and long term prevention. For this can be possible through better understanding of the problems, collective efforts and improved approaches/techniques in planning practice. This may be done through environmental planning practice by preparing environmental management plans by using modern techniques. This includes mapping the characteristics, environmental profile of an urban area and identification of the environmental pollution hot spots; preparing a environmental management plan that includes rehabilitation and mitigation and recommend guidelines for environmentally compatible landuse planning.

Geographic Information System (GIS) is a technique which prepares series of maps with one result. The comprehensive environmental management plan requires a series of maps to understand the area characteristics, to identify the problems and to make way out the solution. GIS technique helps to prepare from reference map or base map to other thematic maps which charecterise the urban area including land use, drainage, topography etc in one hand and specific environmental quality assessment like air pollution potential at source (domestic, industrial, traffic) in different grids (of 1 km X 1 km), water pollution potential, land pollution potential, garbage/solid waste/hazardous waste pollution potential area in other

hand. It means this technique is eligible to prepare point data to areal data in one format. This mapping technique is able to produce all the environmental hot spots due to air pollution, water pollution, solid waste disposal, land use incompatibility etc. and the sources for the same identified. This techniques can analyse the impact of point data to areal impact. Urban environmental magement plan refers mitigation measures and abatement infrastructure and land use controls of an urban premise. The areas of incompatible land uses could be easily recognised through overlay analysis and accordingly planned for shifting either of the source or the receiver to make resilient city. The paper emphasises the process how GIS can be used for pollution abatement and environmental mangement measure for making Sustainable City.

4 AIM OF THE STUDY

The aim of the study is to develop a urban management information system that can act as one of the important input of information to the decision making authority and town planner with the help of which they would be able to regulate the utilization of natural resources, development and expansion of the city, development of infrastructure facility, monitoring of environmental quality and pollution control.

5 OBJECTIVE

- To understand the characteristics of the information input required for urban environmental planning and management.
- To develop a overall architecture for urban information management system
- To develop a module based information system.

6 URBAN ENVIRONMENTAL MANAGEMENT INFORMATION SYSTEM

In the 21st century Indian cities are growing at a very fast rate in terms of its population size and geographical area. The main area of concern for any town planner is that the basic nature of distribution of development in India is regional imbalance. The primacy of the metropolitan towns are acting as magnetic force for pulling the population and it is the major cause for the rural to urban and urban to urban migration of population. There is always a gap between urban resource, infrastructure supply and demand for the same. Under this circumstances society demands for the development and management of a urban planning and management mechanism based on latest updated spatial information fully and reasonably, will have the capability to provide information system for urban planning management, decision making urban planning administration, development of new developmental and pollution monitoring and control mechanism. The uniqueness of GIS technology lies in its basic capability like data capturing, presentation, categorization, data synthesis, simulation of spatial data, easy updation of data spatial analysis.

Basically GIS is a tool towards automation of regional and urban planning department, up to date development and management mechanism and dynamic scientific policy making system. The basic system architecture towards urban management information system is given in fig – 1

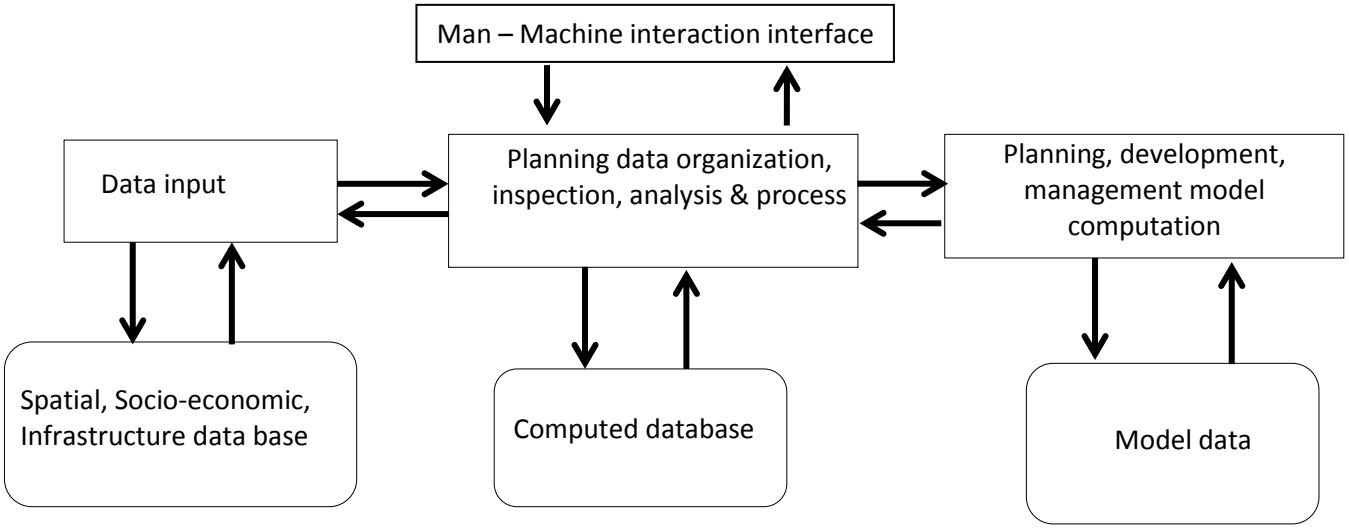

Fig 1: Basic system architecture towards urban environmental management information system

7 DATA MODULES FOR URBAN ENVIRONMENTAL MANAGEMENT INFORMATION SYSTEM

The data and information for urban planning and management information system is basically very complex, multi-disciplinary, and dynamic by nature. The layers of information are spatially and temporally braided. It has spatial data of various natural resources, attribute data to the spatial information, socio economic information, infrastructural information, government policy and planning initiatives. The scale of representing the attribute data should be different at different level . The figure 2 represent interrelationship of various data modules for urban information management system.

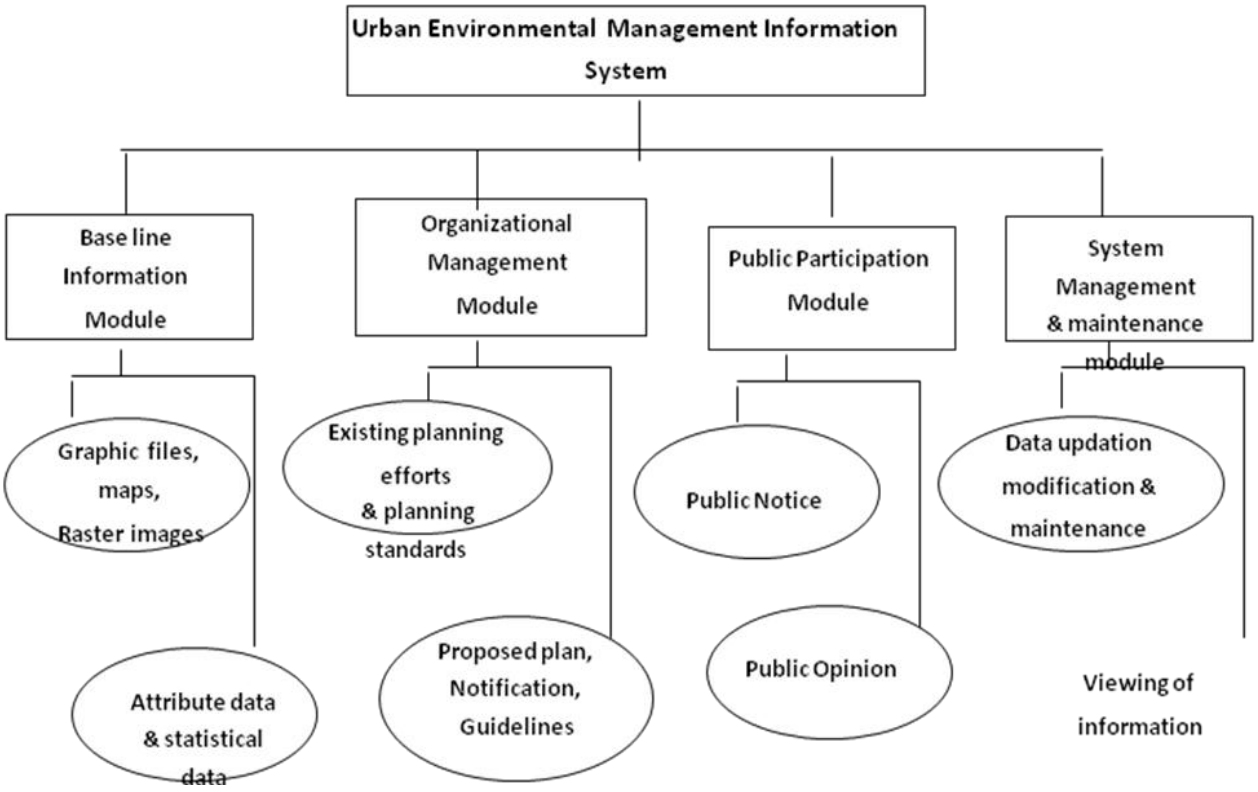

Figure 2 : Data modules for Urban Environmental Management Information System.

(1) Base line information Module:

The base line information module basically comprise of map, graphic, raster image, base line information , attribute data related to spatial information. The module will have the have capabilities of querying building, presentation of the result of the query in both graphical and tabular presentation. The information system will have zooming facilities starting from 1:1or 2 million scale and zooming up to 1: 1000 scale depending upon the resolution of the input map imagery and the level of study (Figure :3)

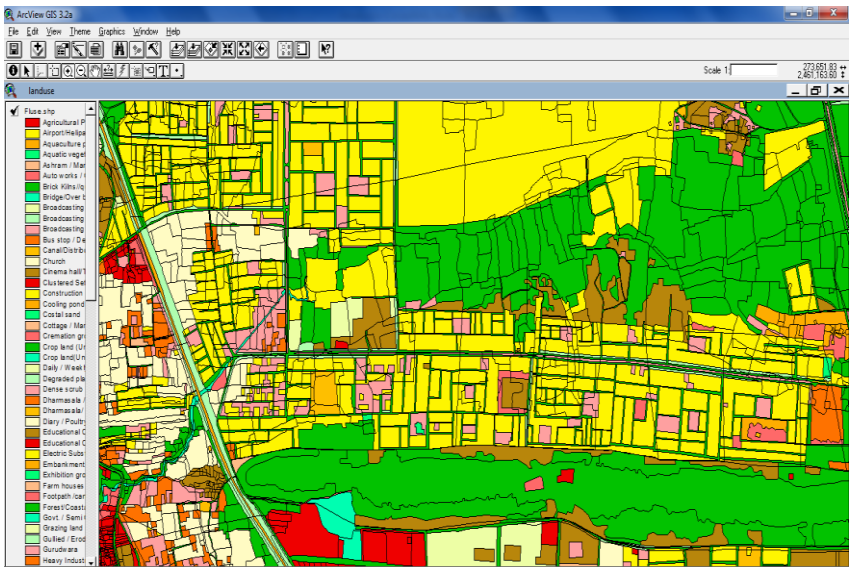

Figure :3 Graphic view of landuse of urban area

The information content of this module will be regional setting, physiography, Demography, Climate , Soil, Drainage system, Landuse, Physical and Social infrastructure, location of Industrial sites, industrial cluster, housing, open areas, natural vegetation, transportation (road, rail, waterways), utilities (water supply, electricity), hot spots, location of monuments, polluted stretch, problem areas, tourist spots, pilgrim areas, tribal settlement , earth quack prone areas and environmental status etc. The statistical information like census information industrial year book, gazetteers etc. information will be the part of this module (Figure: 4)

(2) Organizational Management module :

Broadly speaking in Indian scenario the development, management and decision making bodies are Town and Country planning Organization, Developmental Authority, Municipality, Municipal corporation etc. This module will have three sub modules like basic for Existing developmental plan , Master Plan, Basic Development , planning directives norms, decision towards future development which will help the urban planner and decision makers to carry out the future planning exercise , comparative study for future development, proposal for planning, phasing of development. This module will contain text, and data, map and graphic files with spatio- temporal evaluation characteristics. The basic booklet to be incorporated in thin module will be Master plan, Basic development plan, Building By Law, Environmental Standards, Government notifications, Planning norms, infrastructure development standards various gazetteer, notifications , guidelines and directions published by Government.

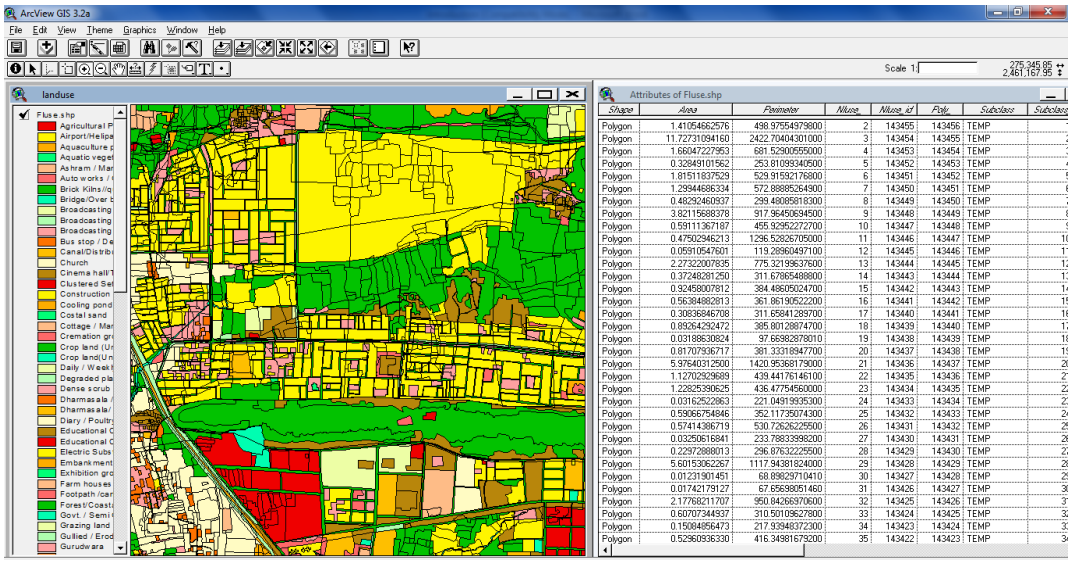

Figure: 4 Attribute Data Ppresentation

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

(3) Public Participation Module:

The module will act as a platform for comparing the state physical, social , economic and environmental development of the particular town with the other town, with the developmental standards, Government notice for public opinion for and proposed development and public complaints, suggestion and opinion for the town , and city development. The features of this module will be GDP, total industrial input and out values, industrial emission, vehicular pollution, waste water discharge, waste generation, infrastructure developmental status, landuse change.

(4) The system management and maintenance module:

The module deals with the maintenance and management of the Urban planning and management information system itself. It is basically a user management module. It deals with the various authorization for access, viewing, updation, modification of data , information etc. The user management function may add and delete users for the system and moreover the module-wise authorization will also vary. The data , graphic and map updation may authorized to different user to update the baseline and other information. The average users will only be able to use data , analyse and compare the data but could not be able to revise , add, delete , modify the data .

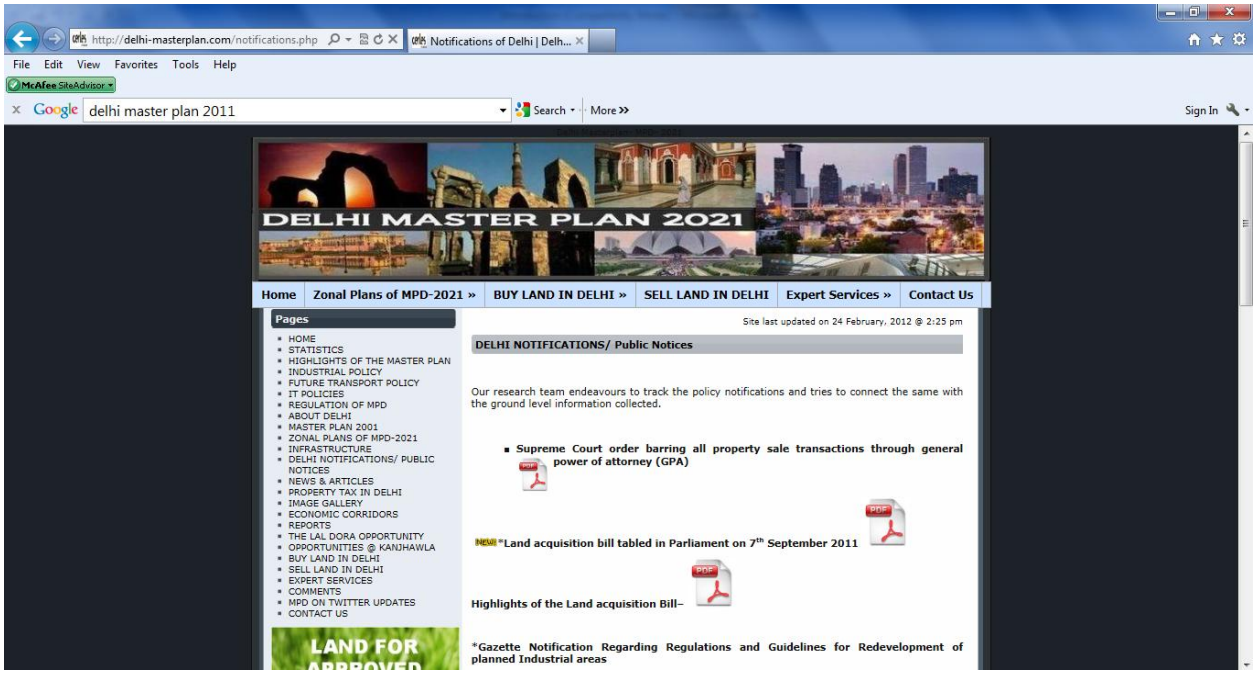

Figure 5: Public Notice

8 OUTCOME OF THE URBAN PLANNING MANAGEMENT INFORMATION SYSTEM:

- A gateway to dynamic planning: A developing country like India which is in the transition stage of office automation this information system will act as platform of integration of traditional data and information system and the modern and dynamic GIS based information system. GIS will not only help in storing, updating, analyzing and presenting the information but also support the information system to connect the site/location specific information with the day to day decision making process.
- Efficient data management : Planning exercise needs a wide range of data and information. In GIS platform every data and information are stored in different coverage, It helps in integration and differentiation of graphic and data base information. This information system will give the capability of comparing the change in landuse pattern, Population density at the national level as well as at the city level. At the city level it can go upto the details of house hold details, location of municipal waste storage point, distribution of power grid, Gas pipelines etc. All these information are to represented and compared graphically and with the data table and text.
- Tools for data analysis: This information system has the capability of performing the user - based data query. The types of data analysis used by the planners, developer, decision maker will be

different from the academician, general public. Ever user will retrieve, plot, analyze the data as per the requirement.

- Transparent planning: The information system will represent the information related to the existing status of infrastructure facility, population density, pollution status , status of solid waste management , status of effluent discharge in one hand and the government proposal, action , plan on the other hand. With the dynamic nature of the information flow the planning, monitoring and management exercise will be more transparent.
- Active public participation in planning: the proposed information system will be web based and it would not be software biased. IT could be opened with any operating system. As all the information are easily available the people will be able to take active participation in the planning and developmental activity.

9 CONCLUSION:

Modern GIS integrates various kinds of advanced, dynamic, multi-layered , time series data and graphical information which transform the tedious data analysis job to a faster, dynamic and realistic planning exercise. Regular updation of information makes the monitoring and management of urban space more transparent and realistic approach towards development . This information system can be used as a tool for urban environmental management as well as it can also be a useful support system for property tax collection, land value evaluation etc.

High Building Density around Subway Stations, Policies and Solutions

Abdolhossein Ardekani

(Abdolhossein Ardekani, Master Student of urban planning, Shahid Beheshti University, Faculty of Architecture & Urbanism, Tehran, Iran, abdolhosseinardekani@yahoo.com)

1 ABSTRACT

Building density is an index for controlling population density. Building at higher densities not only makes more efficient of land but can also deliver high quality. Nowadays by the reason of rapid and sprawl growth of cities and increasing urban services costs a decision should be made to decrease these costs by the means of building density. Also the efficient use of land is an important objective in making development more sustainable. It is embedded in government policy. Compact development not only uses less land, but it also has the potential to create efficiencies in the use of other resources, including energy supply and transportation. Basically public transportation stations and specially subway stations are well proper potential for urban developments because of high level of services of these places. Increasing building density around subway stations is acceptable but just when it doesn't decline the efficiency of urban equipment, facilities and services and also life quality. This paper investigates new faces, approaches and ideas of increasing building density around subway stations and offers polices and solutions to increase building density in low-building density areas around subway stations.

2 INTRODUCTION

Recent moves towards the creation of more sustainable towns and cities that offer a high quality of life whilst minimizing resource consumption (such as energy, land and water), have reawakened interest in the concept of density. The benefits of seeking higher density levels in overall terms are well-recognized-especially in the context of delivering mixed use development where a minimum housing density is required to sustain non-residential uses. Some people continue to equate higher densities with poor urban quality, such as overcrowding and reduced space standards. This misses a fundamental point. Density is only a measure. It is a product of design, not a determinant of it. The aim should therefore be not to achieve a given residential density, but to generate a critical mass of people able to support urban services such as public transport, local shops and schools.

Higher densities focused on urban centers ensure that they remain lively, with local facilities close at hand. Giving people the choice to use public transport, by sitting bus/tram stops or railway stations within walking distance also helps underpin viability by significantly increasing potential custom. This not only applies to residential uses, but to industry, commerce and shopping. The better served and connected a site or development is, the stronger the case for considering higher densities and lower car parking provision.

Building at higher densities not only makes more efficient use of land but can also deliver higher quality. Decisions on what density levels are appropriate for a location can be biased by negative perceptions. Some people imagine high density as being tall building crammed with small apartments which fail to relate to the local context but in fact high density and specially building density can help to the sustainable development. A greater understanding is required of how, with careful planning and good design, higher density schemes can create successful places with a range of housing types, good space standards and an attractive public realm. The efficient use of land is an important objective in making development more sustainable. It is embedded in government policy.

Compact development not only uses less land, but it also has the potential to create efficiencies in the use of other resources, including energy supply and transportation.

From a social perspective, studies have tested the implications of tall residential buildings for the daily functioning of their user-groups, the relationships that exist among the residents and the suitability of high-rise buildings as a living place for different population groups (for example, the studies of Appleyard and Fishman, 1977, and Dornbusch and Gelb, 1977, both of San Francisco; Yeung, 1977, in Singapore; and Ginsberg and Churchman, 1984, 1985, in Israel). The findings point to the importance of investigating the increase in high-rise building.

With respect to location, high-rise buildings in large cities such as New York, Chicago, Philadelphia, Boston, San Francisco, London, Tokyo and Hong Kong were built adjacent to the city centre or subway stations. The

need to locate in proximity to partners and competitors, along with the high consumption of building areas required by the accompanying services sector, attracted economic activities to the city centre. The high price of land, high demand and the characteristics of the consumers combined to motivate developers to build tall buildings (Lim, 1988; Polledri, 1990)

In this paper we will review that how we can promote building density around sub way stations.

3 LITRATURE

3.1 Compact City

The idea of 'Compact City' refers to medieval city or XIXth century city. The Compact City strategy focuses on the form of the city and the efficiency of the distribution of human activities within it, making optimal use of the infrastructure of the city, particularly transport infrastructure, through compact, mixed-use and dense settlement structures enabling effective use of public transport and non car-based movement systems (EUEG, 2004). Benefits of the compact city are cited as: less car dependency, low emissions, reduced energy consumption, better public transportation services, increased overall accessibility, re-use of previous developed land, high quality of life, preservation of green space (Thomas, Cousins in Jenks et al., 1996). Examples of Amsterdam, the pioneer in compact city policies, Hamburg or Copenhagen provide enough evidence for compact development (Sheurer, 2007).

Some advocates of the compact city see its potential in increasing housing density in new mixed use developments. Yet density is not the only measure of a compact city. If we are to achieve the right balance of quality and quantity there must be a limit to the densities in a compact city. That capacity varies from place to place and depends on local requirements, climate conditions and the existing built environment. The aim is to generate a critical mass of people able to support urban services such as public transport, local shops and schools (Llewelyn Davies, 2003). Increasing density requires improving the quality of urban areas to attract people to live and work. Provision of urban open space is necessary for high quality urban environment and may be a source of Environmental, social and economic benefits (CABE, 2001). Especially the economic benefits seem to be interesting, since they might be better arguments than any other in the era of consumption. New tools and methodologies have been developed for better understanding of importance of urban open spaces and the activities that occur in such spaces. Nice view on green and proximity to the park may result in higher real estate prices (CABE, 2005) and in most cases that also results in higher property taxes. Good urban design can also contribute to better, more frequent use of urban open space. In conclusion urban open spaces may contribute to more compact cities for both private and public space-estate owners.

3.2 Transit Oriented Development (TOD)

Transit Oriented Developments (TODs) are higher density mixed use residential and commercial developments set within walking distance of key transit nodes such as rail or bus stations or around activity centres such as major shopping centres/offices. While higher densities are promoted closer to the transit nodes, lower density development is allowed farther away from the transit nodes. TODs aim to encourage increased ridership in public transport, to efficiently integrate land use and transport, and to create integrated liveable communities (Calthorpe and Fulton, 2001; Bernick and Cervero, 1996, Kaufman and Morris, 1995). Cervero suggests that transit oriented development requires the three dimensions of Density, Diversity and Design (3Ds) to make the concept work (Tumlin and Millard-Ball, 2003). In the context of USA, Garde comments of new urbanists projects which are very similar to TOD, pointing out that existing zoning ordinances and subdivision regulations are one of the major barriers to implementing new urbanist projects (Garde, 2004).

For example, in the case of redevelopment projects requiring land assembly, public redevelopment agencies can use the power of eminent domain to acquire the land, bearing initial development costs, to attract private developers. Tax increment funding (TIF) can be used as a tool to support infrastructure and land cost subsidies. Under this arrangement, local governments can use the future potential increases in property tax revenues in the TOD district to invest in infrastructure improvements and issue bonds against future property tax increases (Boarnet and Compin, 1999).

Also, zoning around transit nodes can be used to provide incentive for developing higher density mixed use project as a matter of right or requiring minimum review procedures.

Another form of incentive is the provision of grants to support TOD. For example, the 'Transportation for Livable Communities' program in San Francisco provides small grants to community oriented transportation projects that support walkability, transit use and compact development patterns.

The shift to a more compact form of development will be achieved through increasing the net residential density of major new urban development and on focusing higher density residential development within and around regional activity centers and public transport nodes and corridors.

3.3 Relationship between building density and public transportation

Empirical evidence and the results of a large number of studies suggest that there is strong positive correlation between population density and transit use. The higher the density, the higher the transits use. However, variables other than density – culture, household income, the design and location of transit lines, the management efficiency of transport companies, government transport policies, including subsidies – certainly also influence transit use. The correlation does not imply causality. The relationship between density and transit use in various cities of the world has been documented by Newman and Kenworthy (1989) and Kenworthy and Laube (1999).

Kenworthy established that there is a strong positive correlation between density and transit use among world cities and a strong negative correlation between auto travel per capita and density. But the correlation does not imply that in a given city an increase in density would necessarily result in an increase in transit use or that an increase in transit supply would increase density and transit use. A significant increase in average density in built-up areas is a phenomenon which has yet to be observed in large cities, looking back over the past 50 years.

The correlation between population density and transit use is often difficult to measure because the lack of comparable data across metropolitan areas for density and for transit use and because factors others than density that might influence transit use might be difficult to measure. We compare density in the built-up areas with two types of variable: transit trips per capita and passengers per mile of metro line. These variables are somewhat more abstract than the percentage of transit trips over all trips, but they have the merit of being more accurate.

If we compare population density in the built-up area and transit trips per capita per year globally, we find that low density cities (below 30 people per hectare) have a very low demand for transit (below 70 trips per year or about 7 percent of all trips). Atlanta with about 40 trips per year per capita shows a relatively high demand given its very low density. This would suggest that transit trips in Atlanta are unlikely to increase much in the future as the transit system seems to have already attracted the maximum number of transit passenger compatible with its current densities. The under-utilization of the existing transit network in low density cities suggests that low density might be associated with low demand. In other words, there may be a density below which transit becomes impractical for most travelers compared to alternative means of transportation. Cities with low average densities (below 30 people per hectare [p/ha]) have low transit use, i.e. in these cities transit trip represents less than 10% of all trips. By contrast, cities with densities above 30 people per hectare tend to have higher transit use. For example, a very high density city like Hong Kong (370 p/ha) has a very high transit use: 85% of all trips are made by transit. It is no accident that one of the densest cities in the world is the only one to have been able to develop and operate its metro without subsidies.

While empirical evidence shows a strong correlation between density and transit use, it is important to know whether causality exists and why there might be a density threshold below which transit is ineffective. If a city's density is below this threshold, it could not hope to increase the share of transit trips significantly without first increasing its density.

Population density is not the only factor affecting transit operation; the spatial concentration of jobs and people is certainly as important in determining the viability of transit. The city centre of traditional European and Asian cities is usually the place where the major number of jobs, retail space and cultural amenities are found. The steep density gradients of European and Asian cities point to the primacy of the city centre as a focal point for the majority of transit trips. It is easier for transit operators to operate transit lines with multiple origins (the suburbs) and one destination (the city centre). It is much more difficult to operate transit

routes linking multiple origins to multiple destinations, as recognized by Cervero (1998), one of the strongest advocates of transit. In most "transit cities" the trips toward the centre are mainly by transit while suburb to suburb trips are by car. While rail mass transit, commuter trains, metro, and light rail are well adapted to monocentric cities, buses are the only transit mode which makes sense in a polycentric city where jobs are dispersed throughout the metropolitan area. The more dispersed the jobs, the fewer the passengers per route, the smaller the capacity of the required buses. A related issue is whether transit investments might promote more compact urban development. Most, but not all, of the new rail transit developments are radial systems that either terminate or pass through the CBD. Some argue that this might help to promote downtown or inner-city development around rail stations, and thereby increasing densities. This might happen on a micro scale, e.g. moderate-size infill development.

In Tokyo, we find the combination of a cluster of high-rise buildings and individual high-rise buildings across the entire urban landscape as a result of the absence of clear zoning policies (Bognar, 1997). It is perhaps Singapore, the city-state where 90 per cent of its 3 million populations live in private or public high-rise buildings, that has succeeded best in creating community life in a high-rise environment by implementing a new pattern of high-rise neighborhoods in the Housing and Development Boards new towns. This was achieved by a high level of pedestrianisation and the use of outside space, along with easy walking distances from each building to the neighborhood centre and other facilities (Beng-Huat, 1997, pp. 111–123).

High density presents both opportunities and challenges in the transport arena. It is opportunities that have often been emphasized in the compact city literature. For example, high density offers the opportunity for average trip lengths to be short and to foster successful, economically viable public transport (Puckered and Zupan, 1977). Such high densities also promote a high level of accessibility for non-motorized modes of transport and enable cities to have low levels of energy use per person in transport (Newman and Kenworthy, 1989). The opportunity that high urban density presents to public transport is exemplified by the case of Hong Kong, where in 1990 public transport carried 82 percent of all motorized passenger kilometers. A number of mechanisms explain the potential for high levels of public transport in dense cities but there is not space to go into them here. Figure 4 makes clear that a very high role for public transport is possible in high density cities, even in those with high incomes. However, the examples of Bangkok and Surabaya suggest that high density does not necessarily guarantee the success of public transport. Another opportunity of high densities is the possibility that many trips can be short and therefore easily made on foot or by non-motorized vehicles However, Fig. 5 also shows that although high density provides an opportunity for non-motorised transport to play an important role, it does not guarantee it. For example, Bangkok seems to have remarkably little walking or cycling to work despite its relatively high density. In fact, the graph shows that the levels of non-motorised transport for work trips in the high and very high-density Asian cities in this sample are no higher than levels found in most middle-density cities. This probably reflects the hostility of the street environments for people on foot or on bicycles in most of these cities.

High urban densities also present formidable transport-related challenges, especially for cities where rising incomes have begun to unleash the potential for higher private vehicle ownership and usage. For example, traffic congestion tends to emerge rapidly as dense cities motorize, even if vehicle use per capita remains relatively low. This is not simply a result of poorly developed road systems, since in dense cities' road capacities per capita are inherently and inevitably low. It is physically impossible for dense cities to match the road provision levels of low-density cities. Furthermore, air pollution and other local impacts of traffic can become severe problems for dense cities even at low levels of motorisation. The most successful transport policies in dense cities are those that are compatible with the spatial realities of such urban areas. The voracious demand for space by cars has been understood for many years. An influx of cars therefore creates great difficulties for established dense urban areas and generates substantial pressure for activities to spread out to make way for access by cars. Research on transport space consumption using the product of the space occupied by the time that it is occupied, shows enormous differences (up to 90 times) in space consumption between cars and public transport for a trip to work in a central business district. This approach emphasises the importance of the space consumed for car parking, especially that which is occupied for the entire day in expensive central areas. Unfortunately, the recognition of the inefficiencies of private transport from a spatial perspective has often not penetrated to a policy level. Exploring how developing cities can retain or reinforce transit-oriented urban land-use patterns, even as incomes rise, is an important area for study (Gakenheimer, 1995). The experiences of some of the Asian cities show that, even with their high-

density land-use patterns, there is still potential and a need in dense cities for land use policies to explicitly favour public transport and non-motorised transport. This involves attention to the details of transit-oriented urban form. Unfortunately, there is not space to go into this in detail here. Suffice to say that explicit policies in Singapore, Hong Kong and Seoul are encouraging land-use patterns to become increasingly transit-oriented. In Tokyo, the land-use control system is relatively weak but nevertheless much new development is transit-oriented in its location and design (Hook, 1994), providing evidence that, in conditions of public transport dominance, transit-oriented land-use patterns can naturally develop as a market response. In the other cities in the Asian group, there is a trend for the design details of much new development to be oriented to access by private vehicles, even though densities remain high overall. In Bangkok, Kuala Lumpur, Jakarta and Manila, many new housing, office or shopping complexes built in the recent boom decade (1986 to 1997), and targeted at the newly prosperous middle class, have designs predicated upon private vehicle access. These developing Asian cities run a risk of building traffic disasters into their urban fabrics. This is because densities are still too high to cope effectively with many private cars but the pro-car design features tend to encourage private transport and make the provision of public and non-motorised transport facilities somewhat difficult.

4 HIGH BUILDING DENSITY AROUND SUBWAY STATION

Development densities are “as great as possible” within the context of a particular station and surrounding community. Minimum residential densities around rail stations are high enough to support higher frequency transit service and to foster lively, walkable communities. Housing forms include townhouse, walk-up apartment and high-rise buildings. Minimum employment densities are established in station areas to create a destination which generates transit trips. Below are some examples of minimum densities being used in LRT station areas by other jurisdictions?

The highest densities are ideally located closest to the station, to optimize transit rider convenience. This includes high-density housing and offices. Intensity of development can taper off away from the station, to create an appropriate transition and interface with the surrounding community.

Plans for areas around LRT stations should address the ability to increase density over time. Vacant lots, surface parking lots and existing low intensity uses present opportunities for future infill development. A phasing plan that demonstrates how the station area can intensify over time offers flexibility to meet changing community needs and provides a vision for this transition.

Within the higher density levels which sustain urban life, variations in the net density of built form profiles will occur naturally. This can be enhanced by building up the mass around centers, public transport access points, parks and riverfronts, for example. Shape the mass of built form to frame positive Public spaces.

There is currently a proposal for high-density housing at Yonge Street and Eglington Avenue. This area already contains mixed high and low density housing as well as stores, schools, public buildings, office buildings and restaurants. There is significant controversy surrounding this proposal as many studies have suggested that increasing density will increase traffic in the area thereby lowering the property values in the area.4 However, one could argue that the project is located directly on public transit lines, and would therefore encourage the use of public transit as well as attract residents who are already use public transit. Moreover, the increase in population could stimulate upgrades to the area’s transportation infrastructure. According to a recent issue of Realty Times, high-density housing that generates the need for upgrades to public transportation systems increases the area’s employment, household incomes and property values.

Taking public transport into account in urban planning decisions is an effective way to stop the increase in private car traffic and daily traffic congestion. One of the best incentives for leaving the car at home is a short walk to an attractive public transport station.

5 HIGH BUILDING DENSITY AROUND SUBWAY STATION

5.1 Mixed-land use

High-density, mixed-use development and high levels of transit service are often present together at sites exhibiting a high transit commute mode share and a high midday non-motorized mode share. Unknowns involving causality make it difficult to separate the contribution of each site element to the resulting transit and pedestrian activity (Douglas and Evans, 1997). commercial uses are encouraged to locate at subway

station nodes and development should be more residential in nature adjacent to designated stable residential areas. nature of development along the Sheppard East Subway Corridor should reflect the nature and character of the communities around the subway stations. The mix and range of uses encouraged by this Secondary Plan and the level of development potential are influenced by these characteristics. The key development areas are shown on Map 9-2 and their development will be governed by the following policies. The key development areas are primarily designated Mixed Use Areas and are focused within walking distance of the subway stations.

Development of lands designated Mixed Use Areas will be in accordance with the Official Plan and the fol owing policies:

- Mixed Use Areas may be permitted to be developed primarily for residential uses, however, mixed use developments with non-residential uses such as retail or small offices at grade with multiple residential or offices located above grade are encouraged along the Sheppard Avenue frontage;
- In predominately residential areas within Mixed Use Areas designations, non-residential retail and office uses will be located on properties with frontage or flankage on Sheppard Avenue, Bayview Avenue or Leslie Street. Access to such non-residential uses will be primarily via the arterial road and such development wil not depend upon obtaining vehicular access through local roads serving multiple residential development;
- Within the interior of Mixed Use Areas, a mix and variety of residential buildings, uses complementary and accessory to a multiple residential use and public and private open space areas will be encouraged;
- On lands designated Mixed Use Areas which abut properties designated Neighbourhoods, only residential uses which can be designed to be compatible with the low density character of the stable low density residential properties they impact will be permitted;
- It is intended that as densities are distributed within a comprehensive development area, the highest densities will generally be located closest to the subway nodes, and along the frontages of arterial roads and abutting Highway 401. Densities will be lowered toward stable residential areas where no change in land use policy is introduced by this Secondary Plan.

5.2 Job-housing balance

Jobs-housing balance is a planning tool that local governments can use to achieve a roughly equal number of jobs and housing units (or households) in a jurisdiction. The notion of balancing jobs and housing goes well beyond trying to attain numerical equality. Ideally, the jobs available in a community should match the labor force skills, and housing should be available at prices, sizes, and locations suited to workers who wish to live in the area. Jobs-housing balance is a planning technique rather than a regulatory tool. Nonetheless, various ways exist that the concept of jobs-housing balance can be applied in local land-use regulations and large-scale development reviews.

Any policy that seeks to balance jobs and housing has multiple objectives, but almost all of these objectives will promote smart growth. The leading scholar on the concept of jobs-housing balance, Robert Cervero (1989; 1991), suggests that jobs-housing balance policies can help to reduce urban sprawl and lower energy consumption. The most important objectives of jobs-housing balance policies, in the eyes of those who have implemented them, have been the reduction of VMT and other traffic impacts. Reduced congestion and lower VMT. There is evidence that intensifying housing in downtown areas can reduce peak-hour commute trips into those areas. David M. Nowlan and Greg Stewart (1991), for example, studied commuting to Toronto's central downtown and concluded that inbound trips had been reduced due to the increase in residential population there. The authors estimate that "for each 100 additional dwelling units in the Central Area there has been a reduction of approximately 120 inbound trips during the morning three-hour rush period" (Nowlan and Stewart 1991, 165). In a study of the Greater Seattle-Tacoma region, Lawrence Frank and Gary Pivo (1994) found that travel distances tend to be shorter for commutes to balanced areas (see also Cervero 1996). The San Diego Association of Government's Regional Growth Management Strategy (1991) found that commute trip lengths in sectors with balanced jobs and housing were 8.8 miles, two miles less than the regional average (Ewing 1996, 46, n. 17). The Southern California Association of Government

(SCAG) provides additional evidence of VMT reduction from implementing jobs-housing balancing policies. This policy can be effective with mixed-land use.

Generally, job-hosing balance is a policy that can be effective anywhere to promote building density, because the people who work somewhere, live near their houses. Otherwise accessibility for public transportation will increase.

5.3 Pedestrian design

The quality of walk connections has been shown to influence the distance people are willing to walk. A short walk made difficult or unpleasant by adverse environmental conditions such as high-speed traffic or lack of shade can seem longer while a long but pleasant or interesting walk can seem shorter. It follows logically that quality of the pedestrian connections between the transit stop and the front door of the development should be important to transit usage. In many subway stations, special attention has been given to the pedestrian environment, including streetscape improvements. It is generally held that the placement of parking lots, green spaces, and the buildings themselves can impact the pedestrian and transit friendliness and attractiveness of travel by transit or walking (Arrington et al., 2002). Results from development of an advanced travel demand model set for San Francisco County lend support to the concept that the quality of walk connections to transit is positively related to transit use. Neighborhood vitality at the destination was found to have a strong positive relationship to the choice of all non-auto modes examined (walk, bike, and transit) for most types of trips. Adverse topology (steep gradients and barriers) was nearly as important. Connectivity at the destination was also, for work trips, significantly and positively related to walk and transit choice (Cambridge Systematics et al., 2002). The lesser importance in the San Francisco travel models of connectivity, and the lack of significance of conditions at the trip origin, are likely artifacts of model calibration with travel data from a city with limited pedestrian-friendliness contrasts. Few city/county of San Francisco non-industrial areas have poor pedestrian connections and most neighborhoods are basically pedestrian-friendly.soe strategies that can help to the pedestrian design are:

- Station Area block lengths should range between 400 and 660 feet to facilitate connectivity and pedestrian accessibility.
- Develop primary and secondary bike and pedestrian paths connecting to the Station Area.
- (a) Primary paths attract high pedestrian and bike volumes, associated pedestrian and bike oriented services, and act as the major connections to the station. Primary routes should provide direct access between the station and major pedestrian and bike destinations in the surrounding community. Primary paths should be designed as continuous, convenient, safe and barrier-free routes.

  (b) Secondary paths do not provide direct links to the station, but feed into the primary routes.
- Utilize sidewalk widths adequate for social use (six to twelve feet depending on location and use).
- Provide pedestrian plazas to create social places and to tie buildings and uses together.
- Install direct, continuous, buffered sidewalks across any large parking areas.
- Utilize canopies, awnings, and arcades to provide pedestrian shelter.

5.4 Infrastructure and Facilites

While there is probably no “right” definition of infrastructure, much depending on the context, there is some advantage in reserving the term for structures and facilities that are the result of human intervention, creating something physical that was not there before. This definition can still embrace the movement of soil to create embankments or cuttings as well as the erection of buildings and the laying of lines. The difference between infrastructure and other potentiality factors, such as the location of the region or its natural resource endowment, is that the service bundles inherent in infrastructure have been ‘artificially’ created through investment, whereas location and natural resources are ‘naturally’ given. There are various ways in which infrastructure so defined can be categorized. The simplest is descriptive: Buildings, roads and related items, utilities, etc. However, this is not particularly helpful from an analytical point of view. A more economic approach is to consider supply characteristics, particularly economies of scale, and demand characteristics, particularly the “publicness” of the goods or services provided, and to develop a categorization on this basis. For present purposes, however, we adopt a categorization based on just two characteristics, which highlight

access to the service. We see much of the man-made urban infrastructure as belonging to one or other of two broad types:

• Area Type: Provides services within a defined area (e.g. utilities, transport systems). In such cases, getting the service to users involves distribution costs;

• Point Type: Provides services at a specific point (e.g. hospitals, schools, offices, shops, museums, theatres, etc). In such cases, the equivalent consideration is the cost to users of accessing the facility.

In the urban economics literature, the provision of infrastructure services tends to be viewed as naturally monopolistic because of scale economies. It seems self-evident that setting up rival systems to compete with each other to supply a community would mean duplication and waste. And the more people who can be connected to a system, the lower average costs must be. However, this view overlooks the effect of distribution or access costs.

Higher densities focused on urban centers ensure that they remain lively, with local facilities close at hand giving people the choice to use public transport, by sitting bus/tram stops or railway stations within walking distance also helps underpin viability by significantly increasing potential custom. This not only applies to residential uses, but to industry, commerce and shopping. The better served and connected a site or development is, the stronger the case for considering higher densities and lower car parking provision. If we want to promote density around subway stations, Infrastructure and facilities should be forecast, otherwise building density will not rise by the reason of lack of Infrastructure and facilities.

The policy should be Focus public infrastructure investments where development is most desirable to correct existing deficiencies and ensure capacity for high-intensity around subway stations and also Maximize smart growth planning techniques and opportunities as a mechanism to promote the practical preservation of the floodplain/floodway and to reduce potential runoff into Clear Creek.

There are some strategies for this polices:

- Ensure that adequate public facilities, including streets, drainage, pedestrian and bicycle amenities, are in place in advance of or can be completed concurrent with development in Station Areas.
- Relocate or reconstruct existing facilities that are incompatible with desired Station Area development, such as utility sub-stations, abandoned freight rail spurs, overhead utility lines, or oversized streets or street layouts.
- Coordinate capital improvement plans by the County, Metropolitan Districts and private developers to facilitate TOD development.
- Document baseline infrastructure conditions.
- Ensure that developers and agencies comply with County requirements for road and intersection improvements.
- Implement the findings and recommendation of the Clear Creek Master Drainage Study and other floodplain and drainage studies done by the County or the Urban Drainage and Flood Control District.
- Comply with federal, state and local storm water programs by using 'Best Management Practices' (BMPs) to manage storm water runoff over the life of development and redevelopment projects within the overlay district.

6 CONCLUSION

High building density around subway stations can have to positive effect on using public transportation ,first high building density increase accessibility to public transportation for more persons and the result is that passengers benefit public transportation will increase and VMT will reduce. Second high density cause reducing operational costs of transportation networks that are in the high density areas author to decreasing the time of journey. High rise building without investment can have bad effects on environment sustainability. However in this paper we reviewed some polices and solution to increase building density around subway stations that are mixed-land use, pedestrian design, Infrastructure and facilities and job-housing balance. These police and solutions can not promote building alone. Development intensity and density should be significantly higher in station areas to provide a base for a variety of housing, employment,

local services and amenities that promote transit usage, encourage pedestrian activity and support a vibrant station area community.

1 ABSTRACT

Population changes are part of the transformation in European cities. The growing group of migrants is one element of these transformation processes. Due to socio-demographic changes they are set to play a greater role in the future development. Thus, new mobility needs and requirements as well as increasing cultural and ethnic influences and diversity are new challenges for planners and city authorites. In the context of such re-mixing processes, cities are in demand to reconsider existing management procedures in order to adapt and manage different elements accordingly. This is also true for the transport system that needs to facilitate and support sustainable mobility behaviour. In Germany, nearly 20 % of the population are first- or second-generation immigrants (so-called "people with a migration background"). Despite these facts, little is known about their mobility behaviour, mobility options and needs, and they remain "terra incognita" with regard to their travel patterns. An important and interesting research question is therefore if and how a migration background affects mobility behaviour and transport demand, with such information needed to define whether local infrastructures can fulfil the needs of all inhabitants.

In reply to this, the ILS conducted a pilot study[1] to broaden the empirical basis in Germany and ascertain possible motives and reasons for any differences in mobility behaviour. Results show some interesting differences between the survey's three main target groups ("without a migration background", "with a Turkish migration background" and "with another migration background") regarding mobility-related variables such as driving license ownership, vehicle ownership, personal vehicle availability and usage of different transport modes.

People with a migration background have their own views and needs regarding mobility services and transport infrastructures as parents of schoolchildren, public transport customers, or as employees of different companies. Some also belong to groups with special mobility needs, like elderly people or people with reduced mobility. Up to date it remains an open question if people with a migration background need additional assistance and further services to use all mobility options which are offered by a sustainable, barrier-free and inclusive transport system. So the project paves the way to further research.

2 INTRODUCTION

2.1 Background

In addition to population decline – varying widely from region to region –, the overall ageing of society and changing forms of social life, growing ethnic diversity is a major quantitative and qualitative consequence of demographic change, with nearly 20 % of people living in Germany now having a migration background[2] (Statistisches Bundesamt 2010).

In view of the shift from labour migration to permanent immigration, which continues to take place in Germany, the inclusion of immigrants, their families, and coming generations in societal and political life is

[1] In cooperation with ´Integriertes Verkehrs- und Mobilitätsmanagement Region Frankfurt RheinMain (ivm GmbH)´ and City of Offenbach

[2] The definition of a population group with a migration background was introduced in 2005 by the 'Microcensus', an official representative survey of the population and labour market. The group includes " (…) all persons who have immigrated into the territory of today´s Federal Republic of Germany after 1949, and of all foreigners born in Germany and all persons born in Germany who have at least one parent who immigrated into the country or was born as a foreigner in Germany. The migration status of a person is determined based on his/her own characteristics regarding immigration, naturalisation and citizenship and the relevant characteristic of his/her parents (Statistisches Bundesamt 2012)."

becoming increasingly important. Due to the positive migration balance together with greater follow-up immigration of family members and higher birth rates than among the ethnic German population, the proportion of children and young people with a migration background, as well as older people, is set to greatly increase. From a spatial, societal, and economic point of view, people with a migration background will thus remain a determining factor in urban development.

Urban development policy research and practice, programmes and measures have until now focused on integration, community life, language acquisition, political participation, education, and vocational integration, as well as cultural diversity. What has so far been neglected is the question of the impact of growing ethnic diversity on everyday mobility, transport and traffic in cities and urban neighbourhoods.

There are some initial indications that people's everyday mobility is determined not only by the classical spatial, economic, and socio-demographic factors such as age, gender, education, and employment, but also by national and thus cultural/ethnic background. In particular, there are signs of gender-specific differences in access to and use of different forms of transport (Kasper, Reutter, Schubert 2007).

Although mobility and transport studies have as yet ignored the migration background of transport users, a few studies included their nationality in the bivariate form German/non-German. One of these few studies is MID (Mobilität in Deutschland) 2002, the survey on mobility in Germany. The findings of this ten year-old survey show that immigrants do not necessarily travel less than Germans, but they do so differently. Differences are also apparent between nationalities, with gender variable often having an intensifying effect. For example, whereas on average German women and men made the same number of journeys, among non-German respondents, men made more journeys than women of the same nationality. On average, far fewer non-German women own a car and vehicles are more rarely available to them. As far as driving licences are concerned, there are similar major differences in immigrant groups between men and women (Kasper, Reutter, Schubert 2007 based on MID 2002).

Findings from studies in European and US contexts also suggest that everyday mobility may be determined not only by "classical" factors (age, income, transport facilities, specific location-related spatial factors, etc.), but also by national or cultural/ethnic background and by migration circumstances (e.g. duration of stay in the new country) (DfT 2010; Beckman, Goulias 2008). For example, a study on the mobility behaviour of ethnic minorities in the Netherlands found that immigrants were less mobile than the native Dutch population, mainly differing in their use of public transport and bicycles (Harms 2007).

However, statements about differences in mobility behaviour between Germans and non-Germans, between people with a migration and non-migration background, or between different groups of migrants are very poorly grounded, with research urgently needed.

2.2 Project objectives

In reply to this dearth of knowledge in Germany about the mobility options, needs and behaviour of people of non-German origin (with a migration background), the ILS conducted a pilot study to broaden the empirical basis in Germany and to ascertain possible motives and reasons for any differences in mobility behaviour. Initial indications suggest that everyday mobility may well be determined not only by the "classical" factors, but also by national or cultural/ethnic background.

3 METHOD

3.1 Survey Design

The survey was conducted as a pilot study, designed to combine questions on family background such as citizenship, date of migration and native country with such mobility-related questions as the number of cars and bicycles per household or the availability and use of different transport modes.

The survey took place in Offenbach am Main, a major city with over 120 000 inhabitants. The share of people with foreign citizenship (31 %) is one of the highest in Germany; with even more people accordingly having a migration background. Therefore, telephone interview participants could choose between four different languages. German was by the far most frequently selected (94.0 %), followed by Turkish (4.9 %), Russian (0.8 %) and Polish (0.4 %). The survey took place in September and October 2010. The participants were aged 18 years and above and were allocated by quota to the three main groups "without a migration

background" (n=666), "with a Turkish migration background" (n=631) and "with another migration background" (n=617). In the last group, participants had 54 different nationalities and came from 73 different countries. In addition, each main group was equally divided between women and men. In the following text the results are presented separately for the three main groups.

To facilitate understanding, the group of participants without a migration background is referred to as "German", that of people with a Turkish migration background as "Turkish", and that of people with another migration background as "other-nationality". This reflects the background and not the current citizenship status of the particpants; i.e. Turkish participants who have adopted German nationality are assigned to the Turkish group, due to their Turkish background. When referring to groups with a migration background in general, i.e. without differentiating Turks, the term "non-German" is used.

3.2 Sample description

In total the survey sample contains data from 1914 participants. While non-German survey participants tend to live in or close to the city centre of Offenbach, German ones tend to live more on the city's periphery.

	Without a migration background	Turkish migration background	Other migration background	Total sample
Average age in years (participants age: 18 and above)	59	43	45	49
Average household size	2.0	3.2	2.9	2.7
Percentage of households with children under the age of 18	28.8	55.3	47.9	45.3

Table 1: Sample description by migration background

Regarding some general socio-demographic parameters, there are quite big differences between the three groups (see Table 1). The overall average age of the total sample is 49, pretty close to the average age of the whole population of Germany (aged 18 and above). Looking only at people with German citizenship, to be found in all three groups, average age increases to 52. Similar to the total population of Germany, in our survey Germans are older than non-Germans. Consequently, only 28.8 % of German households live together with children under 18. This contrasts to 55.3 % of participating Turkish households. Household size similarly reflects this pattern, with German households having only two household members on average, while Turkish households have on average 3.2 members, closely followed by other-nationality households.

The older age of German participants is reflected in the high proportion of retired people (48.6 %). By contrast, only 15.1 % of other-nationality participants belong to this group. More than half (53.3 %) of this group goes out to work (part-time or full-time), compared to 46.1 % of Turkish participants and only 38.9 % of German ones. The highest number of unemployed people is to be found in the Turkish group (9.7 %), the least in the German group (1.8 %).

	Without a migration background	Turkish migration background	Other migration background
Below 1,000 €	21.0 %	52.5 %	34.9 %
1,000 € up to 1, 499 €	21.9 %	23.5 %	27.4 %
1,500 € and 2,999 €	49.7 %	21.5 %	33.9 %
Above 3,000 €	7.4 %	2.4 %	3.9 %

Table 2: Household income per month by migration background (equivalent scale: OECD modified scale) 3

Even though many of the German participants are retired, they tend to have a higher household income per month than the other two groups (see Table 2). For example, only 21.0 % of them have a (equivalent scale) household income less than 1.000 € per month, in contrast to 52.5 % of those in the Turkish group. The latter group generally tends to have the lowest household income, followed by the other-nationality group.

[3] In order to reflect that the needs of a household grow with each member but not proportionately, the size of the household and the age of its members are taken into account. An equivalent scale is used following the OECD-modified scale. This scale assigns a value of 1 to the household head, 0.5 to each additional adult member and 0.3 to each child.

4 FINDINGS

The following chapter provides an overview of selected mobility-related survey findings, such as percentages of people holding a driving licence, vehicle ownership and usage of different forms of transport as well as findings regarding satisfaction with the provision of key services. All findings are presented by three migration groups (´Without a migration background (German)´, ´Turkish migration background (Turkish)´ and ´Other migration background (other-nationality)´) and also by gender.

4.1 Driving licence ownership, car ownership and use

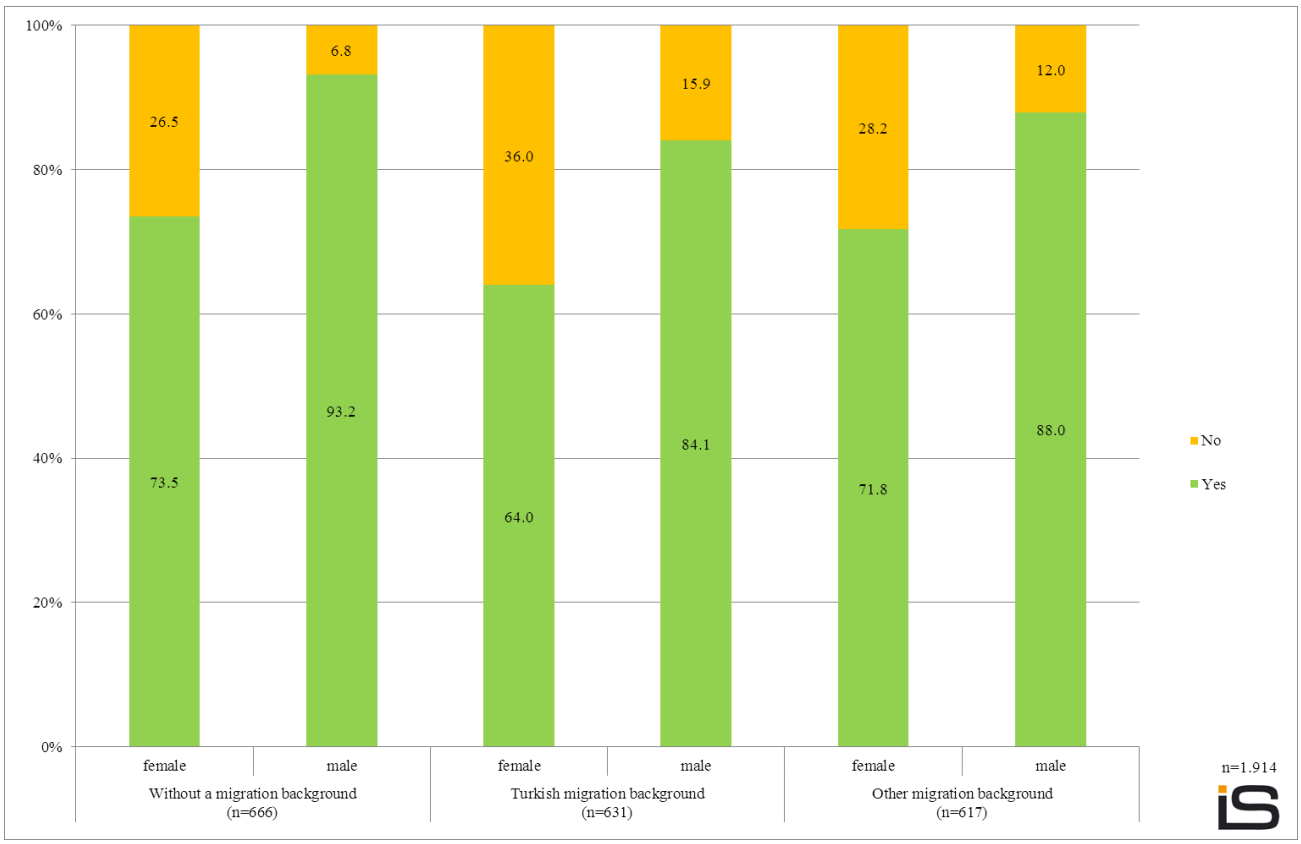

Fig. 1: Car driving licence holders by migration background and gender

As the chart above shows, the proportion of women holding a driving licence is clearly lower in all groups. Whereas 73.5 % of German women hold a driving licence, this figure drops to 64.0 % for Turkish women. It should also be taken into account that 80 % of all female German non-licence holders are over 60 years old. By contrast, the majority of non-German women are considerably younger (between 18 and 39 years old).

Findings on car ownership per household do not show any major differences between the three groups. The majority of all households has at least one car, with only 24.5 % of German households, 21.7 % of Turkish households and 23.5 % of other-nationality households not owning a car. The majority of these non-car-owning households are singles living – as expected – close to the city centre of Offenbach. To find out why these households did not own a car, the respective participants were asked about the reasons why. The majority of German households answered that the main reasons were age and health (reflecting the higher average age of this group), while non-German households cited primarily financial reasons (´Purchase or maintenance of a car too expensive`).

However, car ownership by household-size shows that German households tend to generally have more cars than non-German households – the larger the household, the higher the number of cars in the household. By contrast, in Turkish households the number of cars hardly increases with more household members, with only 23.1 % of 5-person-households having two or more cars.

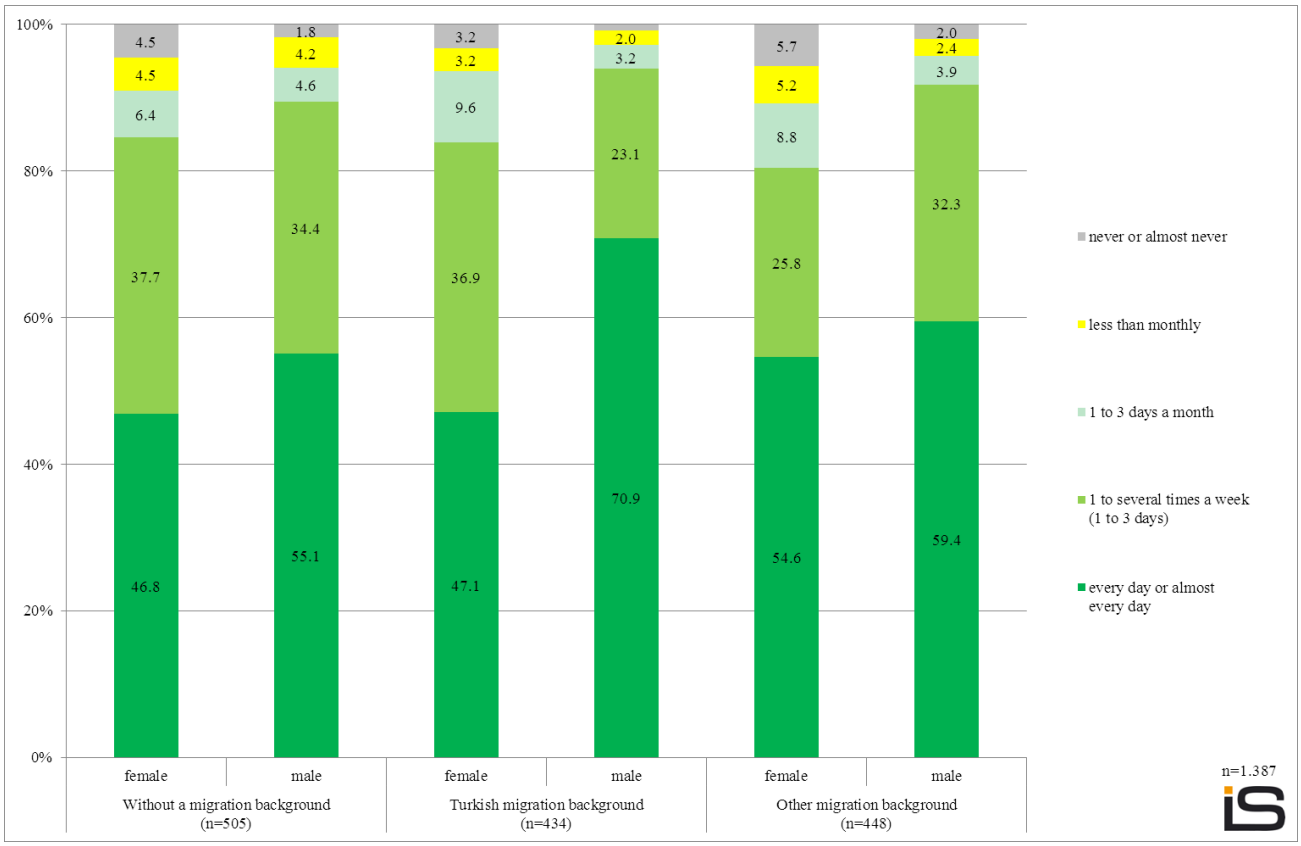

Fig. 2: Car use (as driver) by migration background and gender

Participants holding a driving licence and at least occasionally having access to a car were asked how often they normally use the car as a driver. Fig. 2 illustrates that in all three groups people use the car several times a week, though women use it less frequently than men. Turkish men use the car more often than all others (70.9 % use it every day or almost every day). In addition this group shows the greatest difference between women and men, with only 47.1 % of Turkish women using the car every day or almost every day. German women use the car less than the others but these women are older.

4.2 Bicycle ownership and use

Findings on bicyle ownership per household show no major differences between the three groups, with the majority owning a bicycle. Nevertheless 24.7 % of German households, 22.9 % of Turkish households and 26.8 % of other-nationality households do not own a (useable) bicycle. In all three groups these are mainly people living on their own. In German households nearly every household member has a bicycle – the more members per household, the more bicycles are available. By contrast a relatively high percentage of non-German households - especially other-nationality households and including multi-member households - do not own a bicycle. For instance, 1/3 of 2-person-households and 1/5 of 3-person other-nationality households do not own a bicycle.

Similary, participants with at least occasional access to a bicycle were asked how often they normally used it. Although German participants are on average older than the non-Germans, their bicycle usage is significantly higher: 60.2 % use the bicycle at least once a week in contrast to 45.7 % of the Turkish and 45.7 % of the other-nationality participants. Women also use the bicycle less than men, especially other-nationality women. 41.5 % other-nationality women cycle less than once a month or never. In addition, the main reasons mentioned for someone not using the bike are time constraints (Turkish participants), distance to destinations (not accessible by bicycle) (other-nationality participants) and health restrictions or physical disabilities (Germans).

Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

4.3 Public transport use

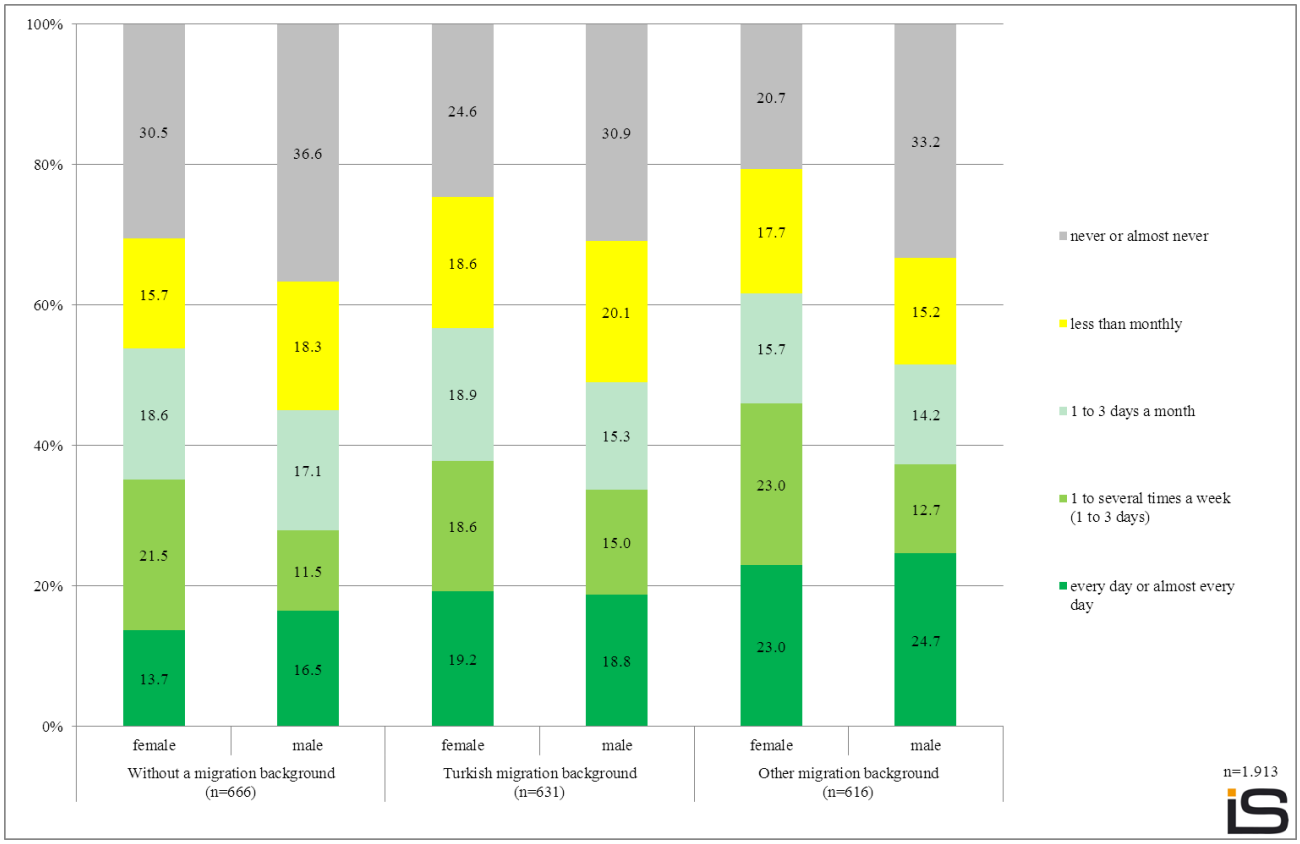

Fig. 3: Public transport use by migration background and gender

To find out more about Offenbach public transport users, participants were asked how often they normally used public transport (bus/local trains). A high proportion of all participants use the public transport system less than once a month or never. For instance, 36.6 % of German men never or almost never use public transport. In all three migration groups women make greater use of public transport than men. Nevertheless 46.2 % of German women, 43.2 % of Turkish women and 38.4 % of other-nationality women answered that they used public transport less than once a month, almost never or never. These results are particulary relevant in connection with the findings on car and bicycle use, with non-German women making lesser use of the car and bicycle but greater use of public transport than non-German men. It should also be noted that the main reason mentioned for not using public transport was the availability and convenience of a car.

4.4 Shopping facilities

Finally participants were asked how satisfied they were with shopping facilities in the district of Offenbach where they live. The findings show that Offenbach is very well equipped with shopping facilities: 77.0 % of German respondents, 82.8 % of Turkish ones and 82.7 % of other-nationality ones strongly agreed or agreed with the statement "My shopping facilities are good". Looking at the findings by place of residence, participants living closer to the city centre show higher agreement than those living on the city periphery.

5 CONCLUSION

What conclusions can be drawn from these findings? The project set out to broaden the empirical basis on mobility behaviour, options and needs of people with a migration background. In summary, the survey provides first important findings on the mobility variables of the sample, indicating certain significant differences between people with and without a migration background and especially between genders. For example, less women hold a driving licence than men. But it seems particularly important that the majority of German women without a driving licence are over 60 years old. By contrast, the majority of Turkish women without a driving licence are comparatively young (18-39 years old). It remains to be seen whether subsequent generations will behave more in line with their German counterparts. Furthermore choice of transport impacts their commuting, childcare or shopping travel patterns. Non-German women – especially

young ones – seem to be a very important target group for public transport and non-motorized forms of transport, thereby guaranteeing their independent mobility.

Findings on the usage of different forms of transport show that women use cars and bicycles less than men in all groups. Though women use public transport relatively more often, the proportion of non-users in all three groups is noticeably high (> 20 %). But the results also indicate differences between the three groups: German women tend to use the bicycle more than the other women in the sample although they are much older. It should be emphasized that non-German women– especially younger generations – need to be encouraged to cycle. For example a number of German cities offer cycling courses for women with a migration background. Such initiatives need to be further developed, together with improvements to the cycling infrastructure.

In addition, the findings on shopping facilities indicate a very positive attitude towards their living environment whether participants have a migration background or not.

More and more people with a migration background are entering Germany's – especially urban – society, they are re-mixing their city and affecting and influencing all aspects of everyday life. Research into the differences in mobility behaviour is becoming increasingly important. Whether as parents of schoolchildren, public transport customers or as company employees, they all have their own views and needs regarding mobility services and transport infrastructures. In addition, some also belong to groups with special needs, like elderly people or people with reduced mobility. To address all these specific needs it is undispensable to conduct more mobility research and include the findings in planning practice. To date the question remains unanswered whether people with a migration background need additional encouragement to use all mobility options. Such active participation needs to be supported by a real choice of mobility options, therefore cities have to offer a sustainable, barrier-free and inclusive transport system. In conclusion, this project provides first important scientific findings on the mobility behaviour of people with a migration background in Germany, a group which is re-mixing the city but is – up to date – almost neglected by mobility research. But, as already said, this project merely paves the way for a lot of absolutely necessary further research.

1 ABSTRACT

Good urban design is not about how places look like, but rather about the art of making places for people and creating public spaces that work for the whole community. Urban spaces suppose to be designed for pedestrians and are expected to fulfill their needs. Therefore, it is of great importance to receive the users' feedback and response in order to tailor our designs to suit them best. However, it is not always quantitative data that explains the user's interaction. Hence, this research focuses on making use of emerging technologies within the field of urban planning to efficiently collect and visualize qualitative data rather than only quantitative data. This happens in pursuit of enhancing the living conditions in our cities, which is the main goal of every planner, developer, politician, and citizen.

This research is investigating a new method of measuring how people feel in their city and how they react to the surrounding built environment with the help of using "SMART-Bands". These devices can measure body parameters in real-time, like skin temperature, skin conductance and heart rate, as indicators for human emotions. This collected data is used to interpret how humans feel and react towards the availability or lack of different urban elements within any studied area.

This paper experiments with those "SMART-Bands" to analyze one of the frequently used paths in the city of Alexandria, the Eastern Harbor. It is a major destination for Alexandrians all year long and during all 24 hours of the day. It represents a substantial recreational facility, as well as hosts a lot of civic and recreational buildings. The two sides of this path have relatively different appearance, pavements, and landscape elements.

The presented paper investigates how people react to those two sides of the same path and tries to link this feedback to the presence or absence of urban design elements and street conditions along that path. It is a pilot study for a more thorough analysis for involving users and their feedbacks - both qualitative and quantitative - to enhance the built environment of major urban areas. That helps re-mixing the city according to pedestrians' needs.

2 INTRODUCTION

Nowadays, the design of urban spaces has got a lot of interests from urban planners as it is the art of making places for people. A foundation with several concepts, theories, and methods that work on the relationship between the built environment and physical activity has been provided and used by urban planners (Susan L. Handy, 2002). Humans often reproduce their experience, so they assume that "things as they are" cannot be changed. Despite the fact that humans accept the world as it is, the community has a remarkable capacity to plan ahead, shape the future, and adapt to new settings (Jackson, 2003).

On the other hand, the built environment for pedestrians has attracted both planners and public health officials promoting policies that improve its quality through mixed land uses, interconnected street networks, sidewalks and other facilities. A growing number of experimental studies have contributed to the debate about the relationship between the built environment and pedestrian behavior (Cao, Handy, & Mokhtarian, 2006). Susan L. Handy (2002) augmented that a combination of urban design, land use patterns and transportation systems that promotes walking and cycling will help to create active, healthier, and more livable communities.

According to Landis, et al (2001), there are several pedestrian models that consider the statistically significant roadway and traffic variables, which describe pedestrians' perception of safety or comfort. Still, a method is needed to objectively quantify this perception in the roadway environment.

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

There is general consensus that pedestrians' sense of safety and comfort within a roadway corridor is based on a complex assortment of factors, such as personal safety, architectural interest, pathway or sidewalk shade, pedestrian-scale lighting and amenities, presence of other pedestrians, conditions at intersections, etc.

All these factors that physically affect pedestrians throughout the built environment still need more studies on the statistically reliable impact on pedestrians' feelings and perception.

3 OBJECTIVES

Improving the quality of life in our built environment is the focal point of every planner, developer, politician, and citizen. This research focuses on making use of emerging technologies within the field of urban planning to efficiently collect and visualize qualitative data rather than only quantitative ones.

The presented study aims to test the usefulness of "SMART-Bands" to sense and chart pedestrians' perception within urban spaces. In spite of the non-representative size of the test sample, this study highlights potentials and limitations of such a tool and technique for aiding urban decision makers. If proven useful, more elaborate studies with bigger sample sizes can be planned and implemented.

This paper presents a sub-study of a wider research that aims at answering the following questions: how do people perceive their environment? How is it possible to collect all of the citizens' impressions in a centralized way and how could these qualitative impressions be visualized?

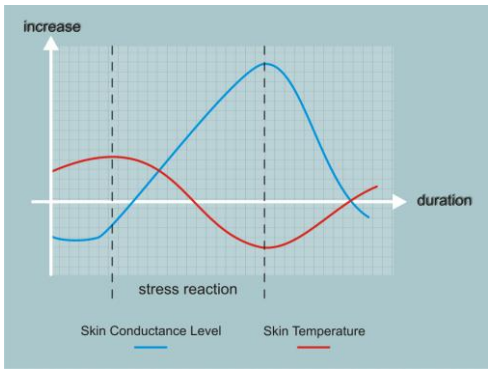
4 METHODOLOGY

The carried out test tracks the stress responses of two participants while walking on both sides of El-Geish Promenade of the Eastern Harbor in Alexandria. While both sides present different urban settings, the study investigates how this influences pedestrians' perception.

4.1 Emotion measurement with physiological vital data

This paper aims to make a contribution to a new method of measuring how people feel in their city. Peoples' feelings and affective emotions are tightly connected with the individual perception. In turn, this perception is linked with the actual surroundings, be it the build environment, pedestrians around or other influencing factors, i.e. traffic or noises. This raises the question how these feelings and emotions, influenced by the individual perception, are objectively measured and brought together with the environment. First, a better understanding of emotions is needed.

Based on previous research in the new field of Affective Sciences (NFS Affective Sciences, 2011) and classical emotion research, emotional reactions are reflected in changes in the activity of the autonomic nervous system. As a result of this activity, specific physiological parameters (e.g. skin conductance and skin temperature) show different values depending on the actual emotion (Kreibig, 2010). These parameters are classified as vital data of the individual. In this context, the so-called method of the psychophysiological monitoring implies the recording of objective vital data in real-time and for every instant. With the help of this data, unswayed affective emotions are derived. In the research at hand, especially mental load (stress) in context with the actual surroundings is observed. Stress can be understood as a product of anger and fear, both considered as highly negative emotions (Bergner et al. 2011).



Figures 1 and 2: The Physiological Stress Reaction (Bergner et al. 2011) and the SMART-Band (own source)

Figure 3: The Study Area with Street Sections along the Path

A negative emotion is given, when the skin conductivity increases and shortly afterwards, the skin temperature drops (Bergner et al. 2011). The following graphical curves illustrate this process (Figure 1). The slope values of the curves can be used for statistical analysis. The mathematical function of these parameters and their curves is simplified with the first derivation. The method of using scoring points (increase in skin conductivity = Scoring +1; decrease in skin temperature = -1) was previously used in several studies (Bergner et al. 2011). In the research at hand a new technical device, the sensor wrist-band

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

called SMART-Band (Figure 2), is used to measure the changing body physiology. The SMART-Band (SMART-BAND by www.bodymonitor.de) was developed by GESIS, the Leibnitz-Institute for Social Science in Mannheim/Germany (Papastefanou 2009).

During the research study, the physiological data is recorded for every second. That is the premise to couple and synchronize the physiological data with GPS- and video camera data. The combination of the different data streams offers new opportunities to understand the complex coherence between the individuals' feelings, emotions, perception and the environments.

This approach was already pursued in several project studies. First test series were done in the emomap-project (Zeile, 2010). Furthermore, the so-called EmBaGIS (Emotional Barrier-GIS)-studies were conducted in the context of urban spatial barriers for handicapped (Bergner et al., 2011). Only recently studies concerning the correlation of stress and noise load and also emotional sensing of urban green areas were carried out (Bergner et al., 2012), as well as another study documenting the perceptional experience of pedestrians participating in one of the demonstrations in Alexandria (Taha, Raslan, and Bergner, 2012).

4.2 Factors affecting pedestrians' perception

To reach an optimum public space usability, a solid guidance is needed that displays the best conditions and designs of the sidewalks, how far sidewalks should be placed from moving traffic, when and what type of buffering or protective barriers are needed and how wide the sidewalk should be. That leads to the need of establishing some measuring factors to assess and plan urban spaces. These factors can be classified into tangible and non-tangible factors.

According to Landis, et al (2001), intangible factors are sidewalk capacity, quality of the walking environment and pedestrian's perception of safety and comfort with respect to motor vehicle traffic. However, the perceived safety or comfort has been a challenging factor to be quantified as a stand-alone performance measure. Contrarily, tangible factors are thought to significantly affect pedestrians' sense of safety or comfort. They include the presence of sidewalks, lateral separation from motor vehicle traffic, barriers and buffers between pedestrians and motor vehicle traffic, motor vehicle volume and composition, vehicle traffic speed, driveway frequency and access volume, among other factors.

Figure 4: Daytime and Nighttime Activities along the Path

4.3 The selected path

El-Geish Promenade, or as Alexandrians call it "El Cornice", is the most famous walked path is Alexandria, either for utilitarian or for recreational purposes. It represents an average of a 4.0 km stretch along the Eastern Harbor (3.87 km on the sea side and 4.30 km on the inner side), from the Citadel on its west end to the Bibliotheca Alexandrina on the east (figure 3).

This path is used by locals to reach the Courthouse-Complex, to access El Mansheya Square and the French Gardens, or to get to the famous Abu-El-Abbas Mosque within the Mosques-Square. Furthermore, this

promenade is used by both locals and foreigners as a major strolling, jogging, recreational and entertainment strip, since it harbors many restaurants, hotels, traditional coffee-houses, shops, as well as public gardens. For the small-budget pedestrians, just sitting by the water-front, watching fishermen in the morning or sipping a cup of tea, eating a corncob or a piece of hot sweet potato at night, it provides the needed get-away after work or in the weekend (Figure 4).

While the inner side of the path is almost completely planted with palms or trees, palms can be found on the outer (water-front) side from the beginning of the path as far as section 9, and again towards the end of the path, across the Bibliotheca Alexandrina.

4.4 The event description

The experiment took place on Thursday, November 3rd 2011 at 8:30 am. It started at the west side of the Eastern Harbor (green node) and ended almost 45 minutes later at Bibliotheca Alexandrina at the east side of the Harbor (blue node). The weather was very pleasant that day, with a clear sky and moderate temperature. Two female participants joined the experiment. Each was equipped with one video camera, one GPS tracker, as well as one SMART-Band. Participant A took the outer side of the path (the one closer to the waterfront), while participant B took the inner path (the one adjacent to the buildings).

5 FINDINGS AND ANALYSIS

Participant A showed more stress responses (112 readings) through the 3.87 km stretch along the waterfront (Figure 5) than participant B, who showed only 46 stress points along the 4.3 km walk at the inner side of the path (Figure 7).

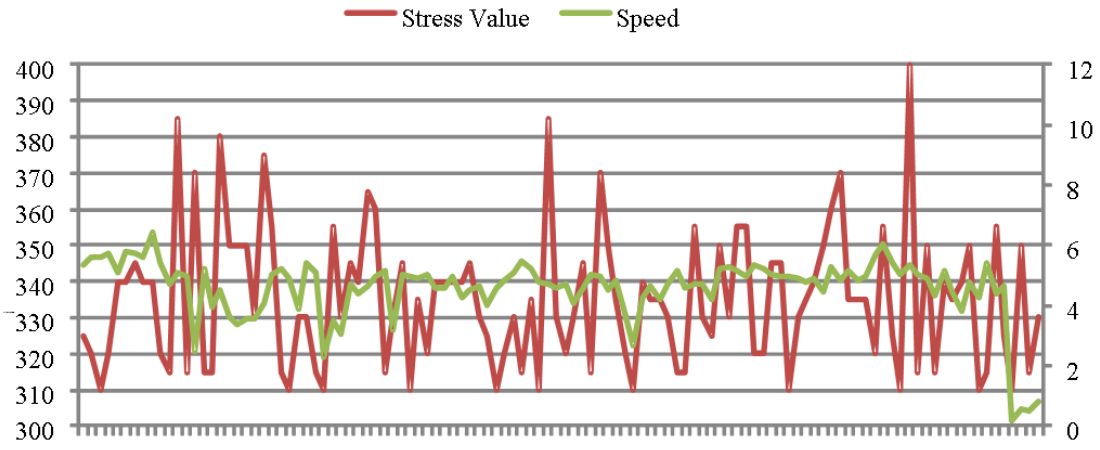


Figure 5: Participant A's Speed and Stress Response by Location

The average pedestrian's speed reaches 4.5 km/hr (Knoblauch, Pietrucha, Nitzburg, 2007). When dismissing extreme values, the speed of participant A varied along the complete path from 7.5 km/hr to 0.04 km/hr (slow speeds were present at the very beginning and at the end of the path), with an average speed of 4.68 km/hr. The average speed recorded at the locations of stress responses is not far from that value. It reached an average of 4.58 km/hr. Extremely slow speed tended to happen at the end of the path, when participant A was first looking for her colleague and then was talking on the phone, stating that she finally reached her target (Figure 6).

Stress responses were spotted when participant A faced pedestrians coming in her opposite direction of travel, when she had to step down or step back on the sidewalk, or when cars or pedestrians blocked her path. Participant's speed did not relate to the altitude of the sensed stress responses at those incidents. Both below-average and above-average speed was spotted at recorded stress points (Figure 5).

The stress points charted by participant B were significantly less in number than those spotted by participant A. However, the same causes triggered the recorded stress responses for both participants. Existing causes were: (1) blocked paths, by cars or by opposite coming pedestrians, (2) stepping down and back on relatively high sidewalks, (3) crossing intersections, especially when they are relatively wide, lack traffic signal lights or have cars coming from more than one direction.

Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

Same as in the case of participant A, Participant B's speed did not relate to the altitude of stress responses. Both below-average and above-average speeds are spotted at recorded stress points (figure 7).

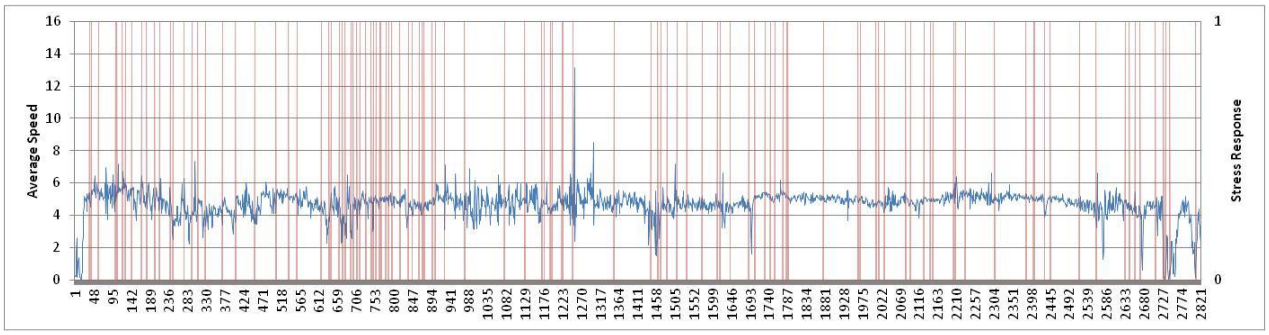

Figure 6: Participant A's Speed and Stress Response along the Path by Time

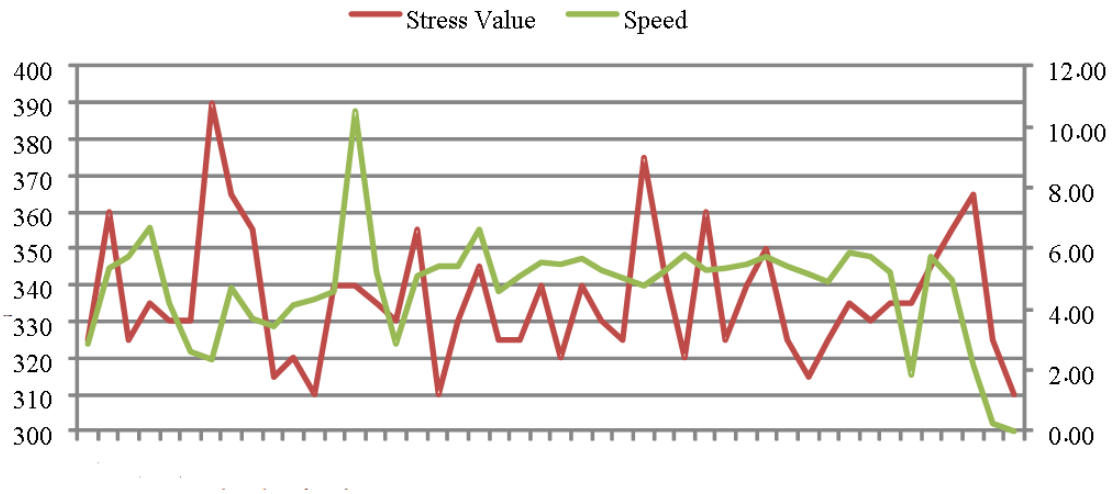

Figure 7: Participant B's Speed and Stress Response by Location

Participant B showed perplexing speed values along the path (Figure 8). Speed ranged from 0.01 km/h to 15.24 km/hr, with an average of 4.68 km/hr. The exaggerated maximum speed values can be caused by inaccuracies in the GPS tracker. When it loses satellite's signal, the following GPS data-pair is farther away than the preceding data. However, the average speed along the complete path (4.68 km/hr) is close to the value of the average speed recorded at the locations of stress response points (4.73 km/hr), which in turn is not far from the average pedestrian speed (4.5 km/hr). As participant B was taking the inner side of the path, which had about 40 intersections, speed variations occurred at those intersections. While in some cases participant B had to slow down or even come to complete stop to wait for a traffic signal or crossing cars, in other cases, she had to speed up to cross the intersection. That was because of the lack of traffic signals or speed tables that slow down vehicular movement that crosses pedestrians' movement.

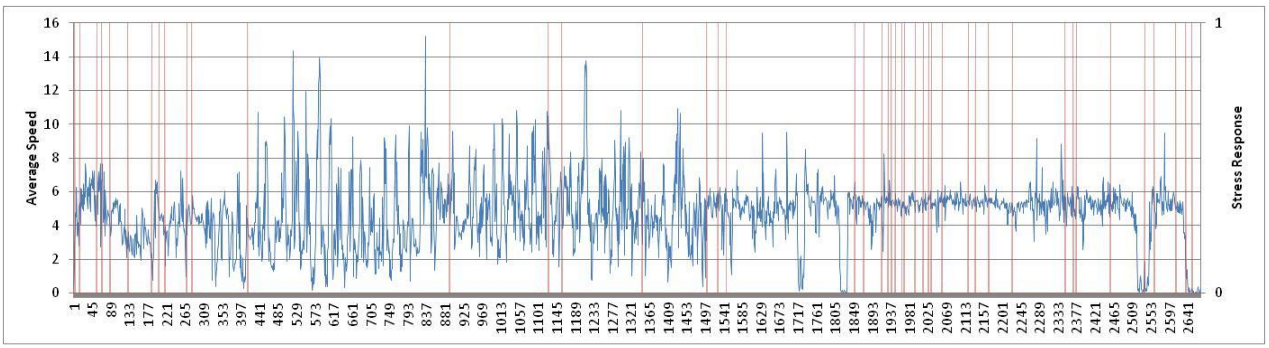

Figure 8: Participant B's Speed and Stress Response along the Path by Time

Participants A and B showed different intensities of stress responses in different zones of the path. When comparing Figures 6 and 8, representing the location of charted stress responses along the path, it is recognized that both participants showed moderate stress intensity at the start of the path. However, while

proceeding with the walk, participant A showed very high intensity of stress responses between sections 3 and 6 and again between sections 9 and 12. On the other hand, participant B had very few stress responses during that whole phase. Instead she had a relatively dense response rate from sections 12 to 15. Approaching the end of the path, both participants reflected more or less medium density stress response rates, although a higher density was on participant A's side.

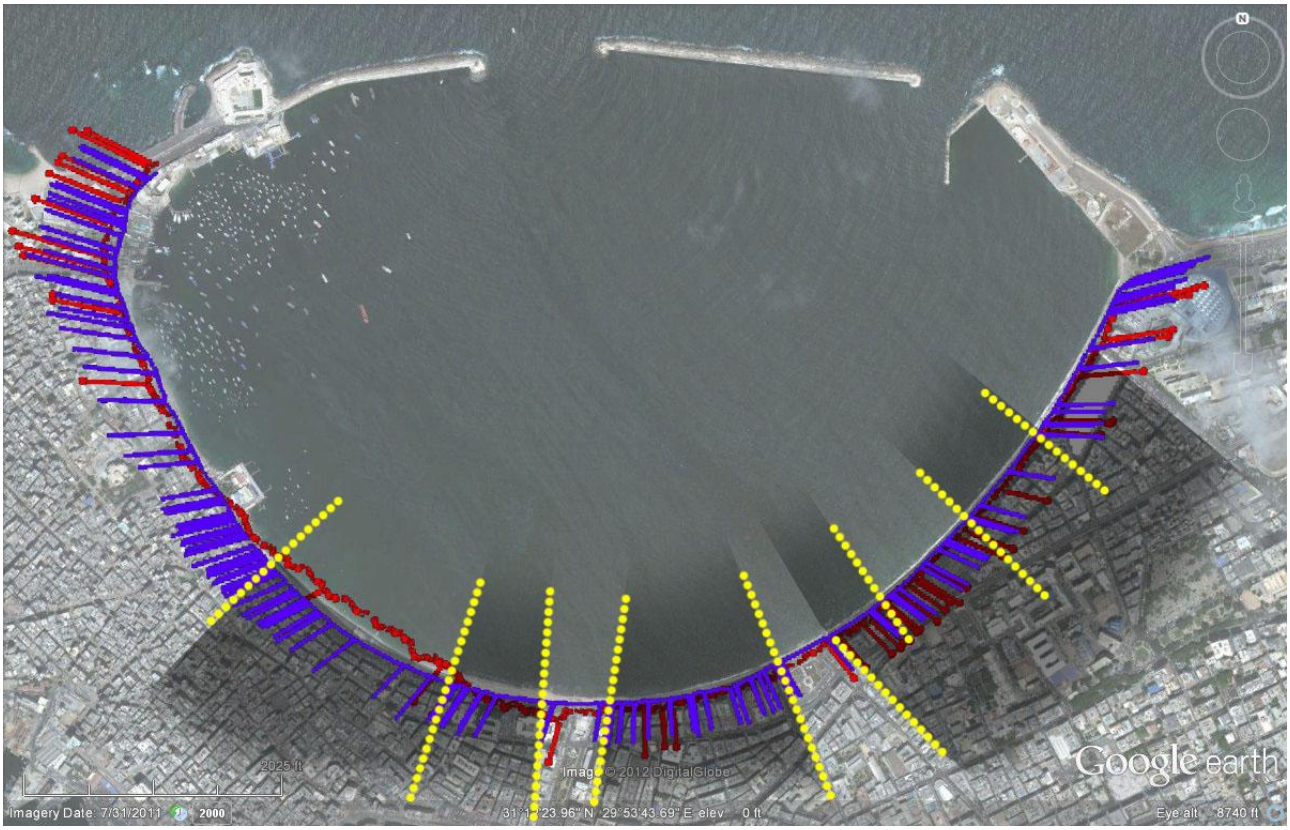

Figure 9: Shaded Zones along the Study Path and Stress Responses from Participant A (blue) and Participant B (red)

Walking in shaded areas or sunny ones did not have any effect on both participants. Figure 9 demonstrates which areas were shaded or sunny on both sides of the path along with stress responses from both participants. During hot summer days, it would have been expected to find dense stress responses in non-shaded areas. However, since the test was taken on a cool November day (where average temperatures range between 19 °C and 22 °C), zones on the path across open spaces, where shade was completely missing, caused no stress at all. At the beginning of the path (for both participants) and towards the end of it (for participant A) shade was missing. However, stress responses were spotted almost with the same density as in shaded areas along the path.

6 DISCUSSION AND RECOMMENDATIONS

Many situations were expected to be stressful out of the comprehension of everyday life, i.e. passing cars. The measurement of physiological indicators shows that in these situations no response was sensed with the SMART-Band.

The intersections at the Unknown-Soldier Monument represent two of the major streets with a high traffic density, where the traffic situation gets often quite chaotic. The first intersection (to the West) is a hub for all sorts of public transportation: taxis, mini-busses and larger busses. While crossing the first intersection, participant A had to take care of mini-busses parked at the intersection, loading and unloading passengers, as well as other vehicles coming from the main street, taking a right-turn (coming from the blind spot of the participant) into the side-street. On the second intersection, participant B had to speed up and dodge vehicles, since there were no means to slow them down by traffic signals or speed tables. However, when participant B was crossing those intersections, no response was sensed (Figure 10).

Figure 10: No Stress Responses were Perceived While Crossing Two Major, High Density Streets

This might be due to several factors. The subject might have been accustomed to those situations, but a foreigner might show some stress if put in the same position. Nevertheless, in the case study some indications which allow raising some hypotheses were observed. There were more stress responses on the sidewalk near the waterfront, than on the sidewalk with buildings on one side and the street on the other. It is assumed that the wider perception of the waterfront participant involves more spatial impressions, which can elicit stress. So the hypothesis is raised that a channeled perception has a more channeled impact on stress reactions in context with the near surroundings. In the study, more influencing factors on the individual perception were observed. Stressful situations were recorded when the participant encounters and perceives other pedestrians or groups. Also the car density and hence the load of noise during the study was higher on the waterfront as on the building side. The many billboards arising attention on both sides of the path were one further influencing factor on perception.

Participant A reflected more stress responses as participant B (112, 46 respectively). This is not only due to the wider perception chances on the waterfront side of the street, but it should also be mentioned that in yet another study, participant A also reflected more responses than participant B while taking the same path. However, while in the previous study stress responses for participant B reached 77% of those of participant A (260, 338 stress responses), in this study they only reached 41%.

These indications show the high complexity of urban open space and its design. In the past it was not possible to objectively measure this complexity in context of human perception. The measurement of unswayed physiological data and thus the individual feelings and emotions in combination with GPS-data offer urban planners new perspectives to understand urban open spaces from the view of its users. Hence, the employment of new technologies to sense space, like the SMART-Band, shows its high potential. But further research with more participants has to be done to get more robust data in case of decision making relying on this data.

7 ACKNOWLEDGEMENT

The authors are grateful to the support of the University of Kaiserslautern for financing the “Laboratory for Monitoring and Spatial Sensing”, including the sensor equipment for this international research project. Also, the authors would like to express their gratitude to the German Research Foundation (DFG – Deutsche Forschungsgemeinschaft) for supporting the project “Development of methods for spatial planning with GeoWeb and Mobile Computing (Städtebauliche Methodenentwicklung mit GeoWeb und Mobile Computing)”.

1 ABSTRACT

Globalization was marked by mobility – mobility of people, goods, capital, ideas and knowledge. As a result, development strategies in many cities have concentrated on the attraction of new investments, multinational headquarters, international events, tourists and high-skilled workforce, on the attraction of part of the global capital. The question is have these strategies been truly successful in the previous decades, can the attraction of foreign capital still be adequate in the challenging times and economical crises.

This paper will explore another possible approach to strategies for improvement of city competitiveness, ones that are more based on inner city strengths and possibilities, which might be more suitable for contemporary times. Some of most recent research shows that global capital and workforce are not as mobile as it was considered, that are rooted in the economical path, social and cultural network of the city. The inner values of the city such as – inner social and business networks, identity and living conditions have strong impact on city competitiveness in global market. Local inner strength of city and its citizens can be the source of city's wealth and resilience in the era of globalization.

This paper will try to give a new way of looking on city development strategies for the improvement of its competitiveness on regional and global scale. It will elaborate the possibilities to reuse existing inner strengths of local production, creativity and innovations in the city, to remix existing and new values and qualities, with the aim of creation of city's growth in the present global conditions.

2 INTRODUCTION

The beginning of contemporary globalization is connected to the technological advances that made transfer of information and people easier and quicker, decreasing the importance of space distance. It is primarily perceived as the process marked by high and quick mobility. Globalization is connected with the transfer of capital across national borders, in order to reduce costs and expand markets (IMF, 2002). On the other hand, it is characterized by high mobility of people, as individual high-skilled professionals and massive low skilled immigrants.

Development strategies of many cities tried to respond adequately to globalization and its processes, looking for the best way to position themselves on the global market of cities. In a struggle for competitiveness cities, relying on the perception of globalization as mobility of capital, concentrated on attraction of global investment, multinational companies, international events and high-skilled workforce. The sustainable positive effects of these strategies on city wealth are questionable, especially in the challenging times of economical crises.

Another perception of globalization sees it as less mobile and more rooted in local environment and relations. Some new research shows that globalization is closer to inter-national mode of economy than borderless global one (Hirst and Thompson, 1996). High mobility of companies and people in globalization is connected to the small elite groups (Birkinshaw, 2006, UNDESA, 2005). Others are embedded in the economical and cultural path of the city, connected to the local social and business networks.

New approach to globalization opens a new understanding of city competitiveness. Inner values of the city, such as inner social and business networks, living conditions and innovation, became the main motors of competitiveness rise for many. The way how cities improved their competitiveness, based on the inner strength, differ from the support to local business and their expansions, increasing its number and their market; creation of conditions for higher cooperation between local companies and knowledge transfer, to making of needed high-skilled and creative workforce.

This paper will explore possible strategies for improvement of city competitiveness based on inner strengths. It will elaborate the possibilities to reuse existing inner strengths of local production, creativity and innovations in the city, to remix existing and new values and qualities with the aim of creation of city's growth in the present global conditions. The aim of this paper is to give new way of looking on city development which might be more suitable for contemporary challenging times.

3 IMPROVEMENT OF CITY COMPETITIVENESS IN GLOBALIZATION MARKED BY MOBILITY

3.1 Perception of globalization as higly mobile

Globalization is not presenting completely new phenomenon. Capital accumulation and its spread over the world existed in the sixteenth century. What is new is the speed of change and transfer. The beginning of contemporary globalization is connected with the 80's of the 20th century, when this term came into use. The term came into use to reflect technological advances that made it easier and quicker to do international transactions and financial flows, movement of people (labor) and knowledge (technology) across international borders (IMF, 2008). Remarkable development in computing power and communications capacity transformed and globalised financial system and production networks (Friedman, 1999).

The contemporary globalization is defined as increasing integration of economies around the world, particularly through the movement of goods, services and capital across borders (IMF, 2002). It is acknowledged that globalization induced high mobility of capital across national borders, in order to reduce costs, improve market access and enhance competitive advantage. Companies internationalized their production process, diffused it to the foreign countries with potentials for more efficient production, while at the same time concentrating headquarters in the globalization centers of world cities (World Bank, 1999).

Beside the high movement of capital, globalization is seen as characterized by high mobility of people, tourists and workforce (Appadurai, 1996, Urry 2000). Deregulation of labour market in globalization induces migration of high-skilled workforce and immigrants. Global elite (Castells, 2000) of managers, creative and high-skill workforce, is seen as individuals that move around freely building portfolio careers rather than looking for steady jobs (Williams, 2009). On the other hand, globalization is manifested through international migration, especially transnational migration (Vertovec, 2004) faster and unpredictably shaped, with no clear point of arrival or departure (Urry, 2000).

"Hyper globalization" theses predicts a "borderless world" of global homogeneity, world of non embedded production and consumption chains, placeless capital, homeless subjects, world where all socialites are formed within context of global flows (Robertson, 1992).

3.2 Strategies for city competitiveness based on attraction of global capital

Globalization has intensively affected cities, provoking rapid and dramatic changes to the cities in the past 30 years. Competitiveness between cities has intensified. Although the competitiveness is not a new phenomenon, what is different in contemporary globalization is complexity and global wideness (Sassen, 2002, p.25). Competition, which was previously primarily between cities of the same nation or same region has expanded to the global level.

Perception of globalization as process of high mobility of capital and people have stressed the position of cities as replaceable entities (Lever and Turok 1999), which can be easily changed, capital or production process can relocate to some other place, people can move to other city. This new position of cities in the constant struggle for better global position has induced the need for new strategies of cities' development. The perception of globalization as mobile has influenced these strategies, putting the emphases on attraction of global capital (investment and workforce) as most important elements for cities' growth and wealth. These strategies, according to the basic element of global capital which wanted to attract, can be divided in the following groups: 1) strategies for attraction of global companies and investment, 2) strategies for attraction of global events 3) strategies for attraction of workforce and 4) strategies for attraction of creativity.

Strategies for attraction of global companies and investment

Modern communication has made it far easier to manage dispersed business operations from centrally located headquarters. Most large corporations found advantageous to locate in the main urban centres in order to have full access to the desired mix of services and other companies (Yusuf and Wu, 2002, p. 1215). In the theory the importance of the cities in the global urban hierarchy has been measured by the concentration of headquarters of important international corporations (Sassen, 2001, Hall, 1966, Borja and Castells, 1997). The higher the concentration of main headquarters the higher is the importance of the city in the global networks and flows.

This theoretical approach had its implications in the development strategies of the cities. Many cities around the world tried to improve their global competitiveness and importance by creating attractive ambience for international companies. By developing attractive international business centres in their cities, enhancing business capabilities and services, creating open market and labour conditions they tried to attract global transnational corporations to the city (Yusuf and Wu, 2002, p. 1215). Reason for this informal competition for global companies is that the existence of high ranking companies reflects economic prestige and instils confidence in future investors (Benton-Short, Price and Friedman, 2005, p. 946). The results varied, from success stories to failures, which invested huge amount of financial and human resources in creating alluring conditions without results. It is questionable whether the attraction of international headquarters improves the city competitiveness or the arrival of international companies is the consequence of cities‘ global position improvement.

Strategies for attraction of global evants

The mobility of people, in the first place the mobility of tourist and travelers, has influenced another strategy for city development – the attraction of global events in the city. Important element of the competition between cities is big global events and festivals, with the aim of attracting attention to city and creating a good image (Stahre, 2004, p.73). The promise of world wide exposure and economic gain has made hosting these major and regularly scheduled cultural and sporting events a lucrative goal for aspiring cities around the world (Short and others, 2000). Gaining some global cultural or sport event presented an opportunity for the city to build new image through big architecture and change in urban development. Significant improvement of city competitiveness through use of global events is questionable in the long run. Next event in the next city averts attention to another city.

Strategies for attraction of workforce

As an equally mobile and important component of globalization is seen migration of people (Sassen, 1999). Castells and Miller say that “while movement of people across borders have shaped states and societies since time immemorial, what is distinctive in recent years is their global scope” (2003, p.1). Globalization, mobility of people and the increasing economic integration of states is accepted that creates a global labour market. In that global market top cities are magnets for the skilled workforce, on a permanent or transient basis (Perrons, 2009). Consequently, migration is a significant component of interregional economic relationships.

The perception of high workforce mobility in global network; the possibility of cities to attract new skilled workforce or lose existing one; have influenced intensely city development strategies. Taking into consideration that human resources play the most important element of city development and wealth, especially high-skilled as they are the base of creation and innovation and at the same time of consumption, and that for demographic, economic and social reasons, all highly-developed economies are relying on immigrant labour at all skill levels (Castles, 2006) it is not strange that strategies for attraction of high-skilled personnel are part of city development. Strategies for attraction of workforce and keeping of the existing differ between cities. They range from creating lucrative tax environment, work environment and network to creation of attractive high qualities of life. That skilled people influence cities‘ competitiveness is easy to prove, but is the city competitiveness enough to attract needed labour is questionable.

Strategies for attraction of creativity

Successful city development in contemporary globalization and post-industrial society is, by some authors, seen as based on creativity. Richard Florida (2002) argues that the leading element of contemporary city

competitiveness is the creative industry; such as IT, design and art, on which cities should concentrate. He argues that capitalism is moving from a system defined by large companies to a more people-driven one and gives the assumption that all cities should compete for creative people, 'the creative class'. To be able to attract dynamic and mobile individuals of 'the creative class' cities need to offer attractive living conditions, e.g. urban buzz, varied cultural life, diversity and tolerance. The concentration of creative people will attract companies. The theoretical work of Florida had strong influence on strategies of large number of cities, large global centres as well as small peripheral ones. They tried to develop environment for 'creative class' and through that improve its competitiveness. But the magnetism of large global cities for creative workforce cannot be created in small cities, or in all big cities.

4 COMPETITIVENESS OF CITIES BASED ON THE INNER CITY STRENGTHS

All the strategies for city development presented above have been based on the attraction of global capital in its different forms with the assumption that global capital in contemporary globalization is highly mobile. These strategies have not been proven to be efficient in practice and lead to sustainable city development. What if the basic assumption is not right, if the global capital is more rooted than presented through these theories?

Most recent research shows that globalization is not characterized by high mobility and that global capital is more connected to local social networks and resources than to global flows, that city competitiveness in globalization, even for the high ranked cities in global urban hierarchy, is more result of the long determined development path based on existing inner city competitive elements and resources than on the short term attraction of global capital.

4.1 Perception of globalization as more rooted

Although the mobile elements of globalization, moving of companies, capital and people, are evident and easy to perceive they are not the only elements of contemporary globalization. Easy transfer of information, images, capital and people emphases this part of global process, hiding other important elements. Some critics of globalization argue that such process is occurring (Petras and Veltmeyer, 2001). For example Hirst and Thompson (1996) see it as inter-national mode of economy, seen as well at the end of 19th century, which is not drastically new.

More recent research shows that globalization is closer to inter-national mode of economy rooted in the local societies and networks. Globalization of companies, and creation of big international headquarters is present, but they are not too mobile. Headquarters relocation to new cities, and even more to new countries, is still relatively rare decision. Relocation projects reflect company's long-term identity as well as short-term continuity (Sweeney, 2003). Opening of new regional branches is usual choice of companies with the aim of exploitation of new markets and network benefits. Data support this thesis. Relocation to new countries is present in only 20% of multinational companies. The percentage is higher within large companies and it decreases in medium and especially small companies (Birkinshaw, 2006). For the medium and small companies local social and business ties and networks are more important for development than positioning in major competitive cities. In the decision for the location of companies existing personal links of managers and owners is the most important factor. This as well influences large companies (Musterd and Murie, 2010).

Although there have been growing levels of human mobility and higher levels of circulation in recent decades as opposed to long-term migration and settlement, this is not exceptional (King, 1998). What is deferent in contemporary globalization is individualization of migration process (Beck and Besk-Gemsheim, 2002), with migration becoming an instrument for personal employment responsibility. But mobility is privilege of small group of people. Only 3% of the world's population are international migrants (UNDESA, 2005). In addition far more people move within their own countries than internationally (Skeldon, 2006). Individual migration decisions are understood as investment decisions based on lifetime economic returns and balanced against the known and unknown costs and risks associated with migration (Stark, 1991). The decision for movement is not light decision, especially when the family is involved, and people are more rooted then placeless. For skilled migrants it is even more difficult, no matter that they are targets of many development strategies, since they face additional employment barriers in the professional regulations of some occupations (Williams, 2009). The temporary skilled professional migration, for a period of several weeks, is more present and used by multinational companies (Millar and Salt, 2008). Even here, rootless

professionals are mostly young and male, while others prefer steady connection with family. The most recent research of Musterd and Murie (2010) shows that people choose places to live, beside the job opportunities, according to the personal links they have in those places.

4.2 Improvement of city competitiveness as a result of growth of its inner strengths

When the globalization is seen from another perspective a new perception of city competitiveness in contemporary globalization opens. Even when the globalization is perceived as less mobile and more rooted the global competition between the cities for the development and part of the global market cannot be excluded. Today it is difficult to find isolated national markets. World Bank indicated significance of competition, saying that cities which manage to use their comparative advantages in global markets will prosper and those who stay isolated will fight for survival. Competition between cities does not just take place on global but also on a regional scale (Brenner, 1999), and it is not only important for big but as well for small and medium cities. What changes with the new perception of globalization is the understanding of how cities can be competitive on global markets. Instead of competing for the part of the global capital city compete for the development ratio and its wealth. This corresponds to the standard competition between cities with the difference in market size.

Development of cities and the rise of their wealth as a result of attraction of global capital have not been proven completely successful. Even the new top global cities tend to be the old global cities reinvented – New York, Los Angeles, London, Paris, Tokyo, Hong Kong… (O`Connor, 2006). The emergence of new top level global cities such as Singapore, Beijing, Sao Paulo, Tay Pay, Mexico City…., are result of the expansion of global market and inclusion of new countries in the global networks. When the cities which managed to improve their competitiveness on global level and their position in urban global hierarchy are examined the results indicate that their advancement was not result of arrival of new companies, investments or skilled labour. The main motor of their rise in competitiveness were inner strengths. The successful cities relied on their development paths and reinvented and re-mixed their potentials to the contemporary globalized market and society (Musterd and Murie, 2010). This supports the Jan Jacobs (1984) theory that cities in order to have successful economy must be innovative. Prosperity or stagnation of cities is based on their ability to continue import/export cycle, on their resources and capacity to come up with innovative response. This is applicable on the import/export cycle of global capital, knowledge, innovation, companies and workforce in the contemporary knowledge global society.

The way how cities improve their competitiveness, based on the inner strength, differ from the support to local business and their expansions, increasing its number and their market; creation of conditions for higher cooperation between local companies and knowledge transfer, to creation of needed high-skilled and creative workforce. For example, Amsterdam had stable trajectory of development towards creative knowledge city, long-term strategies and urban development (Streit, Bontje and dell`Agness, 2010). On the other hand, Munich kept developing its existing competitive industry and complementing it with R&D, which is in connection to their recognizable sectors (Goebel and Thierstein, 2006). Helsinki and Stockholm improved their competitiveness by creation of innovation and IT industry. Helsinki invested in formation of new skilled workforce as generators of development and in the period of 30 years rose a level of high educated people from 6% to 30% (Martin-Brelot and Kepsu, 2010).

The possibilities to improve cities' competitiveness by re-mixing and advancing inner strength do not mean that the success is not possible with strategies based on attraction of global capital. The aim is more to show the other possible way and the side of globalization, less used and marketed.

4.3 Strategies for improvement of city competitiveness based on re-mix of inner strengths

Improvement of cities` competitiveness and their position in the global networks can be achieved by different strategies of enhancement of inner strengths. According to the elements on which emphasis is putted strategies can be divided in the five groups: 1) strategies that enhance cities companies, 2) strategies that enhance cities productivity, 3) strategies that improve workforce, 4) strategies that enhance creativity and innovation and 5) strategies that improve tourism.

Strategies for improvement of cities production

Jan Jacobs (1984) said in her import-replacement theory that successful economy of cities is based on replacement of imports with the local production. In order to be competitive and ensure wealth cities should enhance their productivity, lower import and become exporters of goods. Translated to the strategies for development, this would mean that cities should invest in improvement and development of their own production of goods, based on the existing production trajectories and specific possibilities.

Improvement of cities' production and its regional and global competitiveness can be achieved in different ways, depending on specific conditions. One approach is through government and tax support to preferred production, which has already marked city economy and made it regionally and globally recognisable and competitive. In most cases following the existing production path and further development of its strengths showed to be successful. This approach advantage is in low investment, because of the continuity and already existing elements of preferred production. On the other hand, it is applicable, only if the production has shown to be prosperous. Other approach can be in creation of competitive innovative production from the scratch, changing production specialisation. This asks for higher investment and deeper change of city's functioning. For the cities that have no successful production this might be the only choice.

If the production is not innovative other cities will develop same production of goods and export will decrease, or they would create more efficient ways for the production of same goods and take their position in global market. Relationships between dynamic firms stimulate the circulation of knowledge and improvement of innovation. To achieve this improvement a possible strategy is to create development-production clusters. As Alan Scott (2006) says transfer of ideas in production happens when there is spatial proximity and specialization. Companies profit from each other by exchanging information and knowledge about certain products. Clusters are geographically proximate group of interconnected companies and associated institutions in a particular field, linked by commonalities and complementarities. The prerequisites for the emergence of clusters are qualified labour and strong networks between actors, the existence of universities and research centres (Porter, 1998). To ensure the production innovation a strong cooperation between R&D and production is preferable. This is accelerated by the spatial proximity of institutions and companies, adequate framework for knowledge exchange and the importance of social capital. "It is assumed that innovation generation proceeds most efficiently either in specialized clusters, where inter-firm links play a part, or in areas where industry, academia and other regional actors collaborate with each other" (Zientara, 2008, p.62).

Strategies for improvement of cities companies

In the present economic conditions marked by the global economic crisis, relying on foreign investment is not productive. Instead, cities should concentrate on intensification of relationships among the existing firms and seeking the establishment of new firms. Translated to the strategies for development it would mean that cities` government should support local companies by creating favourable tax, service and business conditions. Existence of adequate and competitive services and infrastructure in city helps companies to develop and enhance their business.

Beside business environment, similarly as with the improvement of city production, governments should encourage cooperation of local companies, the exchange of ideas and knowledge, and collective global presentation. Governments cannot force firms and other participants to cooperate, but they can provide them with favourable conditions. This would mean creation of spatial agglomerations of companies with similar speciality. Firms with similar or closely complementary capabilities should be concentrated. In order to survive on world markets, it is imperative for small and medium companies, which are the carriers of contemporary globalization, to cooperate with each other (Pratt, 2004). For example, Gibney et al. (2009) have argued that in the knowledge-based economy, leadership of place involves leading and holding together a consortium of potentially separate interests that shape place. Supporting cooperation between business and creation of local special business networks is one way to improve local strength and global competitiveness.

The other imperative of cities` government for improvement of competitiveness is helping their local companies to expand and invest in markets abroad. Through cooperation and common performance on broader markets this can be achieved. The other precondition is cities belonging to the global urban networks. The opportunity for cities to position themselves in global networks lies in careful developing of the unique character by segmentation and specialization. Cities should direct their policies towards strategic

sector. With the involvement in special urban networks the cities create conditions for their companies to integrate in global flows. The more networks it is involved the conditions for development of more sectors are created.

Strategies for improvement of cities workforce

Richard Florida stresses that "the key factor of global economy is no longer goods, services or flows of capital, but the competition for people" (Florida, 2007. P.16). This assumption is based on the mobility of creative and global elite. But taking into consideration that permanent movement of high-skilled workers is low and is mostly connected to young professionals the strategies of attraction of skilled workforce show their unsustainability. For the cities that do not belong to the top level global cities and creative centres this is even stronger. As a lack of social capital diminishes a region's ability to capture the gains of economic growth (Putnam, 1993) cities must find the ways to provide needed workforce. The sustainable strategies for this should rely on the creation of workforce, primarily high-skilled and creative. Ways to realize this strategy can be education of citizens, keeping the young professionals in the city and creating the connections with emigrated experts. The effects should not be expected to be visible immediately. They require decades.

Education and increase of high educated people is correlated with density of universities. The higher importance and quality of education stronger and more competitive city's human resources are. Glaeser and Saiz (2003) found that more educated cities grow more quickly than comparable cities with less human capital, because they become more economically productive. The city's government should invest and support initiatives for opening of universities. They should create spatial conditions for universities and research centres. What is important is the connection between the universities and labour market demands. The education should support preferred development and specialization of city. Human resources can be fully activated only if a city's economic base permits the generation of quality jobs. "That is why achieving a smooth integration between the supply from the education system and employers' demand becomes an essential objective for every city" (Mendez and Moral, 2010, p.5).

University centres, together with the adequate job opportunities in the city, are one of the most important elements for keeping the demography positive. Universities attract young people which afterwards decide to stay in that city. On the other hand, the availability of qualitative university keeps the present young from moving to other cities and raises high education by increasing the availability of student places and decreasing costs (Frenette, 2007). Most highly skilled workers in cities have had previous links with the city, either through family networks or the networking established during their studies. About 80% of young creative and knowledge workers have been educated within the region and very often the first reason for being there relates to the presence of a good university (Musterd and Murie, 2010). The connection of university with labour market insures that investment in education will be payable.

Evan when the emigration of citizens is present it can be used for the enhancement of cities inner strengths and global competitiveness. With the rooted cosmopolitanism individuals move cognitively and physically outside their spatial origins, but continue to be linked to the place, to the social networks of their origin. Professionals which are part of the complex international society have primary connection with domestic (Tarrow, 2005). Cities need to develop strategies for keeping connections with their emigrants and ways to keep collaborations with them, especially with innovative and creative elite.

Strategies for improvement of cities creativity and knowledge

Reliance on the outside creative class, when taken into consideration that is not as movable as it was assumed, is under the question. Charles Landry (2000) stresses the importance of creativity of city management, its resident businesses and citizens. The city gets its creative potentials from within itself. This brings the strategies for city competitiveness improvement back to the inner creative potentials and ways how to use, stimulate and enhance it.

The approaches for improvement of cities creativity are overlapping with already mentioned strategies for improvement of production innovation and education workforce. What differs is emphasize on creativity stimulation. The mere presence of creative people in the city is not sufficient to sustain the urban creativity over long period of time. Creativity needs to be mobilised and channelled, to emerge in practical forms of learning and innovation (Scott, 2006). Transferred to the strategies of city development it means that cities

need to develop stimulating environment for creativity. This can be achieved through creation of special creative clusters, artistic quarters and vibrant public places and events. Creation of spaces for meeting and interaction of creative people presents a precondition for exchange of ideas and stimulation of innovations. Of course, this is not enough. To sustain creativity cities need to support creative activities and help them organize common presentation on global market. Even more important is mobilisation of creativity for the real purposes in the city.

On the other end is the correlation between creative clusters and citizens. Through interaction in public arena the spill over effect of creativity on citizens can be achieved, at least in the openness to newness. This spill over effect is important for resident businesses as well. The creativity of city management is crucial. It needs to be creative in finding solution for stimulation of city development and competitiveness on regional and global scale; it needs to be flexible and adoptive to new conditions that change quickly in contemporary globalization. This can be achieved through inclusion of creative and talented people in city government or through the strong collaboration with them.

Creative cities cannot be created from scratch (Hall, 2004), they need history development path. Not all cities can become creative in the way Florida suggests, but they need to be creative in a sense of innovation and adaptability to competitive challenges of global city market.

Different strategies for improvement of city competitiveness based on re-mixing and enhancement of inner strengths are mutually interlinked and influence one another. The success in improvement city competitiveness usually is connected with use of several different approaches that re-use inner strengths, where one or two are more dominant and others complement. The presented strategies do not present the only that can be developed from inner strength of the city. They more present a short reminder how city development and competitiveness can be tackled depending on the city itself.

5 CONCLUSION

The aim of this paper was to bring attention to another perception of globalization, and emphasize another approach to strategies for cities development, strategies which will more use inner cities' strengths and potentials, re-mix them to correspond to contemporary needs in globalized world. This approach is not the only possible, but rather one more alternative for cities.

The global economical crises, which has affected almost all countries and cities around the world in the last four years, has putted under the question the contemporary globalization process and its possibility to induce sustainable development and growth. The fall in available free capital has drastically decreased movement of capital, primarily foreign investment, travel and high-skilled people migration. As a result the strategies for improvement of cities competitiveness, and consequently wealth, based on the attraction of the foreign capital and skilled workforce cannot be adequate. Cities in a need to counteract recession and induce development have to turn to themselves, aiming to create more resilient communities and resilient cities. In a time of ever-increasing uncertainty, the quest for new strategies of city development which will stand unpredictable turbulences is more important than ever.

1 ABSTRACT

Natural disasters affect the performance of urban and regional systems in various forms. Problems caused by unpredictability of the environmental changes can cause inefficiency in short and long-term planning strategies. The importance of avoiding this indicates the necessity of applying appropriate approaches to problem solving in metropolitan planning as well as in disaster management. The process of disaster management and planning in metropolitan areas differ from other urban levels. These difference may be due to such reasons as (a) the importance of responding to disasters in all spatial aspects including social, economic, and physical aspects, (b) the need to act promptly by various stakeholders and players involved in disaster situations and (c) unclearness of the problem which both planning and management systems (i.e., metroplolitan planning and disaster management) have to deal with. It is based on these reasons that the establishment of an integrated disaster management and planning system is crucial specifically in metropolitan areas. Such an integrated planning activity comprises both substantive and procedural aspects including integrated metroplolitan planning and disaster management strategies as well as producing an integrated "spatial metropolitan and disaster management plan" plus specifying the role, functioning and responsibilities of the varied actors active in such an environment.

Tehran (the capital of Iran), a metropolis with more than eight million residents within its statutory boundaries and more than 13 million people residing in Tehran province as the urban region of Tehran, is prone to disasters, that the most important of them would be a severe earthquake. While the last devastating earthquake of Tehran occurred in about mid 1880's, according to studies on the return period of earthquakes, it is estimated that an earthquake with the magnitude of 7 to 8 Richter scale would occur sometime in Tehran in an undefined future. In this respect launching an efficient, while an integrated, planning and disaster management system is a major and crucial concern of policy making in Tehran. Accordingly, this paper has adopted a dual aim of (a) analysing the existing situation of Tehran in terms of disaster management as against metropolitan planning including an identification of the strengths and weaknesses of such a situation, and (b) envisaging the ways and means of integrating the two parallel but highly inter-related areas of metropolitan planning and disaster management

2 INTRODUCTION: ISSUE UNDER STUDY, AIME AND PURPOSE

Large cities and metropolitan areas are the place in which people live, perform their activities and is a place where their assets are concentrated. The high-level of aggregation of human activities makes metropolitan areas increasingly vulnerable to all kinds of disasters, man-made and natural. A natural disaster - usually defined as hazard – is the impact of an extreme and rare natural event that usually overcomes the capacity of communities and organisations and threaten the efficiency and effectiveness of urban physical, social, economic, and natural systems and their planning efforts (refer to & Fleischhauer & Wanczura, 2006: 741).

Application of strategic thinking in spatial planning provides it with a contingency nature. Meaning that spatial planning requires a multi-risk approach to consider all relevant disasters which threatens the vulnerability of a certain area. In such an integrated approach disaster management puts forward a task for spatial planning which enables it - from the beginning of a planning process - to anticipate and consider the consequences of disasters as part of the significant factors in achieving planning goals and objectives (refer to EPSON Monitoring Committee, 2006: 6-7, Greiving and Fleischhauer, 2006: 110).

This paper aims to integrate metropolitan planning with disaster management - with special attention to earthquake as a natural disaster - in Tehran, and envisages agenda such as the followings:

- Analysing the existing situation of Tehran in terms of disaster management within its broad framework of metropolitan planning. This analysis includes an identification of the strengths and weaknesses that such a situation presents.
- Envisaging the ways and means of integrating the two parallel but highly inter-related areas of metropolitan planning and disaster management

In order to achieve these aims a method comprising a four staged process has been devised as follows and as is shown in Figure (1):

- First stage involves studying the conceptual framework produced by reviewing and summing-up the findings of the parallel experiences worldwide.
- Second stage involves analysing the current state of both metropolitan planning and disaster management in Tehran in terms of their linkages so as to find the strengths and weaknesses of such systems. This stage would answer the two following questions of:
- How does spatial planning system in Tehran take into account the risks of earthquake as a natural disaster?
- Which role does spatial planning system in Tehran play in practice in the disaster management process?
- Third stage, based on the conceptual framework produced by reviewing and summing-up the findings of the parallel worldwide experiences as well as the analysis done in the second stage, involves proposing a framework for an integrated spatial planning and disaster management system in Tehran.
- Fourth stage involves the application of the proposed framework in the second stage in Tehran.

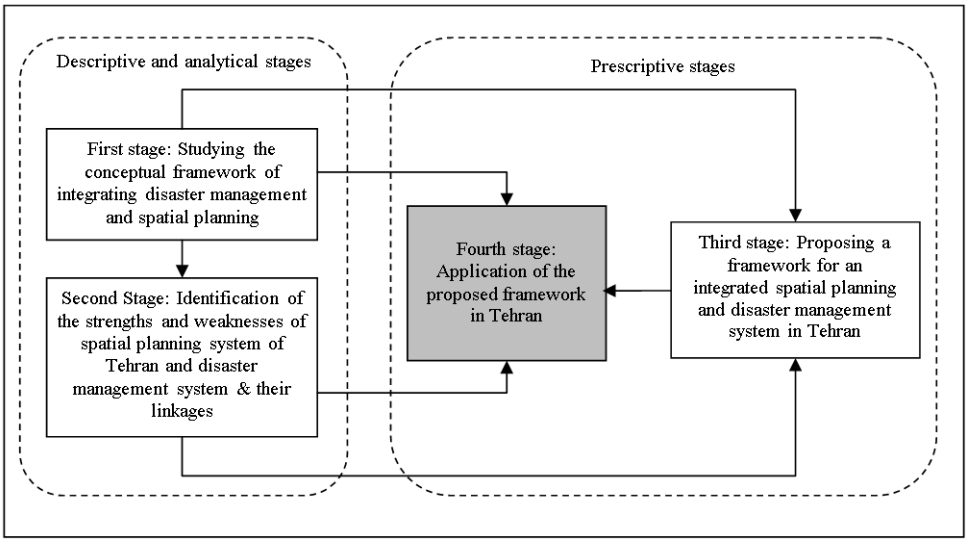

Fig. 1: Flowchart depicting the method adopted in achieving the aims of this paper

3 STUDYING THE CONCEPTUAL FRAMEWORK PRODUCED BY REVIEWING AND SUMMING-UP THE FINDINGS OF THE PARALLEL EXPERIENCES WORLDWIDE

This conceptual framework consists of disaster managment related definitions as well as spatial planning responses to disaster management.

3.1 Disaster

A disaster is the impact of an extreme and rare natural event that usually overcomes the capacity of communities and organisations to cope with which causes severe negative impacts on people, goods, services and/or the environment. A disaster happens when a hazard impacts on the vulnerable population and causes damage, casualties and interruptions. Thus it is a product of the combination of hazard, vulnerability and insufficient capacity or measures to reduce the potential chances of risk (refer to Greiving, Fleischhauer and Wanczura, 2006: 740, Sutanta, et. al., 2009: 342).

3.2 Vulnerability

Vulnerability is the degree of expected damage of natural, socio-economic and physical systems of a community as of the impact and the consequences of natural hazards which is rooted in the interaction between a system and its environment: this is related both to the internal system of a society and the way in which this system interacts with its external environmen (refer to EPSON Monitoring Committee, 2006: 6-7, Chunliang, et. al. 2011: 204). Altogether, two types of vulnerability can be identified: first, the stress-driven vulnerability which refers to the potential of a natural hazard, and second the vulnerability which is related to the potential to react to and/or to endure the hazard. On this basis, reducing vulnerability consists of two main kinds of activities (refer to Chunliang, et. al. 2011: 204).:

- First, removing the causes of the disaster (reducing the hazard),
- Second, removing the effects of the hazard if it occurs.

3.3 Risk

Risk is a combination of the probability (or frequency) of occurrence of a natural hazard and the extent of the consequences of its impacts which is a function of the exposure of assets and the perception of potential impacts as perceived by a community or system (refer to Greiving, Fleischhauer and Wanczura, 2006: 740, Sutanta, e. al., 2009: 342).

3.4 Disaster management

Disaster management can be defined as the organisation and management of resources and responsibilities for dealing with all humanitarian aspects of disasters in terms of activities, programmes and measures which can be commence before, during and after a disaster in order to avoid a disaster, reduce its impact and recover from its losses. Disaster management is a cyclical process which consists of following activities (refer to UNDP, 1994: 13, EPSON Monitoring Committee, 2006: 6-7, Greiving and Fleischhauer, 2006: 114-118):

- Risk assessment: Risk assessment is a combination of these activities (Greiving and Fleischhauer, 2006: 115):
- Risk analysis: The scientific and deterministic task of risk analysis is a mathematical calculation including estimation and description of a hazard – which have been determined based on scientific and technical findings- its frequency of occurrence (hazard component) and magnitude of its consequences (damage potential).
- Risk evaluation: In risk evaluation the outcome of risk analysis and risk perception - which is the overall view of risk as perceived by a person or a group and includes both feeling and judgment – determines the significance of the estimated risks for those affected.
- Mitigation: Mitigation includes a wide range of actions and interventions aiming at long-term goals and objectives that might be designated to reduce the adverse effects of a natural hazards and/or potentially harmful processes before it occurs. Mitigation activities fall broadly into three categories of (a) prevention oriented mitigation, (b) structural mitigation, and (c) non-structural mitigation.
- Preparedness: Preparedness means readiness for short-term activities, such as evacuation and temporary property protection, undertaken as soon as a disaster warning has been received.
- Response: Response indicates short-term initial emergency aid and assistance during or following the disaster as part of the reaction towards it.
- Recovery: Recovery, consist of activities such as the rebuilding of damaged structure, which brings the community back to a normal state

3.5 Spatial planning response to disaster management

Spatial planning response towards earthquake as a natural disaster that contributes to a disaster management system will be discussed in terms of the stages of disaster management process (Table 1).

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

Risk assessment

Sectoral planning is the main existing approach for risk assessment, though the outcome of this task indicates a multiplicity of aspects of a system that might be threatened by disasters. A basic prerequisite for any kind of risk assessment to meet the requirements of spatial planning and be used in spatial planning is the existence of a legally binding basis for risk related information. Meaning that spatial planning needs specific spatially and cartographically presentable information which must fit into the spatial scale to be used on different levels: a basis for decisions about future land-uses/space uses (refer to Fleischhauer, et. al., 2007: 385 and JAICA, 2000: 61).

Disaster management activities	Linkages between spatial planning and disaster management systems	Aims
Risk assessment	• Providing vulnerability-related information for land suitability analysis and future development in spatial planning	• Provide awareness about high-risk, medium risk and low risk areas
Mitigation/ Risk reduction	• Prohibition / restrictions of land-uses and activities based on of identification of risk priority zones	• Reduce building damage and casualties
	• Regulating locations of significant public services of the city	• Reduce vulnerability of public services
	• Decentralisation of elements at risk	• Reduce the risk of failure
	• Decentralisation of population densities	• Reduce casualties
	• Strengthen service networks	• Reduce the risk of failure
	• Application of legislative powers and administrative functions	• Setting up building regulations
Preparedness, response, and recovery	• Distribution of urban facilities and infrastructure necessary to respond to the disaster	• Increase coping capacity
	• Rebuilding planning	

Key:	Main responsibilities of disaster management division toward spatial planning	Main responsibilities of spatial planning toward disaster management division

Table 1: Disaster management activities and linkages of spatial planning and disaster management systems. Source: writers (2012) based on various sources used in this article

Mitigation

For earthquake, preventing the actual geological or meteorological process from occurring is impossible and spatial planning have no potential for reducing earthquakes (refer to UNDP, 1994: 20) so the mitigation strategies fucuse on mesuears to reduce both disaster impacts and damage potential. Spatial planning has the specific responsibility in (a) making decisions on long term utilisation of land and (b) providing community with the adapted spaces to enable it to employ the following mitigation activities (refer to EPSON Monitoring Committee, 2006: 6-7, Greiving, Fleischhauer and Wanczura, 2006: 742, UNDP, 1994, Greiving and Fleischhauer, 2006: 121-122):

- Prohibiting future development in certain areas: Areas identified as high-risk, should be designated as risk priority zones. The effects can be greatly reduced if in highly prone areas development would be prohibited and restricted, especially in terms of public sector facilities which are easier to control than those controlled and decided by the private sector. According to the classification of risk priorities, two types of prohibitation / restriction would be applied:
- Exclusion of all uses, except the priority use. Priority use is the permitted use of land/space due to the possible occurrence of earthquake.
- Exclusion of especially threatened facilities (e.g. schools, hospitals) and hazardous facilities (e.g. chemical plants).
- Regulating land use or zoning instruments: An important measure in reducing the vulnerability of a society is carefully selecting the location of public sector facilities and major infrastructure.

- Decentralisation of elements at risk: Services concentrated are always more at risk than those well distributed all over the city. The same principle applies equally to hospitals.
- Decentralisation of population densities: A denser concentration of people will always be less desirable than a more dispersed pattern. In this context, permitted development densities in urban plans should reveal the spatial distribution of hazard severity. At regional levels, the concentration of population and industry in a city, generally has more disaster potential than extension of development over a broader region.
- Design of service networks to reduce risk of failure: In terms of roads, pipelines, and cables, radial networks are less vulnerable than long lengths of lines in circular systems which are at risk if they are cut at any point.
- Developing safety standards, construction codes and building regulations: Legislative powers and administrative functions are procedural tools aiming at special compulsion to protect buildings or other facilities against potential hazard impacts. Based on the information about potentially hazardous zones, it would be useful to integrate special compulsions within a legally binding urban plan aimed at the protection of buildings that might be developed within threatened areas. These obligations may include safety standards, construction codes and building regulations. Codes are likely to have little effect unless they are enforced by authorities. Such efforts need some requirement as:
- An existing and enforceable system of control.
- Awareness of building developers of the standards, codes and regulations and understanding them to considering them necessary.
- Acceptance by the affected community of the objectives and the authority imposing the controls.
- The economic capability of the affected community to comply with the regulations.

Reaction: preparedness, response, and recovery

Emergency response units are the key actors in reaction. Two elements can be recognized as the spatial planning tasks in the reaction stages (refer to Greiving and Fleischhauer, 2006: 122):

- Distribution of urban facilities and infrastructures necessary to respond to the disaster: Some of these facilities include search, rescue and relief stations, emergency medical and health centres, temporary accommodation and emergency roads. The existence and proper distribution of these features can lead to service quickly after the disaster and consequently reduce injuries and fatalities caused by the earthquake.
- Rebuilding of houses and infrastructure: Urban planning can be understood as a key actor in case of recovery activities after a disaster has occurred. The necessary rebuilding of houses and infrastructure has to be coordinated by planning that is ideally oriented on key risk management principles like avoiding hazardous areas.

4 ANALYSING THE CURRENT STATE OF BOTH METROPOLITAN PLANNING AND DISASTER MANAGEMENT IN TEHRAN

Analysisng the currant state of both metropolitan planning and disaster management in Tehran using the above identified conceptual framework, indicates the gaps (as weaknesses) and linkages (as strengths) in an integrated disaster mangement and spatial planning system in Tehran.

4.1 The role of the disaster management system in Tehran

The Study on Seismic Micro zoning of the Greater Tehran Area" is the most important and comprehensive study of risk assessment in Tehran and Tehran Metropolitan Area. This study has provided a comprehensive seismic disaster evaluation (or vulnerability analysis) based on many types of physical, environmental and socioeconomic data items, including (refer to: JAICA, 2000: 9):

- Earthquake catalogue,
- Active faults,

- Geology,
- Ground property,
- Topography,
- Census of buildings (building distribution and building density by type of structure, storey, and construction year),
- Census of population (population distribution and density),
- Urban facilities (distribution of fire fighting stations, police stations, traffic police stations, hospitals, public facilities, educational facilities, parks and public open spaces),
- Urban utilities (water network, gas network, electricity network, and telecommunication network),
- Road and metro network structures,
- Hazardous facilities (distribution of hazardous facilities).

Based on analysing the above data items, some analytical information is provided as peak ground acceleration, seismic intensity, slope stability, building damage, human causality, utility damage, and structural damages. Using this analytic information, overall earthquake risk of Tehran was evaluated by physical and social indicators as (refer to: JAICA, 2000):

- Hazard and damage: seismic, intensity, building damage and casualties,
- Social conditions: population density, open space, and narrow road.

The final result of risk evaluation presents high-risk districts, medium-risk districts, and relatively low-risk districts of Tehran. This risk assessment does not present a comprehensive and thorough picture required for considering the earthquake's risks in the spatial planning system of Tehran. The main problems of this assessment could be explained as follows:

- At the urban scale of spatial planning, data analysis employed in administratively delineated city sub-districts, or some smaller units is frequent. In Tehran, however, this study presents only concrete and detailed maps for Tehran's 22 urban district boundaries which do not fit in with the suitable scale for urban/ metropolitan planning.
- Considering changing social and physical data (population and density, building distribution and density, urban utility networks and so on), there is no mechanism to update the data and provide reliable and up to date vulnerability-related information for urban planners.
- The study area consists of 22 urban districts of Tehran, but the area beyond the city limits has not been considered in this study agenda: there is no information about the vulnerability aspects of the surrounding areas of Tehran (i.e., Tehran’s urban region).

Although there are some other studies on Tehran or parts of Tehran that present some information or analysis about the vulnerability aspect, but since these studies have been done in diverse years (starting from 1996) and by distinct agencies, they have different study areas, basics and principles, methods and outcomes and thus, they cannot able to be integrated to be used in an attempt towards spatial planning.

4.2 The role of the spatial planning system in Tehran

Tehran spatial planning response in employing mitigation measures of mitigation measures could be explained in terms of procedural and substantial aspects. Procedural aspects refer to planning documents and substantial aspects assess the Tehran urban physical and activity sub systems.

Procedural aspects

Urban planning documents system in Tehran is mainly consisted of two parts: (a) Strategic-Structural Plan of Tehran, and (b) detailed plans of Tehran's 22 urban districts. This two were prepared in Research and Planning Center of Tehran, an organization established to manage the collaboration of Tehran municipality and Ministry of Roads and Urban Development in terms of preparing spatial plans of the city.

Strategic-Structural Plan (2006) of Tehran has been recognized the importance of earthquake risk of this city and developed objectives considering managing this risk like identifying vulnerable areas and developing

planning and construction legislations appropriate to each area. Subsidiary documents of this plan also has been mentioned the necessity of developing construction legislative due to the importance of buildings, their stories and vulnerability of their location, developing legislative regarding risk reduction of utility and transportation networks, developing legislative to restrict building's density and arrangement based on vulnerability-related information and so on. But these have not yet become legal statement, and their implementation mechanisms are not defined yet.

Detailed plan of each Tehran's district is prepared based on an agenda which includes two main parts:

- First, studying and analysis of characteristics and specifications of urban development related issues, which lead to assess the determinant factors and trends of changes, and find the problems in the following categories:
- Land use characteristics,
- Spatial structure characteristics,
- Transportation networks characteristics,
- Environmental characteristics,
- Demographic characteristics,
- Socio-economic characteristics,
- Housing characteristics,
- Financial characteristics.
- Second, formulation of optimal spatial structure elements, including:
- Vision and mission statements,
- Goals statement and spatial strategies,
- Land use structure,
- Transportation network structure,
- Rules and regulations of space use,
- Subject and action area projects and their general framework.

The above tow-part agenda shows that disaster management consideration (such as identification and analysis of threats caused by hazards) is not embedded in, so there is no specific obligatory framework to application of earthquake mitigation measures in the optimal spatial structure proposed by these plans.

Substantial aspects

The most important shortcomings of spatial planning response in terms of urban physical and activity sub systems in Tehran in employing mitigation measures include (refer to JAICA, 2000 and International Institute of Earthquake Engineering and Seismology, 2005):

- Considerations of risk reduction were not observed in current location of public sector facilities and major infrastructure elements.
- Most parts of Tehran water network are more than 30 years old and even in normal conditions are often crushed. Studies indicate that in times of earthquake, fractures of water network in Tehran would disable the entire system.
- Tehran electricity, gas, and communication networks suffer from lack of sufficient strength against earthquakes and complete cessation of these networked is possible.
- Tehran's road and transportation network and traffic congestion in normal conditions shows that this network is also highly vulnerable to earthquake. Collapse of adjacent buildings and /or destroyed bridges will freeze the network and cause disorder in the rescue and relief operations and thus increase damages caused by the earthquake.

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

- Population density in Tehran does not compliance with vulnerability-related information and even some most vulnerable districts (including districts 10, 11, and 12) are the most densely populated ones.
- Not only, there are not enough safe evacuation spaces with reliable accessibility in times of disaster to settle the survivors, but also the distribution of them is inefficient.

Disaster management activities	Strengths and weaknesses in linkages of spatial planning and disaster management systems in Tehran	
	Strengths	Weaknesses
Risk assessment	• Existence of a relatively comprehensive study on risk assessment of earthquake in Tehran. • Provision of the seismic data of Tehran (such as earthquake catalogue, active fault, topography and so on).	• Absence of the up to date physical and social data to evaluate risk of earthquake in Tehran. • Lack of detailed vulnerability related information in scales required in spatial planning (such as sub-districts and building blocks). • Lack of any applicable study on risk assessment of earthquake in Tehran metropolitan area beyond the city with its 22 districts. • Lack of a defined basis for doing studies on risk assessment so that they could be integrated and used in spatial planning.
Mitigation/ Risk reduction	• Increasing attention to the spatial planning role in mitigation strategies in Tehran spatial plans.	• Lack of mitigation consideration in Tehran Detailed Plans' agenda • Lack of detailed and well-defined legislative to regulate the use of lands and spaces, building density, population density and so on. • High vulnerability of Tehran urban utility, urban facility, road and metro network to the earthquake. • Congestion of population and buildings in some of the most vulnerable districts of Tehran.
Preparedness, response, and recovery	• Increasing attention of spatial plans to the spatial planning role in response and recovery strategies.	• Inefficient distribution of emergency stations. • Lack of safe accessibility to the most vulnerable areas in times of earthquake.

Table 2: Describing strengths and weaknesses of linkage between spatial planning and disaster management systems in Tehran. Source: writers (2012) after JAICA (2000) and International Institute of Earthquake Engineering and Seismology (2005)

5 PROPOSING A FRAMEWORK FOR AN INTEGRATED SPATIAL PLANNING AND DISASTER MANAGEMENT SYSTEM IN TEHRAN

To Integrate disaster management process with the spatial planning process, their interrelationships and interdependencies could be studied in three following main lines of activities (refer to Greiving and Fleischhauer, 2006: 111-115):

- First, problem analysis: Problem analysis process starts with the identification of certain conditions in the real world that regarded as unsatisfactory or demanding urgent action. Prerequisite for this phase is planning goals developing which describe the desired future circumstances. Afterward, observation of the environment, surveying and description of the information can be done to identify the dependencies, interactions and interrelations between the current condition and influencing variables. One of these variables is vulnerability-related information which could be provided by Tehran disaster management system through the appropriate and necessary data and assessment methods (such as hazard maps, risk maps and so on) to develop a correct scientific foundation of the decision-making process. Nevertheless, this activity itself depends on preparation of physical data (such as building types, distribution and density) from spatial planning supporting system.
- Second, evaluation of alternatives: In this stage, planning alternatives would be developed and later, they would be assessed to estimate their anticipated impacts through using necessary measures. Considering the impacts of these alternatives on the damage potential and coping capacity of Tehtran could be a significant contribution to the disaster management system, especially in mitigation activities.
- Third, decision-making and implementation: Paying attention to the above considerations in evaluating the alternatives in the line with willing, proficiency, and power of Tehran spatial planning to regard disaster management as an element of planning process leads to establishment of procedures and development of measures contributing to disaster management activities.

These three activities can be categorized in two main parts of (a) providing a scientific base, and (b) making decisions and implementation as shown in Figure (3).

6 APPLICATION OF THE PROPOSED FRAMEWORK IN TEHRAN

An integrated spatial planning and disaster management framework in Tehran consists of two elements, including providing scientific base and taking decisions and implementing.

6.1 Providing scientific base

A scientific basis provide both required spatial information for risk assessment and vulnerability-related information and classification of earthquake-prone areas which enable the spatial planning system to define land and space uses based on alerting about hazardous areas. Provision of this basis requires the following activities:

- Establishment of an information support system, including complete physical data (building type, building distribution, building age, building density, urban facility distribution, urban utility networks, road networks and so on), demographic data, and seismic data for building blocks of Tehran,
- Designing a mechanism to update spatial data in the information support system,
- Designing a mechanism to update population census in the information support system.

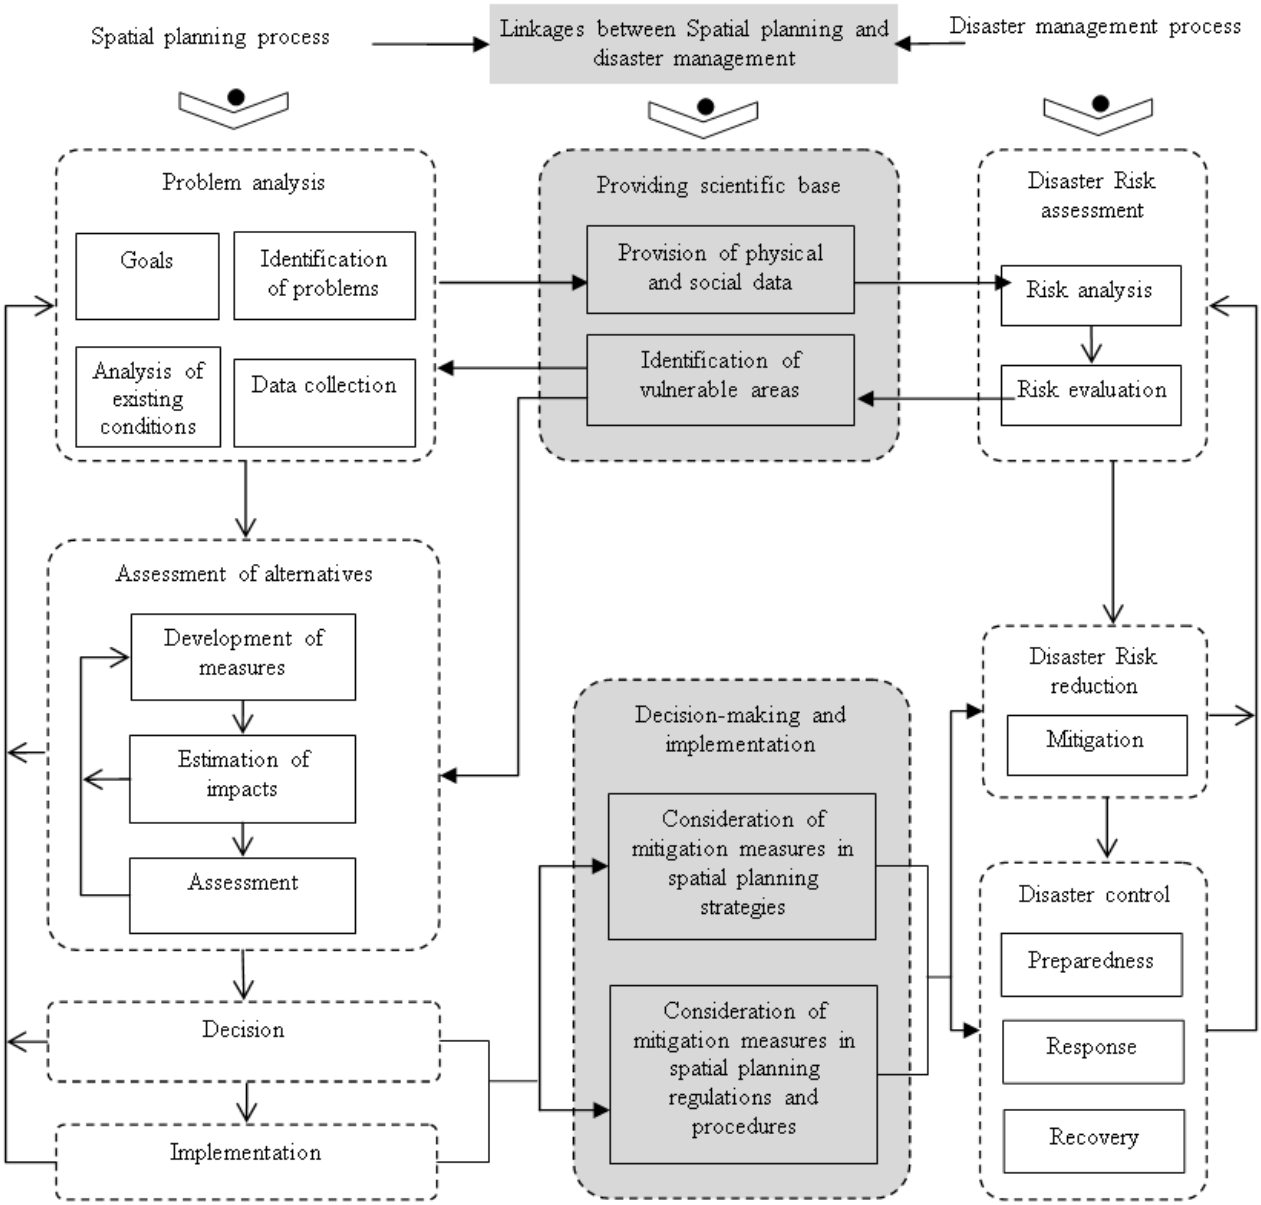

Fig. 3: Integrated framework of spatial planning and disaster management in Tehran. Source: Writers (2012) after Greiving and Fleischhauer, 2006: 116

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

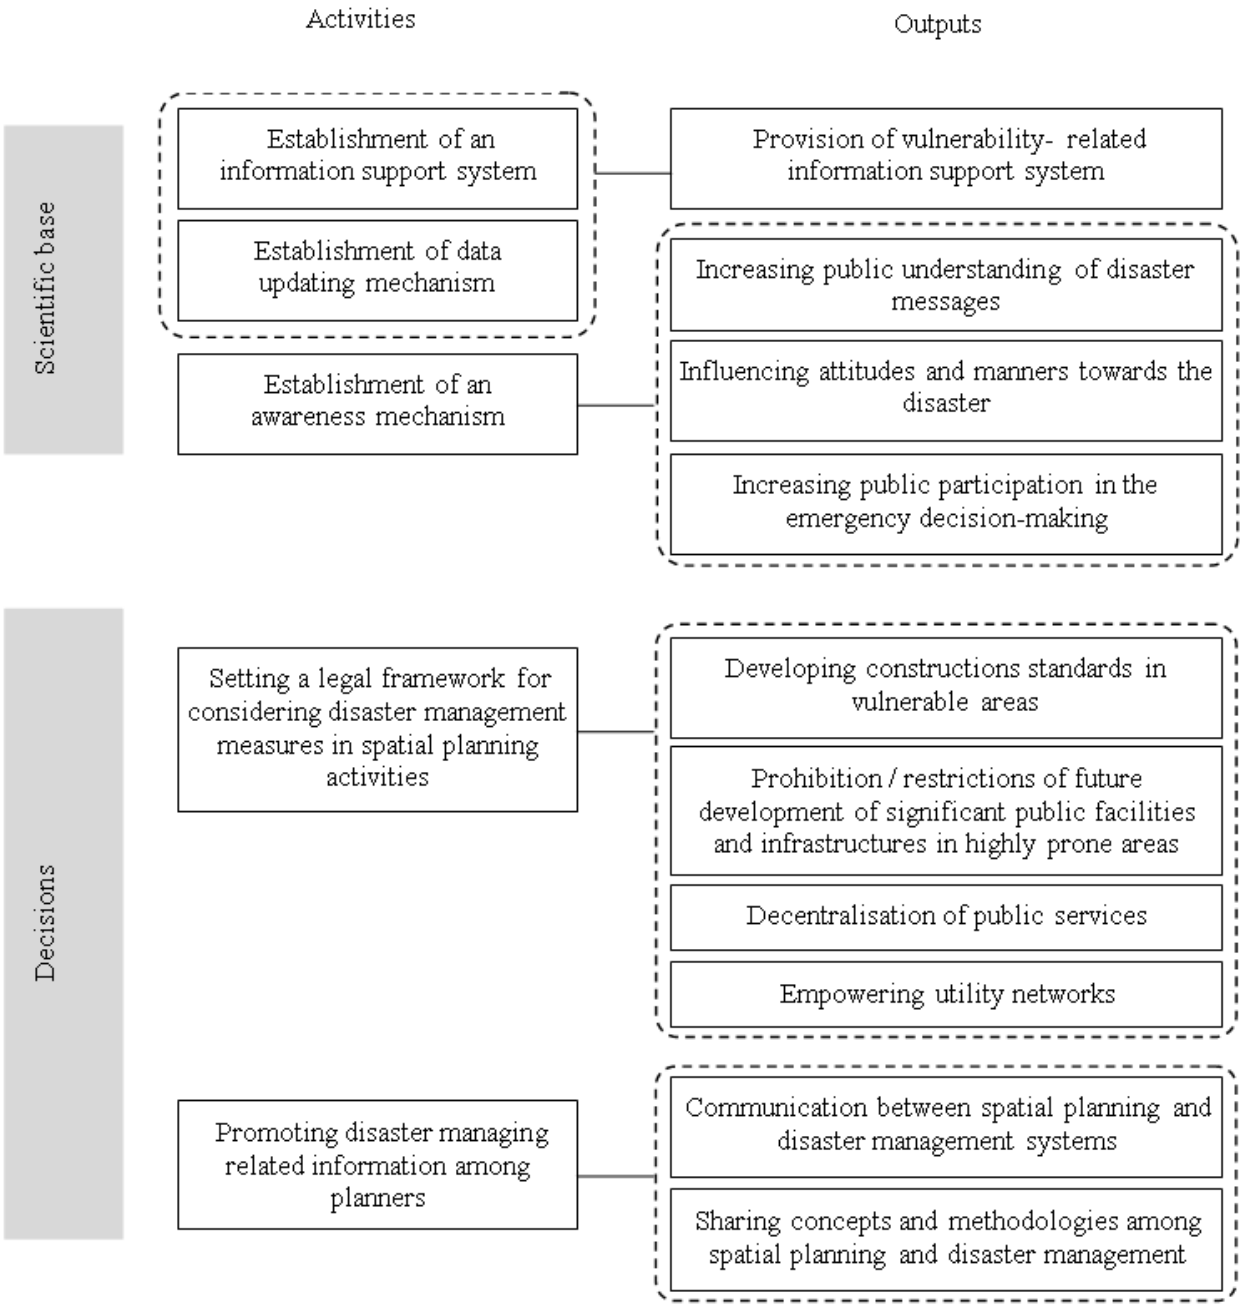

Fig. 4: Application of the proposed framework of spatial planning and disaster management in Tehran. Source: Writers (2012)

Scientific base can also have a different role in raising awareness of Tehran spatial planning officials and experts about disaster management by equip them with information which broadens their view of hazards and risks, since only those hazards and risks that are known can be managed. Moreover, the training of experts engaged in planning is also important in that they may act as multipliers and contribute to the raising of awareness to public. In this situation, the provision of any kind of information (including sources, existing actors and contacts, the cost and effectiveness of different measures, and, etc.) to introduce a disaster management process at the metropolitan level by means of a guideline or a handbook can be seen as a good solution. The guideline or handbook would fulfil these three main objectives:

- Guaranteeing the ability of all receivers of a risk message to understand its meaning,
- Influence receivers of such message to change attitudes towards the disaster and their manners,
- Offering the basis of a two-way communication process which increases public participation in the emergency decision-making.

6.2 Decisions-making and implementation

A legal framework to considerate disaster management measures in planning activities can be seen as the most important need procedurally and legally since it direct spatial planners to take into account earthquake risk while making decisions about urban change and development. Such a framework could include disaster management measures as follows in the spatial plans' agendas:

- Developing spatial construction standards /criteria in vulnerable areas,
- Prohibition and/or restrictions of future development of significant urban facilities and major infrastructure elements in highly prone areas,
- Relocation of hazardous facilities,
- Decentralisation of public services,
- Empowering utility networks through the replacement of damaged parts and switching circular systems with radial ones.

In addition, considering disaster management strategies in spatial planning requires training planners who have skills of understanding seismic map or at least are capable to communicate with the disaster management sector. Cause the lack of shared concepts and methodologies to assess vulnerability may lead to pay little attention to vulnerability in Tehran spatial planning practice. Furthermore, these planners can inform the disaster management system about the real information spatial planning system needs to deal with earthquake in decision-making.

7 CONCLUSION

This article with regard to the important role of spatial planning in disaster management cycle and the connection between the ways of dealing with earthquake and the role of spatial planning, concerns the demands that are made on Tehran spatial planning to integrate with the disaster management system. For the earthquake, preventing the actual geological or meteorological process from occurring is impossible. Thus, disaster management effort toward earthquakes mainly focuses on protection measures related to internal characteristics of the urban system, including city size, density, spatial form, socio-economic development, infrastructures, and the level of emergency response.

Analysis of current state of disaster management and spatial planning systems in Tehran indicates that the main shortages of disaster management system, in terms of its relationship with spatial planning process are lack of maps with suitable scale for urban/ metropolitan planning, lack of mechanism to update vulnerability-related information for urban planners, and lack of vulnerability-related information for the area surrounding Tehran. Additionally, there is no legal framework for taking into account the disaster management considerations in urban planning practises, which leads to high risk of spatial structure and residents of Tehran in times of an earthquake.

In this regard, the proposed framework of integrating spatial planning and disaster management consists of two main elements: (a) setting a supporting scientific base, and (b) making decisions and implementing them according to the mentioned scientific base.

In the scientific base, integrating spatial planning and disaster management process would be occurred in a tow-way relationship: first, spatial planning system provides physical and social data, which is needed for disaster risk analysis of disaster management system, and later, risk evaluation activity of disaster management process identifies vulnerable areas which would be important in analysis of existing conditions, setting planning goals, and assessment of alternatives in spatial planning process.

Disaster risk reduction and control activities would also be integrated in spatial planning process by considering of mitigation measures in spatial planning strategies, regulations and procedures, which are determined in decision-taking and implementation stages of spatial planning process.

In such a framework, the responsibility for disaster management is shared by sectoral planning and spatial planning whereas spatial planning mainly acts in the area of earthquake mitigation due to the long-term character of planning decisions.

Integrative Urban Design Game as a Method for Creating Liveable Urban Ambients

Tatjana Mrđenović

(Tatjana Mrđenović, Teaching assistant, University of Belgrade, Faculty of Architecture, Bulevar kralja Aleksandra 73/II, tmrdjenovic@arh.bg.ac.rs)

1 ABSTRACT

Complexity of urban environments implies new methods that can design urban ambients in sustainable manner. This means that urban design and urban planning must work together in order to achieve flexibility for liveable urban ambients in the process of sustainable urban regeneration. Problem and research questions that guide this work are: How to achieve this kind of disciplinary, interdisciplinary and participative cooperation? Is it possible to overcome main obstacles of interest based urban development? Do traditional methods of urban design and urban planning can achieve the integration? The aim of the paper is testing the "Integrative urban design game", the method applied in the process of urban regeneration of Bač Fortress Suburbium, regarding its possibilities to frame and integrate different rationalities into a coherent future. Different rationalities come from variety of actors and stakeholders in the community seen as carriers of urban vitality and identity. The hypothesis is that the method is in the relation with local context and level of social capital in local communities. Therefore, the expected results of the paper will (dis)prove the integrative "power" of the method using case study as a methodological approach of measuring the level of acceptance and integration among different group of stakeholders.

2 INTRODUCTION

The multilevel dimension of urban design and urban planning and their mutual overlapping in contemporary urban paradigms create rich area for integration of the positive sides of both disciplines in the process of urban regeneration. Urban regeneration is framed by sustainability as "youngest" urban paradigm (Reeves, 2005). Sustainability seeks to integrate aspects, aims, and spaces of "older" paradigms providing liveable places. Furthermore, urban regeneration of protected ambients emphasises the need for this kind of integration. Most would say that it is a subject of integrative protection, however, by my opinion the issue goes beyond this concept. The argumentation for this is in the institutional dimension of sustainable development, crucial for the provision of Healey's "soft infrastructure" and objectification of different worlds into coherent whole.

Therefore, the aim of the paper is to discuss the question when urban design and urban planning should work together to build the institutional space for achieving sustainable places in protected urban ambients. This will be researched by analysis the results of a workshop: "Participatory approach in urban design of public spaces of Bač Fortress Suburbium" held in August 2010 as a part of Summer school of Architecture in Bač. The workshop used the innovated method "Integrative urban design game" (Mrđenović, 2010) to experiment its possibilities to integrate different rationalities in participatory process, as well as to build soft infrastructure for place making. Also, the data acquired from the Report on the results of "Summer school of architecture in Bač 2010", (Architecture, 2010) will provide a base for the conclusions.

In line with this in the first chapter I will discuss the integrative aspects of urban design and urban planning in situations when they should work together, as well as their relation to integrative protection. This discussion will be leaded by multilevel dimensions of the disciplines to produce sustainable, rich and liveable spaces. The second chapter will examine the "Integrative urban design game" regarding its power of integration. It will be analysed from the perspective of making linkages between urban design and urban planning using different methods and techniques form both disciplines. The type of the linkages that method can provide in the community are by my assumption in the relation to the level of community social capital. Conclusions should prove the previously presented hypothesis.

3 URBAN DESIGN AND URBAN PLANNING: INTEGRATIVE DIMENSIONS?

3.1 Overlapping dimensions

The discussion between urban design and urban planning is related to favoured urban paradigm in specific socio-economic context. Therefore, both disciplines can be practiced as blue prints, achieving expected results in top-down instructive process of policy decision making. This paradigm is usually seen as rational -

positivistic one where hierarchy of planning system is deterministic and strict. On the other hand, the disciplines could be practiced as iterative and integrative processes of achieving mutual consensus among relevant stakeholders. These processes are practiced in collaborative and sustainable paradigm. Sustainability evaluates urban design and planning solutions by the quality of process, regarding the level and type of participation. These I would say antipode positions of urban design and urban planning in different paradigms mostly make assumption and opinion that urban planning and urban design have strict boundaries. I believe that these boundaries are rather dashed then solid.

Therefore, the point that I stand for is the one where urban design is seen as multidimensional process of subjective-imaginative, communicative-creative, interdisciplinary and technical activities (Madanipour, 1996). Also, urban planning seen as a process in contrast with blue-print planning has its communicative-creative, interdisciplinary and technical dimension (Healey, 1997). The subjective-imaginative and creative dimension of urban design is powerful integrative force regarding different kinds of integration. As it is presented the most of the process of urban design and urban planning are overlaping. Therefore, urban design is also seen as decision making process that goes through the phases of strategic planning. This dimension equalizes the discipline to urban planning. Most would ask: So, what is the difference between urban design and urban planning? I would answer the imagination of urban designers. And this is crucial for making quality of places nevertheless the theory in which we explore and practice urban design and planning.

I would say that urban design and urban planning are overlapping in all dimensions except subjective-imaginative (Figure 1). This dimension is essential for the process of quality place making in sustainable regeneration. According to the principles of New Urbanism these qualities are: "…neighbourhoods should be diverse in use and population; communities should be designed for the pedestrian and transit as well as the car; cities and towns should be shaped by physically defined and universally accessible public spaces and community institutions; urban places should be framed by architecture and landscape design that celebrate local history, climate, ecology, and building practice…" (CNU, 1996).

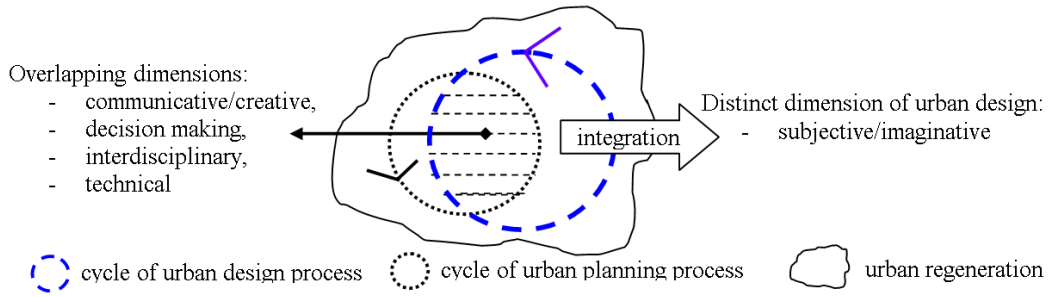

Figure 1: Overlaping and distinct dimension of urban design and urban planning in the process of urban regeneration

By my opinion these qualities are achieved in the overlapping areas, leaded by imagination of urban designers. According to Landry, Harvey, Jacobs, Dovey the imagination of urban designers is crucial for quality place making, integration and rationalization of different ideas and creativities in wide participation process practicing Dovey's "power-to" rather then "power-ower" in the creative milieu for open communication(Landry, 2005) (Jacobs, 1992) (Dovey, 1999). This integration leads to Harvey's "making sense together" for Habermas's communicative action (Harvey, 2007) (Habermas, 1984).

3.2 Integrative urban design and planning regarding protection

As it is said urban design and urban planning should work together in order to achieve quality of place making in urban regeneration. The integrative dimension lies in urban design, particularly in the imagination of urban designers as artisans. By my opinion all the other dimensions have "corrective" role in rationalization of urban designers' imagination and social creativity. Therefore, urban design seen as a process plays an integrative role in urban regeneration, as well as between two disciplines (Mrđenović, Integrative Urban Design in Regeneration - Principles for Achieving Sustainable Places, 2011) (Mrđenović, Urban Design and Urban Planning in Global Positioning of Local Identities, 2011) (Mrđenović, Urbana regeenracija zaštićenih ambijentalnih celina u kontekstu održivog razvoja - Podgrađe Tvrđave Bač / Urban regeneration of protected ambients in the context of sustainable development - Bač Fortress Suburbium, 2011). From this point after I will look on two disciplines as "fusioned /united" (Figure 2) regarding

achieving betterment of urban regeneration. Also, I will call them using term Integrative urban design. This will be especially important for the discussion of their role in urban regeneration of protected urban ambients. The attribute 'protected 'will lead discussion among "fusioned disciplines" and integrative protection.

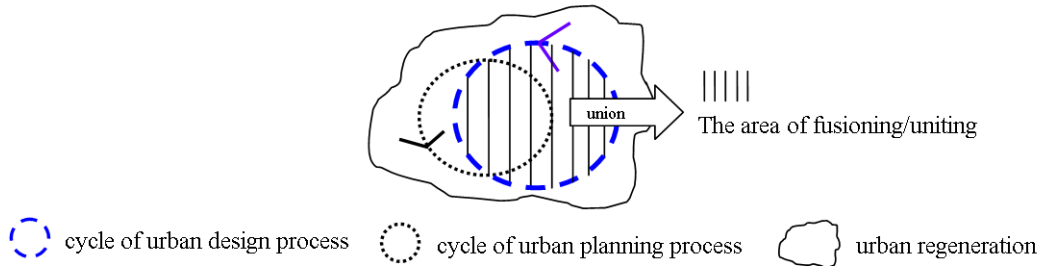

Figure 2: The area of "fusioned/united" disciplines of urban design and urban planning creating the process of Integrative urban design

Integrative protection as a discipline is in line with international documents on UN, EU and ICOMOS level that seeks to "bring life" into protected urban areas according to the principles of sustainability (UNESCO, 2005), (ICOMOS, The Stockholm declaration, 1998) (ICOMOS, The Nara document on authenticity, 1994) (ICOMOS, DECLARATION OF TLAXCALA, 1982) (ICOMOS, Resolutions of the Symposium on the introduction of contemporary architecture into ancient groups of buildings, 1972)(EU, 1996). This means integrative protection, also integrates different sectors of sustainability: economy, society, environment and institutions through encouraging public participation to be active in the promotion of cultural heritage in line with contemporary concept of cultural tourism (Dojčinović 2005). This kind of integration leads to promotion and protection of non-renewable resource like cultural-historic heritage. This process also leads to social cohesion among local people, who brings life into physical structure, and who are carriers of social and knowledge of past times. This is essential for holistic approach between past, present and future and our responsibility to preserve past and present cultural practice for future generations (Figure 3).

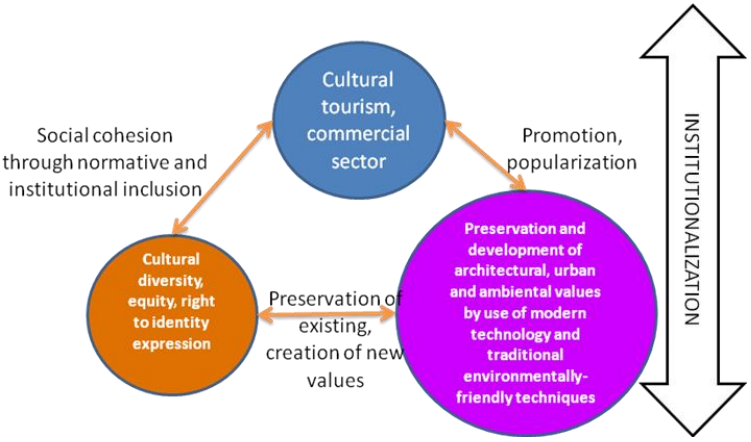

Figure 3: The model of sustainable development for the regeneration of protected urban areas (Mrđenović, Urbana regeenracija zaštićenih ambijentalnih celina u kontekstu održivog razvoja - Podgrađe Tvrđave Bač / Urban regeneration of protected ambients in the context of sustainable development - Bač Fortress Suburbium 2011)

This holistic interpretation of cultural goods is the best described in Stockholm declaration: "These rights assume the need to recognize, appreciate and maintain heritage, and to improve and respect a framework for action. They assume appropriate development strategies and an equitable partnership between society, the private sector and individuals to harmonize interests affecting cultural heritage, and to reconcile preservation with development." (ICOMOS, The Stockholm declaration, 1998) . According to the previously discusses I rise a question: What is the role of the united urban planning and urban design (integrative urban design) in development of protected urban areas if integrative protection already covers it?

By my opinion the role is in Lefebre's "spatial reproduction" (Lefebvre, 1991) of "social and knowledge of past and present times" creating place that brings contemporary life into past structures, interpreting past activities and enabling them into space. This "place making thing" is crucial for the pivotal role of "united disciplines" in protected ambients, as I claim for "new universality" in "golden unity" for "colourful

fragments" (Mrđenović, Urban Design and Urban Planning in Global Positioning of Local Identities, 2011). Here, integrative protection has a corrective, rational, role regarding what should or should not happen in the place. In line with this, the process of creating the place should be leaded by integrative urban design. According to Amsterdam Declaration: "...conservation calls for artists and highly-qualified craftsmen whose talents and know-how have to be kept alive and passed on." (EU, European Charter of the Architectural Heritage, 1975). It seems like integrative protection and integrative urban design are in conflict, both creating liveable places in protected ambients. In further discussion I will make these fuzzy issues more clear regarding the process. Figure 4 gives more clarity to this fuzziness.

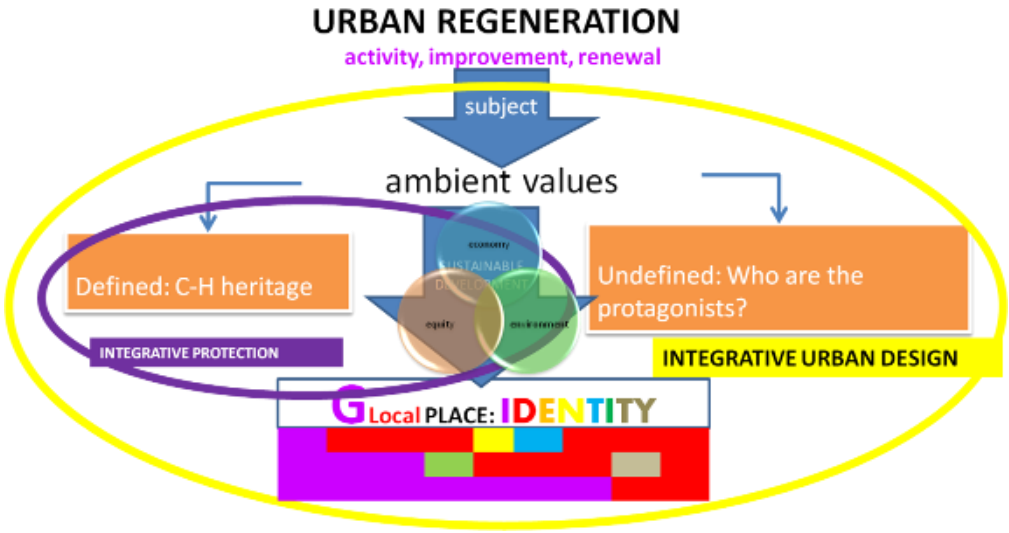

Figure 4: The relation among urban regeneration, urban design and integrated protection (Mrđenović, Urbana regeenracija zaštićenih ambijentalnih celina u kontekstu održivog razvoja - Podgrađe Tvrđave Bač / Urban regeneration of protected ambients in the context of sustainable development - Bač Fortress Suburbium 2011)

This question is related to the favoured urban paradigm in the process of urban regeneration. The need for protection calls for rational and positivistic approach, when experts put standards and assure their implementation; while collaborative approach assure sustainability of protected urban ambients, creating "liveable places" that carry past tradition, urban forms, morphology and contemporary ones oriented towards future development fitting into wider plans and policies. According to Gospodini: "...it can be said that urban space morphology and urban design are gradually becoming significant parameters or resources in urban tourism development." (Gospodini, 2001).Therefore, I believe that the type of the urban regeneration process (more rational or collaborative) as well as used methods in the process will make clearer picture on the discipline that should have a leading role in the specific phase of the urban regeneration process.

4 INTEGRATIVE URBAN DESIGN GAME: THE UNITY POWER

4.1 New method for integration

I will now introduce the "Integrative urban design game" (Mrđenović, 2010) as a new method firstly used in the workshop: "Participative approach in urban design of public spaces - Bač Fortress Suburbium" (Mrđenović, Workshop: Participative approach in urban design of public spaces - Bač Fortress Suburbium / Radionica: Participativni pristup u oblikovanju javnog prostora - Podgrađe tvrđave Bač, 2010). The workshop was a part of "Summer school of Architecture in Bač 2010" with a mission to create Healey's "soft infrastructure" (Healey, 1997) through educational process on sustainable urban regeneration and integrative protection among local and regional stakeholders. The method went through different phases of "fusioned disciplines" using various methods and techniques seeking to integrate them creating "new golden unity" (Mrđenović, Urban Design and Urban Planning in Global Positioning of Local Identities, 2011) for Habermas's "communicative consensus" (Habermas, 1984), and Landry's "creative milieu" (Landry, 2005) towards achieving quality of future public spaces.

Related to the discussion in the previous chapter the method integrates different types of methods and techniques supporting wide range of purposes in the multidimensional process of sustainable urban regeneration. In general my criteria for systematization of the methods are based on their support in:

- Phase of integrative urban design,
- Level collaborativeness,
- Type of rationality.

Figure 5: Gradual - incremental creation of the mimicry model of future public space of Bač Fortress Suburbium as a result of Integrative urban design game (Mrđenović, Workshop: Participative approach in urban design of public spaces - Bač Fortress Suburbium / Radionica: Participativni pristup u oblikovanju javnog prostora - Podgrađe tvrđave Bač, 2010)

Regarding this I would say that integrative urban design and integrative protection use different methods according to the criteria. The former uses both rational and collaborative in all phases of the process, while the latter uses more rational and expert ones due to its corrective and normative role in the process of promotion and protection of built cultural-historic herritage.

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

Here I would point out again the role of integrative urban design (fusioned disciplines) in this process, which is assuring liveable places with specific glocal identity making them recognizable on global map. On the other hand, integrative protection should prevent the 'dark side' of globalization that is by Nara document characterized as homogenization of cultural expressions. "In a world that is increasingly subject to the forces of globalization and homogenization, and in a world in which the search for cultural identity is sometimes pursued through aggressive nationalism and the suppression of the cultures of minorities, the essential contribution made by the consideration of authenticity in conservation practice is to clarify and illuminate the collective memory of humanity." (ICOMOS, The Nara document on authenticity, 1994) Therefore, the Integrative urban design game is in line with the one of the document's suggestion to develop innovative methods and processes that will treat cultural heritage in integrative manner according to local context. (ICOMOS, The Nara document on authenticity, 1994).

"Integrative urban design game" seeks to play among various interests and rationalities in fair manner using Habermas's "communicative ethics" (Habermas, 1984). In that play it integrates different processes of urban design, such as the subjective-expressive, social-creative, social-communicative, technical-rational, and interdisciplinary. The aim of this method is to develop different types of rationality in wide community participation process towards achieving the quality of place using a creative game in the visualization of space. The method applied on Bač Fortress Suburbium is rationalized in the key segments of the process, using argumentative and expert methods. In this way, it created 'future image' of the place through its spatial visualization, using three-dimensional and two-dimensional presentations, drafts, drawings and text, different expert methods of polling, interviewing, context analyses, morphological analyses, as well as collaborative methods that support argumentation by use of different diagrams such as problem tree and tree of aims and measures (Figure 5).

The essence of "Integrative urban design game" is to establish a relation between different types of rationality, as well as between the phases of the urban regeneration process. As a method, it implies a continual procedure in the development of social creativity, as well as its rationalization. In the light of creating the conditions for communicative action in the regeneration processes and unity of reality fragments, the method integrates the advantages and disadvantages of the two most present paradigms in urban decision-making, the rational-comprehensive and collaborative; changing the role of urban design in the integrative processes. Therefore, in the situations of urban regeneration of protected urban ambients the method is appropriate for shaping the places in overlapping area of urban design, urban planning and integrative protection (see Figure 1) using mimicry three-dimensional model of present, and future place bringing into light the richness of cultural diversity of past, present and future times through wide participation. This mimicry model is also a polygon for integration of different types of appropriate methods, as well as phases of the process (Figure 5).

4.2 The power/acceptance of the method

In this chapter I will argue the method regarding its power to integrate different rationalities, values, cultural practices and interests into coherent whole, through its acceptance and level of participation among relevant stakeholders on local and regional level. The basic data will be acquired through analysis of the workshop as a case study, as well a on the Report on the results of "Summer school of architecture in Bač 2010", consigned to the Ministry of education and science in 2010, by University of Belgrade – Faculty of Architecture (Architecture, 2010). It is important to emphasise that Municipality of Bač is national, multiethnic and multicultural community.[1] Accortding to this fact In the workshop participated relevant stakeholders on regional and local level representing cultural diversity:

- "Province Institute of Cultural Monument Protection",
- "Directorate for Urban Construction of Bač Municipality",
- "Tourist Organization of Bač municipality",

[1] According to the records of Statistical Office of the Republic of Serbia in Bač municipality live: 47.33% Serbs, 0.35% Montenegrians, 5.02% Yugoslavs, 0.04% Albanians, 0.02% Bosniaks, 0.01% Bulgarians, 0.06% Bunjevci, 6.18% Hungarians, 0.07% Macedonians, 1.35% Muslims, 0.55% Germans, 1.98% Romas, 3.55% Romanians, 0.04% Russians, 0.06% Rusyns, 20.02% Slovacs, 0.05% Slovenians, 0.57% Ucrainians, 8.65% Croats, 0.83% Czechs, 3.27% uncomited. (RGZ, 2011)

- "Fund Centuries of Bač",
- "Radio Bačka" and
- Local population of Bač Suburbium.

The process of "Integrative urban design game" was created regarding following phases: (1) Preparation of the participative procedure, (2) Defining the desired future – visioning, (3) Analysis of problems and potentials, (4) Defining strategic objectives and measures for public space improvement, (5) Testing the place making solutions through mimicry model.

In the first phase the interviews and questionnaires for local people and relevant stakeholders were done as an expert method giving relevant inputs for further process cycle. The questions were structured regarding:

- The present usage of public space by local people: level, way and regime;
- The wishes and ideas of future usage of public space by local people: spaces for socialization, interaction among cultures, festivals;
- The memories on how the public space was used in past time;
- The existing and future plans and projects for the Suburbium regarding its protection and development: potentialities and obstacles.

These preparatory activities included field inventory like sketching, urban morphology analysis, photographing, measuring. The preparation phase gave a solid grounding for the workshop.

The workshop was held in Bač Fortress Suburbium and was designed as one and a half day training using "Integrative urban design game" as a method for consensus building through art and design. Therefore, the workshop had also, the educational aim. This leaded towards building capacity of local community on sustainable urban regeneration of protected urban ambients. The other phases of the process were done with high level of participation by all relevant stakeholders (see Figure 5) where the author of the method facilitated the process by encouraging creativity, argumentative discussion, making conclusions using text, slogans, images, sketches, 3D model and other types of methods and techniques. Also, students from Faculty of Architecture in Belgrade, students participants of "Summer school of Architecture in Bač 2010." enabled Landry's creative milieu through generating ideas and enabling their flow. In that manner the "Integrative urban design game" integrated different types of methods as well as different ideas, values, interest into "golden unity" of urban design of mimicry model of future public place (see Figure 5).

Also, the results generated by the method are and will be incorporated in future documents, plans and projects regarding Bač Fortress Suburbium. According to the Report on the results of "Summer school of architecture in Bač 2010" (Architecture, 2010), the results will be used mostly by the "Province Institute of Cultural Monument Protection", "Directorate for Urban Construction of Bač Municipality", "Tourist Organization of Bač municipality", "Radio Bačka" in their future activities and programs regarding the sustainable urban regeneration of the Suburbium and its promotion towards cultural tourism. Therefore, I can conclude that the method had powerful force regarding the integration of multicultural values, interests and ideas among stakeholders form public and civil sector ("Fund Centuries of Bač" has a role of financing activities and it is inside local authority), as well as among vertical integration of different institutional jurisdictions. Also, it integrated various types of methods and techniques that were tailored made according to specific socio-cultural and urban context. In line with this I can conclude that the method is more open than strict, giving a skeleton for adopting it to various urban contexts in the process of sustainable urban regeneration.

5 CONCLUSION

The discussion went through presentation of different options regarding fuzziness among disciplines of urban design, urban planning and integrative protection in sustainable urban regeneration. This fogy issue leaded towards further examination of overlapping dimensions among disciplines, their union and dashed boundaries. I conclude that urban design, seen as multidimensional process with subjective-imaginative dimension, has a leading role in place making and "bringing life" into protected urban ambients, making them liveable places. This process is supported by other dimensions regarding sustainable paradigm where urban design and urban planning are overlapping: communicative-collaborative, social-creative, decision

making-integrative, technical-positivistic. This overlapping area I call integrative urban design (Mrđenović, 2011). In line with this integrative protection has a "corrective role"due to protection of non-renewable resources such a built cultural-historical heritage is. Therefore, the positivistic rationality in this type of urban regeneration should come from integrative protection, while integrative urban design should provide communicative consensus among different rationalities, values, cultural practices and interest bringing them into "golden unity".

Also, the "Integrative urban design game" as an innovative method (Mrđenović, 2010) integrates different types of methods and techniques that varies according to the phase of the process, type of rationality and level of collaborativness they support. The method uses mimicry three-dimensional model/skeleton of present place as a polygon for wide participation and creating creative milieu for communicative action. Therefore, the "skeleton" is incrementally built by relevant stakeholders integrating their values using different expert, collaborative, argumentative, creative methods and techniques like: text, drawings, slogans, sketches, photographs, problem tree, objective tree; appropriate for each phase of the process. The analysis of the case and the report showed that the method was highly accepted among stakeholders as they plan to use its results in future. Also, the method used training as an instrument for building capacity and developing social capital in local community through interactive education. Finally, the method enabled creating liveable ambients through developing social capital, "soft infrastructure" and creating a framework for future plans and actions regarding protection and promotion by stakeholders from public sector on local and regional level.

1 ABSTRACT

Etwa die Hälfte ihres verfügbaren Einkommens geben deutsche Haushalte für das Wohnen und die Mobilität aus. Ausgangsthese des vom deutschen Forschungsministeriums geförderten Projekts €LAN ist, dass die Energiepreise mit hoher Wahrscheinlichkeit beides deutlich teurer machen werden, da das Ölfördermaximum unmittelbar bevorsteht. Die Energiepreisentwicklung wird erheblichen Einfluss auf Landnutzung und Mobilität haben, da es die Standortwahl von Haushalten und Unternehmen, das Mobilitätsverhalten, die Wohn- und Gebäudekosten sowie die kommunale Einnahmen- und Ausgabensituation betrifft. Zudem spitzen steigende Energiekosten vor dem Hintergrund des demographischen Wandels Fragen der Daseinsvorsorge insbesondere im ländlichen Raum weiter zu.

Das Projekt €LAN setzt sich zum Ziel, die Betroffenheit von Haushalten, Unternehmen und Gebietskörperschaften zu analysieren und ihre Anpassungsreaktionen mit Hilfe eines räumlichen Wirkungsmodells zu simulieren. Es geht zudem vor allem der Frage nach, wie Entscheidungsträger aus Verwaltung und Politik in den kommenden Jahren angemessen mit der Energiepreiszunahme umgehen können. Dabei wird erwartet, dass steigende Energiepreise einen erheblichen politischen Handlungsdruck generieren. Anpassungsmöglichkeiten und -strategien bedürfen dabei einer räumlichen Spezifizierung zwischen Städten und ihren Umlandgemeinden und dem ländlichen Raum.

Das Projekt koppelt daher die räumliche Wirkungsmodellierung und politische Handlungs- und Reaktionsmuster in einem Verbundvorhaben. Die Kopplung erfolgt über ein Simulationsexperiment. In dessen Verlauf werden die Handlungsreaktionen von relevanten politischen Akteuren in einem Planspiel abgefragt und zu politischen Rahmensetzungen für die folgende Simulationsperiode verdichtet. Dieser experimentelle Regelkreis dient als Grundlage für die Ableitung umsetzungsorientierter Handlungsempfehlungen, die in einem transdisziplinären Prozess entwickelt werden.

In diesem Paper wird zunächst der Ansatz des €LAN-Projekts vorgestellt und dann das integrierte Landnutzungs- und Verkehrsmodell für die Metropolregion Hamburg, bei dem in einer Multi-Agenten-Simulation Demographie und Unternehmensentwicklung, Arbeits-, Wohnungs- und Gewerbeimmobilienmarkt sowie Verkehrs und Flächenentwicklung für Szenarien von 2010 bis 2035 unter den Bedingungen steigender Energiepreise abgebildet werden, erläutert.

2 WAS BEDEUTEN STEIGENDE ENERGIEPREISE FÜR DIE SIEDLUNGSENTWICKLUNG?

Etwa die Hälfte ihres verfügbaren Einkommens geben deutsche Haushalte für das Wohnen und die Mobilität aus (Statistisches Bundesamt 2010). Ausgangsthese des vom deutschen Forschungsministeriums (BMBF) geförderten Projekts €LAN ist, dass die Energiepreise mit hoher Wahrscheinlichkeit beides deutlich teurer machen werden, da das Ölfördermaximum unmittelbar bevorsteht (IEA 2009). Die Energiepreisentwicklung wird erheblichen Einfluss auf Landnutzung und Mobilität haben, da sie die Standortwahl von Haushalten und Unternehmen, das Mobilitätsverhalten, die Wohn- und Gebäudekosten sowie die kommunale Einnahmen- und Ausgabensituation betrifft. Zudem spitzen steigende Energiekosten vor dem Hintergrund des demographischen Wandels Fragen der Daseinsvorsorge insbesondere im ländlichen Raum weiter zu.

2.1 Das Projekt €LAN

Das Projekt €LAN setzt sich zum Ziel, die Betroffenheit von Haushalten, Unternehmen und Gebietskörperschaften zu analysieren und ihre Anpassungsreaktionen mit Hilfe eines räumlichen Wirkungsmodells zu simulieren. Projektpartner sind das Institut für Verkehrsplanung und Logistik der TU Hamburg-Harburg, das Institut für Raumordnung und Entwicklungsplanung der Universität Stuttgart (IREUS) und das Finanzwissenschaftliche Forschungsinstitut an der Universität zu Köln (FiFo) in Zusammenarbeit mit dem Institut für ökologische Raumentwicklung Dresden (IÖR).

Es geht zudem vor allem der Frage nach, wie Entscheidungsträger aus Verwaltung und Politik in den kommenden Jahren angemessen mit der Energiepreiszunahme umgehen können. Dabei wird erwartet, dass

steigende Energiepreise einen erheblichen politischen Handlungsdruck generieren. Anpassungsmöglichkeiten und -strategien bedürfen dabei einer räumlichen Spezifizierung zwischen Städten, ihren Umlandgemeinden und dem ländlichen Raum.

Das Projekt koppelt daher die räumliche Wirkungsmodellierung und politische Handlungs- und Reaktionsmuster in einem Verbundvorhaben. Die Kopplung erfolgt über ein Simulationsexperiment. In dessen Verlauf werden die Handlungsreaktionen von relevanten politischen Akteuren mittels einer „Planspiel"-Methodik abgefragt und zu politischen Rahmensetzungen für die folgende Simulationsperiode verdichtet.

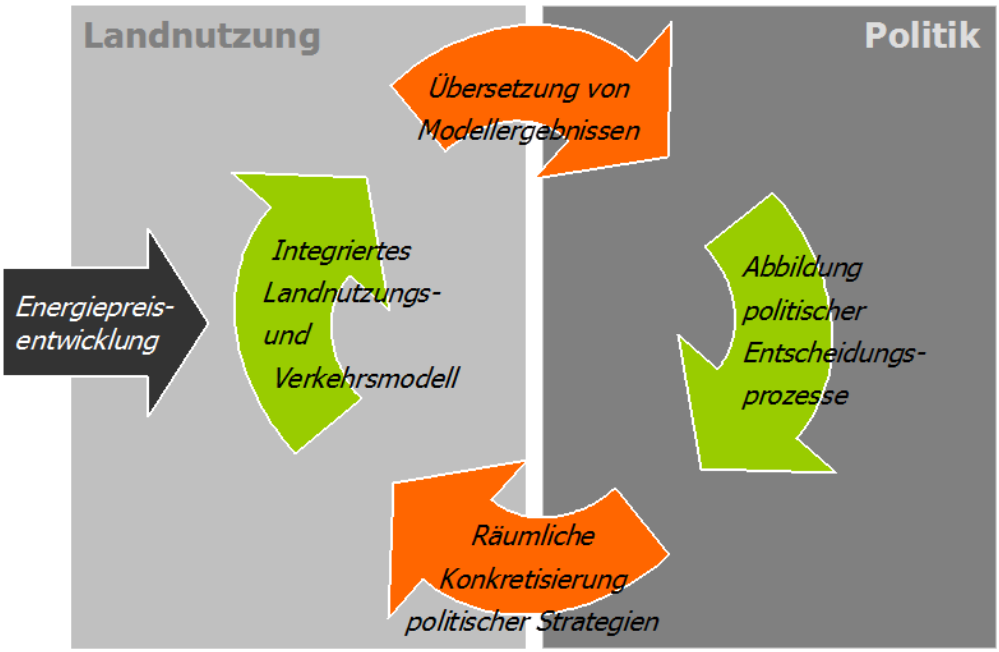

Fig. 1: Ablauf des Projekts €LAN

Dieser experimentelle Regelkreis (Fig. 1) dient als Grundlage für die Ableitung umsetzungsorientierter Handlungsempfehlungen, die in einem transdisziplinären Prozess entwickelt werden.

In diesem Paper soll das integrierte Landnutzungs- und Verkehrsmodell vorgestellt werden und die Fragen diskutiert werden, wie steigende Energiepreise auf Landnutzung und Verkehr wirken, welche Strategien Politik und Planung zur Verfügung stehen und welche zentralen Wirkungszusammenhänge dafür im Modell abgebildet werden müsssen.

2.2 Warum haben steigende Energiepreise Auswirkungen auf Siedlungsentwicklung und Verkehr?

Die heutigen Sieldungsstrukturen und Verkehrssysteme haben sich in den letzten Jahrzehnten bei relativ geringen Energiepreisen herausgebildet. Die Siedlungsentwicklung war lange gekennzeichnet von einer Suburbanisierung von Haushalten und (teilweise) Unternehmen: mehr Wohnfläche in Gebäuden mit einem hohen Energieverbrauch, einer steigenden Motorisierung und immer weiteren Wegen zur Arbeit, zum Einkaufen und in der Freizeit.

Bei in Zukunft weiter steigenden Energiepreisen sind Haushalte mit höheren Nebenkosten und Verkehrsausgaben konfrontiert. Dabei sind vor allem Bewohner von Wohnungen und Häusern mit großem Energieverbrauch sowie die Haushalte, die weite Wege zur Arbeit und zu anderen Aktivitäten mit dem Pkw zurücklegen, betroffen. Dies trifft Haushalte mit mittlerem und geringem Einkommen, für die sich bei immer geringerem verfügbaren Einkommen für andere Konsumbudgets ein steigender Handlungsdruck ergibt (Fig. 2).

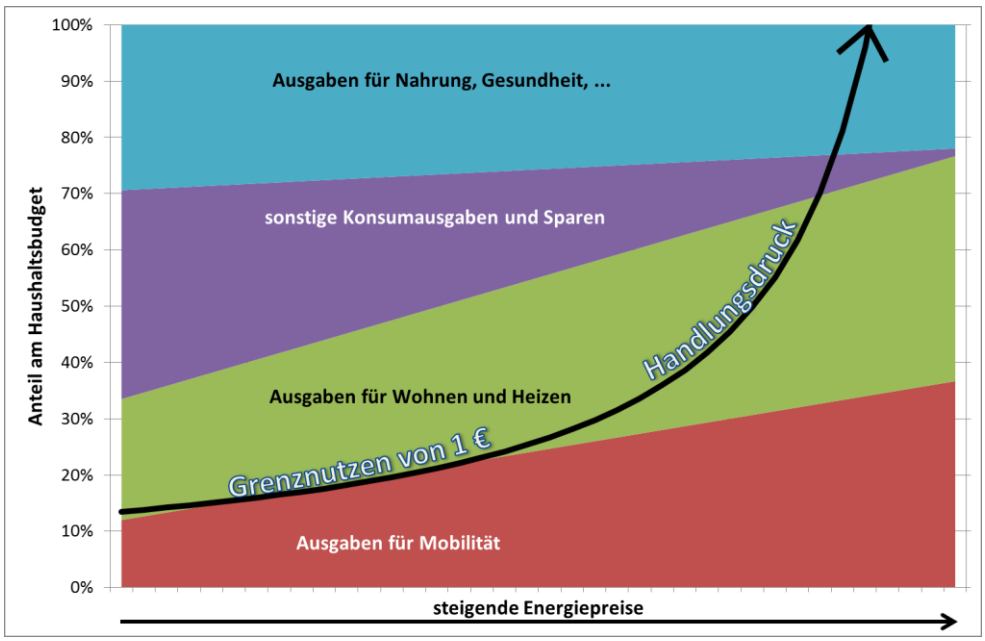

Fig. 2: Haushaltsbudget

Mögliche kurz- und langfristige Anpassungsreaktionen liegen in einer

- energieeffizienteren Pkw-Nutzung
- einer verstärkten Nutzung günstigerer Verkehrsmittel (ÖPNV, Fuß- und Radverkehr) einer räumlichen Reorganisation (Aufsuchen näher gelegener Einkaufs- und Freizeitziele, der Suche eines näher gelegenen Jobs oder schließlich die Suche nach einer neuen Wohnung, die kürzere Wege zur Arbeit und zu anderen täglichen Aktivitäten ermöglicht)
- einer Suche nach einem besser bezahlten (Vollzeit-)Job
- und schließlich der Einschränkung von Aktivitäten oder dem Kürzen von anderen Haushaltsbudgets

(vgl. Gertz et al. 2008).

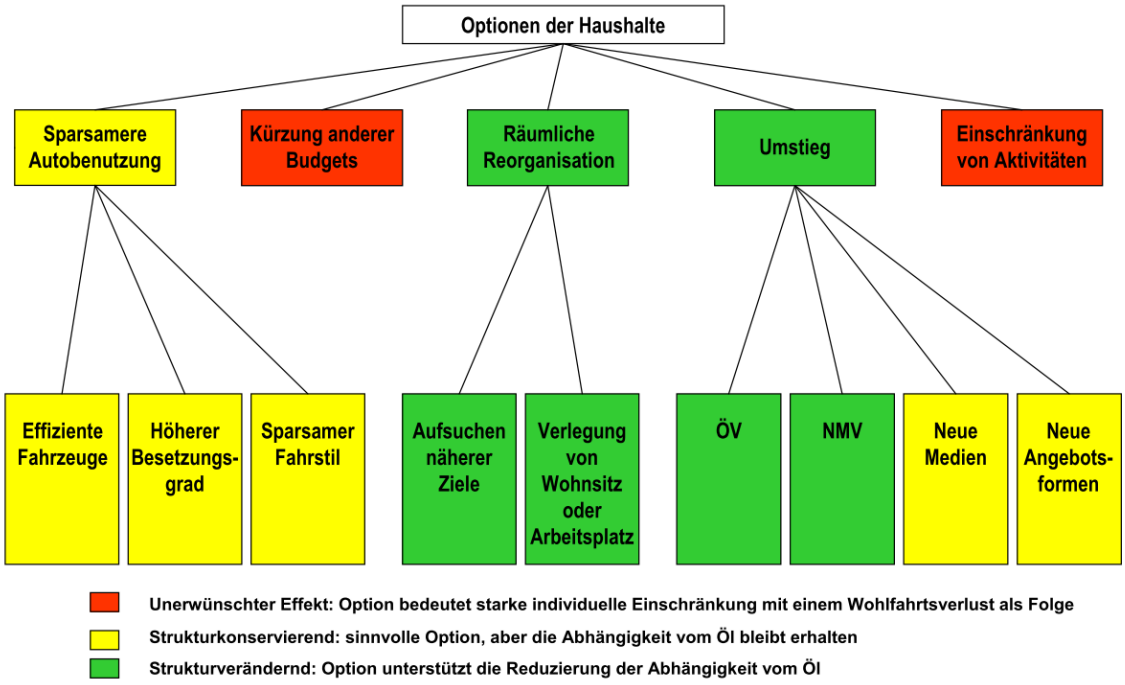

Fig. 3: Mögliche kurz- und langfristige Anpassungsreaktionen auf steigende Energiepreise (Quelle: Gertz et al. 2008)

Gerade bei der räumlichen Reorganisation (Jobwechsel, Umzug) sind die individuellen Entscheidungen von den Wechselwirkungen zwischen Angebot und Nachfrage auf dem Arbeits-, Wohnungs- und Immobilienmarkt abhängig.

Zur Abbildung dieser komplexen Entscheidungen und Wechselwirkungen wird ein integriertes Landnutzungs- und Verkehrsmodell eingesetzt. Im folgenden Abschnitt wird ein Überblick über die Gesamtsimulation gegeben und insbesondere die Teilmodelle des Wohnungs- und Immobilienmarkts vorgestellt. Dabei wird ein Focus auf die Frage gelegt, wie die Prozesse der Reurbanisierung, Innenentwicklung und Gentrifizierung abgebildet werden können und wie eine Wirkungsabschätzung verschiedener Handlungsstrategien von Politik und Planung, die im Planspiel diskutiert werden sollen, erfolgen kann.

3 DAS INTEGRIERTE FLÄCHENNUTZUNGS- UND VERKEHRSMODELL

Intgrierte Flächennutzungs- und Verkehrsmodelle wurden seit den 1970er-Jahren weltweit entwickelt. Einen Überblick über Integrierte Landnutzungs- und Verkehrsmodelle finden sich bei Wegener und Fürst (1998), Torrens (2000) und Wegener (2004). Im deutschsprachigen Raum sind als Anwendungen integrierter Modelle bekannt: Das makroskopische IRPUD-Modell für die Region Dortmund (Wegener 1998) und dessen mikroskopische Weiterentwicklung ILUMASS (Beckmann et al. 2007), das Dresden-Modell (Rümenapp 2004), die Anwendung der mikroskopischen Simulation UrbanSim (Waddell 2002) für die Region Zürich (Löchl 2007) sowie das systemdynamische Modell MARS für die Region Wien/Bratislava (Pfaffenbichler et al. 2007). Eine Diskussion der Vor- und Nachteile makros- und mikroskopischer Modellansätze findet sich bei Wegener (2009).

3.1 Gesamtstruktur des €LAN-Modells

Für €LAN wurde eine im Wesentlichen dynamische, mikroskopische Multi-Agenten-Simulation mit einigen makroskopischen Teilmodellen entwickelt, die mit dem mikroskopischen Steuer-/Transferleistungsmodell FiFoSim (Peichl and Schaefer, 2009) gekoppelt wird.

Das Modell soll Entscheidungen von Haushalten und Betrieben sowie die Entwicklung von Gebäuden und der Flächennutzung in der Metropolregion Hamburg (4.5 Mio Einwohner, 2 Mio Jobs, 1 Mio. Gebäude) von 2010 bis 2035 simulieren.

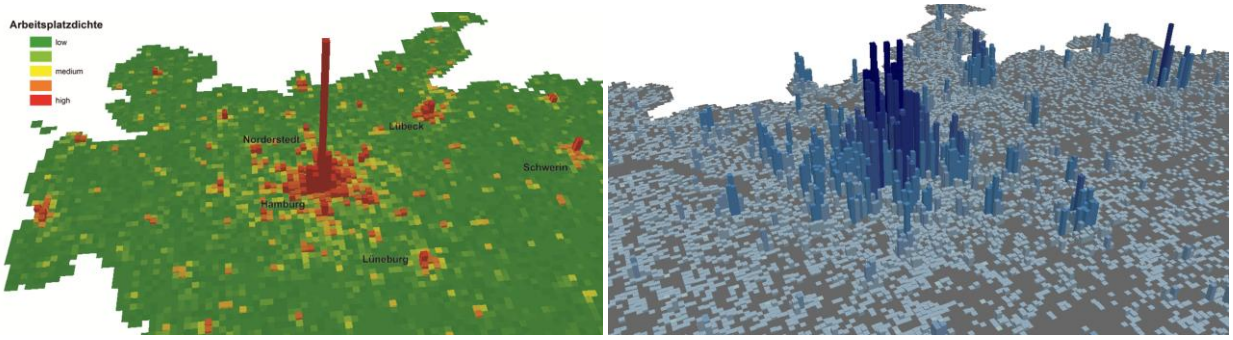

Fig. 4: Arbeitsplätze und Einwohnerdichte in der Region Hamburg

Diese synthetischen Haushalte und Personen, Betriebe und Jobs sowie Gebäude mit Wohnungen und Gewerbeeinheiten wurden auf der Basis verschiedenester Datenquellen generiert (amtl. Statistiken auf Gemeinde/Stadtteilebene, amtliche Geodaten, Mikrogeographische Daten kommerzieller Anbieter generiert und werden weiter mit Hilfe verschiedener Mikrodatensätze (Mikrozensus, Sozio-Ökonomisches Panel SOEP) weiter attributiert. Daten zum Gebäudebestand, die auf der Basis topographischer Karten generiert wurden (Meinel 2008) werden weiter um Informationen zu Sanierungszustand und Energieverbrauch sowie Miet- und Kaufpreisen auf der Basis eines umfangreichen Datensatzes von Immobilien-Angebotsdaten ergänzt.

In jedem Simulationsjahr werden verschiedene Teilmodule durchlaufen, welche die demographischen Prozesse, die Entwicklung von Betrieben und Jobs (Firmographie), den Wohnungs- und Arbeitsmarkt, die Immobilien- und Flächenentwicklung sowie den Verkehr abbilden. Da der Fokus des Modells auf der Simulation der Wirkungen von Preisänderungen auf Standort- und Mobilitätsentscheidungen unterschiedlicher Haushaltstypen liegt, werden die Haushaltsbudgets (Einkünfte, Steuern/Abgaben, Ausgaben für Energie, Mobilität und Wohnen und sonstigen Konsum) abgebildet. Haushalte, deren verfügbares Einkommen nach Abzug von Energie-, Wohn- und Mobilitätskosten sinkt, spüren einen besonderen Handlungsdruck und werden verstärkt Anpassungsreaktionen auf steigende Energiepreise

zeigen. Das Modell FiFoSim ermittelt zudem die Konsequenzen der Trends und möglicher fiskalischer und sozialpolitischer Handlungsoptionen der Planspielakteure auf die öffentlichen Haushalte.

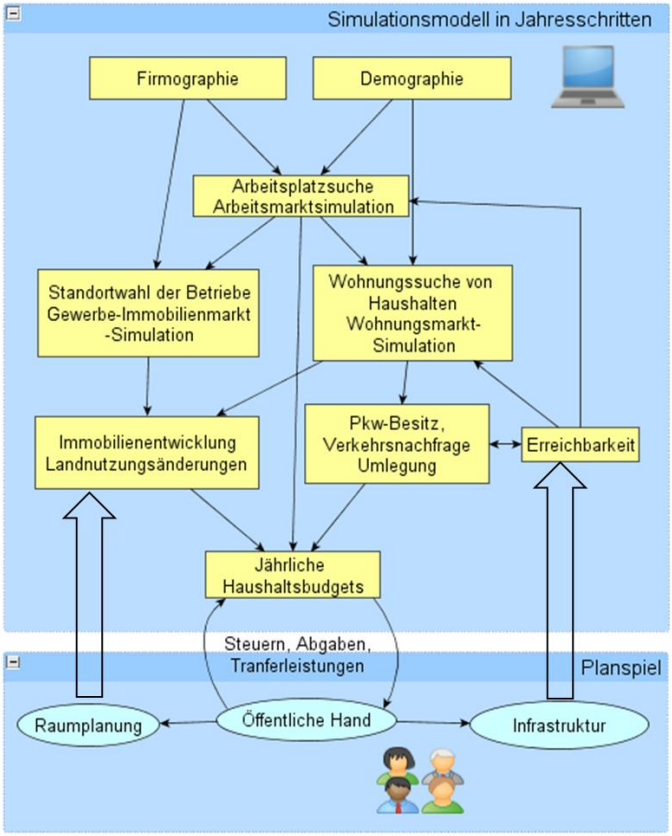

Fig.5: Modellstruktur (Quelle: nach Bohnet/Gertz 2011)

Abbildung 5 zeigt die Gesamtstruktur des Modells. Im Folgenden soll das Arbeitsmarktmodell, das Wohnungsmarktmodell, die Immobilienentwicklung und das Verkehrsmodell abgebildet werden.

3.2 Das Arbeitsmarktmodell

Das Arbeitsmarktmodell bildet das Arbeitsangebot und die Arbeitsnachfrage ab. Zunächst wird ermittelt, welche Personen einen Voll- bzw. Teilzeitjob suchen und welchen Bildungsgrad und Qualifikation sie mitbringen. Diese Modelle wurden empirisch auf der Basis der SOEP-Daten (Wagner et al. 2008) geschätzt. Dabei wird in Abhängigkeit der Erreichbarkeit (Pendelzeiten und -Kosten) für jeden Jobsuchenden simuliert, wo in der Region sie sich auf passende Jobs bewerben.

Die Arbeitsnachfrage ergibt sich aus dem „Firmographie-Modell“, das (Wachstum, Schrumpfung, Fluktuation, Schließungen und Neugründungen, sowie Umzüge von Betrieben abbildet). Bei der Standortwahl neugegründeter und umziehender Firmen spielen je nach Branche unterschiedliche Standortfaktoren eine Rolle (Arbeitkräfteangebot, Flächenverfügbarkeit, Kundennähe, Erreichbarkeit von Infrastruktureinrichtungen, z.B. des Flughafens, s. folgende Abbildung).

Das Arbeitsmodell geht nicht von einem Gleichgewichtszustand aus. Vielmehr ist es eine dynamische Simulation, bei der sich Jobsuchende auf Stellen bewerben und die Betriebe dann den passendsten Bewerber auswählen (Distanzfunktion aus Qualifikation und bisheriger Branche). Erhält ein Bewerber mehrere Jobangebote, so wählt er den mit dem höchsten Lohn abzüglich Pendelkosten. Bewerber können in einer Simulationsperiode keinen Job finden und passen dann ggf. ihre Suchkriterien an (weitere Pendelwege werden in Kauf genommen). Jobs können unbesetzt bleiben, wenn sich keine passenden Bewerber finden. Dies ist bei steigenden Energiepreisen für schlecht erreichbare Gewerbegebiete mit gering entlohnten Jobs zu erwarten, zu denen das Pendeln sich nicht mehr lohnt.

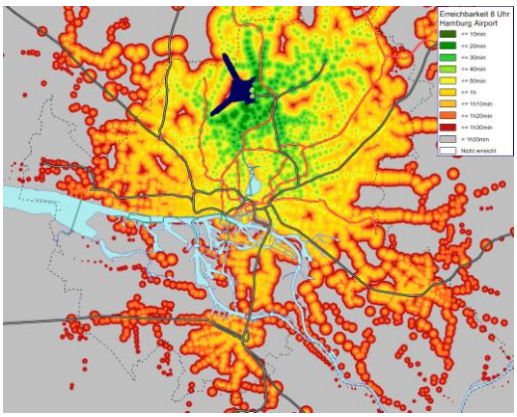

Fig. 6: Erreichbarkeit des Flughafens mit dem ÖPNV

3.3 Das Wohnstandortwahl und Wohnungsmarktmodell

Die Wohnstandortwahl wird als mehrstufiger Prozess abgebildet. Zunächst wird auf Basis der Daten des SOEP ermittelt, welche Haushalte aus welchen Gründen als Nachfrager auf dem Wohnungsmarkt in Erscheinung treten (Matthes 2011, 2012). Neben Wohnungs- und Haushaltsbezogenen Gründen können hierbei auch zu hohe Wohnnebenkosten und Mobilitätsausgaben bei steigenenden Energiepreisen berücksichtigt werden.

Dann wird definiert, welche Art von Wohnung sie suchen (Größe, Haustyp, Eigentumsform, maximaler Kauf/Mietpreis) und wo sie suchen. Der Suchraum wird dabei wesentlich von der Erreichbarkeit des bisherigen Wohnstandorts (als Fokus der sozialen Kontakte), der Arbeitsplätze der Haushaltsmitglieder und der Erreichbarkeit von Infrastruktureinrichtungen bestimmt.

Die Haushalte bewerben sich dann auf passende angebotene Wohnungen im Suchraum, der Vermieter/Verkäufer bietet die Wohnung dann dem Haushalt mit dem höchsten Zahlungsfähigkeit an. Haushalte, denen mehrere Wohnungen angeboten werden, wählen in einer Monte-Carlo-Simulation eine Wohnung auf der Basis einer Nutzenfunktion aus. In die Nutzenfunktion fließen neben dem Preis, den Wohnungseigenschaften auch Eigenschaften des Ortsteils/Stadtteils und der Erreichbarkeiten ein. Wohnungen, die ein Haushalt nicht nimmt, werden dem nächsten Bewerber angeboten. Damit ein (freiwillig umziehender) Haushalt die neue Wohnung wählt, muss der Nutzen der neuen Wohnung den Nutzen der alten Wohnung zuzüglich der Transaktionskosten übertreffen.

Im Jahr 2012 ist eine Befragung von kürzlich umgezogenen Haushalten zu ihren räumlichen und sachlichen Suchkriterien und zu ihren Entscheidungskriterien vorgesehen, um auf dieser Basis unter Zuspielung der Daten nicht gewählter Wohnungen die Modellparameter des Wohnstandortwahlmodells ökonometrisch zu schätzen. Für eine erste Modellversion müssen allerdings zunächst Modellparameter aus anderen Studien (Dittrich-Wesbuer et al. 2008, Vallée et al. 2012, Kühl et al. 2012) „guestimated“ werden.

Haushalte, die in einer Simulationsperiode keine Wohnung gefunden haben, passen im nächsten Monat ihre Suchkriterien an (Preis, Größe oder Lage). Wohnungen, die nicht vergeben werden, stehen leer und werden in der nächsten Simulationsperiode wieder angeboten.

Analog zu den Wohnungen werden auch Büro-, Einzelhandels- und Geberbeflächen an flächensuchende Betriebe vergeben. Die Angebotspreise werden am Ende des Jahres angepasst. In einem Ort/Stadtteil mit hohem Leerstand werden die Angebotspreise gesenkt, bei geringem Leerstand werden sie erhöht. Dabei können vorgeschlagene Maßnahmen der Wohnungspolitik berücksichtigt werden.

3.4 Immobilienentwicklungsmodell

Immobilien altern und entsprechend verschlechtert sich mit den Jahren der Sanierungszustand und die Energieeffizienz. In einem Investitionsmodell wird simuliert, ob die Eigentümer Immobilien (energetisch) sanieren, leerstehende Gebäude abreissen oder Wohn- in Bürofläche oder umgekehrt umwandeln. Dabei wird wie bei der Simaltion der Immobilienpreise die Nachfrage nach den einzelnen Gebäudetypen berücksichtigt, die sich in den Leerstandsquoten im Ort/Stadtteil widerspiegeln.

Bei hoher Nachfrage werden bei verfügbaren Bauflächen im Gebiet neue Immobilien gebaut. Die verfügbaren Bauflächen werden durch die Flächennutzungsplanung gesteuert. Ausgeschlossen sind Flächen,

die durch eine „Negativplanung“ (Flächen für Natur- und Landschaftsschutz, Grünflächen und Verkehrsanlagen für Straßen, Bahn- und Hafen) für eine bauliche Nutzung nicht in Frage kommen. Dabei könnten z.B. in Abhängigkeit der im Planspiel definierten planerischen Strategien Festlegungen zu erlaubten Nutzungsarten und Baudichten definiert werden.

Durch diesen Modellansatz soll der Tatsache Rechnung getragen werden, dass sich ein immer größerer Anteil der Immobilienentwicklung in der Region im Rahmen von Umnutzungen und Nachverdichtungen bestehender Gebiete vollzieht und der Neubau „auf der grünen Wiese“ in den zentralen Bereichen kaum mehr möglich ist. Zudem erlaubt dies auch die Abbildung gemischter städtebaulicher Nutzungen, was in vielen Modellen, die in Nordamerika entwickelt wurden, nicht vorgesehen ist.

3.5 Verkehrsmodell und Erreichbarkeiten

Der Verkehr wird in einem hybriden Mikro-/Makromodell simuliert. Der Wirtschaftsverkehr wird in einem vereinfachten makroskopischen Nachfragemodell als Verkehrsströme zwischen Verkehrsknoten sowie Betrieben verschiedener Branchen abgebildet.

Im Arbeitsmarktmodell wurden schon die Arbeitsorte aller erwerbstätigen Personen lokalisiert. Für die Haushalte wird daher zunächst mit einer mikroskopischen Monte-Carlo-Simulation der Pkw-Besitz und die Verkehrsmittelwahl auf dem Arbeits-/Ausbildungsweg modelliert. Dabei fließt neben Haushaltstyp und dem einkommensabhängigen verfügbaren Mobilitätsbudget die Erreichbarkeit des/der Arbeitsplätze und der Einkaufs- und Freizeitgelegenheiten mit und ohne Pkw als nutzenbasierter Erreichbarkeitsindikator ein (Bohnet 2008, 2010). So kann z.B. konsistent abgebildet werden, dass bei steigenden Energiepreisen ein Pendler auf den ÖPNV umsteigt und der Haushalt ggf. deshalb auch den Zweitwagen abschafft.

Ein ergänzendes Modell zur Wahl des Pkw-Typs und der Antriebsart (Elektromobilität...) ist für eine zweite Stufe des €LAN-Modells vorgesehen.

Die Verkehrsnachfrage (Ziel- und Verkehrsmittelwahl) im Einkaufs-, Erledigungs- und Freizeitverkehr wird dann in einem klassischen makroskopischen Verkehrsmodell berechnet.

Die gesamte Verkehrsnachfrage wird dann auf die Netze des Kfz-Verkehrs und ÖPNV in 4 Zeitscheiben (HVZ morgens, NVZ, HVZ nachmittags, SVZ) umgelegt und so Reisezeiten und -kosten berechnet.

Auf der Basis dieser Reisezeitmatrizen und der simulierten Raumstruktur werden Erreichbarkeitsindikatoren berechnet, die nicht nur mit dem Verkehrsnachfragemodell iterativ rückgekoppelt werden, sondern auch in der nächsten Simulationsperiode in das Wohnungs- und Arbeitsmarktmodell einfließen. So können auch die Wirkungen von Infrastrukturmaßnahmen auf die Raumentwicklung abgebildet werden (z.B. Erreichbarkeitsveränderungen auf den Arbeitsmarkt durch einen neuen Autobahnring).

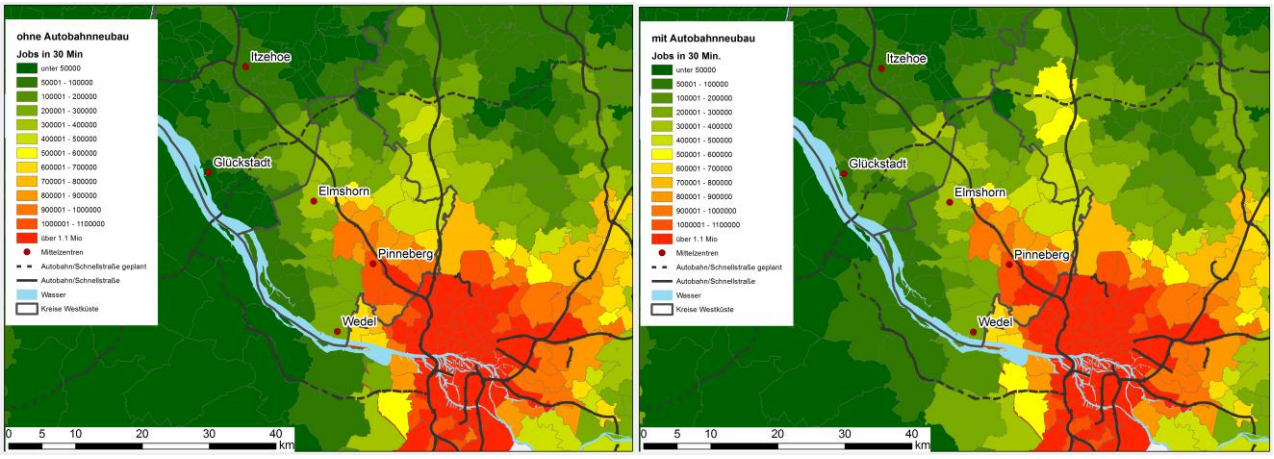

Fig. 7: Wirkungen der geplanten Nord-Umfahrung Hamburg auf die Erreichbarkeit von Arbeitsplätzen in 30 Min. mit dem Pkw (Off-Peak)

4 FAZIT UND AUSBLICK

Mit dem vorgestellten integrierten Flächennutzungs- und Verkehrsmodell für die Metropolregion Hamburg sollen die komplexen Wechselwirkungen zwischen Energiepreisentwicklungen, Raum- und Verkehrsentwicklung abgebildet werden. Das Modell befindet sich zur Zeit in der Entwicklung. Die meisten

benötigten Datengrundlagen wurden aufbereitet, einige Modellbausteine bislang fertig gestellt, andere sind im Stadium der Parameterschätzung. Im 1. Halbjahr 2012 soll das Gesamtmodell dann funktional und im Hinblick auf seine Sensitivität gegenüber Maßnahmen und Trends getestet sowie anhand weiterer Datengrundlagen aus der Region validiert[1] werden, bevor es im Jahr 2013 im Planspiel mit den Praxisakteuren aus der Region eingesetzt wird.

Ziel ist es, zu testen, wie die Resilienz unseres Raum- und Verkehrssystems am Ende des Ölzeitalters bei steigenden Energiepreisen verbessert werden kann. Wir glauben, dass ein Umbau des Verkehrssystems durch eine intensive Förderung der Nahmobilität und des ÖPNV sowie eine Siedlungsentwicklung mit mehr Mischnutzung an integrierten, gut erreichbaren Standorten erforderlich ist, um den Stresstest (Wulfhorst) des Peak Oils zu bestehen. Allerdings gibt es aufgrund der komplexen Wechselwirkungen und Nutzungskonkurrenzen keine einfachen Lösungen, wie sich an der aktuellen Debatte um die Gentrifizierung innerstädtischer Quartiere zeigt.

In einer Policy-Analyse wurden sechs grundsätzliche Politik-Strategien identifiziert, mit steigenden Energiepreisen in den verschiedenen Politikfeldern (Stadtentwicklung, Verkehrspolitik, Fiskalpolitik, Sozialpolitik, Umweltpolitek) umzugehen. Dabei reicht die Spannbreite vom „nichts machen“ über verschiedene Formen des „Gegensubventionierens“ bis hin zu proaktiven Strategien, die Innovationen bei der Energieeffizienz und bei alternativer Energiequellen für Mobilität und Wohnen fördern oder gar einen Strukturumbau weg von einem ölabhängigen Siedlungs- und Verkehrssystem fördern. In folgender Tabelle sind exemplarisch einge ausgewählte Maßnahmen aus den verschiedenen Politikfeldern im Sinne dieser Strategien aufgeführt.

Politikfeld	Grundsätzliche Politikausrichtung				
	„nichts machen“	Gegensubventionieren (I): „Energiesteuern senken“	Gegensubventionieren (II): „Härtefalltarife“	Innovationsoffensive	Strukturumbau
Stadtentwicklung			sozialer Wohnungsbau		Konzentration der künftigen Bautätigkeit auf nichtautoabhängige Standorte
Verkehrspolitik			, Pendlerpauschale	Elektro-Mobilitäts-förderung	ÖV-Ausbau
Fiskalpolitik		Energiesteuer-senkung			
Sozialpolitik			Wohngeld		
Umweltpolitik					verbindliche Dämmstandards

Table 1: Grundsätzliche Politikausrichtung beim Umgang mit steigenden Energiepreisen und ausgewählte Handlungsoptionen nach Politikfeldern

Ein integriertes Flächennutzungs- und Verkehrsmodell, könnte einen Beitrag dazu leisten, diese und andere Lösungsoptionen auf ihre Wirkungen auf verschiedene Bevölkerungsgruppen differenziert zu untersuchen und die politische Debatte, die sich bei stark steigenden Energiepreisen verschärfen wird, zu versachlichen. Bislang ist es allerdings in der Planungspraxis wenig geübt, langfristige Modelle zur Entscheidungsunterstützung einzusetzen. Daher sollen im Planspiel in einem „geschützten Raum“ gemeinsam mit den Akteuren aus Politik und Verwaltung wertvolle Erfahrungen gesammelt werden.

[1] Eine an sich wünschenswerte Modellvalidierung anhand von Modellläufen über die letzten Jahrzehnte, die von unterschiedlichen Phasen schnell steigender und fallender (realer) Ölpreise gekennzeichnet waren, ist aufgrund der Datenlage zur Zeit leider nicht möglich.

Intra-Urban Differentials in Poverty and Livelihoods in Selected Residential Neighbourhoods of Lagos Metropolis

Taibat Lawanson

(Dr Taibat Lawanson, University of Lagos, Nigeria, Department of Urban and Regional Planning, tolawanson@gmail.com)

1 ABSTRACT

This paper critically examines Home Based Enterprises (HBE's) in residential areas of the Lagos Metropolis in order to determine their major characteristics as well as the effects their activities have on Urban Planning.

Data was obtained by the administration of structured questionnaires on HBE owners in buildings with more than one informal economic activity. 929 questionnaires were administered in 5, 18 and 31 low, medium ann high density residential neighbourhoods respectively. 712(76 %) were fully completed and thus fit for analysis. Analysis was by simple descriptive statistics as well as chi square among others.

The research revealed the importance of informal activities, particularly home based enterprises, as a major source of employment, income and services in urban areas. It was discovered that about 45 % of the respondents rely solely on their home enterprises and would otherwise have been destitiute. 29.7 % of respondents earn between N7,500 and N15,000 monthly from their home enterprise. Across the income groups, multiple income earners are prevalent in the family. Also respondents are involved in multiple streams of income with 18.76 % being also employed in the formal sector of the economy.

The paper concludes by suggesting recommendations for harnessing HBEs at minimal cost to the environment. These recommendations include enabling the informal economy, encouragement of collective action and implementing planning reforms as well as embracing pro-poor planning and restructuring the National Poverty Eradication Programme

2 INTRODUCTION

Poverty is an outcome of economic, social and political processes which most often result into the deprivation poor people face. Evidence of this phenomenon is quite common in both urban and rural areas. Though income data is scarce, low social indicators highlighting poor living conditions have existed for decades. While quantitative measurements are difficult to generate, the visual aspects of urban poverty are easy to record and according to Asaju (1996), they include extreme slum conditions, lack of basic services, ill health and malnutrition.

For many low-income households, the dwelling is one of the few resources that they have for generating income and they do this either through passive activities such as renting out rooms or more active home based enterprises (HBEs)(Tipple, 2000). Owners of HBEs have been able to consolidate their dwellings through the income from these micro-enterprises and many households would not have been able to afford their dwellings without the HBEs (Tipple, 2000). HBEs, which form a significant proportion of informal economic activities, are of particular interest to the urban planning professional.

This study investigates the activities of homebased enterprises across residential neighbourhoods of the Lagos Metropolis and the urban planning implications of their activities.

3 OVERVIEW OF THE STUDY AREA

The study is set in the Lagos Metropolis, Lagos State, South Western Nigeria, on the narrow coastal plain of the Bight of Benin. Lagos Metropolis is situated within latitudes 6o 23′N and 6o 41′N and longitudes 2o 42′E and 3o 42′E. It comprises settlements that have grown from predominantly farming and fishing villages to highly urbanized settlements. Lagos Metropolis is bounded in the west by Ojo and Ijanikin, Lekki Peninsula in the east and Ikorodu and Alagbado towns in the north. Water is the most significant topographical feature in Lagos State as water and wetlands cover over 40 % of the total land area within the State.

Lagos is regarded as a mega city, because its population is estimated to be about 12 million people, with a population density of 20,000 persons/sq km (Mabogunje, 2002). Lagos state is on a built-up land area of about 18,558 Hectares made up of about 9,669 hectares (52.1 %). residential, commercial, 1,021 hectares (5.5 %); industrial, 1,448 hectares (7.8 %); institutional and special areas, 2,784 hectares (14 %); transportation 3,340 hectares (18 %), and open spaces 52 hectares (2.8 %). The Lagos metropolis comprises

88.7 % of Lagos State (Lagos State Economic Summit,2001). Based on its high urbanization rates and dense population, the poverty level in the Lagos Metropolis is quite high.

UNDP (2003) estimates that 51 % of men and 54 % of women resident in Lagos live below the poverty line. Lagos is simply the biggest node in the shantytown corridor of 70 million people that stretches from Abidjan to Ibadan: probably the biggest continuous footprint of urban poverty on earth, (Davis, 2006). The urban poor, who are dominant in Lagos, are transforming the city to meet their needs, often in conflict with official laws and plans. They reside in the slums and squatter settlements scattered around the city and are predominantly engaged in informal economic activities which encompass a wide range of small-scale, largely self-employment activities.

Lagos metropolis is stratified into various neighborhoods according to income levels. The income indicators used include some socio-economic characteristics of the neighborhoods, for example, type of accommodation (duplex, bungalow, flat, rooming), quality of buildings (good, dilapidated), monthly income of household etc. The income groups identified include; low income/high density, medium income/medium density and high income/low density.

4 LITERATURE REVIEW

Urban poverty, in particular, has been exacerbated in Nigeria by low levels of social development resulting from corruption, misallocation of funds, poor investment habits, poor family planning habits, minimum wage laws and declining life expectancy. The Human Development Report (2004) rates Nigeria as the 24th poorest country in the world. 70.2 % of the population live below the United Nations Poverty cohort (US$1 per day).

Though many studies have been carried out on urban poverty and the informal sector, most of them have been in socio-economic, cultural and political settings quite different from what obtains in Nigeria. Bartone (1991),from a study of selected towns in the United Kingdom, posited that economic disadvantages usually as a result of unemployment/ underemployment are the root cause of urban poverty and consequently environmental degradation. Buvinic (1997) from studies cutting across Zambia and Bolivia submitted that poverty, especially when feminised, slows global economic growth. Other studies include Eversley (1990), Satterthwaite (1992), Menwhta (2000) and Gardener (2002). Studies on home based enterprises have been carried out in South Africa (Cross et al, 2001, Napier et al, 2005), India (Kellett and Tipple, 2000), Colombia (Gough and Kellett, 2001) and Zambia (Kazimbaya-Senkwe, 2004).

Reasonable research has been carried out on the twin issues of poverty and the informal economy in Nigeria. They include those of Okojie (1987) who did a measurement of poverty among women and their households in Benin City; Ogundele (1997) sought to develop an urban management framework for poverty reduction in Nigeria, while Olanrewaju and Okoko (2000) assessed women organizations and poverty reduction in Akure. Aina (1990) analysed the shantytown economy of Makoko, Lagos and discovered that the informal sector represents both the efforts and the response of low-income urban dwellers to cope with their problems of housing and seeking a livelihood. Other studies include those of Dawson and Oyeyinka (1993), Adeshina (1994), UNDP (2000), Olanrewaju and Okoko (2000), and Afolayan (2006).

These studies have highlighted the fact that poverty is a consequence, not only of the misfortunes and limited capabilities of individuals, but also of the structure and processes that determine the distribution of income. Furthermore the informal economic sector, estimated to employ over 80 % of the working population of Nigerians, provides a wide range of income generating opportunities for those lacking skills or opportunities of entering the formal sector. Participants in the informal sector are unable to separate economic life from such other aspects of social life as culture, religion, kinship and lineage. This necessitates an investigation on the HBEs which is the manifestation of the home as residence and survival mechanism

5 RESEARCH METHODOLOGY

The study population are Home Based Enterprises (HBEs). Small scale businesses located in and adjacent to residential buildings with multiple trade, service and production enterprises were sampled. The population was stratified on the basis of residential neighbourhood density into low, medium and high density residential areas. Administration of questionnaires within each of these subsets was by simple random sampling.

Questionnaires were administered to obtain data on components of poverty and livelihood. Questionnaires were structured to collate information on economic conditions and quality of life; socio-economic and socio-cultural peculiarities, environment and housing conditions.

929 questionnaires were administered in the 16 local government areas that make up the Lagos Metropolis. This comprised of 75 questionnaires in 5 selected low density neighbourhoods; 301 questionnaires in 18 selected medium density neighbourhoods and 553 questionnaires in 31 selected high density residetnial neighbourhoods respectively. Of these figures, 712 (76 %) were fully completed and form the basis of this paper.

Data analysis encompassed univariate analysis using descriptive statistics, bivariate analysis by adoption of the chi square test and multivariate analysis including analysis of variables

6 DATA DISCUSSION

6.1 Spatial Distribution of Household Characteristics of Respondents

The respondents are made up of 51.8 % male and 48.2 % female. Results indicate that most of the respondents are within the working ages of 16 to 45 years, making up 82.5 % of the population. The population is relatively literate based on UNESCO standards, with about 74.6 % having a minimum of secondary school education. 19.5 % of low income respondents have only primary school education, compared to 15.6 % of middle income respondents and 9.5 % of high income respondents. Only 8 % of the population has no formal education.

Average household size is 4-6 for the entire households sampled. Household size of more than 10 occurs more among the low income class (14) compared to the high income (1). The study also revealed that over 60 % of the respondents are migrants to Lagos, who have lived in their neighbourhoods for more than 10years. The major consideration for choosing the specific neighbourhoods is that it is profitable for business and that the average rent is relatively affordable.

Table 1: Socio-Economic Characteristics of Respondents

The relationships between income levels and household characteristics are further corroborated by chi-square tests as displayed in Table 2. The table shows that there are no significant differences in the gender distribution of the respondents. However there are significant differences in the levels of educational

attainment, household size and age with significance level of 0.000. It can therefore be concluded that the household grouping of respondents is a function of the educational attainment, household size and age.

Pearson Chi Square	*Chi Square Value*	*Degree of Freedom*	*Level of Significance*	*Comment*
Gender	558.384	1	.374	Not Significant
Age	.789	4	.000	Significant
Highest Level of Education Attained	224.816	3	.000	Significant
Household Size	384.758	3	.000	Significant

Table2: Chi Square test for Household characteristics and income classification of Respondents

6.2 Spatial Distribution of Income and Assest Ownership of Respondents.

It was discovered that about 45 % of the respondents rely solely on their home enterprises. 29.7 % of respondents earn between N7,500 - N15,000 monthly from their home enterprise, while 21.1 % earn below the national minimum wage of N7,500. This set of people automatically fall under the absolute poor category and their HBEs are subsistence enterprises. Across the income categories, multiple income earners are prevalent in the family. Also respondents are involved in multiple streams of income with 18.76 % being involved in formal employment. Other sources of income include income from abroad and returns from thrift/ cooperative collaborations.

Table 4: Analysis of Variance test for Income Distribution of Respondents

6.3 Spatial Distribution of Employment of Respondents

Only about 19 % of the respondents are employed in the formal sector. Of these, 7.7 % work with the government, while the others are employed in private companies. Over half of the respondents are involved in informal trade activities. These range from petty trading to hawking, selling of cooked food, raw farm produce and other minor household items. Informal service sector accounts for 38 % of the respondents. These activities include hairdressing and barbing, tailoring, secretarial services, horology, sign writing, photography and auto repair services. Informal manufacturing is done by 7 % of the respondents and includes cobbling, production of sachet water and packed food, nylon production, crafts, carpentry and metal works.

Table 5 shows that more than 70 % of the businesses are sole proprietorships. Source of funding for most of the businesses is a combination of savings, thrift and cooperative loans. Only 45 % of the respondents claim to have registered their businesses with any government body, with about 26 % operating with local government trade permits.

Majority of the enterprises employ between one and four apprentices. Only 17 % of the businesses have more than five staff. Business location is usually rented shops for about 65 % of the respondents, with about 15 % of them operating along the street. About 9 % use part of their living quarters for their enterprise. More than 90 % of the respondents live within the vicinity of their businesses. i.e. less than 2 km

While 81 % of the respondents are wholly engaged in the informal economy, 7.7 % hold government jobs while 11.09 % are privately employed. About half of the respondents are engaged in the informal trade sector. 38 % offer services while manufacturing only accounts for about 7 %. This disparity may be due to the fact that skills are required for services and manufacturing. They are also relatively capital intensive since one will need to purchase equipment and plants to operate in the subsector.

Over 80 % of the respondents run kinship based enterprises in which the ownership of the business lies with them and/or members of their families. Average staff strength is 2. About 35 % of the businesses are run by single individuals, while 43 % have paid employees or apprentices of between one and three. Only 17 % employ more than three workers. Unpaid family workers make up about 8 % of the staff strength.

About 65 % of the businesses are located in rented shops while 10 % use part of their living quarters as commercial entities. 28 % of respondents engage in their commercial activities outdoors. 27 % of respondents in the high income areas use open sheds while none are located on the street. This may be because high income areas are usually planned and any disruption to the aesthetics and harmony of the environment are frowned on. 25 % of respondents in the middle income area and 14 % of those in the low income area operate on street premises. It was also discovered that about 97 % of the respondents live within the neighbourhoods of their businesses, 80 % reside less than 1km from their businesses.

Business registration status is weak as more than 50 % of the businesses have no form of registration with appropriate authorities. About 26 % have local government trade permit; while only 10 % of the respondents have registered their businesses with the Corporate Affairs Commission. However, it was discovered that all the respondents pay daily service charges to itinerant agents of the local government.

Sources of funding for business are multiple with the predominant ones being savings, thrift and cooperative loan. The reliance on bank loan occurs for less than 1 % of respondents and this may be attributed to the fact that most HBEs lack legal status and so are unable to access credit from the formal financial sector.

Table 5: Spatial Distribution of Employment

The relationships between income levels and informal employment characteristics are further corroborated by chi-square tests as displayed in Table 6. The table shows that there are significant differences in the categories of informal activities engaged, nature of business and type of business registration as well as staff strength.

Pearson Chi Square	***Chi Square Value***	***Degree of Freedom***	***Level of Significance***	***Comment***
Category of Informal Sector	3.365	4	.499	Significant
Nature of Business	22.567	8	.004	Significant
Business Registration	16.171	8	.040	Significant
Source of Business Funding	26.476	10	.003	Significant
Staff Strength	11.931	6	.064	Significant

Table 6: Chi Square test for Informal Employment characteristics and income classification of Respondents

6.4 Determining the Spatial Pattern of Informal Activities in the Study area

To determine the spatial pattern of home based enterprises in the study area, Hypothesis 1 is tested. It states that

H0: Home based enterprises are not evenly distributed within the study area

H1: Home based enterprises are evenly distributed within the study area

The Nearest Neighbour Analysis was used to determine the pattern of distribution of home enterprises in the study area.

The formulae for the Nearest neighbour analysis is as follows Rn = $2\bar{d}\sqrt{\frac{n}{A}}$

Where Rn = Nearest neighbour Index

A = Size of the Area Concerned

$\bar{d}$ = Mean Distance between Points

n = Number of Points

The base map of the study area was generated and the coordinates for all the points where questionnaire administration occurred were imputed. Out of the 712 points located, midpoints of every cluster were identified and polygons generated to determine the distance from the nearest neighbour.

Using the formulae above, the following values were obtained

A = 402637675.457 sq m

$\bar{d}$ = 1134.086 m

n = 101

On computation , the value obtained for Rn = 0.99332.

Rn values range from zero to 2.15. Rn values of between +1.5 and 2.15 signify a significant element of regularity. Significant element of clustering is signified when the Rn value is between 0 and 0.5. Values in between these figures point to a random distribution of identified phenomenon. With Rn value of 0.919, it means that there is no regular pattern to spatial distribution of home enterprises within the study area.

Casual observation corroborates this statistics as the phenomenon was prevalent across the three residential densities in no clear pattern. Clusters of specific trades and services were identified across the neighbourhoods and some clusters had concentration of more than one prevalent HBE.

7 POLICY ISSUES AND RECOMMENDATIONS

The research revealed the ubiquitousness of informal economic activities, particularly home based enterprises, as a major source of employment and income in urban areas. HBEs have provided means of survival to many who would otherwise have been unemployed otherwise. Many have improved their

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

capabilities and incomes. This suggests that it is possible for home based economic activities to be the launch pad for upward economic mobility especially for the absolute poor.

The prospects for reducing urban poverty in developing countries depend critically on the overall economic performance of these home based enterprises and indeed the informal sector as it employs a preponderant percentage of the working population. With the requisite support from appropriate authorities, poverty and low capacity for enterprise can be mitigated significantly.

The major policy implications from the findings of this research are therefore outlined as follows:

(1) Enable the Informal Economy

(2) Encourage Collective Action for Informal Enterpreneurs

(3) Articulate the National Poverty Alleviation Policy and Restructure the National Poverty Eradication Programme

7.1 Enabling the Informal Economy

The Informal Economic Sector should be recognized economically as a viable and legitimate means of sustenance. Support for the sector can include creating a new scale for the registration of such enterprises with the Corporate Affairs Commission. This scale must have fewer conditions attached to it and a more flexible regime for operations. Enabling the informal economy will give the practitioners access to credit and thus many will be able to grow from subsistence enterprises to growth enterprises. This will also benefit the government because, according the informal sector legal status renders returns from informal activities taxable.

From the results of the survey, it is evident that entrepreneurs in the informal sector frequently face the problem of acquiring suitable premises and sites for their commercial activities. In addition, restrictive policies of local municipal authorities and planning agencies regarding location amounts to harassment and on other occasions leads to fire hazards, public health hazard and traffic congestion. At other times, there is a lack of basic services - roads, drainage, water, etc. In this connection, especially for the trading sub-sector, efforts could be made to set up small market areas in existing neighbourhoods for the manufacturing and servicing sub-sectors, workshop clusters and light industrial estates located at strategic points in the city can be developed. The advantage of this approach is that firms could be provided with adequate infrastructural facilities, paid for by the artisans in easy instalments and this would also reduce the threat of eviction that most informal sector operators experience and which has an adverse impact on their production and quality of life. Furthermore, the environmental impact of their activities will be better monitored as certain standards will be required such as types and materials of kiosks, sphere of influence and even quality control of their outputs.

7.2 Encouraging Collective Action for Informal Enterpreneurs

The study revealed the importance of their cooperative societies as lenders and protective cover for the HBEs. Collective action and organizational membership have a positive influence on productivity. This calls for government support to relevant collective actions.

Collective action has to be carried out at different levels. At local level, collective action should take the form of cooperatives or associations to increase bargaining power in economic terms and in political participation, and thus to obtain better services which in turn facilitate market access and increase productivity as well as protection. At national level, policies have to be promoted in favour of the sector – from infrastructure to credit, industrial and trade policies.

Cooperatives must have better organization and self-regulation to be able to engage more constructively with government and other development partners, and to increase their power to lobby, negotiate, and influence public policy in favour of their sector. They could pool resources through clustering and other ways of cooperating that foster mutual support to help their businesses grow and mature. They will be better organized and able to access credit from formal financial channels.

Collectively they must curb some of the socially unacceptable strategies that tend to discredit them, such as adulteration, crime, and other sharp practices, and confine themselves to genuine activities for livelihoods.

7.3 Articulating and Implementing the National Poverty Alleviation Policy

The National Poverty Eradication Council must, without delay form the National Poverty Alleviation Policy. This policy must set forth strategies aimed at promoting a high and sustainable rate of economic expansion and job creation through programmes aimed at evolving an enabling environment for poverty alleviation; providing basic infrastructure necessary for the growth of the informal sector; expanding opportunities for the poor to engage in gainful economic activity by widening their access to land, credit and other factors of production; channeling the benefits from increased participation in the world economy towards the poor segments of the society through policies promoting the expansion of labor intensive exports such as agriculture, and a reduction of trade restrictions on consumer goods.

The blue print of the National Poverty Eradication Programme must also be modified and implemented without political interference. Emphasis should shift from ad-hoc measures to developing programmes that will bring about sustainable improvements in the quality of life of majority of the population. Vulnerable groups must be given special concessions such as reduced interest rates for loans for women and identified absolute poor. Those informal entrepreneurs that show innovation and ingenuity must be encouraged through the patenting of their products and legislation that insisits that at least 40 % of government supplies must done by these local merchants.

8 CONCLUSION

Effective urban poverty control can only be actualized through the application of a pragmatic approach involving civic reorientation, urban redevelopment and the entrenchment of a result-oriented system of urban management.

Pro poor planning is a marriage of Community Development and Urban Economic Development. Communities suffering economic insufficiency, stagnation or decline often seek remedies for these shortcomings through strategic economic development planning. Such activity aims to amass within communities and regions the resources needed to insure employment opportunity, to supply necessary public and private goods and services, and thereby to sustain or improve the quality of life

For the future, Pro-poor Planning Strategies must be adopted for the planning of cities and new towns. Physical planning of the city must be placed at the service of the fight against poverty, creating a facilitating environment for the development of informal activities, by delineating certain areas as market areas within residential neighbourhoods, encouraging mixed use development and making provision for light industrial areas to serve cottage industries

This study had discovered that home based enterprises, apart from having a positive effect on average household income also have a positive economic impact on the general welfare of the local neighbourhood. If, in the attempt to improve the housing environment, livelihoods are destroyed through inappropriate attitudes towards home based enterprises, then sustainable livelihoods and indeed sustainable development remain a mirage. On the other hand, if improvement policies assist the viability of HBEs, and accept them as a component in the quality of life in a neighborhood, then settlement improvement and poverty mitigation will be a reality. The resulting economic and environmental dynamics will then help to reduce the unemployment and misery of urban areas.

(Ayub Nalbandi Bukani, Member of Architecture Scientific Association, Faculty of Architecture,Tabriz Branch,Islamic Azad University,Tabriz, Iran)

1 ABSTRACT

This paper introduces and focuses on an Iranian architectural element which has been designed to have the solutions of human comfort and use and save natural energies. A free and smart element which like a layer in front of the main body of buildings apears and prevents the direct sunshine to the building and like a cover creates shadow and a cool atmosphere in front of the main building and by this way, it has been as the creator of sustainability in Iranian architecture. First of all we will have an introduction and history of this Iranian invention and then we will focus on its climatical values and then its effects on architecture of old houses in Iran.

2 ARCHITECTURE AND SUSTAINABLE ENERGIES

Sustainability and the ways of uses of natural and renewable energies, is one of the most important cases which should be paid attention alot. Houses are one of the main consumers of energy in urban scale which paying attention to their details and the correct ways of their architectural design, can reduce the nonrenewable energy uses and increase the natural energy uses and sustainability. In fact, architecture and a fine design can save energies and human and the correct way of uses of energies can save architecture and human again.

3 IVAN

Before coming to the architectural details of Ivan and its relationship with energy, we will have some descriptions of what the Ivan is in different definitions. In some traditional believes, Ivan is an element to separate the outside and inside of a place or atmosphere [1]. In an other definition, it is like a space infront of a building with some columns [2]. In fact, it is an element to create shadow and was used as a tool to make connection between the house itself and natural atmosphere of outside [Fig.1].

Fig. 1: Ivan, an element of Iranian architecture infront of an old house

It should say that Ivan was not just used as an element of houses. It was also used for some other public traditional and religious buildings of Iran such as mosques or even for some govermental buildings such as palaces, but as its main sustainable effect was shown on houses, this research is focusing on houses and their sustainable potentials. As the history and the researches show, Ivan is an Iranian invention which was used in this country from their ancient kingdoms such as Achamedian and Ashkanian [3], but the main uses of this element in the houses started in Iran in Safavi and Qajar period.

As the main land of Iran includes the hot and dry region, So it was necessary to create some things to provide the coolness and prohibit the hot weather and it has some columns and also it was usually decored by some Iranian decorative organs [Fig.2].

Fig. 2: Ivan, with decorative organs and columns

4 IVAN, ARCHITECTURE AND SUSTAINABILITY

During focusing on sustainablity details of Ivan, we should pay attention to both beauty and functional aspects of it too. Ivan was used as a lateral architectural instrument to increase the beauty of the building, but the main use of that was its functional aspect and its sustainability creating. The South side of houses need to have enough natural light as the living room of Iranian old houses called "Tanabi" is usually designed in this side but in some parts of this hot country this sunshine and natural light can cause some problems and if there is no shell in front of this hot side of houses, inside of houses will be so hot. So, we need to save the natural South light without making inside so hot too [Fig.3].

Fig. 3: The beauty and functional aspects of Ivan

Making somewhere cool or hot needs energy, and this energy should be provided. Iranian traditional architects had tried to use natural energies in their most designs and by this way, they were making a house

or any other building sustainable. Ivan, like a shell in front of the houses, with its climatic effect, creates an environmental conditions and a spatial variety. When it`s in front of a building, as it is not like a rough wall with some simple windows, it invites the natural lights inside as much as it`s possible and by creating the shadow makes the main body of building and also the meddle space cool [Fig. 4].

Fig. 4: Ivan and the meddle space between it and the main body of the building

By designing and using this element, with out burning fossil and nonrenewable energies, Ivan uses natural energies and creates shadow and makes the house cool with out decreasing the light inside.

5 CONCLUSION

Having two or even more benefits together beside each other makes the architectural design process hard, but Ivan makes this request easy. It makes the Iranian old house beautiful, it causes to have the natural light inside and also by using the natural energies and making the building cool causes the sustainablity for Iranian old houses and this traditional element can be used as a pattern for today and also future architectural design to save the energy sources.

Key Impacts of Economic Integration of Kazakhstan on Spatial Development of Its Settlements

Madina Junussova

(Madina Junussova, Candidate of Architecture, Design Institute Kazgiproprad-1 LLC, Gogol str. 84 A, office 104, 050000 Almaty, Kazakhstan, mcny@rambler.ru)

1 ABSTRACT

This paper aims to show any specific impacts of economic integration of Kazakhstan on its border settlements. Addressing this issue is certainly indicated in view of the potential development of the Eurasian Economic Community (EurAsEC). Over the last few years the EurAsEC member countries have decided on the formation of a Customs Union and a Single Transport Space as parts of the future establishment of a "common economic space" - a single market for goods, investment, and labour.

Economic integration of Kazakhstan might change the distribution of available resources (especially cross-border natural resources) within a country as well as between neighbouring countries, which has positive as well as negative impacts on the development of border settlements.

The positive impact of integration is linked to better access to foreign demand, market potential and development of cross-border network infrastructure. However most of the settlements are still based on an industrial economy of raw-materials and current economic development trends are too remote from being able to satisfy world demands of hi-tech goods. Thus it is difficult to assess which urban and rural market areas of the country could benefit from the Eurasian integration.

The task of planners is to prepare basic spatial models for all settlements' benefits, taking into account key impacts of economic integration.

2 RELEVANCE OF THE STUDY TO THE CONFERENCE THEME

What functions will settlements carry out? How will they depend on external factors like world economic crisis and demographic changes? How can Kazakh modern cities and villages respond better to economic integration processes? How could intensification of exchange of international goods and information, as well as a rise of human mobility due to development of international communication, transport and logistic systems shape our urban and rural areas in the future?

All the answers to the above questions cannot be given at a single city scale. As professional planners we should stop thinking only about "urbanism" or "how to make cities more comprehensive", but try to consider new possibilities of how cities can share their potential and energy with other neighbouring living environments, for example less developed medium-size cities, small towns and villages. This is especially relevant, when building an open economy that affects directy weak urban and rural areas in some developing countries like Kazakhstan which are already losing their economically active population.

The idea of presenting this paper within the framework of the CORP2012 topic named "RE-MIXING the city" is to attract the attention of planners to specific regions comprising new kinds of living areas where functions are remixing at the scale of urban and rural networks.

3 CONCEPTUAL FRAMEWORK

3.1 Introduction to the case study

In the light of the current interdependence between local and global markets, building a competitive urban systems based on the economy of settlements should be a considerable issue at all levels of planning in Kazakhstan.

It is obvious that our living settlements are becoming increasingly sensitive to global trading trends. The 2008 financial crisis, which translated into a global economic crisis, impacted on trade and stopped capital from flowing into some developing countries like Kazakhstan (fig.1). With oil prices dropping, Kazakhstan faced a fall in the value of the exports of its raw materials' from $76.4 billion in 2008 to $48.2 billion in 2009.

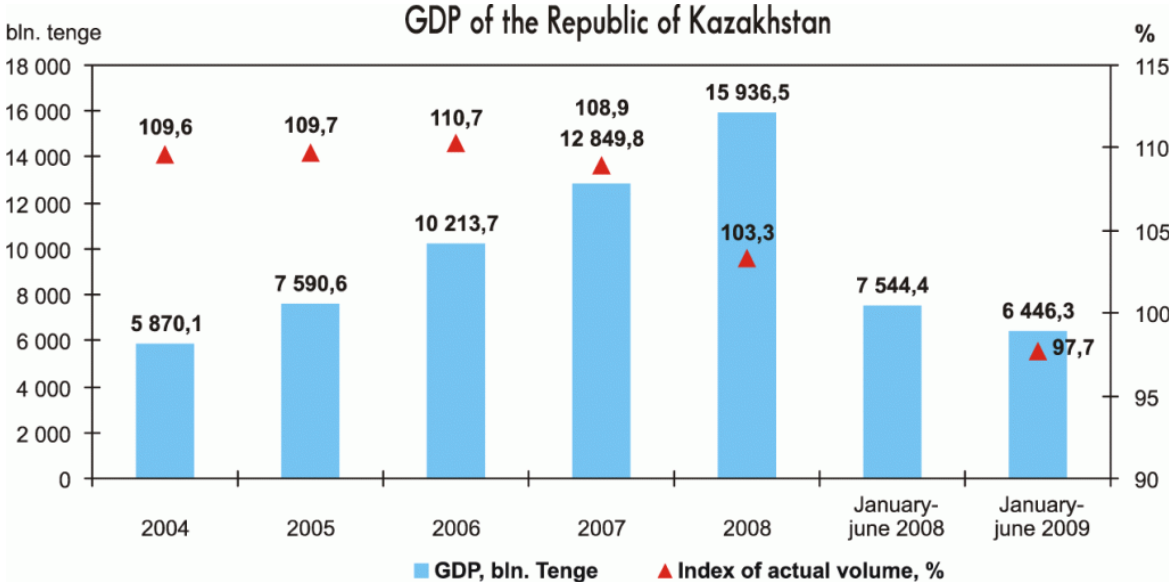

Fig. 1: GPD of the Republic of Kazakhstan.

At the same time, trade relations have become more intense and far-reaching, incorporating areas such as service trade, foreign investment, intellectual property and regulatory regimes. These tendencies are a clear reflection of the growing integration of the world economy and the "internationalisation" of policies that were once considered domestic.

In this regard the government of Kazakhstan is pushing actively a course of integration of the country into global economic processes. Accession to the World Trade Organisation (WTO) has always been and remains a foreign policy priority for Kazakhstan. Kazakhstan has also worked intensely to create a Customs Union, which is viewed as a practical realisation of the idea held by the President of Kazakhstan of economic integration of Eurasian countries similar to the European Union announced by him in the mid-1990s.

All above mentioned facts have resulted in the project named "Assessment of the Influence of Current Economic Integration on Urban and Rural Areas and Their Production Systems of the Republic of Kazakhstan" in the framework of the development of the General Strategy of Spatial Organisation of Kazakhstan. The implementation of this project is presented in this paper.

3.2 Methodological approach

Owing to a shortage of time for the project development and lack of funding for field surveys, our team of experts developed its own methodological approach that helped to concentrate our attention on only key links between external and internal forces of production.

Main technological scheme

The main technological scheme (fig.2) illustrates our general methodological approach to the assessment of the key impacts of the economic integration on urban and rural areas of Kazakhstan.

The first scheme, like the other methodological models, is presented in a geometric form of a circle which helps to strengthen multi-dimensional effects from an outward economic influence on the territorially closed "urban and rural areas and their production systems", located right in the centre of the figure.

The outer grey circle aims to show "main world demand trends" taking into account integration steps already undertaken by Kazakhstan with its neighbouring states in the framework of the Eurasian Economic Community (EurAsEC). Trade and transit potential, as significant world economic tendencies, are also highlighted within the grey circle, where attention is paid to future development of EurAsEC via the establishment of a "Custom Union and Single Transport Space".

Externally impacting key factors of world demands are then compared with current economic development tendencies of the regions, with particular attention to the valuable roles of logistic and transport systems which are physically linking up the living and working environments of urban areas.

Three main levels of economic integration - "spatial", "territorial" and "regional" - are artificially included in the parts of the chart which shows the "current economic tendencies" and the "urban and rural areas and their production system". This was done due to their importance in the development of recommendations and proposals towards building functional linkages between regional urban and rural systems and the world market, following the assessment.

Moreover all proposed recommendations are grouped into three main trends, represented as blue rectangles and placed in the outer grey circle of world trends that offer potential capacities for the domestic production systems to be competitive in the global market.

The first group of proposals named "development of service and trade in services" is concentrated around recommendations of strategic steps for sustainable regional integration, with the help of systematic development of trade potential and spatial integration in response to main trends of world demand.

The second group of proposals is oriented towards "development of export of high quality goods". They take the form of strategic actions aiming at sustainable territorial integration which relies on transit potential, as well as on spatial integration processes.

The most important programmed strategic activities on regional integration and territorial integration form part of the third group of proposals called "cross-border cooperation", where the key role is given to border settlements of Kazakhstan.

Further conceptual models represent the development of the key ideas included in the main technological chart in detail.

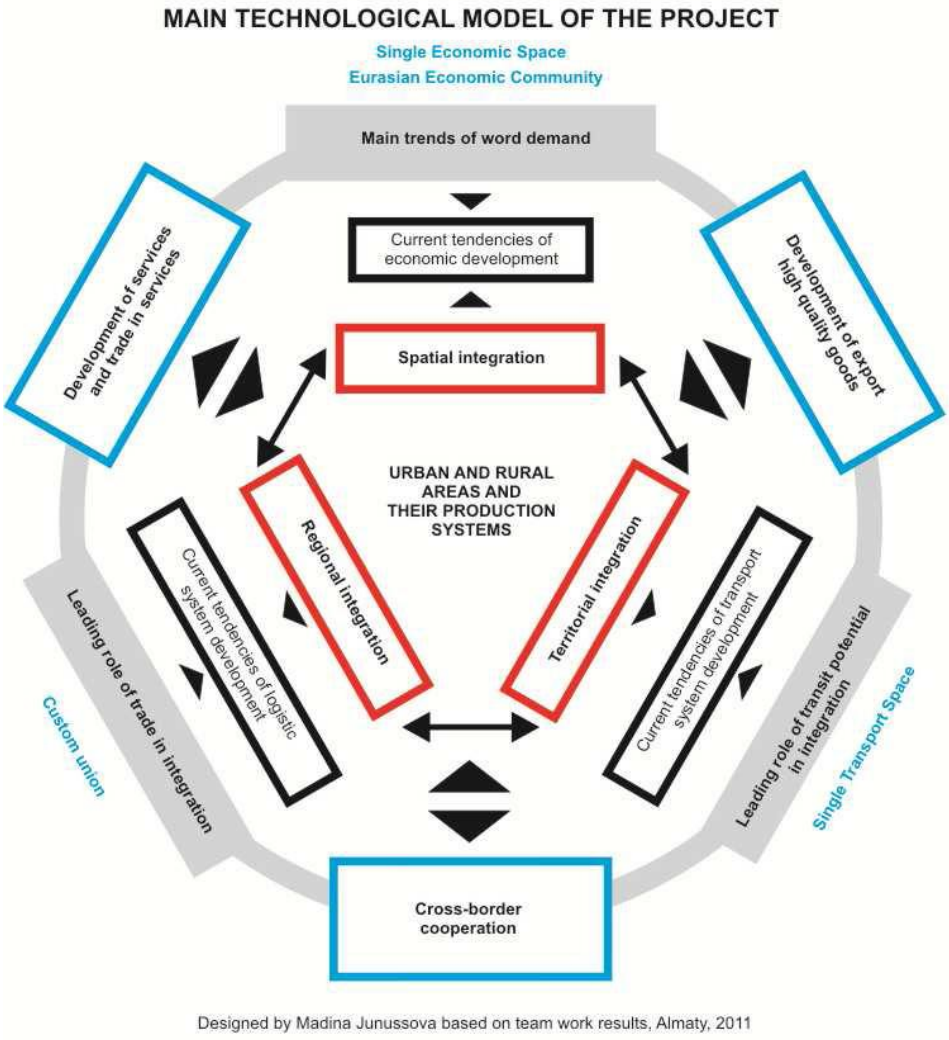

Fig. 2: Main technological scheme of the project.

Conceptual Model of Projection of World Demand

The first conceptual model (fig.3) displaying projection of the "main world demand trends" based on "current economic tendencies" was developed by researching and selecting relevant comparable indicators which illustrate external and internal trends that could be used to highlight key impacts of economic integration on production components of urban and rural areas.

An example is the confrontation between the world trend of "increasing demand for new, higher quality energy- and resource- efficient products and the current domestic trend of "insignificant growth of the service sector as opposed to the rise of production in the sectors of industry and agriculture". This study was using external market indicators from open sources, such as WTO, EurAsEC and CU databases and compared them with internal market indicators extrapolated from data of the State Agency on Statistics and databases of local regional administration.

On the one hand the results of the above mentioned analysis make it possible to identify the level of sensitivity of each specified region of Kazakhstan to the impact of economic integration. On the other hand the results could serve as a good foundation for the development of recommendations for further research needed to be carried out on these issues within the framework of the long-term project of A General Strategy of Spatial Organisation of Kazakhstan.

In addition, this model is also designed to uncover potential negative effects of spatial integration, such as increasing functional pressure on the transformation of large cities, in particular their continuous growth and territorial expansion. These processes immediately cause segregation and degradation of smaller towns and other settlements that would not be able to obtain any profit from external economic demand, due to their small sizes, isolated locations and low functional and technological capacities.

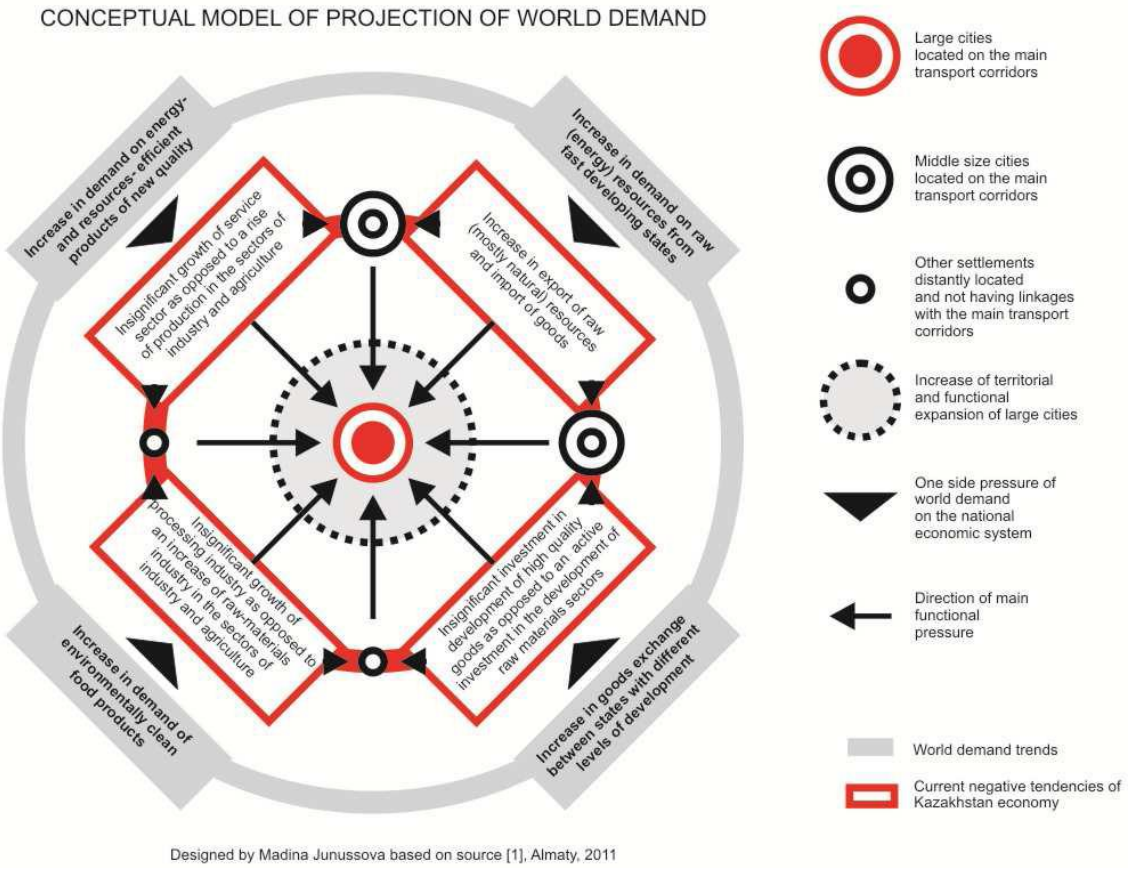

Fig. 3: Conceptual model of projection of world demand.

Conceptual Model of Separation of Key World Trends

The second conceptual model (fig.4) is designed to identify key world trends in line with competitive advantages of Kazakhstan based on its unique geopolitic situation in the heart of the Eurasian continent. These key world trends could be used to transform current negative economic tendencies into positive ones, based on a programmed investment orientation aimed at sustainable development of "territorial systems of

settlements" in Kazakhstan (the term used for the description of interlinked urban and rural areas in the project).

The formation of domestic trading potentials should be based on the development of logistic agricultural and industrial production sectors connected with programmed arrangements of territorial systems of settlements, whereby some functions of large cities are delegated to middle size cities located on the main transport corridors.

The development of such a transit potential is realised through the establishment of a multi-modal transport system which provides better travel conditions for passengers, together with the transfer of other material resources, in accordance with programmed arrangements of territorial systems of settlements, whereby some activities taking place in large cities are transmitted to remotely located medium size and small settlements.

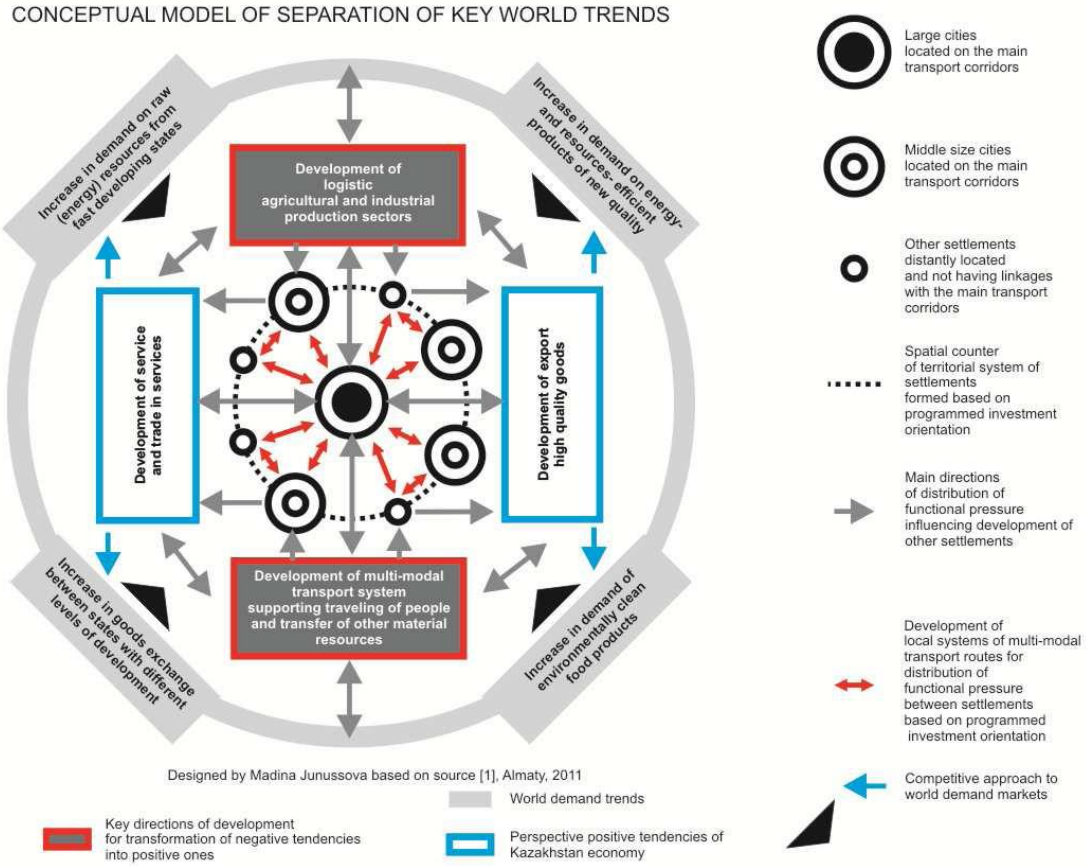

Fig. 4: Conceptual model of separation of key world trends.

4 ECONOMIC INTEGRATION: CURRENT TENDENCIES – WORLD TRENDS – KEY POTENTIALS

4.1 Current Economic Tendencies of Development in Kazakhstan

Kazakhstan keeps staying in a position of key supplier of the world markets with a large amount of raw and precious natural resources. Conversely, the analysis of economic change Kazakhstan shows that during the last 5 years its proportion of GDP indicates an insufficient development of its service sector (fig.5).

Although the country is continuosly investing in its infrastructure its economy remains heavily reliant on natural resources. The production of mining still repesents a donimating sector, with the biggest part belonging to the production of fuel and natural energy resources, particularly the production of crude mineral oil and accompanying gas (fig.6).

Since 2005 the government of Kazakhstan has initiated several state programmes focused on stimulating the innovative economy. The Territorial Development Strategy of the Republic of Kazakhstan to 2015 (adopted in 2006) was one of the first documents with a long term state planning vision taking into account interdependence of local settlements and world market economies (fig.7). However its main planning goal continued to attribute the main advantages to the large cities and the transport routes of national importance

as the main centres and backbone of its spatial economic development strategy with almost no chances for other settlements to participate. According to the Government (Strategic Plan 2020) future industries also should primarily be established in the countries main urban centres, such as Almaty (largest city of Kazakhstan with population about 1.5 million) and Astana (capital of the country), which already benefit from a competitive economy, enjoying separate state budgets, highly skilled human resources and having very attractive work and living places.

Fig. 5: Structure of GPD of the Republic of Kazakhstan.

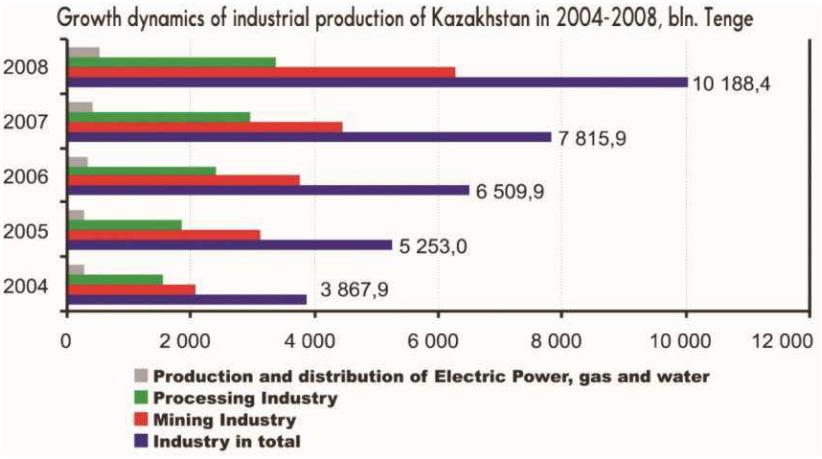

Fig. 6: Growth dynamics of industrial production of Kazakhstan in 2004-2008.

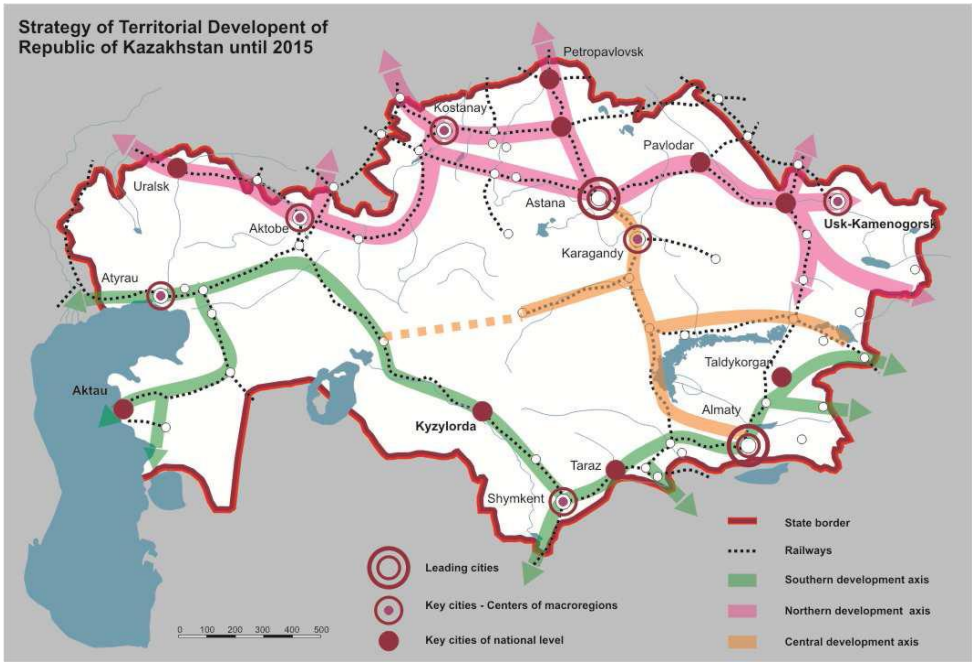

Fig. 7: The backbone centres and development axises of strategic territorial development of Kazakhstan until 2015.

The 2008 Territorial Development Strategy was followed by regional territorial development strategies till 2015, including separate strategies for Almaty and Astana. Only few such regional strategies, like those for the Almaty and Mangystau Regions, considered any impact of the external market forces on the local settlements economies.

Taking into account all the above mentioned currently dominant directions of the development of the state economy, the project team of experts carried out a detailed survey on current economic tendencies of all Kazakhstan's regions, with special attention to urban and rural border areas. This survey resulted in the selection of four main groups of negative trends, namely:

- Insignificant growth of the service sector as opposed to a rise of production in the sectors of industry and agriculture;
- Insignificant growth of processing industry as opposed to an increase of the raw-materials industry in the sectors of industry and agriculture;
- Increase in export of raw (mostly natural) resources and import of goods;
- Insignificant investment in the development of high quality goods as opposed to active investment in the development of raw materials sectors.

4.2 Main World Trends and Kazakhstan Integration Perspectives

The historic formation and development of urban areas of Kazakhstan have a straight link with the establishment of its modern state borders. Owing to this fact more than 80% of Kazakhstan's current population is living within border areas. Almost all transport links are concentrated within border regions widely used as the main international transit corridors serving international trade functions:

- Northern Corridor of Trans-Asian Railway Main (TARM): Western Europe – China, Korean Peninsula and Japan via Russian and Kazakhstan (section Dostyk – Aktogai - Sayak – Mointy – Astana – Petropavlovsk (Presnogorkovskaya));
- Southern Corridor of TARM: South-Eastern Europe – China and South-Eastern Asia via Turkey, Iran, Central Asian states and Kazakhstan (section Dostyk – Aktogai – Almaty – Shu – Arys – Saryagash);
- TRACECA: Eastern Europe – Central Asia via the Black Sea, Caucasus and the Caspian Sea (section Dostyk – Almaty – Aktau);
- North-South: Northern Europe – Gulf States via Russia and Iran, with Kazakhstan's participation in the following sections: sea port Aktau – Ural regions of Russia and Aktau – Atyrau.

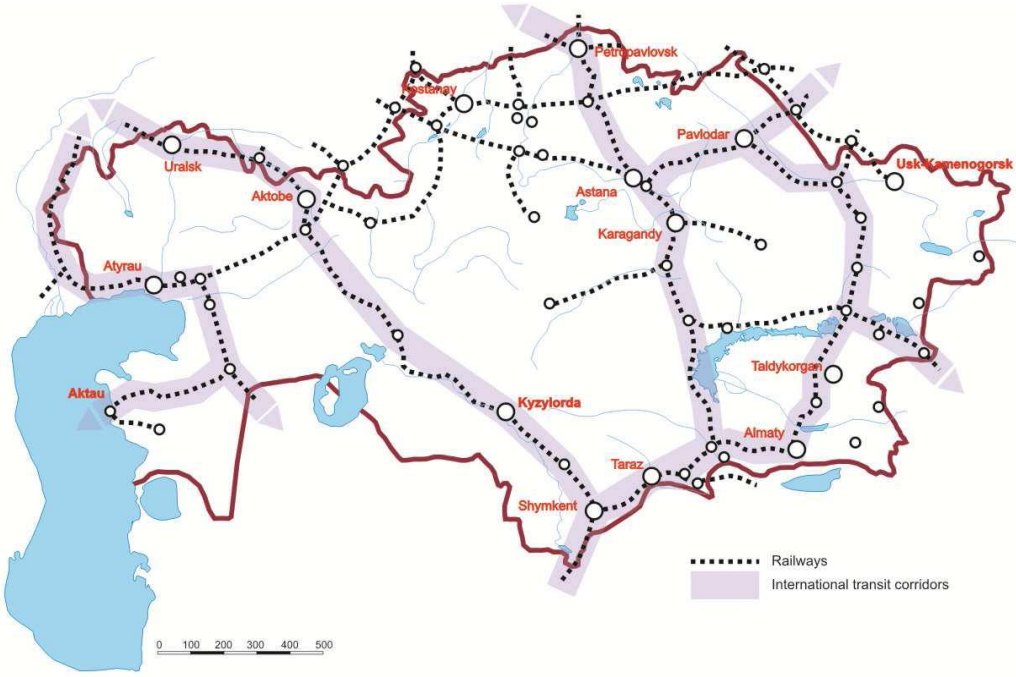

Fig. 8: Main transit transport corridors of the Republic of Kazakhstan.

Located in the centre of Central Asia with no access to open seas (although with access to the western regions of the Caspian Sea) Kazakhstan is highly dependent on its neighbouring states for international trade. This is one of the reasons for Kazakhstan to be an initiator of economic cooperation and integration processes with its close neighbouring countries.

Kazakhstan plays an active role in promoting the Shanghai Cooperation Organisation (SCO). In the past years, economic cooperation within SCO has been developing rapidly which is reflected in interstate trading operations and investment in general. China with its growing economy mostly imports raw materials from Kazakhstan and has a competitive advantage in production due to its low cost labour and huge market size. Currently, China is also intensively investing in the development of its western region Xinjiang bordering with East-Kazakhstan and the Almaty region of Kazakhstan.

Kazakhstan understands the importance of integrating with its other bordering states. It is worth to highlight its economic cooperation with Russia, especially within the framework of the Eurasian Economic Community (EurAsEC). The integration of five member states Belarus, Kazakhstan, Kyrgyzstan, Russia and Tajikistan, EurAsEC, was established with the aim to develop economic cooperation and trade and to coordinate the actions of Community states during growing integration into the world economy and the international trading system,

Although the EurAsEC Customs Union (CU) was adopted by the heads of six member states (6 October 2007) the initial stage of the Customs Union is formed only by three Community countries – Belarus, Kazakhstan and the Russian Federation, with the other EurAsEC members joining at a time when their economies and legislative systems are ready.

Local as well as foreign experts identify many advantages for Kazakhstan's economy to be driven by Eurasian integration with neighbouring Russia. However our study concentrated on the main impacts of Kazakhstan's role as mediator of integrating urban and rural economies into the world economic processes, with special focus on border areas.

Four of the selected main current direction of regional economic development in Kazakhstan mentioned above were used as a starting point to confront them with the most popular world demand trends derived from the latest world wide forecasts. The project team reviewed several reports of different internationally respected organisations like UN, FAO (UN), World Energy Council, World Bank and etc which provide expert views on the future development of world trends until 2050. Almost all the reports identify four main world dominating trends with relevance to Kazakhstan's current regional economic development conflicts:

- Increase in demand of innovative energy- and resource- efficient products;
- Increase in demand of environmentally clean food products;
- Increase in demand of raw (energy) resources from fast developing states;
- Increase in exchange of goods between states with different levels of development.

Due to the fact that two last trends also serve as the main backbones of EurAsEC, further integration through Custom Union - CU (based on free trade) and Single Transport Space - STS (development of common transit transport corridors) could be used as the key tools of territorial and further regional integration as a means to transform a post-industrial location-based economy into an innovative network-based economy.

The EurAsEC Custom Union - as distinct from the previous stage of integration, the free trade zone – presupposes free movement throughout the common customs territory, not only of goods produced therein, but also of goods from third countries freely circulating in the territory. The idea of the development of EurAsEC STS is based on the arrangement of better transportation of cargos, mostly along the existing transport corridors that helps to attract more transit.

As the above mentioned activities of promotion of trade and transit are being implemented without paying much attention to the real future of the simultaneous development of logistic and transportation in response to current development trends of the urban and rural border areas, our team of experts found it vital to propose a conceptual vision of their potential integration (as a positive feedback to the economic integration) (fig.9).

We fully understand that each region of Kazakhstan needs to be analysed in more detail, including field market research and social surveys. Nevertheless, positive effects from the simultaneous development of

logistic (using CU advantages) and multi-modal transportation system (using STS investment) can only be achieved by implementating at least two main steps, namely:

- Involvement of planners in the development of flexible investment programmes at local and regional settlement levels that would aim to keep a balance between production fitting both local and global market demands and helping to find the most appropriate sectors for the introduction of logistic productions;
- Building an appropriate planning platform for merging the state (central) level and regional and local (bottom) level initiatives of economic integration, taking into account the development of competitive urban and rural areas by promoting the construction of inter-settlements high-speed public transport passenger systems.

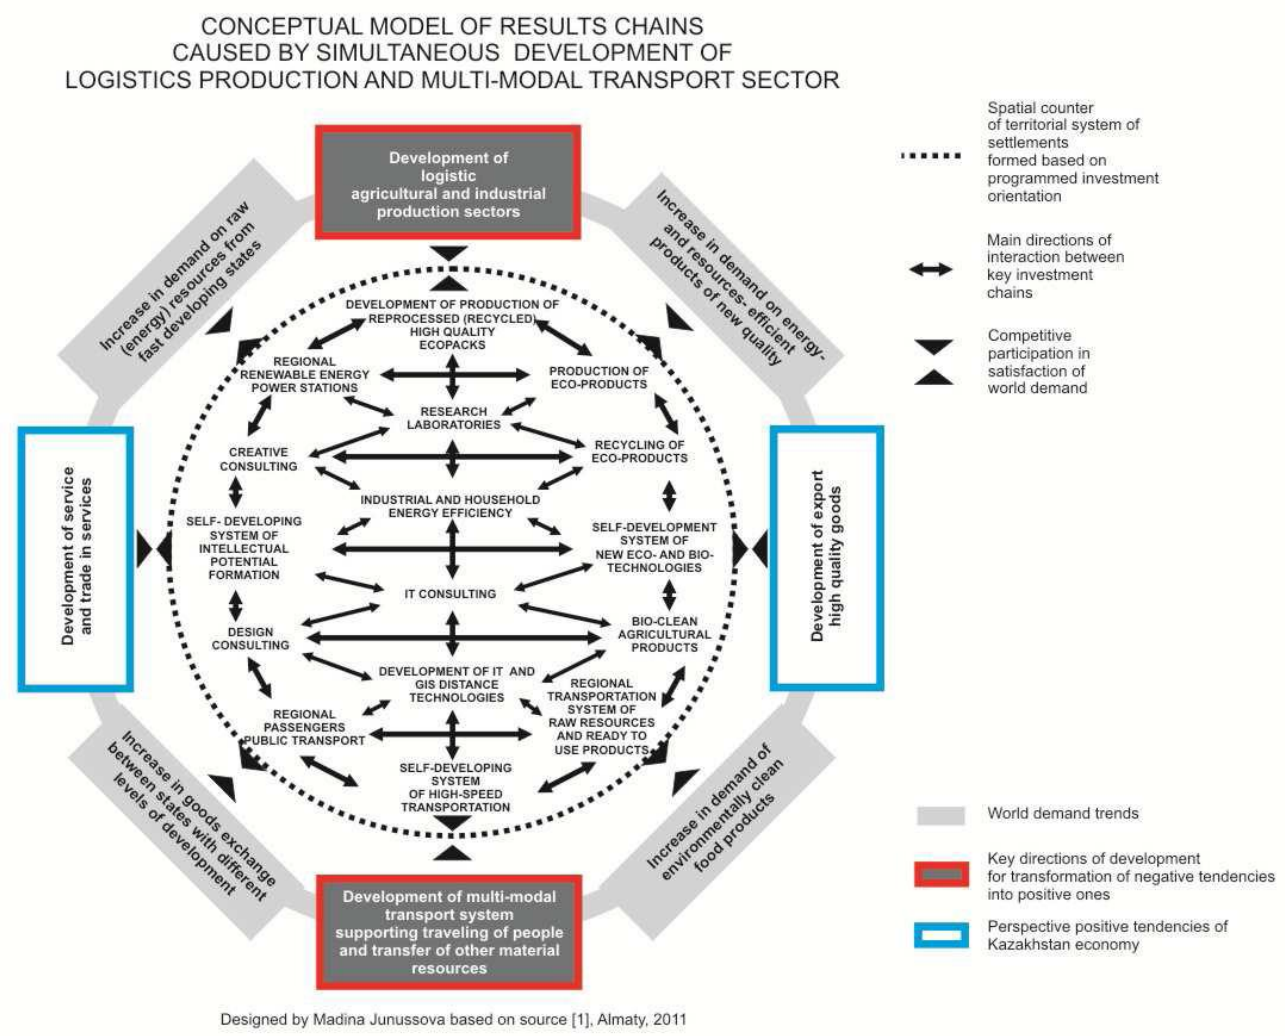

Fig. 9: Conceptual model of results chains caused by simultaneous development of logistic production and multi-modal transport sector.

5 CONCLUSION

With the introduction of EurAsEC Custom Union all production forces of urban and rural areas of Kazakhstan become a part of the wider market. The top level inter-state integration shouldn't be implemented separately from regional and local level integration, as only large scale, technologically and functionally rich systems of the Kazakh settlements could be competitive with the world's largest cities like Moscow.

At present, most of the top-down integration decisions are not fully understood by local administrations in the regions. However there is growing demand for the development of cross-border cooperation between border regions of Kazakhstan and regions of its neighbouring states that could serve as a good base for linking regional and spatial economic integration.

The EurAsEC management committee has a complex structure with many different types of councils responsible for the development of common approaches. However, it is still lacking any initiatives driven by the urgent needs of cross-border local initiatives, like:

- cross-border rivers under pressure from overuse of water and poisoning pollutants;
- cross-border migration with growing numbers of economically active educated population leaving;
- lack of innovative cross-border infrastructure;
- low capacity for the creative use of available natural resources and etc.

In this regard it may be too early to analyse any real positive impacts of economic integration mainly provoked by central level decisions, without any visible support of strong cross-border cooperation in planning a sustainable future for commonly used natural resources and production forces of urban and rural settlements.

1 ABSTRACT

The Roman Limes is the only European cultural heritage which interconnects ten European countries. Three of these countries have now decided to develop and implement a Mobile Information System for the tourism exploitation and marketing of this cultural heritage. Germany, Austria and Bulgaria will develop a "role model" for adaptation in order to connect all touristic sites in the ten European countries along the Roman Limes via mobile services. Since the Limes is often not accessible or not recognisable, new mobile service applications are vital to create an understanding and awareness of the historical setting that is often in the countryside. Designated target is to advance sustainable tourism and to support the mobility especially in rural European regions by the practical application of highly innovative mobile services. These services will enable information brokering, booking of rooms, travel mobility and additional functions for visitors as well as located people. Technologically it is about the interaction amongst mobile Internet, Global Positioning System, mobile phone camera and social networks. Therefore, a "Limes-App" will be developed including video player, navigation module, social media connection and an Augmented Reality Viewer. The Mobile Information System will base on Limes-relevant data and informations, displayed especially as historical reconstructions and other visualisations. Best practice models in context to the European LIMES project will be made public and applicable for the seven other European countries along the Roman Limes. In addition, the European Union has decided to launch a "data-roaming cut-off safeguard" [European Union 2010] for international mobile use and to cut the prices for calls and mobile Internet step by step in the next few years [European Union 2011]. This results in excellent conditions for the project which will help to valorize the cultural route of the Roman Limes, to capitalise its economic potential and to support sustainable tourism networks and structures in Europe.

2 THE LARGE SCALE DEMONSTRATOR CONCEPT OF THE EUROPEAN UNION

The "Expert Panel on Service Innovation" in the European Union (EU) published a report "Meeting the challenge of Europe 2020: The Transformative Power of Service Innovation". The strategy of Europe 2020 is a smart, sustainable and inclusive growth which in the context of service innovation leads to the vision of a "fundamental system transformation in almost all areas of the economy" [MAYO et al. 2011, p.1]. Technology innovation has to be combined with the development of policy through the lens of the customer. The role of the service element forms an important part of modern business and provides much of the technical and social infrastructure. Innovations in these service systems have the potential to profoundly influence other sectors [MAYO et al. 2011, p.7]. To support innovation in complex conditions the EU has improved the concept of demonstrators. These demonstrators – as innovation management tools – shall "provide a way of de-risking innovation by providing a staged process in which a range of solutions are initially developed, tested and then selected for further rounds of support" [MAYO et al. 2011, p.18]. There are numerous small-scale prototype demonstrators and a smaller number of large-scale near-market demonstrators. "Given the size of the European market, this should provide the basis for European standards to play an important role in developing global standards, thereby ensuring a level playing field for EU firms in global markets" [MAYO et al. 2011, p.18]. For different challenges there will be several demonstrators [MAYO et al. 2011, p.20f]:

- The focus on sustainable communities highlights the importance of ecological change and reflects the need for transition of industrial areas and the development of smart cities.
- The focus on the creation of dynamic regions takes care of the need to improve poorer, remote regions in Europe with particular reference to smart and sustainable tourism.

The focus on sustainable coordinated transport has the target to promote sustainable mobility by the reduction of carbon emission and the improvement of efficiency and predictability of the transport system.

The European Mobile and Mobility Industries Alliance (EMMIA) implemented the concept of large-scale demonstrators to prove the feasibility of exploiting innovative mobile services to foster sustainable tourism in rural areas. In 2011 two large-scale demonstrators were launched by the European Commission's Directorate-General for Enterprise and Industry: The demonstrator "CULTWAyS – CULtural Tourism WAys through mobile Applications and Services" [CAPRA 2011] and the demonstrator "LIMES – Large Scale Innovative and Mobile European Services for Culture Tourism in Rural Areas". The main objectives of the project are

- to network tourism sites along the Limes in all respective countries,
- to develop innovative mobile services along the route which support information, brokering, travel mobility and additional services for visitors as well as local people,
- to support via these services new businesses along the route,
- to create income and jobs for rural areas,
- to make the European identity and the common European history visible and perceptible for visitors from all over the world.

3 MOBILE SERVICE FOR CULTURE TOURISM

3.1 The Limes in the Demonstrator Regions

After defeating the Carthaginians in 241 BC the Romans began to expand their sphere of influence in the western Mediterranean Sea. By striking back the attack of Hannibal in 202 BC the Roman Republic ruled the territory of today's Spain and southern France. From now on the Roman expansion went on towards the east under the pretext of supporting small kingdoms against the attacks of big powers like Macedonia or Syria. Other kingdoms surrendered in preemptive obedience [DEMANDT 2003, p.73f].

Gaius Julius Caesar conquered Gaul in 58-51 BC and was appointed as dictator of the Roman Empire. This empire subsequently expanded until it surrounded the whole Mediterranean Sea. The expansion stopped in "Germania Magna", when the Roman army under Varus suffered overwhelming defeat in the Teutoburg Forest in campaign against the Cherusci in 9 AD. As result the Rhine and the Danube were the natural borders of the northern Roman provinces [DEMANDT 2003, p.79f].

Fig. 1: The Roman Empire at its greatest extent in 211 AD – source: CAVAZZI 2009

In 43-44 AD Britain and in 74-85 AD the territories between Rhine and Danube in today's Southern Germany were brought under Roman rule. To ensure customs revenue and security along the borders the Romans built a visible dividing line, which was built up in the period following. This "Roman Limes" represented the border line of the Roman Empire at its greatest extent until the beginning of the 3rd century AD. Partly it was fortified with walls, towers and forts – especially in Britain (Hadrian's Wall and Antonines Wall) and in today's Germany ("Germanic Limes" and "Raetian Limes"). In fact, the word "Limes" was not only used to indicate the imperial frontier or a fortified border. It was used as an administrative term, indicating a military district, commanded by a dux limitis [ISAAC 1988, p.125ff].

Now the Large Scale Demonstrators of the European LIMES project pick up the northern Roman border line to develop mobile services and revive the intercommunity along the Roman Limes. The three Large Scale Demonstrator Regions in particular are Rhineland-Palatinate in Germany with the "Limes Germanicus", Lower Austria along the Danube and the city of Rousse in Bulgaria, also located at the Danube.

Fig. 2: Limes sights in Rhineland-Palatinate (Roman fort in Holzhausen), in Austria (reconstruction of thermea in Carnuntum) and in Rousse, Bulgaria (Roman fort "Sexaginta Prista"). Sources: JOST 2012, OLSCHINSKY 2011, KABAIVANOVA 2005.

3.2 Requirements of Mobile Services in the Demonstrator Regions

Based on a study of the "Branchenverband BITKOM" 83 % of the German population owns a mobile phone. At the end of 2011 there were about 112,03 million contracts in Germany. This shows that some users have more than one contract (e. g. surf-sticks, tablet PCs). In Germany there are four major mobile network operators [KURTH 2011, p.51]:

- Telekom Deutschland (31,2 % market share)*
- Vodafone D2 (32,9 % market share)*
- EPlus (19,8 % market share)*
- Telefónica Germany O2 (16,2 % market share)*

* retrieved 3rd quarter in 2011

To guarantee a save and fast data transfer rate, it is necessary to have at least UMTS connection (3G-network) at the major stations of the mobile information system "Limes". For textual information the EDGE data rate is adequate, but not for larger data like videos or Augmented Reality applications. As an evaluation of the network coverage in the three partner regions shows, there is a very good 3G-network coverage along the Limes in Bulgaria and Austria. The Limes in Rhineland-Palatinate runs through rural areas, where is often a lack of 3G-networks – so there isn't a well-performing Limes information system verified.[1] Therefore the Limes information system has to offer an open wireless Internet access point (e. g. WLAN) at the main sights. In addition some applications, like videos and textual information, should work offline – the user can download the data at the wireless Internet access points and get the information at places with no mobile internet access or with low network coverage.

The framework of smart phone usage in Bulgaria (only 9 % smart phone users in 2011) requires a mobile information system, which works with a "basic-version" on older mobile phones with only mobile internet access. So the system should base on a mobile website. This also guarantees the function of all kind of smart phone operating systems. Applications like Augmented Reality or offline navigation are only suiting to smart phones and should be part of an additional "App". This "App" should be provided for the operating systems

[1] Own evaluation, based on data of the mobile network operators.

Android OS and Apple iOS – in the three partner regions this operating systems are very popular. Generally, there is still a problem of high cross-border costs for mobile internet usage: Because of the roaming costs, consumers are not willing to use the mobile internet in foreign countries. These problems show that the mobile service that will be developed in context to the LIMES project has to meet several requirements, which are very different from region to region and will hopefully get easier to handle in future.

Certainly, the European Union has decided to cut the roaming costs step by step in the next few years and the mobile network coverage will improve in all European countries [European Union 2011]. Another future perspective are mobile NFC (Near Field Communication) services that are generally able to stimulate future growth by involving transportation, ticketing, retail, access and more. The aspects of "Connected Living" can create new service concepts and business models that are being used to address a range of new markets [GSMA 2012].

New target groups – especially younger generations – can arise because of the majority of young smart phone and mobile internet users. In this context the system has to offer an additional value. Individual tourists need the profound information but also have to be entertained. To develop an attractive application which can be used more than once it has to include a social interaction tool and a playful element. According to the needs of outdoor tourists as well as historically interested culture tourists there should be a kind of "Story" that surrounds the mobile Limes application.

3.3 Contents of the "LIMES-App"

The information of a mobile application called "LIMES-App" has to be suitable for tourists and local people as well. There should be as much interaction as possible, so the users can give an input about gastronomy, hotels or events by rating, commenting, etc. At the same time the quality of information must be guaranteed. Additionally there has to be a booking option for accommodation and the opportunity to navigate to the next points of interest. To make the "LIMES-App" attractive to younger target groups it is planned to implement some playful elements such as collecting aspects or games, which might work on static PCs but evolute their full range of gratification only on-site at the Limes. Other multimedia like videos, 3D-models etc. should be part of the information and entertainment, too. Generally, social interaction is one of the major points the application has to offer to found a kind of "Limes community". In addition, the technology of Augmented Reality can be included for better orientation, navigation and as a playful tool, maybe as Augmented Reality game. In the first step these contents were sorted into four categories, which enable different ways of access to the Limes experience:

- Information about the Limes and additional aspects like weather, public transportation, etc.
- Offers like gastronomy, accommodation, events, etc.
- Social Media for the connection of users via Facebook, Google+, FlickR etc. or a special "Limes community".
- Games that work offline (like people are used to it), but also in combination with social media or Augmented Reality.

Fig. 3: "LIMES-App" ("Dummy"-Version), source: Own figure

4 IMPLEMENTATION AND REPLICATION IN EUROPE

The LIMES project will have extraordinary impact as the project organisation already includes all relevant players Europe wide. Limes representatives of the United Kingdom, the Netherlands, Slovakia, Hungary, Croatia, Serbia and Romania were invited to this proposal for fostering replication and extension of the project outcomes in their respective countries. They will participate in all partner meetings with the task for checking the transfer potential in their countries – either as actors or communicators.

Actually, the Limes is a premium destination for culture tourism although much of its potential has not been exploited so far. This is mainly due to the fact that only a small part of the Limes is accessible at the moment: the Limes runs through rural regions which are not fully developed for tourism. On the other hand, the European Limes countries have numerous museums, historic routes, archaeological sites and hidden places of interest along the Limes. These single places are not networked yet, and binding them together via mobile services offers an outstanding chance for developing especially rural areas.

The European Limes countries are very different in their access to the Limes: The United Kingdom, Austria and Germany represent countries which are very far in their tourism exploitation of the Limes, while especially Eastern countries are at the beginning of the development of tourism activities. Beyond these differences, none of these countries actually seems to have mobile services available for Limes sites in rural areas. The development of these areas is the common goal for all the member states which want to work together in the LIMES project.

Additionally, it is also part of the project to cooperate with other European Large Scale Demonstrators like the project CULTWAyS, which covers the topic of European historical, cultural routes – in particular the Way of St. James in Germany, France and Spain and the Roman Via Claudia Augusta in Germany, Austria and Italy. Overall, the mobile services developed in the context of the projects LIMES and CULTWAyS shall be adoptable for other European regions with other priorities.

5 CONCLUSION

The Limes has a big potential for tourism especially in times of general mobile availability. New ways of interregional communication between tourists and locals in Europe. Social media can bring virtual and real life into rural areas by playfully connecting people, who are more and more used to in smart phones and social media. The target is to create a wide community about the Limes on all leading social media platforms, like Facebook, Google+, FlickR etc. So the users will have the possibility to exchange their experiences at the Limes and the region (for example tips for sights, accommodation, events, etc.).

For the social media application it is useful to create a communication platform for Limes-tourists, Limes stakeholders and other, local people in the region. So on, there will be the possibility that they generate more and more content for the mobile information system and bring and keep the Limes community alive.

Finally, there should be a story told with the Limes application, which is interesting and participative for a lot of people and attracts them to come to the Limes region. At the same time the local people and economy has to be convinced to take part at the Limes community by advertising the system, offering information, sponsoring or participating by a benefit scheme or by offering attractive specials. This will lead to an added value, which satisfies tourists as well as local people and economy.

Livability and Social Integration vs. Economic Crisis and Trends of Transition: Case Study of Local Planning in Belgrade

Biserka Mitrović, Sanja Simeunčević

(Biserka Mitrović, MSc, Assist. Prof., MArch, Faculty of Architecture University of Belgrade, Bulevar kralja Aleksandra 73/2, biserkamitrovic@gmail.com)

1 ABSTRACT

The paper discusses the negative influence of global economic forces and transition changes against the intention of local municipalities and local inhabitants to achieve better quality of life and better social integration in local environment.

Strong economic crisis affecting cities worldwide and transition trends in post-socialistic countries are the most significant drive force of the development/decline of Serbian cities. It reflects on changing the city structure, lessening the functional diversity and shrinking the public space as most vulnerable and least profitable areas in the city. Public interest and the public space in the current context of legislation, arbitrary treatment of singular locations by some institutions and professionals and pressures of the capital is increasingly losing its significance.

On the other hand, even in such conditions the awareness of local municipalities and local inhabitants about the quality of life as well as about the importance of involvement in participation process as a way to impact local livability has grown during the past decade. Such actions of local community rely upon the strong theoretical background focusing sustainable and integrative urban design approach and protection and enhancement of public space and public realm, as well as upon the principles of social integration and cohesion for the local community.

Following the approach of "learning from mistakes", the paper presents an example of treatment of sports and recreational facilities within residential areas in Belgrade in the current local planning practice, discussing how this treatment can be considered in sustainable way, resisting the transition trends and economic crisis forces and making the local city space more resilient and livable. As a result, this approach also brings other benefits to the city as whole, making planning procedures more effective and sustainable and creating additional value to the city areas.

2 INTRODUCTION

This paper will present one of possible scopes to the current planning practice in Serbia, specially pointing out the investors' attitude about the public space and also the way how local communities try to balance public and private interest. The framework is defined by the socio- economic context and transitional changes in an ex-socialistic country towards market oriented economy.

Though the process of transition lasts for more than a decade, the direction of planning process and effective model for planning practice are not yet clearly defined. Some of the questions still waiting for answers are related to: sustainable framework which 'works' under condition of discontinuity and growth instead of development; experiences from other countries which are not quite transferable; balanced planning intervention in the market in favour of public realm; dilemmas about lessening the public sector, understood as a category inherited from socialism, etc.

We will try to offer some answers analyzing as a case study three sports and recreational areas in Belgrade, not having and ambition to give final answers but to provoke for further discussion. The approach is based equally on ecological, social, economic and institutional sustainability, thus creating conditions for a realistic community development based on the economic resource preservation.

3 PUBLIC INTEREST, PUBLIC LAND USE AND SUSTAINABILITY

The understaning of public interest relies on the premise that public interest has a different understanding, scope and importance in every socio - political environment. The concept of public interest is equally related to land construction land on which it exerts, land use (transportation, infrastructure or recreation areas) or activities of public interest, as is the case with activities related to the environmental protection or cultural

heritage protection. Public interest in Serbia in the situation of a flexible interpretation of the plans, the current legislative context, arbitrary treatment by some of institutions and the pressure of capital is losing its importance.

The basic understanding of the concept of public interest is tied to the notion of public good, which represents the area or activity whose use by individuals or groups does not diminish the possibility of use by another individual or group. By classical definition, private capital is (mostly) not interested for public good.[1]

For socially balanced city, social consensus about definition and coverage of public interest is vitally important, as well as consistent implementation of decisions related to the protection and promotion of public interest within the given limits. Since the city of Belgrade has a legacy in this regard, there is a need for redefining the public interest in areas/purposes/activities that are or have been related to it.

On the other hand, the most important foundation of sustainable development rely upon economic, ecological and social cohesion. Sustainable cities follow an integrated and long-term development that does not question the development of future generations. Among the most important features of the development of sustainable cities are: effective economy, lower external and social costs, social progress and strengthening of the civil society,[2] which together form the basis for long-term qualitative development. At first seen as an approach that is primarily related to environmentally issues, sustainable development of the city today is also based on: quality of life as the most important value, respect for human dimension, comprehensive and integrative approach to development and planning,[3] preservation of natural, economic and social resources for future generations and social equity and cohesion,[4] and many more.

In this light, this paper emphasizes the social component of sustainability through the vision of social balance and social cohesion in the city. City of social balance is equally good for all citizens within possibilities and constraints. The implementation of the concept is conditioned by harmonized needs and interests of all social groups. The concept focuses on the desirable or optimal development of social/public services that are covered by compulsory social care for local community and are mostly treated as non-profitable, such as: (public) education, health, social care, child daycare, culture and sports and recreation.[5] Guaranteed elementary education, primary health care and preschool children care is the level of social concern defined by the international documents (eg. Agenda 21, Habitat Agenda, New Athens Charter, etc.) and by international organizations (UNEP, UN HABITAT, WHO, UNICEF, etc.).

The concept of social cohesion is based on creating the conditions for fulfilling the needs of different population groups, regardless of their political, economic or social power, therefore manifests concern for "non-productive" population groups, such as children, youth, elderly, people with special needs, etc. It can be argued that validation of the concept is based on the quantity of actors which would support it, instead on the power/dominance actors able to impose their model of development. Including a wider range of actors has a strategic importance because it goes beyond short-term effects in the urban space and activities that respond to the trends and uncontrolled privatization processes.[6]

The city of social balance tends to minimize the social inequities which manifest as spatial inequities and make the city territory more inconsistent. By balanced spatial development and social and spatial cohesion, several positive effects can be achieved: minimizing the difference between center and periphery, the development of secondary centers and the optimal equalization of quality of life in the city.[7] The concept gives priority to the public space in the city and does not favor (economic) growth at any cost. Imperfections of market mechanisms, the effects of unlimited economic growth and points of spatial conflict, being the weak points of contemporary city, present the starting point of defining socially sustainable city.[8]

Operationalization of the principles of socially sustainable city should be expressed through at least:

- Social sustainability and the application of the principle of equality by creating the spatial conditions to minimize social differences and favoring social and territorial cohesion.
- Sustainable urban planning - local planning strategy which take into consideration the welfare of the local economy and population;
- Sustainable land use;
- Institutional sustainability, which includes improvement of procedures and institutional arrangements and introduction of integrated approach.

4 TRANSITION AND THE CONCEQUENCES REFLECTING ON PUBLIC SPACE

The trends of privatization and the encouragement of the flow of capital in transition countries are shaping the understanding of public interest. Local political surrounding is usually strong support to such trends and it is by its nature oriented towards short-term effects and much less focused on long-term strategy of the city development.

Not having intention to elaborate many positive and negative effects of transition in Serbia, we shall review only the significant effects in the public sector. The ownership transformation and privatization of public enterprises and public services, private use of public urban construction land, legislative support for the private ownership of urban construction land and reduced financial support for the public sector are just some of the current changes and problems in the transition period.

In economic terms, the goal of transition should be a provision of conditions for the introduction of organized and systematic market relations, healthy competition and the supply and demand within the framework of welfare state. In the countries with long tradition of market relations, the rules arranging the relationship between private and public sector are defined and respected, as well as the level of state and local government intervention in the market, according to established criteria (although we cannot say that these relations are always fully defined and unambiguous). The fundamental problem arises in the absence of these criteria. Then the solution for the most conflict situations in urban environment between public and private interest is solved in the process of arbitrary and ad hoc decision making. The situation in Serbia, although the transition takes a long time, indicates the lack of criteria and standards and lack of clear policy and strategy development for the public sector and also the propositions under which it can be transformed in the process of transition.

In this context, sustainable planning and market demands in the current urban planning practice in Serbia are generally seen as conflicting concepts that mostly exclude each other. It is very common situation in the urban planning practice that sustainable solutions are usually not interesting to the market and investors, while on the other hand investors' interests in many cases cannot be understood as sustainable. Furthermore, local government generally neglects some aspects of sustainability, such as institutional or economic.

5 TREATMENT OF SOME SPORTS AND RECREATIONAL AREAS IN BELGRADE IN THE CONTEXT OF TRANSITION AND SUSTAINABLE DEVELOPMENT

Trends of the transformation of public urban construction land and public buildings in Belgrade in recent years illustrate the above standpoint. This is particularly visible when it comes to sports and recreational areas which used to be public during the socialistic period. As a case study for this paper three examples of planning treatment for sports and recreational areas in Belgrade will be presented, following the approach of learning from mistakes.

In Belgrade, over more than a decade, we are witnessing an ownership transformation of many health, education, sports, recreation and similar facilities. Privatization of public land and buildings is happening ad-hoc and decisions are made individually and utterly arbitrary. In this way the market behavior in relation to public spaces and facilities, enters "back door", without having analyzed the concept of development or strategic orientation.

We have to emphasize the unjustly neglected fact that we are discussing a very important resource – public facilities infrastructure/network, legacy from different sociopolitical environment. This infrastructure/ network are often overwhelmed by problems related to the maintenance, lack of financial resources and

qualified working staff, nevertheless it is still a relatively diversified and balanced network. Let us mention the fact that many developing countries, with different or similar sociopolitical and economic history does not have such capital (as is the case with many Asian countries).

Of particular concern is the general social approval and support to these models of behavior in space. Public facilities have been transformed for other purposes, privatized and new, commercial facilities have been introduced. Sometimes, they even are not brought to a new purpose. As an argument and justification for such actions, greater efficiency after the ownership transformation, the need for rationalization of some services, high maintenance costs and hiring qualified work force are brought up. This way, the standard of living, which is tihgtly bond to the quality and spatial distribution of public services, and which has already been getting worse for other reasons, is imperiled. Hereby, the essential connections between the public facilities network development and the concept of social cohesion and social sustainability has been left out of sight.

Belgrade has several sports facilities and complexes of national and international importance which are designed for professional sport and big sports events,[9] also more than 25 sports facilities and complexes, dispersed in urban districts and secondary urban centres. Nearly each of the 16 Belgrade municipalities has at least one sports facility. In addition, there are hundreds of sports and children's playgrounds in the city, relatively evenly dispersed. All these facilities were situated on the public urban construction land. Such ownership implied the obligation for the custody and tending by the city government institutions, particularly Belgrade Land Development Public Agency as the main holder. The ownership also obliged for further financial commitments to build, equip and maintain through the Belgrade Land Development Public Agency (using the City budget financial resources), as well as for the City Secretariat for Youth and Sports and Ministry of Education and Sport (Directorate of Sports). (using the State budget financial resources).

On the other hand, Belgrade Land Development Public Agency financed most of Belgrade detailed regulatory plans. These plans should have been defined in accordance with the sports and recreation development policy, the State and local regulations and the ownership status (Since according to The Planning and building Act (2003, Republic of Serbia) all urban plans, including Belgrade General Plan had a power to define public and private ownership over the urban construction land).

Under the conditions of the lack of funds, the City has encouraged private initiative and the ad-hoc solutions. However, to facilitate the financing of sports facilities and complexes by private individuals and firms, the status of the land had to be changed. So the land of complexes with high potential, such as stadiums of Partisan and Red Star sports clubs, received the status of private urban construction land. City Budget and Administration has certainly made a significant benefit by such transformation, understanding it as a short-term action and considering it as an "exemplary market adjustment," but what about the City and its citizens? Belgrade has irretrievably lost a significant part of urban resources – urban construction land, and citizens, to say the least, the ability to influence this process.

A similar trend is established in relation to local/district sports and recreational centers and the need to transform the ownership and the status of urban construction land again occurred. Such was the case with the Sports and recreation complex Olimp, in Belgrade municipality Zvezdara territory. However, given the lower level of attractiveness of these sites and land, no significant interest was manifested in its privatization.

[9] Mentioned categories are defined by the Sports and Recreation Facilities Act (Sl. Glasnik RS 17/96.).

From the long-term point of view, the consequences of the approach “less interest – less action” by the City government is more convenient for the development of the city than it is the case with short term actions and decisions. The problem is, however, that the solutions resulted from the daily political decisions, non-compliant initiatives and in the absence of defined and clear attitude and criteria of city authorities and central government institutions. Inconsistency and lack of communication between different levels of institutions makes their acting quite "unsustainable", creating a gap that will emerge "planning" decisions of very questionable quality.

On the other hand, the citizens and the Administration of the local community of Zvezdara have showed a great interest to keep the Olimp complex as a public facility. During the long and controversial process of designing and adopting the local regulatory plan of the Sports and recreation complex Olimp and the surrounding housing blocks, the citizens have taken the solid and consistent standpoint about the preservation of the local green, sports and recreational areas. Even though the Planning and Building Act (2003, Republic of Serbia) have given the citizens the chance to participate in the planning process only at the moment the draft plan version was almost finalised (that is, during the public review procedure) citizens of the local community of Zvezdara have made a significant pressure to the local and city administration bodies to get involved more often, thus making a great impact on the planned solution. The City municipality Zvezdara supported and confirmed the citizens‘ standpoint by municipal assembly decisions.

After a couple of years of negotiation with the City administration and urban planning bodies, The local municipality administratives of Zvezdara have managed to keep the local sports and recreation complex olimp for its citizens. The status and the ownership over the urban construction land assigned to the sports complex have remained public.

Though the case study of sport complex of Olimp in Belgrade shows that the city administrative bodies lacked the understanding of the citizens’ interest and also had a little respect to the sustainable idea ‘think globally – act locally”, it also tells a lot about the awareness of citizens about their own quality of life and livability. It is specially important having in mind the citizens of Serbia are not yet fully informed or/and educated about the planning process participation and that they are still not involved in great number, although it is an established practice in many countries. The described situation should not be an unusual and extraordinary process, given that the detailed regulatory plan, as the most detailed planning document is the most understandable planning document to ordinary citizen.

The described examples clearly suggest the need for policy development in the field of public service, with careful, systematic and balanced harmonization of private and public sector and also the need for stronger legal and institutional support for participation in the planning process.

6 CONCLUSION

Summarizing, we have recognised the potentials, problems and limitations in the current state of the public sector and public services in Serbia and we point out some directions for solutions.

Potentials are as follows:

- Public services network consisting of many subsystems is in great need of transformation, reorganization and modernization.

- Sports and recreation facilities infrastructure makes it one of the vital segments of future urban development in Belgrade.
- Some of the most important problems and constraints in this field are:
- Public sector and public urban construction land and facilities are exposed to the serious consequences of uncontrolled or poorly controlled development.
- Different and often conflicting aspirations and actions of institutions, as well as different groups of actors.
- Absence of policy development and regulatory fragmentation.
- Arbitrariness in decision-making regarding the development and transformation of public services.
- Future solutions must certainly be based on goals and objectives relating to:
- Development of public services in order to create favorable social environment.
- Availability of public services for all citizens.
- Encouragement of the development of public services since they support the communication.
- Spatial distribution of public services as a way of meeting the needs of population equally.
- Balancing the quality of public services.
- Protection of public spaces and promotion of public interest.
- Minimizing the spatial differences in the development of the city arising from social differences and differences related to the development of public services, thus achieving consistent and balanced development of urban territory.
- Application of the principles of sustainable urban renewal, including social regeneration.
- Overcoming institutional separation of management, planning, funding and implementation in the field of public services.
- The integral part of the solution should be the criteria for qualitative and ownership transformation of public services.

Mitnahmesysteme als Ergänzung des öffentlichen Personennahverkehrs (ÖPNV) in ländlichen Räumen – das Beispiel „Mobilfalt“

Volker Schmitt, Carsten Sommer

(Dipl.-Wi.-Ing. Volker Schmitt, Universität Kassel, Fachgebiet Verkehrsplanung und Verkehrssysteme, 34109 Kassel, v.schmitt@uni-kassel.de)
(Univ.-Prof. Dr.-Ing. Carsten Sommer, Universität Kassel, Fachgebiet Verkehrsplanung und Verkehrssysteme, 34109 Kassel, c.sommer@uni-kassel.de)

1 KURZFASSUNG

Schrumpfung und Alterung der Bevölkerung haben vor allem im ländlichen Raum gravierende Konsequenzen für den öffentlichen Personennahverkehr (ÖPNV): Die Schüler als hauptsächliche Fahrgastgruppe des ÖPNV in ländlichen Räumen gehen in ihrer Anzahl deutlich zurück, gleichzeitig werden die Schulwege länger, sodass für die öffentliche Hand die Beförderungskosten steigen. Eine zweite wesentliche Nutzergruppe, die Erwerbstätigen (Berufspendler), nehmen in Ihrer Anzahl ebenfalls ab, sodass insgesamt die Stammkunden des ÖPNV wegbrechen, die Bündelungseffekte entfallen und damit die Systemvorteile des traditionellen Linienverkehrs – die Beförderung großer Fahrgastströme – nicht mehr greifen.

Eine übliche Reaktion auf diese Entwicklungen waren in den vergangenen Jahren vor allem Angebotsreduzierungen und die Einführung bedarfsgesteuerter Verkehre wie Anruf-Sammel-Taxen oder Anrufbusse. Dabei werden Fahrten nur dann durchgeführt, wenn sie innerhalb einer Voranmeldezeit (mindestens 30 bis 60 Minuten vor der gewünschten Abfahrt) angefordert wurden. Ein Nachteil dieser Verkehre ist, dass die Gesamtkosten im Gegensatz zu konventionellem Busverkehr mit der Nachfrage steigen, sodass die öffentliche Hand bei starker Nutzung finanzielle Risiken eingeht.

Andererseits überlagern sich in vielen ländlichen Regionen Abwanderung und Alterung der Gesellschaft. Der daraus folgende Rückzug von Angeboten und Einrichtungen führt zu längeren Wegen. Dies kann insbesondere im Zusammenhang mit zu erwartenden Kostensteigerungen im Verkehr zur Exklusion bestimmter Personengruppen führen.

Vor diesem Hintergrund werden aktuell in mehreren Regionen Deutschlands Ansätze entwickelt, bei denen der ÖPNV durch private Mitfahrgelegenheiten ergänzt werden soll. In diesem Beitrag soll das Projekt „Mobilität im ländlichen Raum/Mobilfalt“ unter Federführung des Nordhessischen Verkehrsverbundes (NVV) vertieft betrachtet werden, dessen Betrieb zum 1. Oktober 2012 in drei Pilotgebieten in Nordhessen starten soll. Bei Mobilfalt wird damit erstmals in Deutschland ein privates Mitnahmesystem in den ÖPNV integriert.

2 HERAUSFORDERUNGEN FÜR DEN ÖFFENTLICHEN NAHVERKEHR IN LÄNDLICHEN RÄUMEN

2.1 Der demografische Wandel in Deutschland

Die Anzahl der Einwohner in Deutschland geht bereits seit 2003 zurück. Laut der 12. koordinierten Bevölkerungsvorausberechnung sinkt die Bevölkerungszahl bis 2060 auf 65 bis 70 Millionen Menschen gegenüber 82 Millionen im Jahr 2008 [STATISTISCHES BUNDESAMT]. Zudem altert die Bevölkerung deutlich, insbesondere steigt der Anteil der Hochbetagten (80 Jahre und älter) von 5 % im Jahr 2008 auf etwa 14 % der Bevölkerung im Jahr 2060.

Dabei unterscheidet sich die Bevölkerungsentwicklung sehr stark zwischen einzelnen Teilräumen, verursacht im Wesentlichen durch Wanderungsprozesse. Während die Bevölkerungszahl bis 2025 in einigen Ballungsräumen wie Köln/Bonn, dem Rhein-Main-Gebiet und im Süden und Südwesten Deutschlands noch zunimmt, sind starke Rückgänge in Ostdeutschland, aber auch in weiten Teilen Westdeutschlands zu erwarten. An Ballungsräumen betrifft dies in erster Linie das Ruhrgebiet und das Saarland, außerhalb der Ballungsräume werden deutliche Bevölkerungsrückgänge in den nördlichen Teilen Bayerns und Hessens, in Südniedersachsen sowie in Süd- und Ostwestfalen erwartet (Abb. 1). Neben der zahlenmäßigen Bevölkerungsentwicklung spielt auch die Alterung der Bevölkerung und die Abnahme der Schülerzahlen eine wichtige Rolle. In vielen ländlichen Räumen überlagern sich die Prozesse der Schrumpfung und Alterung (Abb. 2).

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

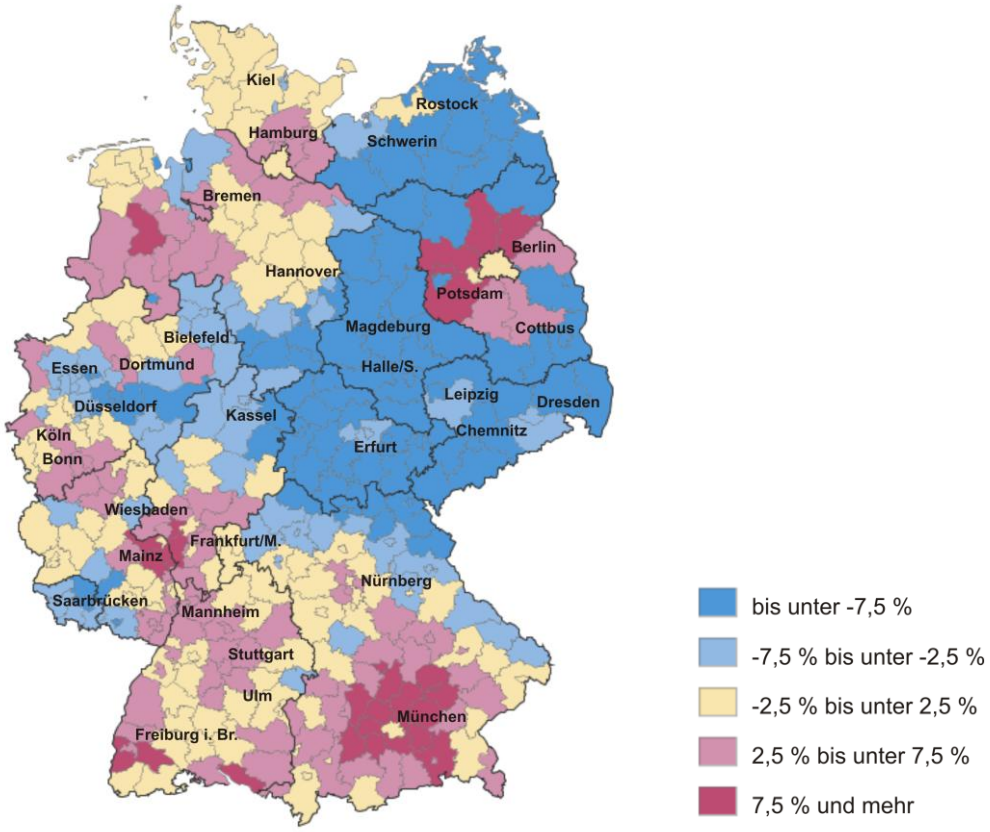

Abb. 1: Bevölkerungsentwicklung 2009 bis 2025 in %, Datenbasis: Laufende Raumbeobachtung des BBSR, Bevölkerungsfortschreibung des Bundes und der Länder, Kartenquelle: BBSR Bonn 2012.

Die dargestellten Entwicklungen haben besonders in ländlichen Räumen Konsequenzen: Zurückgehende Einwohnerzahlen bedeuten, dass die Zahl potenzieller Nutzer von Infrastruktureinrichtungen und Angeboten zurückgeht. Dies kann dazu führen, dass sich Anbieter von Dienstleistungen wie Versorgungseinrichtungen aus dem ländlichen Raum zurückziehen. Beispiele hierfür sind die Konzentration von Einkaufsmöglichkeiten oder der Rückzug von Ärzten auf dem Land („Landärztemangel“). Damit wachsen die Distanzen, die zu überwinden sind [BMVBS 2010:22 ff.].

Dies kann zur Folge haben, dass Menschen, die aus Alters- oder Gesundheitsgründen nicht mehr Auto fahren können und deren Wohnorte durch den ÖPNV schlecht erschlossen sind, vermehrt vom gesellschaftlichen Leben exkludiert werden.

2.2 Entwicklung der Verkehrsnachfrage und Folgen für den ÖPNV

Die geringere Bevölkerungsdichte im ländlichen Raum bedeutet eine geringere Verkehrsnachfrage, die sich zudem weniger bündeln lässt. Das Verkehrsangebot in der Fläche lässt sich derzeit dennoch häufig vor allem durch Linienbusverkehr charakterisieren, der sich im Wesentlichen an den Erfordernissen des Schülerverkehrs orientiert. 70 bis 90 % der Fahrgäste im regionalen Busverkehr sind Schüler [BERTOCCHI 2009]. Dies bedeutet, dass das Verkehrsangebot nur eingeschränkt für andere Fahrgäste nutzbar ist. Gründe sind einerseits die angebotenen Relationen, Linienführungen und Abfahrtszeiten, die auf die Nachfrage und Belange des Schülerverkehrs ausgerichtet und daher für andere Fahrgastgruppen teilweise unattraktiv sind, andererseits fehlen während der Nachfragespitzen oft die Beförderungskapazitäten in den Fahrzeugen für zusätzliche Fahrgäste.

Aus diesem Grund trifft der Rückgang der Schülerzahlen den ÖPNV vor allem in ländlichen Räumen und führt zu Rückgängen der Fahrgeldeinnahmen und staatlicher Zuschüsse. Gleichzeitig ist zu erwarten, dass die Distanzen im Schülerverkehr wachsen, da die Entwicklung der Schülerzahlen eine Konzentration der Schulstandorte erwarten lässt und der Anteil der Abiturienten unter den Schulabgängern wächst [SOMMER 2005].

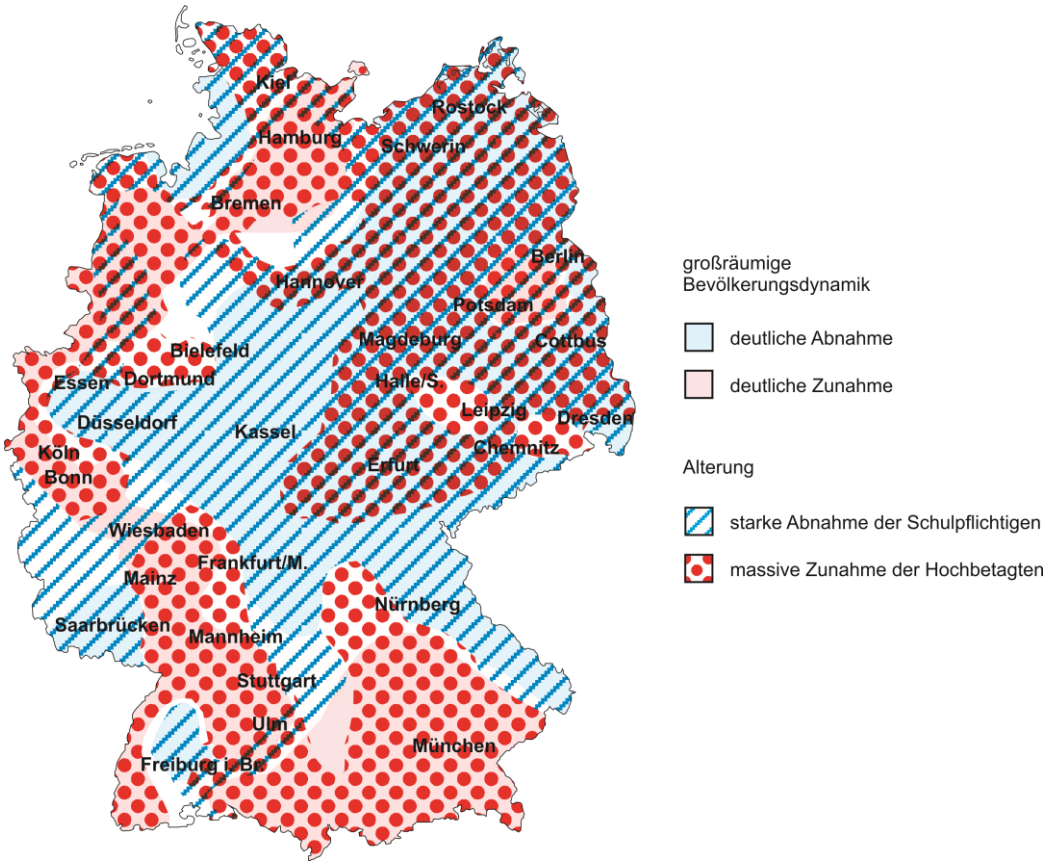

Abb. 2: Ausprägung von Komponenten des demographischen Wandels bis 2025, Quelle und Datenbasis: BBSR-Bevölkerungsprognose 2005-2025/bbw

Da die Zahl der Erwerbstätigen ab ca. 2020 abnimmt und diese Abnahme in ländlichen Räumen überdurchschnittlich verlaufen wird, sind auch im Berufsverkehr kaum Impulse für die Verkehrsnachfrage zu erwarten. Auch die wachsende Zahl der Senioren wird nicht zu wesentlichen Steigerungen der Fahrgastnachfrage führen: Mit dem Eintritt in den Ruhestand gehen die Weganzahl und Weglänge im Mittel zurück, zudem nehmen Führerscheinbesitz und Pkw-Verfügbarkeit bei künftigen Senioren noch zu, sodass die Zahl der sogenannten „Zwangskunden“ unter den Senioren abnimmt [SOMMER 2005]. Aktuell wird zwar eine Zunahme der Verkehrsleistung im ÖPNV bei jungen Erwachsenen beobachtet, allerdings ist dieser Effekt überwiegend in Ballungsräumen zu beobachten [ZUMKELLER et al. 2011].

Ein weiterer Faktor, der dämpfend auf die Nachfrageentwicklung wirkt, ist die künftige Entwicklung der Nutzerkosten des Verkehrs. Laut einer Abschätzung der Mobilitätskosten bis 2030 von InnoZ und WVI GmbH werden die Kosten für die Nutzung sowohl des Individualverkehrs als auch des ÖPNV bis zum Jahr 2030 gegenüber 2008 rund doppelt so stark steigen wie die Lebenshaltungskosten. Ferner ist davon auszugehen, dass aufgrund höherer Ausgaben für Gesundheit das Kostenbudget geringer ist, das für Verkehr zur Verfügung steht und daher die Fahrtanzahl und die Fahrtweiten zurückgehen. Daher erwarten die Autoren, dass es mehr Menschen geben wird, deren Teilhabe an motorisierter Mobilität aus Kostengründen zusehends eingeschränkt wird [HUNSICKER/SOMMER 2009].

2.3 Zwischenfazit

Aus diesen Entwicklungen ergibt sich, dass ein attraktiver ÖPNV mit klassischen Betriebsformen in dispers besiedelten Räumen nicht wirtschaftlich zu betreiben ist und daher Angebotsanpassungen vor allem in Tagesrandzeiten und auf tangentialen Verbindungen notwendig sind. Dies kann jedoch in eine Negativspirale aus Attraktivitätseinbußen und weiteren Nachfragerückgängen führen [BERTOCCHI/WEISSHAND 2011]. Exklusion aus finanziellen Gründen und die Konzentration von Infrastruktureinrichtungen führen dagegen dazu, dass ein ÖPNV-Angebot eine Voraussetzung für gesellschaftliche Teilhabe und ein Element der Daseinsvorsorge ist.

3 AKTUELLE LÖSUNGSANSÄTZE

Neben verschiedenen Angebotsmaßnahmen im ÖPNV wurden seit den 1980er Jahren und vor allem verstärkt seit den 1990er Jahren verschiedene flexible Bedienungsformen eingeführt, die nur nach Vorbestellung verkehren. Typische Formen sind

- Bedarfslinienverkehre (fester Linienweg, Bedienung nur nach Bedarf),
- Richtungsbandverkehre (genauer Linienweg zwischen definierten Start- und Zielhaltestellen ergibt sich aus den zuvor angemeldeten Zu- und Aussteigewünschen) oder
- Flächenbetrieb (keine Linienwege festgelegt bzw. Zu- und Ausstieg innerhalb eines Bedienungsgebiets überall möglich) [BMVBS/BBSR:5].

Eine Kombination aus flächenbedienenden Bedarfsverkehren und einer (beschleunigten) Expressbuslinie ist der Richtungsband-Expressbus-Betrieb: Dabei wird eine Buslinie durch das Einsparen von Umwegen so beschleunigt, dass sich attraktive Fahrzeiten ergeben, während der nicht mehr vom Expressbus bediente Bereich von einem bedarfsgesteuerten Verkehr bedient wird, der mit der Expressbuslinie an einem Umsteigepunkt verknüpft ist [BERTOCCHI 2009]. Ein weiterer Ansatz ist der Einsatz von Rufbushaltestellen, die nur dann bedient werden, wenn der Bus über einen Rufknopf an der Haltestelle angefordert wird. In Deutschland und Österreich sind derzeit mehr als 50 Rufbushaltestellen in Betrieb [SCHNEIDER et al. 2011].

Der Handlungsdruck, der durch die dargestellten Entwicklungen vorhanden ist, zeigt sich auch darin, dass das Bundesministerium für Bildung und Forschung den von 2001 bis 2004 den Förderschwerpunkt „Personennahverkehr für die Region“ gesetzt hat, in dem in ganz Deutschland verschiedene flexible Bedienungsformen analysiert und evaluiert wurden [BMVBS/BBSR:12f.]. Ein Nachteil von flexiblen Bedienungsformen ist ein finanzielles Risiko in Bezug auf Betriebskosten und Investition in Fahrzeuge. Kosteneinsparungen werden dort, wo der Linienverkehr bereits auf ein Minimum (Schülerverkehr) reduziert ist, nicht erwartet [BMVBS/BBSR:54 f.].

Eine weitere Reaktion auf die Mobilitätsbedürfnisse in der Region ist der Bürgerbus. Träger ist in den meisten Fällen ein gemeinnütziger Verein, der auch die ehrenamtlichen Fahrer der Kleinbusse zur Verfügung stellt. Der erste Bürgerbus in Deutschland fuhr bereits 1985, im Jahr 2010 gab es mehr als 150 Bürgerbusse. Bürgerbusverkehre existieren vor allem in ländlichen Regionen, vereinzelt aber auch in Großstädten [PRO BÜRGERBUS NRW].

Als Mitnahmeprojekte als Ergänzung des ÖPNV sind ein Projekt der Bergischen Universität Wuppertal sowie das Projekt „Carlos“ in Burgdorf (Kanton Bern, Schweiz) zu nennen, die beide allerdings nicht über die Pilotphase hinaus fortgesetzt wurden. Das Projekt „Nimm mit – steig zu“ wurde in den 1980er-Jahren in Niedersachsen als Pilotversuch eingeführt. Es wurden gesonderte Haltestellen für private Mitnahmen unabhängig von vorhandenen Bushaltestellen eingerichtet. Außerdem wurden Ausweise zur Identifikation für Fahrer und Mitfahrer eingeführt. Die Akzeptanz blieb deutlich geringer als erwartet. Das System „Carlos“ basierte auf ortsfesten Säulen, an denen eine Mitnahme zielbezogen angefordert werden konnte. Allerdings war die Auslastung der Säulen deutlich zu gering für einen kostendeckenden Betrieb [VDV 2009].

Darüber hinaus sind aktuell Mitfahrzentralen in der Einführungsphase, die eine Fahrtenvermittlung mittels verschiedener Medien, vor allem Smartphones, und enger Anbindung an soziale Netzwerke im Internet und an Navigationssysteme anbieten. Im Gegensatz zu bereits etablierten Mitfahrzentralen im Internet bieten diese Systeme eine Fahrtenvermittlung in Echtzeit und zielen auch auf die Vermittlung kurzer (auch innerstädtischer) Mitfahrdistanzen ab. Zu nennen sind Anbieter wie „car2gether“ in den Regionen Ulm und Aachen [CAR2GETHER], „flinc“ [FLINC] oder „PocketTaxi“ [POCKETTAXI]. Diese Systeme sind allerdings nicht als Teil des ÖPNV-Angebots konzipiert.

Enger mit dem öffentlichen Nahverkehr verzahnt ist das Projekt “immer mobil”, dessen Feldtest 2011 in Oberbayern durchgeführt wurde. Mit dem Projekt soll die Information über verschiedene Verkehrsangebote verbessert werden. Neben dem klassischen ÖPNV-Angebot wird zusätzlich über Fahrtangebote mit Bürgerbussen oder Sammeltaxen in Echtzeit informiert. Die Ergebnisse des Feldtests und einer Abschlussumfrage werden derzeit ausgewertet [IMMERMOBIL].

4 DAS BEISPIEL MOBILFALT

4.1 Grundkonzept

Die Oberziele von Mobilfalt sind die Erhöhung der Lebensqualität und der Attraktivität des ÖPNV im ländlichen Raum, die Sicherung der Daseinsvorsorge sowie die Erhöhung der Wirtschaftlichkeit im ÖPNV (eine höhere Betriebsleistung zu gleichen Kosten). Diese Oberziele werden anhand von Teilzielen konkretisiert, für die Indikatoren zur Messung der Zielerreichung festgelegt werden.

Das Konzept sieht vor, das vorhandene ÖPNV-Angebot durch private Mitfahrangebote zu ergänzen. Privatpersonen, aber auch Dienstleister wie Pflegedienste, Fahrdienste oder Kurierdienste, die in der Region unterwegs sind, sollen ihre Fahrzeuge effizienter auslasten können, indem sie Personen mitnehmen. Dadurch soll die zeitliche und räumliche Verfügbarkeit des ÖPNV deutlich verbessert werden. Die Integration eines Mitnahmesystems als Teil des öffentlichen Verkehrsangebots ist die Innovation und das Alleinstellungsmerkmal von Mobilfalt.

Mobilfalt-Fahrten sollen vor allem das Verkehrsangebot zwischen Ortsteilen oder kleinen Gemeinden und dem jeweils nächsten Zentrum mit zentralörtlichen Einrichtungen und Anschlussmöglichkeiten an das übergeordnete ÖPNV-Netz ergänzen. Dazu werden einerseits zu vorhandenen Linienbusfahrten zusätzlich Mobilfalt-Fahrten angeboten und neue Linien definiert, die ausschließlich aus Mobilfalt-Fahrten bestehen. In der Regel soll sich aus dem herkömmlichen Verkehrsangebot und den zusätzlichen Mobilfalt-Fahrten ein Stundentakt ergeben, in Schwachlastzeiten teilweise auch ein Zweistundentakt. Es handelt sich also um ein bedarfsgesteuertes Verkehrsangebot, das fahrplan- und haltestellengebunden ist und auch als Fahrplantabelle dargestellt wird. Der Ein- und Ausstieg soll an bestehenden Bushaltestellen und zusätzlich einzurichtenden Mobilfalt-Haltestellen möglich sein.

Damit die Nutzung von Mobilfalt für Anbieter von Fahrten und für Mitfahrer so sicher wie möglich ist, ist vorab eine Registrierung erforderlich. Die Anbieter von Fahrten sollen aus Sicherheitsgründen erst nach einer Überprüfung durch die Gemeindeverwaltungen in den Pilotgebieten Mitfahrten anbieten können.

Die Fahrtauskunft und Buchung erfolgt internetgestützt über ein IT-gestütztes Buchungs- und Abrechnungssystem, das für Mobilfalt entwickelt wird. Mit diesem System können sowohl Fahrer eine Fahrt anbieten als auch Mitfahrer sich über Fahrtmöglichkeiten informieren und Fahrten buchen. Darüber hinaus sind Buchungen telefonisch oder im persönlichen Kontakt auch über eine Mobilitätszentrale in der Kreisstadt Eschwege möglich. Die Fahrtvermittlung zwischen Fahrer und Mitfahrer soll automatisiert und in Echtzeit ablaufen.

Als Anbieter, Vermarkter und Koordinator von Mobilfalt tritt der Nordhessische Verkehrsverbund (NVV) auf. Wer Mobilfalt als Mitfahrer innerhalb der Pilotgebiete nutzen will, bezahlt an den NVV einen Fahrpreis von 1 Euro je Fahrt. Gibt es für eine bestimmte angefragte Fahrt keine Mitfahrgelegenheit, stellt der NVV eine Ersatzbeförderung mit Taxen sicher („Mobilitätsgarantie“), die den Fahrgast ebenfalls je 1 Euro je Fahrt kosten soll. Wer im Rahmen von Mobilfalt jemanden mitnimmt, erhält vom NVV eine streckenabhängige Kostenbeteiligung. Die Zahlung des Fahrpreises und die Auszahlung der Kostenbeteiligung erfolgt über das Buchungs- und Abrechnungstool.

Das Buchungs- und Abrechnungssystem enthält auch eine Bewertungsfunktion, mit dem Fahrer bewertet werden können. Dies dient der internen Qualitätssicherung.

Zur Identifikation zwischen Fahrer und Mitfahrer und gegenüber der Mobilitätszentrale soll eine Mobilfalt-Card im Scheckkartenformat eingeführt werden. Die Mobilfalt-Card ist als Marketinginstrument ausbaufähig, denkbar sind Kooperationen, etwa in Form eines „Mobilfalt-Rabatts“ bei verschiedenen Partnern.

Ein ähnliches Projekt wie Mobilfalt ist im Odenwaldkreis in Südhessen („Odenwaldmobil“) geplant. Dort sollen ebenfalls private Mitnahmen das Verkehrsangebot ergänzen. Allerdings besteht ein Unterschied zu Mobilfalt im vorgesehenen Fahrtenangebot, das bei „Odenwaldmobil“ keine Abfahrtszeiten für die privaten Mitnahmen vorab festlegt, sondern die Abfahrtszeiten sich aufgrund des Mitfahrtenangebots ergeben. Ein weiterer Unterschied ist eine Preisdifferenzierung, abhängig von der zeitlichen Flexibilität der Fahrtwünsche. Bei Nutzung eines Linienbusses sollen für den Fahrgast geringere Kosten als bei Inanspruchnahme einer Taxibeförderung entstehen. Derzeit werden noch wirtschaftliche und rechtliche Fragestellungen geklärt, ein Termin für die Betriebsaufnahme ist noch nicht bekannt [OREG].

4.2 Projektpartner

Mobilfalt wird vom Land Hessen im Rahmen der „Nachhaltigkeitsstrategie Hessen“ gefördert. Die Federführung bei „Mobilfalt“ hat der NVV. Als Aufgabenträger für den regionalen Busverkehr arbeiten die drei lokalen Nahverkehrsorganisationen im Projekt mit, in deren Zuständigkeitsgebiet die Pilotgebiete liegen. Das Fachgebiet Verkehrsplanung und Verkehrssysteme der Universität Kassel übernimmt im Projekt Mobilfalt die wissenschaftliche Begleitung.

Die Ausarbeitung der Fahrtenangebote in den Pilotregionen erfolgt durch zwei Planungsbüros. Ein wichtiger Beitrag, um Akzeptanz zu erreichen, ist die enge Zusammenarbeit mit Bürgermeistern, Kommunalpolitikern und sogenannten Starthelfern. Diese Starthelfer sind engagierte Bürger, die vor Ort für Mobilfalt werben und Teilnehmer gewinnen sollen.

4.3 Bedienungsgebiete

Mobilfalt soll in drei Pilotgebieten in Nordhessen erprobt werden (Lage siehe Abb. 3, Strukturdaten siehe Tab. 1). Das nächstgelegene Oberzentrum ist die Stadt Kassel mit rund 195.000 Einwohnern.

Die Stadt Niedenstein liegt ca. 24 km südwestlich vom Kasseler Zentrum und grenzt an die Stadt Baunatal (27.811 Einwohner), in der sich ein VW-Werk mit mehr als 13.000 Beschäftigten befindet. Zwei Buslinien bedienen die Stadt.

Das zweite Bedienungsgebiet umfasst die Gemeinden Herleshausen, Nentershausen und die Stadt Sontra, die einen „Zweckverband Interkommunale Zusammenarbeit“ bilden. Herleshausen und Sontra haben jeweils einen Bahnhof, der im Stundentakt bedient wird. In den drei Gemeinden verkehren außerdem elf Buslinien.

In der Stadt Witzenhausen gibt es einen Bahnhof in der Kernstadt, der zweimal stündlich bedient wird, und einen Bahnhof im Stadtteil Gertenbach, der stündlich bedient wird. In der Stadt verkehren acht Linien, davon sind zwei Linien ein Stadtbussystem mit Ringverkehr in der Kernstadt. In Witzenhausen befindet sich ein Fachbereich der Universität Kassel mit 817 Studierenden [UNIVERSITÄT KASSEL], darüber hinaus ist die Stadt ein regional bedeutender Gewerbestandort.

Für die Pilotgebiete Herleshausen/Nentershausen/Sontra und Witzenhausen hat das Hamburger Büro Gertz Gutsche Rümenapp (GGR) eine Untersuchung der Erreichbarkeit wichtiger Ziele mit dem ÖPNV, differenziert nach Zeitfenstern für verschiedene Wegezwecke, durchgeführt. Darin ergab sich unter anderem, dass die Erreichbarkeiten vormittags am besten sind, abends jedoch außerhalb der Zentren und abseits von Bahnstrecken nahezu keine ÖPNV-Angebote bestehen. Ganztags deutliche Erreichbarkeitsnachteile wichtiger mittelzentraler Orte aufgrund langer Reisezeiten wurden für die Umgebung von Sontra festgestellt [VFR WERRA-MEISSNER].

Pilotgebiet	Einwohnerzahl (30.06.2011)	Fläche [km^2]	Einwohnerdichte [Einwohner/km^2]	Anzahl Ortsteile inklusive Hauptort
Niedenstein	5.273	30,41	173	5
Witzenhausen	15.378	126,69	121	17
Zweckverband Interkommunale Zusammenarbeit	13.765	227,87	60	
- Herleshausen	2.925	59,52	49	10
- Nentershausen	2.887	57,06	51	6
- Sontra	7.953	111,29	71	16

4.4 Evaluationsbeitrag der Universität Kassel

Die Evaluation gliedert sich in die Prozessevaluation und die Wirkungsevaluation. Die Prozessevaluation fokussiert auf die Mittel und Abläufe, durch die eine Maßnahme umgesetzt wird. Sie bezieht sich auf alle Umsetzungsebenen einer Maßnahme und beobachtet alle Schritte der Maßnahmenkonzeption und -umsetzung. Die Wirkungsevaluation misst und bewertet die Effekte einer Maßnahme anhand eines Zielsystems.

Ziel der Evaluation ist es, Empfehlungen zu geben und die Chancen einer erfolgreichen Umsetzung durch Berücksichtigung der Rahmenbedingungen zu erhöhen. Außerdem sollen Erkenntnisse gewonnen werden, um übertragbare Empfehlungen für ähnlich strukturierte Regionen zu geben.

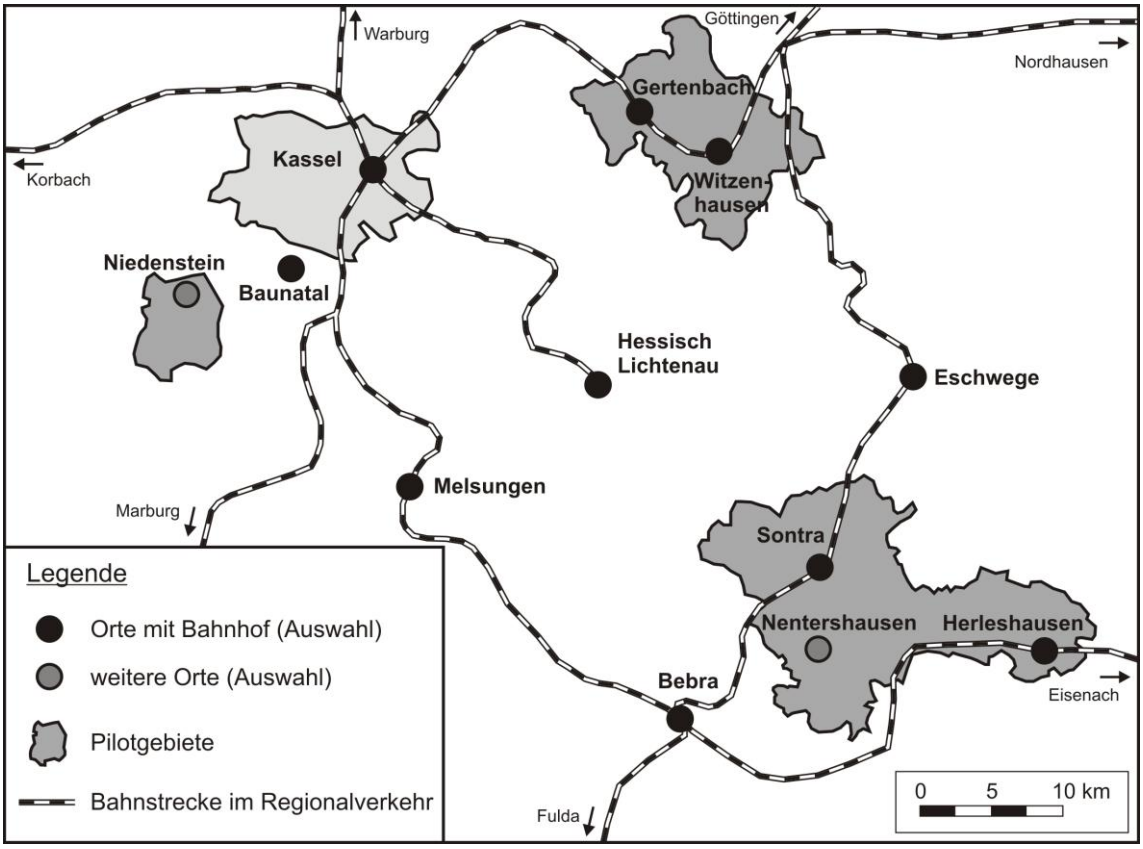

Abb. 3: Lage der Pilotgebiete von Mobilfalt, Quelle: eigene Darstellung

Prozessevaluation

Während der Konzeptphase arbeitet das Fachgebiet Verkehrsplanung und Verkehrssysteme der Universität Kassel bei der Aufstellung des Zielsystems mit und begleitet fachlich die Erstellung der verkehrlichen Konzepte. Zudem führt das Fachgebiet mit Versuchspersonen einen Test des Anmelde- und Buchungstools durch, bei dem die Bedienbarkeit und die Prozessgestaltung des Tools geprüft werden (so genannter Usability-Test). Die intuitive Bedienbarkeit ist ein wichtiger Aspekt bei der Entwicklung des Tools, um keine Zugangsbarrieren für wenig interneterfahrene Menschen aufzubauen.

Im Kontextmonitoring sollen relevante Änderungen externer Rahmenbedingungen auf das Projekt identifiziert auf ihren Einfluss auf den Erfolg von Mobilfalt untersucht werden. Diese Rahmenbedingungen lassen sich in ökonomische (z. B. Kraftstoffpreise), politische und soziale Rahmenbedingungen (Änderungen bei den Akteuren vor Ort) unterteilen. Sie werden kontinuierlich während der gesamten Projektlaufzeit erfasst und hinsichtlich ihrer jeweiligen Relevanz beurteilt.

Während der Testphase wird die Nutzung des Systems kontinuierlich beobachtet: Aus den Daten des Anmelde- und Buchungstools lassen sich quantitative Merkmale der Nutzung auswerten, so z. B. die Entwicklung von Anzahl und Struktur der Nutzer (registrierte Fahrer und Mitfahrer, Nutzungshäufigkeiten nachgefragter Relationen und zeitliche Verteilung der Fahrtwünsche). Die „Aussteiger“ aus dem System (Personen, die nicht weiter an Mobilfalt teilnehmen wollen) werden befragt, um die Ursachen für den Ausstieg zu erfahren und aufgrund dieser Information das Mobilfalt-Konzept und die Umsetzung zu verbessern. Zusätzlich werden ausgewählte bevölkerungsrepräsentative Gruppen (ÖPNV-Kunden und Nicht-Nutzer, differenziert nach Merkmalen der Soziodemografie und des Verkehrsverhaltens) mehrfach während der Projektlaufzeit befragt. Die Ergebnisse dieser Befragungen und die Daten aus dem Anmelde- und Buchungstool fließen nicht nur in die Prozessevaluation, sondern auch in die Wirkungsevaluation ein.

Wirkungsevaluation: Ermittlung verkehrlicher, sozialer und wirtschaftlicher Wirkungen

Neben den oben genannten Daten soll darüber hinaus eine kombinierte Online- und schriftlich-postalische Befragung etwa ein Jahr nach Aufnahme des Mobilfalt-Betriebs durchgeführt werden. Damit sollen unter anderem das realisierte Verkehrsverhalten, aber auch Einstellungen und Kenntnisse zu Mobilfalt und zur Nutzung des ÖPNV erfasst werden. Dadurch sollen Verhaltensänderungen durch Mobilfalt erfasst werden.

Schließlich folgt die Untersuchung der Wirtschaftlichkeit nach betriebs- und volkswirtschaftlichen Kriterien. Betriebswirtschaftlich spielen vor allem die Kosten für die Entwicklung des Abrechnungs- und Buchungssystems und die laufenden Kosten für Mitnahmeentschädigungen und Ersatzbeförderung sowie für Marketing eine Rolle. Ferner sollen die Erlöse abgeschätzt werden. Diese Aufgabe erfordert unter anderem eine Abschätzung des zusätzlichen Verkehrs im ÖPNV, der durch Mobilfalt induziert wird. Dies bedeutet, dass Wirkungen auf den übrigen ÖPNV mit einbezogen und erfasst werden müssen. Diese Wirkungen könnten Steigerungen der Fahrgastzahlen im übrigen ÖPNV durch verbesserte Erreichbarkeit von ÖPNV-Knoten, aber auch Kannibalisierung des bestehenden ÖPNV durch Mobilfalt-Fahrten sein.

Ein aus wissenschaftlicher Sicht sehr wichtiger, jedoch auch komplexer Punkt ist die Abschätzung volkswirtschaftlicher Nutzen. Eine wichtige Rolle wird dabei die Erfassung und Beurteilung der Nutzen sein, die durch das verbesserte ÖPNV-Angebot und damit durch Möglichkeiten zur Teilhabe entstehen.

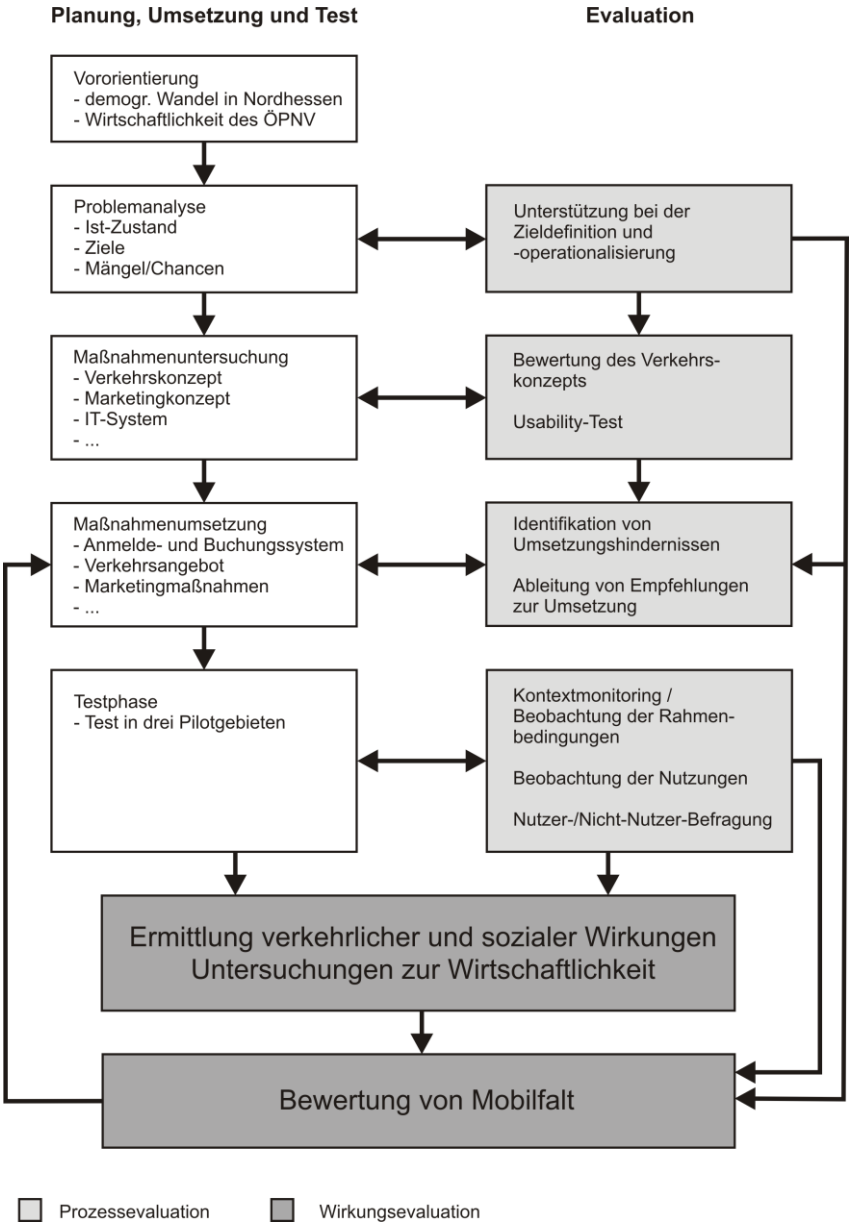

Abb. 4: Prozessevaluation und Wirkungsevaluation in Planung, Umsetzung und Test von Mobilfalt. Quelle: eigene Darstellung

5 AUSBLICK

Derzeit werden die Fahrtangebote von Mobilfalt im Detail geplant. Während der Planung werden die Starthelfer in den Pilotgebieten als Multiplikatoren eingebunden. Sie spielen eine zentrale Rolle im Marketingkonzept, das neben klassischer Werbung und Öffentlichkeitsarbeit auf die Wirkung von Multiplikatoren setzt. Ziel ist, damit einerseits eine ausreichende Zahl von Fahrtanbietern zu finden, andererseits aber auch eine hohe Nutzung sicherzustellen.

Parallel dazu läuft die Implementierung des Buchungs- und Abrechnungssystems, dessen Bedienbarkeit die Universität Kassel in einem Usabilitytest untersuchen wird.

Der Betrieb von Mobilfalt soll in den drei Pilotgebieten zum 1. Oktober 2012 starten. Die Pilotphase soll bis Ende 2014 andauern, dann werden erste Ergebnisse der Evaluation durch die Universität Kassel erwartet.

Mixed Building use Promotes Mixed Urbanity: Insights from Historical Use-neutral Architecture

Angelika Psenner

(DI Dr. Angelika Psenner, Vienna University of Technology, Dep. of Urban Design, apsenner@email.archlab.tuwien.ac.at)

1 ABSTRACT

Starting from the idea that we no longer want to go on with the separation of housing, working and leisure within the city and its quarters—as it had been codified by the Charta of Athens and in succession by many legal advices, like the development, land use and master plans of the different cities; but which in the end leaded to dormitory suburbs, nightly depopulated business district and almost deserted urban open spaces, that redundantly have to be dumped to the overwhelming traffic (the other outcome of urban functional separation)—we deeply consent that *remixing* is the adequate answer. The newly planned and developed city quarters all over Europe—like HafenCity Hamburg, Seestadt Aspern—represent this new approach.

This *remixing* has to be enabled not only within the quarter or within the upper and lower levels of a house—by putting a certain number of shops underneath a traditional residential building on top—but it actually has to be enabled throughout *the whole building* and throughout every single building. And the mix has to be really richly varied and flexible at any time of the buildings' lifespan. Units shall be used as apartments and after some years—if the tenants or owners change, or if the residents' perspectives have changed—the units shall be easily converted into offices or studios or even gymnastic halls and restaurants.

The architectural concept that offers the solution to this task does not have to be complex nor does it have to be expensive. Actually Vienna already disposes such an architectural structure that evidently does fulfil the mission: The *Gründerzeit architecture* easily performs the task of being use-neutral.[1]

Fig. 1: Gründerzeit houses in Viennas 9th district © Angelika Psenner

These properties, built between 1848 and 1918, currently command a high value in the real estate market, reflecting a lively demand for both the buildings and the flats. This fact is surprising given that the drawbacks of these historic buildings are well known. That would be:

- Densely built-up areas: The GZ districts lack a sufficient balance of accessible outdoor recreation areas.[2]
- High vacancy rate on the ground floors.[3]
- Expensive overhead, high maintenance costs, and sparse population.

Therefore, what is it that accounts for the high market value of GZ buildings? First of all the generous ceiling heights have to be mentioned. Typically measuring between 3.20 and 4 metres—on ground floors, up to 5 metres—they basically constitute the framework for the 'grand and lordly' façades. The extravagant floor

[1] One quarter of the apartments in Vienna is located in GZ buildings. (see also: Psenner, 2011a, 196)

height also allows for diverse use: the modular and small-scale structure of the units can be merged or separated as required, while at all times conserving the well-balanced spatial proportions.

Right from the beginning, GZ buildings were used for both living and working; And to this day they accommodate uses as diverse as apartments, hotels, offices, kindergartens, cinemas, churches, fitness centres… even boulder climbing halls are situated in GZ houses.

1.1 Research question

What motivated investors to place so much importance on high ceilings – in spite of the fact that GZ buildings are said to be the prototypes of profit-driven capitalistic ideas? How have the high ceilings paid their way? What did their profit-value consist in?

By quoting original literature of the time the paper will offer a most astonishing answer to this question and with this a new approach to the ongoing discussion about the value of use-neutral architecture.

2 INTRODUCTION: THE VIENNA GRÜNDERZEIT BUILDING

2.1 Apartment Buildings as Objects of Speculation

The Gründerzeit period is marked by an unrestrained unfolding of the liberal-capitalist spirit that drove the industrialization of the Habsburg Monarchy. While housing previously had been an occasional source of income for large property owners, it was during this period of economic liberalism that it became a full-blown object of speculation.[4]

One of the conditions that allowed for this extraordinary building boom was the so-called Grundentlastung (agrarian reform), implemented in the years following the abolition of manorialism in 1848. Aristocracy lost ownership of most of their land, which reduced their economic influence and in consequence led to a boost in the real estate market.

A second condition was *migration*: within eight decades Vienna's population grew from 440,000 in 1840 to 2,238,545. Most of the population was absorbed within the suburbs, where the population grew from 242,000 in 1870 to 1,011,000 in 1910 (Bobek, Lichtenberger, 1978, p. 30-31), resulting in an excessive demand for and overcrowding of apartment buildings. In 1894, the Viennese Architect Lothar Abel (1841-1896), published a widely read article about the overwhelming "housing question": *"Das gesunde, behagliche und billige Wohnen" ("Healthy, Comfort¬able and Affordable Living").*

So-called building speculation, which considers a house not as a property but as a commodity, is the real cancer of our current art of building. These speculators start out by calculating the rent that they want the house to yield (...). In order to obtain this rent, the building costs are set at a certain level, and this level must not be exceeded under any circumstances. (...) Normally the price obtained does not buy very much, and this is compensated for by economizing in the building's masonry, its wooden structures, etc., just as much as is required for the initial calculation to work. Moreover, since the building does not yield any rent while being constructed, it must be completed with a time that is too short for it to be proper and solid. (Abel, 1894, p. 132-133)

2.2 Living and Working in a Gründerzeit Building

Bobek and Lichtenberger's standard work *Wien: bauliche Gestalt und Entwicklung seit der Mitte des 19. Jahr¬hunderts* (Vienna: Architectural Form and Development Since the Mid Nineteenth Century) offers illuminating data that provide a view of living conditions in the apartment buildings:

In 1869, 72 % of all apprentices and 22.9 % of the workers lived in their respective employers' buildings. Consequently, the proportion of non-family residents (workers, lodgers, so-called Bettgeher,[5] apprentices) in a household was as high as 42.6 %. 55.1 % among the 179,388 industrial employees had no apartment of their own, they were lodgers or Bettgeher in their employers' households.[6]

[4] In 1860 Vienna had half a million inhabitants and 8,493 landlords (Fellner, 1860, p. 5.), whereas at the height of the Gründerzeit period (1870–1890), 18.9 % of the residential buildings in the city and its suburbs yielded such high returns that the owners were able to live on this income alone (Bobek, Lichtenberger, 1978, p. 38).
[5] Literally 'bed goer'; lodgers sharing the same bed in day and night shifts.
[6] Bobek, Lichtenberger, 1978, p. 35-38.

The economic structure of Viennese GZ-industry was dominated by small businesses, which were all based in residential buildings. Only a few among the businesses covered in the 1869 business census had more than 10 workers—and only businesses located in the suburbs (like beer breweries) had more workers.[7]

Generally apartment buildings were used both for *living* and working. Yet, even on the *bel etage* itself 'stately', sizeable apartments existed next to offices of doctors, *lawyers*, factory-owners, and so forth.

Use-neutral Gründerzeit Architecture

Given their historical use, GZ buildings must be considered as beeing *use neutral*: they served both as residences and workplaces—largely due to the fact that in the 19th century there was little separation between living and working. The residents' way of life always comprised every possible form of expression: the 'residential' quarters were used for eating, sleeping, cooking, working, etceteras.[8]

For our purposes, the question of the 'hardware' is of interest: the scope of possibilities that GZ architecture was—and still is—capable of providing. Use-neutral and open-use architecture is primarily defined through a flexible room model[9] and adequate ceiling heights. The flexible room model secures the possibility of adaptation: a renovation can be carried out—and even reversed—at any time. Tenants and owners can thus design apartments and workplaces according to their own ideas and needs. In some cases, when the ownership permits it, apartments can be joined together, transgressing allotment boundaries. When smaller units are merged into a large space, it is the generous ceiling height of GZ buildings that ensures adequate room proportions. In this way, a GZ apartment building can accommodate spacious, prestigious offices for lawyers, for instance, as easily as day care centres for kids, coffee houses, community centres, yoga schools, and so forth—they all find their place in the GZ structure. At the same time, the supply of smaller housing units has again increased in order to accommodate the increasing number of single-person households. High ceilings allow for the creation of large units while also retaining the possibility of returning to a smaller scale.

So how did this happen? What motivated investors to place so much importance on high ceilings while GZ buildings are said to be the prototypes of unlimited profit-driven liberalistic-capitalistic ideas?

3 ON THE GENEALOGY OF THE VIENNESE GRÜNDERZEIT BUILDING: THE HISTORICAL DEVELOPMENT OF THE GRÜNDERZEIT BUILDING STRUCTURE10

3.1 Building Height and Ceiling Height

The total height of the average GZ building was originally set at 4 storeys. From 1868 on, 5 storeys were allowed—including a mezzanine[11] and the ground floor; additionally, these 5 storeys were limited with a

[7] The 1859 Trade Act resulted in a liberalisation of what previously had been a guild-controlled industrial structure. With the new act, taking up a trade required only registration with the authorities and was otherwise free of restrictions. There were only 14 trades that required a business permit. Even though the stock crash of 1873 resulted in a return to a guild-based approach to the economy, the economic structure remained dominated by small businesses.

[8] Moreover, the apartment building harboured people of different social strata: members of the bourgeoisie, factory owners, intellectuals, entrepreneurs, craftsmen, handymen, day labourers...all lived under the same roof. Communal life was ordered by rigorous behavioural codes and strict hierarchies. Still, everyone used the same entrance and the same stairway—a circumstance that met with disapproval in some countries and social circles. The explanation for this dense intermingling of social strata, unique in Europe, rests in a mix of socio-historical, economic, and cultural factors—a discussion exceeding the scope of this paper.

[9] This aspect is not addressed here as there already exists a wide range of publications, e.g. Erich Raith, Stadt-morphologie, 2000.

[10] In Vienna, construction regulations were introduced in 1829. In 1830 the first building regulation act was issued. The regulations written by von Mühlböck in 1843 (the contents of which coincided with those of 1830) represented the construction decrees then in force in 8 topics, 3 sections, and a total of 30 articles. The Gründerzeit period underwent a total of 4 different issues of the applicable building regulations. As mentioned, the first regulations were issued in 1830, followed by a second one in 1859 and a third one in 1868. The latter comprised as many as 93 articles and was amended in 1870 in response to the changes required by the introduction of the metric system. The last relevant issue of the building regulations was released in 1883 and for the most part remained valid up until the first third of the 20th century, with one amendment enacted in 1890.

[11] In his PhD dissertation, *Graz, Strukturwandel einer Stadt im Lichte ihrer Bauvorschriften (1856-1968)* Peter-Heinz Marauschek attributes the existence of the mezzanine to a circumvention of the article 17, according to which "new

total height of 13 fathoms (equivalent to 23.77 metres). When the metric system was introduced in 1870, the maximum building height was increased to 25 metres. The building regulations of 1881 allowed 0 metres for the upper edge of the flooring of the uppermost floor. Also coinciding with the introduction of the metric system, the minimum ceiling height was increased from 2.74 (circa 1843 and 1868) to 3 metres.

Taking these different conditions into account and assuming a ceiling structure of approximately 40 centimetres, a discrepancy among the various height requirements becomes apparent—a discrepancy that circumscribes the actual excessive storey height without, however, explaining it. It is becoming clear that the ceiling heights of 3.20–4 metres (more on the ground floor) characteristic of the Viennese Gründerzeit building cannot be accounted for on the basis of building regulations. Instead, a formula is revealed, that is, the difference between the maximum building height (25 metres) and the largest allowed number of storeys multiplied by the minimum ceiling height (5 x 3.40 = 17 metres).[12]

What motivated speculating investors to incur this additional expenditure?

3.2 Ceiling Height Value in Public Health Economy

By the late nineteenth century, GZ Vienna was considered to be particularly densely populated. Additionally, Vienna had been repeatedly afflicted by epidemics, which drew considerable attention to the sanitary problems in the city's apartments. Time and again 'physicists' and doctors were invited to participate on commissions in order to draft expert opinions regarding public health care, and subsequently, to aid the reform of building regulations. Examples include the 1882 *"Bericht des Ausschusses der k.k. Gesellschaft der Ärzte zur Berathung der Reform der Wiener Bauordnung"* (report of the Imperial Medical Society on Suggestions for a Reform of Vienna's Building Regulations), and Carl Haller's lecture, held in 1864 on behalf of the Imperial Society of Physicians in Vienna with the title *"On the Ventilation of our Apartments"*.

Research on sickness and mortality in our capitals…has shown that the course, the direction, and the duration of our most common epidemics are most evident at locations without a sufficient renewal of the air, and that improvements—such as they are manifest in the great successes of our charitable construction societies—do the most towards changing that situation. This research has also revealed that the dominant disease of our time, tuberculosis, which reaps away the most beautiful among our youths, and often also the blossoms of our intelligence with its cruel hand, killing 6000–7000 people in Vienna every year, has its main source in an insufficient breathing process. (Haller, 1864, p. 16)

When one compares the living situation in five of Europe's largest cities, the enormous influence that apartments have on the moral and physical condition of the population becomes mathematically evident. As mentioned previously, there are 7 persons to one building in London, 35 in Paris, 58 in Berlin, 52 in St. Petersburg, and none less than 59 in Vienna. As the number of inhabitants per house increases, mortality also increases, for out of 1000 people 24 die in London, 25 in Berlin, 28 in Paris, 41 in St. Petersburg and 47 in Vienna. (Abel, 1894, p. 347)

The theories about 'systematic air renewal' and 'ventilation' merit special reference. Developed by Paul Traugott Meissner, professor of technical chemistry in Vienna, it was received and disseminated as a "path-breaking thesis" across Europe.[13]

Of air layers in inhabited rooms there are always three, that is, the lower one, on the floor of a room, where carbonic acid, the heaviest among the gases make-up the air, will accumulate, in as much as through the breathing process so much of it is given off that it can no longer be bound by the atmospheric air. This is a

buildings (...) may only be built four storeys high: Evidently, the preferred way of circumventing this norm was via the entresol (mezzanine)—a low in-between storey located between the ground and the first floor, or between the uppermost floor and the roof—which had to be considered a storey in the terms of the 1868 law." (Maruschek, 2010, p. 98) Other theories attribute the mezzanine to the storey tax, to be circumvented by the terms 'mezzanine' or 'entresol'. This is an assumption for which no evidence has so far been found: documentary research at the City of Vienna's departments for legal matters of construction (Municipal Department 64) and for accounting and fees (Municipal Department 6) as well as in the city archives yielded no results.

[12] In relation to this consideration, the maximum allowed upper edge of the uppermost floor (20 metres) must be juxtaposed to the calculated height of 4 x 3.40 = 13.60 metres.

[13] "Die Ventilation und Erwärmung der Kinderstube und des Krankenzimmers", (Ventilating and Heating Nurseries and Sickrooms), 1852. (Research on ventilation has also been carried out by Eugène Peclet, Pat Arnott, and David Boswell Reid.)

case that frequently occurs in souterrain and basement units. Furthermore, the middle air layer will take up the lighter atmospheric gases, and finally on top of those there will be the even lighter putrid gases, mainly nitrogen and all the carbohydrates. Most of the ventilation installations siphon off the uppermost layer of air, which results in a continuous exchange of air in the room. (Abel, 1894, p. 227)

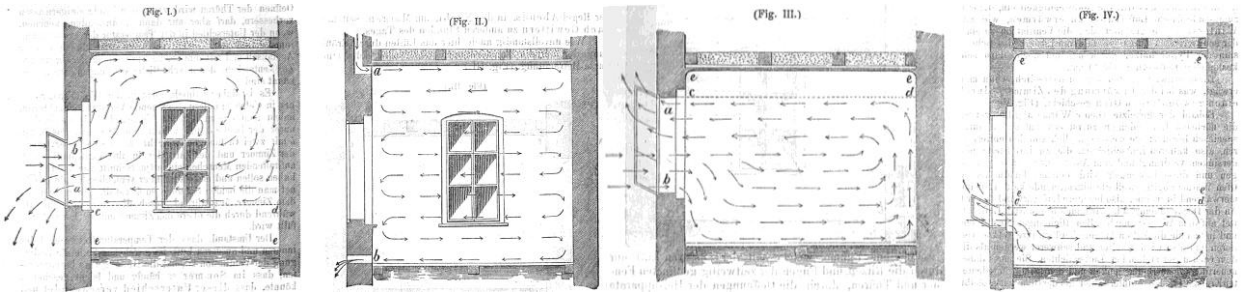

Fig 2: theories on ventilation, according to Carl Haller, 1864, p. 25-31

Returning once more to the harmful effects of putrid air, there can be no doubt that it gives rise to the most problematic of health disorders. Even when the degree of contamination does not reach very high levels, it is the permanence of the effect of the room air that will increase the propensity for illnesses: a poor diet, anaemia, and the like—we can easily tell these things by the room dweller's pale complexion. (Alsberg, 1882, p. 32)

The concept of 'air layers' led to specific advice for architects and builders:

As is known, high rooms are much healthier than low ones, because in the former the air will always be pure, and high rooms can accommodate a greater volume of air on the same amount of surface.…However, in the case of finer residential building's elegant rooms one must not fail to consider the architectural conditions, and one will therefore give smaller rooms a lower ceiling than large ones. All the while, one should not have rooms with a ceiling lower than 3 metres, especially when the room also serves as a sleeping room, in part because it would be unhealthy and there would be a lack of air supply, in part because of the danger of fire, as lamps placed on the table and the heat of the fireplace would then be too close to the ceiling. (Abel, 1894, p. 276)

From this point of view, small children were thought to be particularly at risk, which is why the practise of mounting cradles and children's beds on high base frames became widespread:

Fig 3: children's furniture; left: lowered cradle from the Biedermeier era (around 1820/1825) (Pressler/Straub, 1991, p. 94), right: child bed with high base from the Gründerzeit era (around 1860) (Ottillinger, 2006, p. 134)

Another highly dangerous effect of contaminated room air is that in children it very often causes scrofula as well as increasing the propensity to catarrhs, the English disease (rickets), and similar conditions, thus paving the way for later infirmity already in childhood. (Alsberg, 1882, p. 32)

A further health and sanitation argument in favour of high ceilings was made in connection with 'scientific explanations' of the salutary effects of light and sunshine:

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

Looking now at the effect of the illumination from the façades and the windows, we notice that the same amount of light entering through the windows will create a better illumination of the rooms where the ceilings are higher and the buildings less deep.…In buildings with small apartments, a ceiling height of circa 3 metres corresponds to a depth of approximately 10 metres, while buildings with large apartments have a depth of circa 12 metres with a ceiling height of circa 3.6 metres. The lower floors of a building usually have higher ceilings, and rightly so, as this allows the limited light supply to be largely compensated for by better conditions inside the building. (Serini, 1913, p. 9)

Against the background of these arguments, it also becomes clear why the windows in Gründerzeit buildings were made both as high and narrow as possible, and why a greater ceiling height is required on the ground floor. Even though the building regulations stipulated a ceiling height of 'only' 3 metres, there was a general recognition that heavily used rooms—considering a per-head-space requirement of 4 square metres (!) – required a large air volume. Health considerations along with the desire for sufficient light must, therefore, be seen as the reason for the familiar and excessively high GZ rooms.

3.3 The Market Value of Ceiling Height

"Whenever I consider purchasing something, I must know its value at least approximately in order not to be deceived." (Řibřid, 1913, p.3)

From our current understanding, the original, historic value of a GZ property is not easy to comprehend. However, economic perspectives from the period offer insight into this phenomenon; for instance, in the book of architect and city-employed builder L. Kurzweil: *Wert- und Rentabilitätsberechnung von Zinshaus-Realitäten; Mit besonderer Berücksichtigung der Amortisation* (*Calculation of Value and Cost-effectiveness of Apartment Buildings, with Special Consideration of Amortisation*). Kurzweil intended the book as a "Ratgeber für Hauskäufer, bzw. – Verkäufer, für Architekten, Baumeister, Hausadministratoren und sonstige Interessenten" (guide for buyers and sellers of houses; architects, builders, building administrators, and other interested parties). Using complex tables, the author computes purchase value, depreciation, and total fees[14] (taxes, charges, dues, etceteras), based on the various rental tax regulations that applied to the buildings.

According to Kurzweil, the price of a property was determined by three different factors: simply put, one could say that the value of a property was determined by the value of the *building lot*, the so-called *building value*, and the *earning rate* (resulting from the rental income). "The earning value by itself does not represent the value of the building….The true value of a building is determined by adding up the value of the building lot with the building value and the earning value, and then dividing the total by two." (Řibřid, 1913, p.13).

Consequently, the **estimated value of a property** is the result of the mean value between the cost of production (value of the lot and the building) and the earning value. Thus, it is not the rental income alone that determines the value of a building.

Land Value, Building Lot:

In addition to its size, the value of a building lot is determined by its location and its shape (configuration).

Configuration: Small and shallow real estate lots achieved a lower sales price than wide lots of medium depth—in other words, pieces of land that were suitable for the construction of double blocks. Deep lots were considered less desirable because of the unfavourable ratio between the high rated front building and the low rated apartments of the back building. (Bobek/Lichtenberger, 1978, p. 50). What mattered was primarily the width of the main building front: a wide front combined with a shallow lot depth was considered a desirable building lot configuration. (see Řibřid, 1913, p.8) "As is known, we determine the value of an apartment by the number of its street-side rooms." (Abel, 1894, p. 301)

Location: In his 1901 analysis "Die Entwicklung der städtischen Grundrente in Wien" (The Development of Urban Land Rental in Vienna), Paul Schwarz finds a marked decline in land prices towards the urban periphery. This concentric structure was overlaid by sectors with (greatly) increased land prices. The western and north-western sections of the city, between the Vienna valley and the Danube canal, were considered particularly expensive, while districts such as Margareten met with little demand (Schwarz, 1901, cited in

[14] For example, there was a fee for a 'vault guard' (responsible for publicly accessible street level and basement spaces) that operated in the first district only. Depending on the location and type of the buildings in question, the fee was divided into four categories ranging from 6 to 44 crowns.

Bobek/Lichtenberger, 1978, p. 50). The reasons for this are to be found in the city's topographical building history[15] as well as the stage of completion of the urban transit infrastructure.[16]

Building Value:

The building value is determined by the size of the built-up surface, by the building materials, as well as by the number of storeys and the exterior and interior fittings. Naturally, the more abundant these fittings, the higher the building value will be. (Řibřid, 1913, p.8)[17]

The evaluation was, thus, based on the number of square metres of built-up surface, and on a specific multiplier for the fittings. The design of the façade played an important role in this, too.[18] There were other designations at work as well: "basic one-story buildings", "more elaborate buildings", with basements, without a souterrain, without a mezzanine, with hard floors on the street side, and soft floors on the yard side, and so forth. Furthermore, buildings were differentiated by "elegant interiors: hard floors on all storeys, kitchens with firebrick floors, the whitewashing of the walls done with more than three cartridges; apartments of three or four rooms on the lower floors" and finally those "equipped with all comforts". In the case of the latter, the definition presumes that "everything be: lavishly decorated and furnished" with "elegant business parlours, and furthermore a souterrain, a mezzanine, and an attic with a laundry".

In the case of a single-floor building, 1 square metre of building surface is valued with 498 crowns. For additional floors, more is calculated, that is, 80 crowns for the second floor, 77 for the third, 73 for the fourth, and 42 crowns for rooftop artist studios. In the case of corner buildings, 6 % is added to the square metre value. (Řibřid, 1913, p.9)[19]

Many of the early Gründerzeit buildings—particularly in the main commercial streets, where they often lasted less than 50 years—were replaced by the turn of the century (1900).

Return on Investment, Rental Rates

The actual rental income, that is, the return on investment, accounted for a small part of a property's value, and was by no means as central as one might assume from today's point of view. Moreover, it was a known fact that rental income reports were manipulated through the distinction between gross returns and net income:

In order to correctly determine the gross return, it is not sufficient…to merely look at the tax declarations, for these may be incorrect for a number of different reasons; they may state too high or too low of an income and thus not correspond to the actual state of affairs.…Moreover, it often happens that building proprietors seeking to sell their buildings try to increase the rents—even if only for a short period of time—without consideration as to whether such inflated rents can be maintained in the future. (Řibřid, 1913, p.11)

The net income resulted from the gross returns from rental payments less the housing rent tax (after substracting the tax benefits[20]), reduced by all additional charges and dues (provincial, municipal, schooling,

[15] Aside from the all-determining topographical factors, the main radial roads played a particularly important role in the Viennese case.

[16] In the early Gründerzeit there was no public transportation in the city. A record in 1850 identifies 700 rented two-horse carriages and 60 wagons (so-called Zeiselwagen). The first horse-drawn railway was inaugurated in 1856. In 1872, 900 fiacres, 1100 one-horse carriages, and 960 horse-drawn wagons were registered.

[17] The construction time for a "normal or slightly better, multi-storey building" is estimated to be 1.5 years—that of a two-storey building, 1 year. (Řibřid, 1913, p.6)

[18] It seems all the more odd that in the 1950s and 60s removing facade ornaments was promoted by the city by means of the law. Evidently, decorative facade plastering had lost its importance in the post-war period and, being out of step with current notions of architecture, were often viewed as bothersome. In the same period, the old buildings in German cities underwent what was called *Entstuckung*, or de-plastering.

[19] The building value also included the so-called Interkalare, the loss of interest on capital during construction. The law of 9 February 1892 (Imperial Legal Gazette #37) introduced a 24-year rent tax exemption for the construction of "healthy and inexpensive" apartments for labourers, indicating only two requirements: apartments underneath street level were excluded from this tax exemption, while the minimum size for one-room flats was 15 square metres, and multi-room flats 40 square metres, with 30 square metres and 75 square metres being the respective upper limits. Another law on tax exemption for workers' homes was passed in 1903 (Imperial Legal Gazette #6, 1903), this time with detailed requirements. (Marauschek, 2010, p. 6)

etc.), reduced by the amortisation of the construction capital, that is, the time dependent devaluation,[21] reduced by the cost of building maintenance, fire insurance, chimney sweeping fees, building administration (including an apartment for the concierge), floor lighting, and finally the cost of vacant apartments or shops.

3.4 The Stadthaus-Image as Market Value

The *Stadthaus* (urban building), through its vocabulary of forms, catered to certain perceptions of value, which in turn co-determined its market value. It distinguished itself clearly from the rural or single-family home. Consider the following experimental scenario: in what way does the façade of a GZ apartment building change if its height is reduced (while the vocabulary of forms remains unchanged)? The images reflect the problem: the one on the left is the original, while on the right the building has been reduced to 17 metres, applying the minimum ceiling height of 3 metres required by the building regulations. The clumsy proportions are much closer to the formal expression of a country house. Even though this building would meet the building regulations, it would hardly have been perceived as 'valuable'.

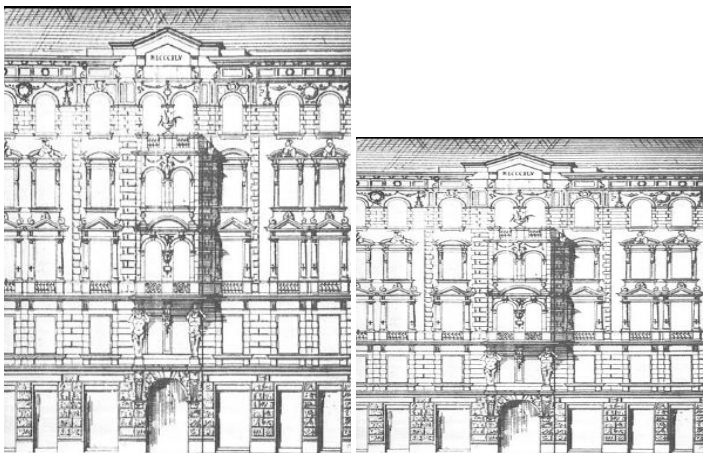

Fig 4: Front of a four-storey apartment building from the high Gründerzeit. Original picture (left): Bobek/Lichtenberger, 1978, p. 120

The rich and magnificent façade is the cheese with which to catch the mice. One must not hold this against the builders, even though they may often be pointed at as scapegoats when they abet construction speculation. (Abel, 1894, p. 227)

Most of the apartment buildings are erected with the intention to accommodate as many tenants as possible, while decorating the façade with all kinds of terracotta or cement ornaments, such as can readily be obtained from factory storehouses. (Abel, 1894, p. 99)

Furthermore, in this little book [note: the treatise by Eitelberger and Ferstel, critiziced by the author] the modern apartment building-monsters are accused of feigning a palace-like appearance, without having the essential attributes of such a grand building, which is only a way of expressing how regrettable it would be if the countryman ever reached a level of wealth that would allow him to afford himself a stately home with high ceilings and windows, instead of his seven-shoe high thatched hut, for he would then, in spite of the architectural oddities that such buildings will always retain, still come closer to the wealthy citizen, or even the lordly manor. Besides, such frivolous builders are also accused of being extravagant and vain enough to install double doors and Venetian blinds, while the tenants are accused of requesting the same, which are sheer luxury and fitting for a palace, but not a townhouse! (Fellner, 1860, p. 10)

Attempting to establish through research the reasons for the excessive ceiling heights of the Gründerzeit buildings has been demanding. Apparently, we are looking at knowledge that was immanent in a system or within society; in other words, its content was considered so obvious and 'logically evident' that it was deemed unnecessary to make it explicit.

A **'valuable' building of this period necessarily had to have a 'stately' appearance,** because the value hierarchies of the Gründerzeit were influenced by the bourgeois ideology of the Vormärz period. The latter was oriented towards neo-classical images and details as well as elements of the Renaissance with a preference for triangular, segmented gables, and **'stately' sizes and proportions.**

[21] Buildings constructed with fire-proof materials were expected to last 130-150 years, those with standard materials 70 to 100 years. Currently the amortisation period for new buildings is 66.67 years. (Standard, 2011, p. 11).

Whenever the architectural forms of the Gründerzeit were questioned by contemporaries, it was not because of the ceiling height.[22] After all, the necessity of high ceilings had been 'scientifically proven' (see the previous section on air layers and ventilation), and furthermore, the added cost of constructing high ceilings, being covered by higher return on investment and the greater market value it generated, did not actually to add to the costs.

Who has not observed the practices of our local masons! Several workers stand in one place, duly lining up the bricks one after the other; once they have thus completed a row, there are hands who bring in the liquid mortar, applying it upon and between the seams by using large spoons. The complicated process, requiring much supervision but little action, is completed…. (Velleman, 1872, p. 62)

In his 1872 treatise "Die oeconomische Bedeutung der Bauordnung in Oesterreich" (The Economic Significance of Building Regulations in Austria) architect and engineer G. Vellemann identifies what he considers to be adverse conditions in the construction industry. Looking at his meticulously recorded price lists, it becomes evident that during Vienna's GZ period, masonry work was carried out consistently by day labourers, keeping the price per cubic metre of walling exceptionally low.

4 CONCLUSION

The Gründerzeit apartment building represents an architectural form of use neutrality that is empirically evident. Its openness to different forms of use, historically proven and established over the decades of its existence, is based on the following attributes:

- a simple and flexible room model
- high ceilings
- high perception of prestige (value) reflected in fittings, ceiling height, and façade

The market value of the GZ building was originally also determined by its prestige value, that is, by its fittings and details. Such symbols of prestige have remained in demand until the present, expressing themselves in the materials used (hard wooden floors, double wing doors, etc.) and in particular in a 'stately' façade. What seems to matter most with regard to the latter are not the plaster ornaments, but out-of-proportion ceiling heights.[23] Thus, ceiling heights that seem above-average from our point of view, and for which sanitary considerations are co-responsible, are ultimately also an investment.

The fallout of economic and financial crises has lead to a re-discovery of Vienna's apartment buildings as objects of investment.[24] While the demand for this investment had its peak about two years ago—and major institutional investors have since pulled out of the active buyers' market—a lively interest in apartment buildings remains.

Even without elaborating on economic factors such as income, old-age provision, reinvestment of earnings, etceteras, the appeal of the Gründerzeit apartment building can be described in terms of a *variable* based on *subjective* preferences. Today it is the Gründerzeit building's generous offering of space that is the real reason for the renewed interest in it as a 'commodity'. This is true, not least of all, because it offers the possibility of open-ended usage, thus catering to a wide range of interested parties, rather than limiting itself to a specific segment of the market.

Current architectural forms lag behind this kind of thinking. We are continuing to build apartment and office buildings as entities separate from each other, and with a maximum ceiling height of 2.50 metres.

[22] Instead, the general line of argument called for low-rise garden cities as in Britain. This type of criticism was expressed, for example, by the architect and Senior Building Official Professor Leopold Bauer (1872-1938), by the architect Lothar Abel (1841-1896), and by the lawyer and politician Erich Koch-Weser (1875-1944), who praised the virtues of the English, Dutch, and Belgian "small building", and considered the "large building", that is, the tenement house, as the root cause of his era's housing problems. Moreover, he was of the opinion that "everything that constricts the city—for example, greenbelts and the like—had to be avoided" since they created a lack of space that caused houses to "stretch upward".

[23] GZ buildings keep their value even when plaster decorations are removed—a practice promoted by the city administration in the post-war years in the name of progress and modernity.

[24] Prices on the apartment building market have consistently been rising since 1988, with the exception of a few intervals. (Standard, 2011, p. I 11)

Given the circumstances discussed here, an updated interpretation of building regulations is required—one which might bring the vision of a mixed-use and compact urban structure within reach.

1 ABSTRACT

Tablet-PCs wie das iPad bieten für die (Stadt-)Planung eine Vielzahl an neuen Möglichkeiten – wie etwa zur Optimierung von Organisations-Prozessen, Visualisierung von Geodaten und Datenbearbeitung. Intuitive multi-touch Steuerung, große Bildschirme, mobiles Internet, digitale Karten und Funktionserweiterungen via Apps erlauben die Erfassung, Darstellung und Bearbeitung von Geodaten vor Ort.

Baulücken stellen für viele Gemeinden und Städte ein Handlungserfordernis dar, da sie das Ortsbild stören und (zumindest teilweise) Kosten verursachen. Andererseits stellen sie ein großes Potential für die Nachverdichtung und funktionale Ergänzungen dar. Die Herausforderung ist dabei eine genaue, schnelle und korrekte Datenerfassung und -verarbeitung. Eine Ortsbegehung ist neben der Luftbildanalyse zur Überprüfung der im Voraus gewonnenen Erkenntnisse unumgänglich.

An dieser Stelle liefern Karteneditoren auf Smartphones und Tablet-PCs einen neuen Lösungsansatz. Sie ermöglichen eine Digitalisierung von Punkten, Linien oder Flächen und den zugehörigen Informationen direkt über den Touchscreen während der Ortsbegehung. Durch eine Echtzeit-Synchronisation mit digitalen Karten (z.B. Google Maps), stehen diese georeferenzierten Informationen direkt mit Abschluss der Digitalisierung auf dem PC im Büro bereit und können dort weiter verarbeitet, sprich ins verwaltungsinterne GIS eingepflegt werden.

Im Rahmen eines Studienprojektes an der TU Kaiserslautern am Lehrstuhl für Computergestützte Planungs- und Entwurfsmethoden (CPE) und einem Kooperationsprojekt mit der Gemeinde Haßloch (Pfalz) sowie der Verbandsgemeinde Deidesheim wurde ein Brachflächenkataster sowie eine Methode zur mobilen Bestandsaufnahme entwickelt und in der Praxis getestet. Beispielhaft werden in diesem Paper der Funktionspluralismus anhand eines konkreten Beispiels und der damit verbundene methodische Mehrwert für die Planung an der Erfassung von Baulücken gezeigt.

2 EINFÜHRUNG

Baulücken stellen für viele Gemeinden und Städte ein Handlungserfordernis dar, da sie ästhetisch beeinträchtigend wirken („das Ortsbild stören“) und für die Gemeinde Kosten verursachen können. Andererseits stellen sie ein großes Potential für die Nachverdichtung und funktionale Ergänzungen dar. Vor dem Grundsatz der Innenentwicklung und dem 30ha-Ziel ist eine bestandsorientierte Stadtentwicklung strategisch sinnvoll.

Hierfür ist eine genaue Kenntnis über die aktuelle Baulückensituation innerhalb eines Gemeindebereiches von Nöten. Die Herausforderung besteht darin, Daten über die Quantität (die Anzahl der im Gemeindegebiet befindlichen Baulücken) sowie die Qualität (die charakteristischen Eigenschaften) zu sammeln und zu verwalten. Eine der wichtigsten Methoden zur Verwaltung von Brachflächen ist die Erstellung von sogenannten Brachenkatastern (vgl. Streich 2011, S. 27). Diese Register oder Geografischen Informationssysteme (GIS) helfen, die erfassten Informationen zu verwalten, zu analysieren und fortzuschreiben. Aufgrund der Analysefunktionen von GIS stellen digitale Brachflächenkataster die Basis für ein umfangreiches Flächenmonitoring dar, um strategische Handlungen und Maßnahmen im Sinne eines nachhaltigen Flächenmanagements zu definieren.

Im Rahmen der Verwaltungsmodernisierung wird eine kontinuierliche Verbesserung der Verwaltungsabläufe angestrebt. Um die moderne Verwaltung zu erreichen, wurden für Rheinland-Pfalz acht Modernisierungsfelder definiert (ISIM 2012). Das durchgeführte Projekt steht hierbei im Kontext der Modernisierungsfelder „Planungs- und Prozessoptimierung“ sowie „eGovernment“ und soll Methoden und Techniken für eine Verwaltungsvereinfachung entwickeln.

3 TECHNISCHE GRUNDLAGEN

Der Einsatz von mobilen Geräten stellt einen Mehrwert für die Planung dar, da die aufgenommenen Informationen direkt vor Ort digitalisiert und die Attribute digital eingegeben werden können. Dementsprechend werden zunehmend mehr mobile Geräte bei Bestandsaufnahmen eingesetzt. Der Fokus in dem durchgeführten Projekt lag in der Nutzung von neuen multifunktionalen, mobilen Geräten wie Smartphones und Tablet-Computern.

Es kamen iPhone und iPad, beides Produkte von Apple, zum Einsatz. Im Gegensatz zu rein GPS-gestützten Geräten zur digitalen Bestandsaufnahme bieten diese Geräte den Mehrwert, dass sie multifunktional einsetzbar sind (Textbearbeitung, Präsentationen, Kommunikation, Foto-Slideshows, Datenbearbeitung, etc.). Für Planungsbüros relativieren sich damit die hohen Anschaffungskosten (etwa 500 – 600 €), da sie einen erweiterten Funktionskatalog als bei reinen GPS-Geräten erhalten.

Als Karteneditor wurde My Maps Editor von NextBusinessSystem Co., Ltd. in der Version 4.1 installiert, der bei iTunes kostenlos downloadbar ist (und aktuell in der Version 4.43 vorliegt).[1] Die Internetverbindung erfolgte über eine monatlich buchbare Datenflat von 1 GB (Kosten 9,90 €). Das Datenvolumen reichte für das Projekt vollkommen aus.

Die Grundstückflächen wurden in dem Geografischen Informationssystem Quantum GIS bearbeitet, das als kostenfreie Open-Source-Version unter der GNU-General-Public-Lizenz[2] zur Verfügung steht. Diese wurden im *.kml-Format exportiert und in den My Maps Editor integriert, sodass die Bearbeitung ermöglicht wurde.

4 ANWENDUNG IN DER PRAXIS – DAS BEISPIEL HASSLOCH

Im Rahmen des Projektes wurde für die Gemeinde Haßloch ein Baulückenkataster entwickelt. In einem ersten Schritt wurden unterschiedliche Baulückenarten definiert, die Bestandsaufnahme durchgeführt und anschließend das Baulückenkataster mittels einem GIS aufgesetzt.

4.1 Definition von Baulückenarten

Um Baulücken hinsichtlich ihrer Eigenschaften und Potentiale voneinander zu differenzieren, wurden sie im Rahmen des Projektes in verschiedene Kategorien unterteilt. Dies ist wichtig, um die jeweils verschiedenen Möglichkeiten zur Weiternutzung und damit verbundenen Anforderungen genauer zu definieren. Die nachfolgende Abbildung zeigt die vier definierten Arten von Baulücken und ihre spezifischen Eigenschaften.

	Klassische Baulücke	Geringfügig genutzte Fläche	Fläche mit Entwicklungs-potential	Gewerbebrache
unbebaut	✓	(✓)	✓	✓
Planungsrecht vorhanden	✓	✓	✗	✓
Erschließung gesichert	✓	✓	✗	✓
keine Boden-ordnung notwendig	✓	✓	✗	✓

Abb.1: Definition von Baulückenarten und ihre jeweiligen Eigenschaften für die Gemeinde Haßloch (eigene Darstellung).

Zwischen den Arten Klassische Baulücke und Geringfügig genutzte Fläche besteht nur bezüglich der aktuellen Nutzung ein Unterschied. Geringfügig genutzte Flächen weisen aktuell eine Nutzung auf, die allerdings einem Bauvorhaben oder einer anderen Nutzung jederzeit problemlos weichen könnte. Demnach vermitteln diese beiden Baulückenarten das typische Bild einer Baulücke: Eine weitestgehend leere, brach liegende Fläche in der Nachbarschaft eines bebauten Gebietes. Geeignet sind diese beiden Arten zur Nachverdichtung durch Wohnbebauung, aber auch zur Gestaltung von hochwertigen Freiflächen (Grünflächen, Spielplätze, etc.) im Sinne der Innenentwicklung. Flächen mit Entwicklungspotential unterscheiden sich in ihren Eigenschaften hingegen deutlich von den beiden vorigen. Insbesondere die

[1] http://itunes.apple.com/de/app/my-maps-editor/id389114621?mt=8, Zugriff am 25.02.2012.
[2] http://www.gnu.org/copyleft/gpl.html, Zugriff am 25.02.2012.

Baureife ist hier noch nicht gegeben. Diese sind in der Regel große, zusammenhängende, unbebaute Flächen, die nicht im bebauten Zusammenhang stehen. Eine solche Fläche ist beispielsweise eine Außenbereichsinsel im Innenbereich. Gewerbebrachen unterscheiden sich hinsichtlich der Rahmenbedingungen (BauNVO) für die spätere Nutzung von den anderen Baulücken und kommen damit lediglich für Interessenten in Frage, die eine entsprechende gewerbliche Nutzung der Fläche anstreben (vgl. Broschart et.al. 2011a).

4.2 Erstellung des Baulückenkatasters

In einem nächsten Schritt wurde das Baulückenkataster auf Basis des Geoinformationssystems Quantum GIS erstellt. Dieses sollte folgende Zwecke erfüllen:

- Erfassung von Brachflächen innerhalb des Untersuchungsgebietes,
- Verlässlichkeit und Vollständigkeit der Daten,
- Visualisierung der Informationen in einer geobezogenen Darstellung.

Zudem sollten Datensätze in unterschiedlichen Zeiträumen erstellt werden, um die Brachflächenentwicklung retrospektiv darstellbar zu machen und verschiedene Datensätze für ein langfristiges Monitoring zur Verfügung zu haben. Hierfür waren mehrere Schritte notwendig.

Identifikation von Verdachtsfällen – Auswertung von Luftbildern

Zunächst wurden potentielle Brachflächen, sogenannte „Verdachtsflächen“, durch eine Luftbildanalyse und die Auswertung der Liegenschaftskarte definiert. Aufgrund fehlender Aktualität sowie möglicher Fehler in der Interpretation ist hierbei nur eine grobe Einschätzung möglich, die im Nachgang überprüft werden muss. Außerdem können nicht alle aufzunehmenden Attribute über die Luftbildanalyse erfasst werden. Weitere Informationen zur Beschaffenheit der Baulücke müssen deshalb bei der Bestandsaufnahme vor Ort erfasst werden.

Verifizierung vor Ort – Mobile Bestandsaufnahme

Die Verdachtsfälle wurden durch eine vollständige Begehung des Untersuchungsgebietes verifiziert und ergänzt. In Kleingruppen wurden sämtliche Brachflächen aufgenommen und den vier Baulückenarten zugewiesen. Hierbei wurden die Daten auf iPhone und iPad gespielt, sodass diese Daten vor Ort zur Verfügung standen.

Auf diesen mobilen Geräten können existierende Katasterdaten, wie bspw. Grundstücke, aus dem GIS exportiert, überspielt und zur Bearbeitung bereitgestellt werden. Mit Google Maps als Viewer (aber auch mit anderen Programmen problemlos möglich) können diese Daten georeferenziert angezeigt und bearbeitet werden. So können die im Vorfeld herausgefilterten Verdachtsflächen direkt in der Karte verzeichnet werden. Dies erleichtert zum einen die Überprüfung und ermöglicht die digitale Änderung und Ergänzung von Attributen (z.B. zu Nutzung, Lage, Besonderheiten). Grundstücke, die sich als Baulücke erweisen, können mit ihren Attributen verifiziert und weitere, die im Voraus nicht als Verdachtsflächen aufgefallen sind, einfach ergänzt werden.

Abb.2: Linkes Bild zeigt die Standortermittlung mittels GPS (vgl. blauer Punkt) und Flächendigitalisierung vor Ort mittels Karteneditor (blaue Fläche). Rechtes Bild veranschaulicht die Eingabemöglichkeiten in die Attributtabelle (eigene Darstellung).

Die Geräte können auch zur Navigation und als Straßenatlas genutzt werden. Ein weiterer Vorteil ist, dass mittels des installierten GPS-Moduls der eigene Standpunkt immer nachvollziehbar ist (Geo-Ortung). Das sogenannte Tracken erlaubt außerdem die Aufzeichnung der gesamten Wegstrecke, was die Nachverfolgung der gesamten Ortsbegehung und hiermit das Erkennen von nicht erfassten Gebieten ermöglicht. Die dabei erzeugten Geodaten helfen weiterhin, Fotos, die während der Bestandsaufnahme gemacht werden, zu georeferenzieren (das sogenannte Geotagging). Mittels Timestamp (der exakten Zeitangabe) können Geokoordinaten und Fotos zusammengefügt werden, sodass alle Fotos genau ihren Aufnahmestandpunkten zugeordnet werden können.

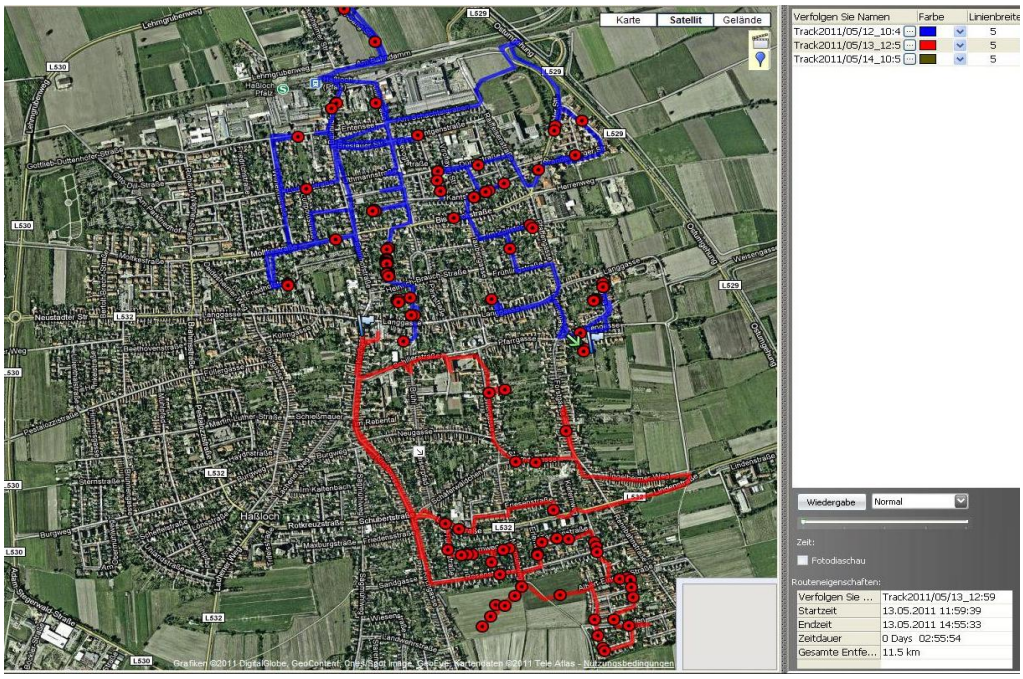

Abb.3: Beispiel für per Tracking aufgezeichnete Wegstrecken bei Bestandsaufnahme (eigene Darstellung).

Demnach integrieren iPad und iPhone mehrere Aspekte in sich, die für eine Bestandsaufnahme wichtig sind. Sie helfen bei der Orientierung (Standortermittlung, Navigationssystem, integrierter bzw. online abrufbarer Stadtplan mit Luftbildern), ermöglichen eine Flächendigitalisierung sowie die Datenbearbeitung (Ergänzung und Änderung von Attributwerten) und bieten die Möglichkeit des Trackens der Wegstrecken sowie des Geotaggings. Zudem liegen all diese Daten digital vor und können dank mobilem Internet direkt mit der Datenbank synchronisiert werden.

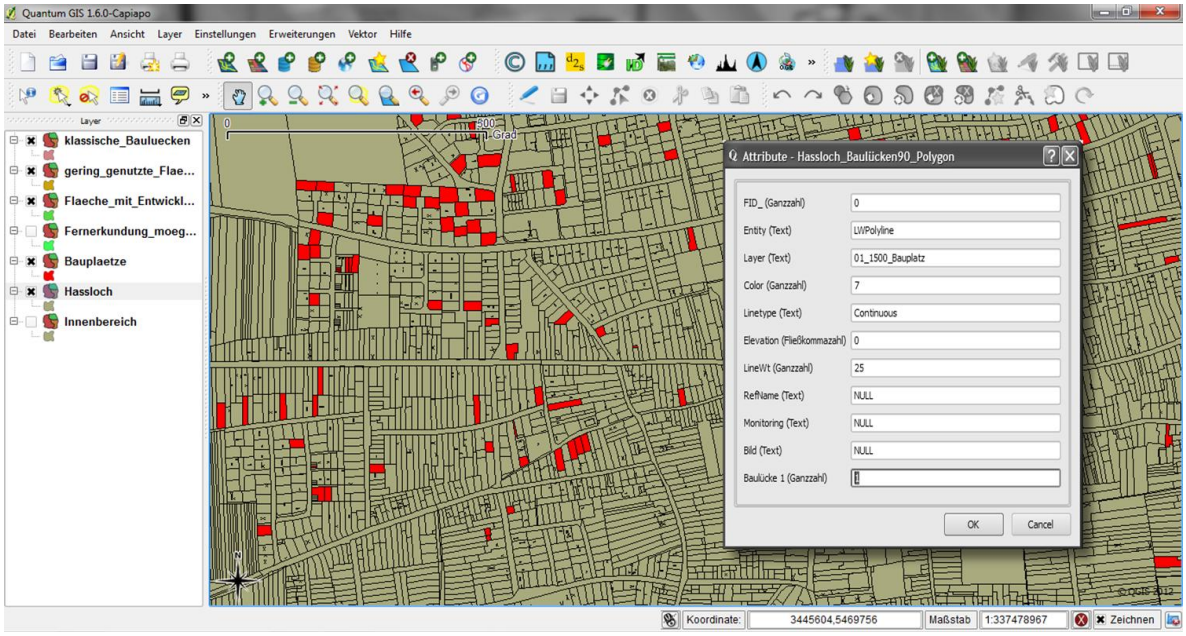

Abb. 3: Dateneinpflege ins Desktop-GIS

Datenbearbeitung – Dateneingabe am GIS

Aufgrund der mobilen Bestandsaufnahme mittels Tablet-PC liegen die Informationen in digitaler Form vor. So können durch die Verknüpfung mit der Datenbank die Daten digital überspielt werden. Allerdings war die Übernahme der Attribute in das GIS aufgrund des protypischen Verfahrens nicht möglich, sodass nun zwei Datensätze vorlagen. Dementsprechend mussten die georeferenzierten Daten mit der im Desktop-GIS vorliegenden Liegenschaftskarte abgeglichen werden. Die aufgenommen Attribute wie bspw. der Straßenname müssen manuell eingepflegt werden. Dazu werden in der Attributtabelle des GIS die entsprechenden Informationen der jeweiligen Baulücke zugeordnet und eingegeben. Hierdurch wird es möglich, im GIS eine Fläche auszuwählen und sich per Mausklick die Informationen und Eigenschaften zu dieser Fläche in der Attributtabelle anzeigen zu lassen. Auf diese Weise fließen alle aufgenommenen Informationen an einer Stelle zusammen und liefern so die Grundlage für ein umfassendes Flächenmonitoring.

Auswertung und Analyse – Das Baulückenkataster

Die im GIS zusammengeführten Informationen stehen nun der Gemeinde für die Auswertung und Analyse bereit. Alle Baulücken wurden mit folgenden Attributen aufgenommen:

- Grundstücks ID
- Adresse (Straßenname und Hausnummer)
- Fläche
- Nutzung (falls vorhanden)
- Baulückenart
- Bodenrichtwerte
- Lage im Geltungsbereichs eines Bebauungsplans

Des Weiteren wurden Fotos der jeweiligen Baulücke aufgenommen und im Nachgang mit den GPS-Wegstrecken synchronisiert. Die Funktionalität des GIS erlaubt Abfragen und die Erzeugung von thematischen Karten. Zudem wurden im weiteren Verlauf ein im *.pdf-Format vorliegendes Baulückenkataster von 1990 digitalisiert, so dass für die Jahre 1990 und 2011 die Daten der Baulücken vorliegen. Dies ist die Grundlage für ein langfristiges Monitoring und ermöglicht die Auswertung über die Veränderungen in der Anzahl, Größe, Lage von Baulücken zwischen 1990 und 2012. Diese analytischen Möglichkeiten sind der strategische Mehrwert, den ein solches Kataster bietet.

Visualisierung und Kommunikation – Konzept für ein Baupotentialkataster

Der Mehrwert der erhobenen Informationen besteht nicht nur in der Nutzung für verwaltungsinterne Fachplanungen, sondern eignet sich gut für die Kommunikation mit der Öffentlichkeit. Zum einen könnte von Seiten der Verwaltung Interesse hinsichtlich der Präsentation der erfolgten Arbeit bestehen, zum anderen kann hiermit ein Informationstool erstellt werden, welches für Bauinteressierte eine wichtige Informationsbasis wäre. Die Veröffentlichung von Flächen, die für eine Bebauung zur Verfügung stehen (Baupotentialflächen) erleichtert Bauinteressierten das Auffinden von für sie interessanten Flächen und kann im optimalen Fall die Verwaltung entlasten, indem erste Anfragen (zu Lage, Größe, umgebender Bebauung, Bodenrichtwerte) nicht mehr telefonisch beantwortet werden müssen, sondern transparent im Internet abrufbar sind. Dementsprechend wurde das Konzept eines Baupotentialkatasters entwickelt und in technischer Hinsicht überprüft.

Bei der angedachten Veröffentlichung von Daten sind die Themen Datenschutz und persönliche Rechte zu beachten. § 200 Abs. 3 des Baugesetzbuches definiert die Voraussetzungen, unter denen spezifische Informationen in einem sogenannten Baulandkataster veröffentlicht werden dürfen. Demnach kann die Gemeinde sofort oder in absehbarer Zeit bebaubare Flächen in Karten oder Listen auf der Grundlage eines Lageplans erfassen, der Flurstücksnummern, Straßennamen und Angaben zur Grundstücksgröße enthält. Diese Flächen können sodann in den Karten oder Listen veröffentlicht werden, sofern der Grundstückseigentümer von seinem Widerspruchsrecht keinen Gebrauch macht. Die geplante Veröffentlichung hat die Gemeinde einen Monat zuvor öffentlich bekannt zu geben und die Grundstückseigentümer auf ihr Widerspruchsrecht hinzuweisen (Stüer 2009:612).

Da die Zielgruppe eines Baupotentialkatasters nicht Experten, sondern Bürger und damit mehrheitlich Laien in Bezug auf GIS sind, sollte eine höchstmögliche Benutzerfreundlichkeit (Usability) erreicht werden. Aus diesem Grund eignen sich für eine Veröffentlichung allgemein gebräuchliche und kostenfrei zugängliche Programme. Dies können digitale Karten wie Google Maps und OpenStreetMap oder auch virtuelle Globen wie Google Earth sein (vgl. Höffken 2011). So können die Daten im *.kmz-Format auf der Webseite der Gemeinde zum Download angeboten werden, wodurch sie von Interessierten heruntergeladen und in Google Earth betrachtet werden können. Mittels Programmierschnittstellen (APIs) können digitale Karten direkt auf der Webseite der Gemeinde eingebunden werden, und stehen damit zur freien Betrachtung bereit.

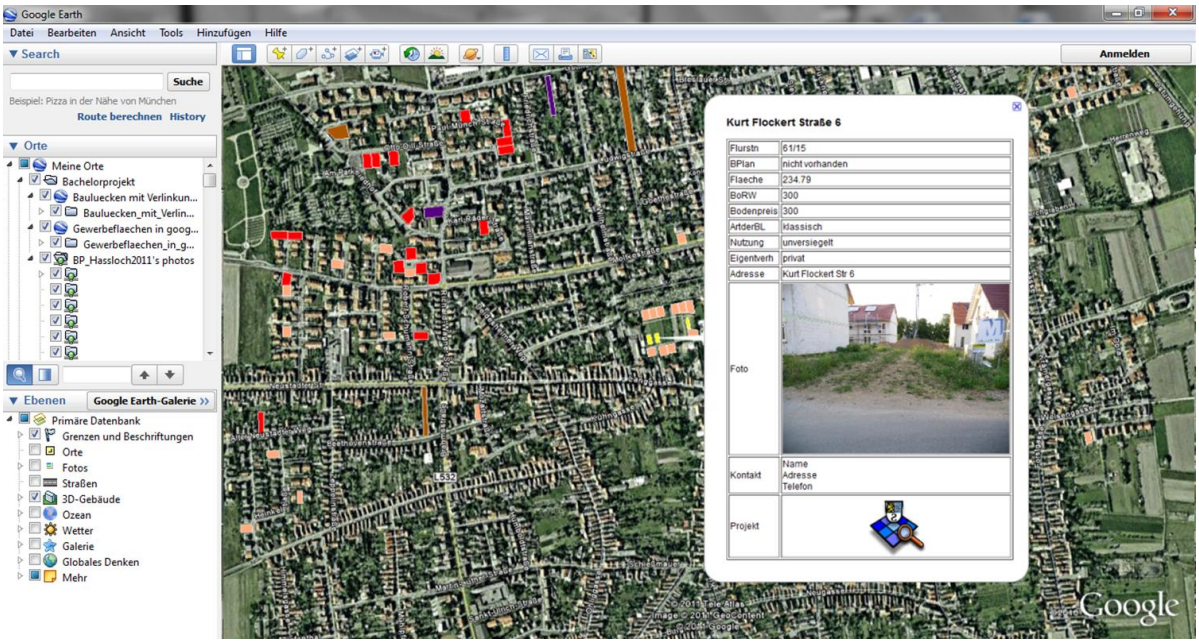

Abb. 4: Prototypisches Beispiel für die Bereitstellung der Baupotential-Information mittels Google Earth (eigene Darstellung).

4.3 Fortschreibung

Die Flächen innerhalb eines Gemeindegebiets unterliegen ständigen Entwicklungen: Durch den Abriss von Gebäuden entstehen neue Baulücken, vorhandene Baulücken können durch eine Bebauung geschlossen oder mit einer sonstigen Nutzung versehen werden. Um die Aktualität der Baulückenerfassung für die Gemeinde dauerhaft gewährleisten zu können, ist eine Fortschreibung des Katasters unumgänglich. Die Herausforderung liegt darin, die in der Gemeinde eingehenden Informationen zu Bebauungen, Zwischennutzungen, Abrissen etc. zu bündeln und kontinuierlich in das vorhandene GIS einzuspeisen, damit der Datensatz fortgeschrieben wird und aktuell bleibt. Im Rahmen des Projekts wurde ein idealtypisches Ablaufschema entwickelt, welches versucht, auf Basis der aktuellen Verwaltungsabläufe den Informationsfluss zu optimieren und die Fehlerquote zu reduzieren (vgl. Broschart et.al. 2011b:82).

Die konkrete Umsetzung ist allerdings nicht nur eine Frage des Work-Flow-Managements und der Prozessgestaltung, sondern eng mit technischen Fragen verbunden. Denn der angestrebte Informationsfluss muss seine technische Entsprechung in Form von zusätzlichen Attributwerten in der Datenbank, weiteren inhaltlichen Ebenen und neuen Menüpunkten (z.B. Häkchen für „Abriss erfolgt“) finden. Dementsprechend ist ggf. neben der Fachstelle auch die IT-Abteilung für die technische Anpassung des GIS mit einzubeziehen.

4.4 Zwischenfazit

Das erstellte Baulückenkataster liegt nun der Gemeinde vor und erfüllt die in 3.2 definierten Zwecke. So wurden durch Vorauswahl und Ortsbegehung alle Brachflächen innerhalb des Untersuchungsgebietes erfasst, und die Kategorisierung sowie vollständige Erfassung garantieren die Verlässlichkeit und Vollständigkeit der Daten. Diese liefern damit ein zutreffendes Bild der aktuellen Situation (sowie der von 1990) und sind in einer geobezogenen Darstellung aufbereitet worden, um eine verständliche Visualisierung der Informationen sowie lage- und themenbezogene Abfragen zu ermöglichen. Das Baulückenkataster muss nun von der Gemeinde in ihr GIS implementiert und fortgeführt werden. Zudem wurde ein einfaches und nutzerfreundliches Konzept zur Bereitstellung der Baupotentiale entwickelt.

5 METHODISCHE ERKENNTNISSE UND WEITERER ENTWICKLUNGSBEDARF

5.1 Methodisch-technische Erkenntnisse

Datenerfassung

Die Bearbeitung der Daten erfolgte zunächst mit Quantum GIS. Die exportierten Daten wurden auf die mobilen Geräte exportiert und in den My Maps Editor eingespielt, auf dem eine Bearbeitung möglich war. Dementsprechend konnten vor Ort die digitalen Informationen bearbeitet, gelöscht und ergänzt werden, da eine Punkt-, Linien- und Flächendigitalisierung vor Ort möglich ist. Die Vorteile des iPads waren:

- Lange Akkulaufzeit (bis zu 8 Stunden)
- Integrierter GPS-Empfänger (zur eigenen Standortsuche, Tracking der Wegstrecken, Geotagging der Fotos)
- Nutzung von online Kartendiensten wie Google Maps, aber auch die offline Nutzung von Geodaten und Luftbildern
- Gute Bedienbarkeit, also eine hohe Usability (Touch-Screen, guter Workflow, Systemstabilität)
- Schnellstart-Funktion (kein Hochfahren des Systems notwendig)
- Kostenlose Apps (im untersuchten Fall die Nutzung von My Maps Editor. Allerdings gibt es hier noch viele weitere Apps, die weiter entwickelt werden; zudem werden durch die Community immer neue Tools entwickelt, sodass langfristig noch viele weitere Funktionen und Apps zu erwarten sind.)
- Praktisches Format (relativ flach und handlich; dementsprechend besser zu transportieren, als die etwas „klobigen“ GPS-Geräte)
- Großer Bildschirm

Für Smartphones zeigte sich, dass sich der kleine Bildschirm für eine länger dauernde Nutzung z.B. bei einer umfangreichen Bestandsaufnahme nicht eignet. Allerdings haben Smartphones den Vorteil, dass sie aufgrund ihrer Größe leichter zu transportieren sind. Als dauerhafter Begleiter, eignen sie sich gut, um einzelne Nachbearbeitungen zu realisieren. Der My Maps Editor ermöglichte den georeferenzierten Import, Bearbeitung und Export. Zudem ist die Software kostenlos nutzbar.

Dateneingabe ins GIS

Die erfassten und korrigierten Daten konnten digital ausgelesen und im *.kml-format exportiert und georeferenziert in das GIS eingelesen werden, was die weitere Datenbearbeitung vereinfachte. Aufgrund der Verknüpfung mit der Datenbank via mobilem Internet konnten die Daten im Cloudcomputing-Verfahren aktualisiert werden.

Zwar ist es möglich, die erfassten Attribute direkt in das GIS zu importieren. Allerdings können die neuen Attribute mit dem bestehenden Datensatz nicht aktualisiert werden, da die Attribute nach aktuellem Stand nur unsortiert in einem Bemerkungsfeld aufgenommen werden können. Die Zusammenführung beider Datensätze muss demnach manuell erfolgen, was sich als zeitaufwendig herausstellte. Dieser „Flaschenhals“ reduziert den potentiellen Zeitgewinn.

Datenverwaltung im GIS

QunatumGIS eignet sich, um die Daten entsprechend der Anforderungen zu bearbeiten und zu analysieren. Zudem existiert die Option, die Daten in unterschiedlichsten Formaten zu exportieren, womit die Weiterbearbeitung und Visualisierung ermöglicht wird. Damit ist Quantum GIS ein gutes, kostengünstiges und vielseitiges Tool.

5.2 Weiterer Entwicklungsbedarf und methodische Herausforderungen

Trotz der zahlreichen genannten Vorteile gibt es weiteren Entwicklungsbedarf in technischer und methodischer Hinsicht. Insbesondere ist hierbei das Problem der Synchronisation von bestehendem Datensatz im GIS und dem bei der Bestandsaufnahme neu erzeugten Datensatz zu nennen. Inwieweit dies von NextBusinessSystem Co., Ltd. realisiert wird, ist nicht bekannt. Dementsprechend wird im Rahmen des DFG-geförderten Forschungsprojektes am Fachgebiet CPE „Städtebauliche Methodenentwicklung mit

GeoWeb und Mobile Computing“ nach alternativen Apps gesucht und die Entwicklung eigener Apps angestrebt. Dies wäre auch im Sinne einer langfristigen Fortschreibung ein wichtiger methodischer Baustein.

Zudem wird angestrebt, die alternativen Möglichkeiten zu Google Maps, insbesondere von OpenSource Projekten zu erforschen. Hierbei scheint der Einbezug von OpenStreetMap vielversprechend. Gleichzeitig sollen im weiteren Verlauf auch andere Betriebssysteme als das IOS von Apple genutzt werden. Insbesondere das Open Source Betriebssystem Android bietet hier viele Möglichkeiten und offenere Programmierschnittstellen. Dies könnte langfristig Lizensierungsvorteile zu dem sehr restriktiven Apple-System bieten.

Ein wichtiger, nächster Schritt ist die methodische und technische Optimierung der Fortschreibung des Katasters. Die bereits realisierten, technischen Möglichkeiten haben sich als gut und vielversprechend für neue Wege der Bestandsaufnahme herausgestellt. Die Fortschreibung ist bisher nur konzeptionell entwickelt worden. Neben der technischen Umsetzung muss ein Verfahren entwickelt werden, welches in die bestehenden Verwaltungsabläufe integriert werden kann. Dies betrifft bspw. Fragestellungen, wie die technische Ausstattung, Möglichkeiten zur Webseitenintegrierung, die Schulung von Mitarbeitern in Bezug auf neue Techniken und Methoden sowie technische Implementierung in die bestehenden Verwaltungs-Systeme. Dies soll in weiteren Kooperationsprojekten mit Kommunen erfolgen. Auch datenschutzrechtliche Fragen bei Nutzung von Cloud-Computing-Diensten und Applikationen sollen im weiteren Verlauf genauer beleuchtet werden.

6 AUSBLICK – NÄCHSTE SCHRITTE

Die neuen technischen Möglichkeiten erlauben die Entwicklung ganz neuer Verfahren und Konzepte. So ist ein interessanter Ansatz, die Ergänzung des aktuellen Baulückenkatasters durch Crowdsourcing-Verfahren. Dabei wird unter Crowdsourcing das Auslagern einer Tätigkeit an eine (große) Gruppe von Leuten verstanden, was durch die interaktiven Möglichkeiten des Web 2.0 nun einfacher möglich ist (vgl. Höffken, Streich 2011). So kann die Fortschreibung der Daten kontinuierlich erfolgen, indem sie nicht mehr zentral von einer Stelle aus durchgeführt wird, sondern von vielen Teilnehmern kollaborativ erfolgt. Im Gegensatz zur zentralen Gesamterfassung werden an dieser Stelle nur noch Veränderungen einzelner Baulücken punktuell aufgenommen. Um den Nachbearbeitungsaufwand zu minimieren und die Aufnahme der Baulücken für Jedermann möglichst einfach zu gestalten, empfiehlt sich der Einsatz vorgefertigter Formulare anstatt der bisher eingesetzten „Notizfunktion“ im My Maps Editor. Realistisch wäre bspw. die Entwicklung einer App, mit der Verwaltungsmitarbeiter neue Baulücken (bzw. deren Nutzungsänderung) direkt via Smartphone einpflegen könnten. Eine passwortgeschützte Zugangsberechtigung erlaubt die Nutzung nur durch autorisierte Mitarbeiter, sodass keine Falschinformationen entstehen. Hierbei läuft eine Kooperation mit dem Deutschen Forschungszentrum für Künstliche Intelligenz (DFKI) in Kaiserslautern, welches die RADAR-Plattform (Resource Annotation and Delivery for Mobile Augmented Reality Services) entwickelt hat, die sich für den Zweck einer Baulückenmeldung per Crowdsourcing-Verfahren eignen würde (vgl. Memmel 2011).

Abb. 6: Beispiel für die Visualisierungsmöglichkeiten mittels Augmented Reality (eigene Darstellung).

Fernerhin bieten Smartphones neue Möglichkeiten zur Visualisierung von Baulückeninformationen. Mit Augmented Reality-Browsern könnten die Baulücken und ihre Eigenschaften als digitaler Inhalt georeferenziert als Realitätsüberlagerung dargestellt werden. Die Informationen können vor Ort, leicht verständlich visualisiert werden. Insbesondere die AR-Darstellung eignet sich zur Visualisierung von möglichen Bebauungen oder zukünftigen Zwischennutzungen mit 3D-Gebäudemodellen.

7 DANKSAGUNG

Die Autoren möchten sich bei allen Studierenden bedanken, die im Rahmen des Studienprojektes mitgewirkt haben und damit einen wichtigen Beitrag geleistet haben. Weiterer Dank gilt den Kollegen vom Fachgebiet Prof. Dr.-Ing. Bernd Streich, Dr.-Ing. Peter Zeile und Dipl.-Ing. MSc. Jan Exner für wertvolle Anregungen und konstruktive Kritik.

Modelling Affective Responses to Space

Silvia Klettner, Georg Gartner

(Proj. Ass. Mag. BA Silvia Klettner, Institute of Geoinformation and Cartography, Vienna University of Technology, silvia.klettner@tuwien.ac.at)
(Univ. Prof. Dr. Georg Gartner, Institute of Geoinformation and Cartography, Vienna University of Technology, georg.gartner@tuwien.ac.at)

1 ABSTRACT

Most geospatial applications rely on objective GIS data to provide services and decision support. These objective GIS data store abstractions of the real world, especially focusing on physical features. However, research on environmental psychology suggests that all stimuli, including large-scale environments, are perceived not only according to physical features, but also in terms of people's affective responses towards them (Russell, 2003). These responses may influence a person's behavior and decision-making in space. For example, some environments might be experienced as stressful with the consequence of avoidance; others might lead to preference and approach (Kaplan & Kaplan, 1989; Nasar, 1984). Although it is well accepted, that people's wellbeing and behavior is influenced by external cues, subjective geo-information has not yet been incorporated in existing geospatial applications, such as in navigation support. Therefore, we propose that in order to provide better services, geospatial applications need to consider people's affective experiences in space. This paper will give an introduction into types of affective responses and methods available to indicate them. We will report on results from our ongoing research project, which aims to model people's affective responses to urban space, and to incorporate this affective data into navigation services for pedestrians.

2 INTRODUCTION

A number of studies in the field of environmental psychology indicate that characteristics of indoor and outdoor environments influence people's wellbeing (Ulrich, 1984; Kaplan, 1993; Hartig & Staats 2006), preference (Nasar, 1984; Kaplan & Kaplan, 1989), satisfaction (Hur et al., 2010), and evoke behavioral changes in space, such as social interactions and intensity of land use (Sullivan et al., 2004), perceived walkability (Leslie et al., 2005; Schmidt et al., 2011), and walking route choices (Zacharias, 2001; Borst et al., 2008).

Data about people's preferences and avoidances of environments may be applicable in various fields of research - one of which is navigation. Borst et al. (2008) studied route choices of elderly people in relation to environmental attributes. Their findings suggest that people do not simply decide for the shortest route, but that decisions in space are influenced by various characteristics of the environment, such as parks, slopes, trees, front gardens, or shops. Consequently, data about people's perception of space can be used to better predict people's route choices, and support spatial behavior in a realistic, user-oriented way (Borst et al., 2009). However, people's perception about environmental characteristics have not yet been incorporated into navigation services. In order to offer services that more adequately support and suit users' needs and preferences, data about people's perception of and feelings in space must be collected. Such subjective data can be assessed through various approaches, such as self reports, physiological recordings, or field observations. Recently, with the ubiquity of smartphones and increasing interests on Web 2.0, researchers start to explore using smartphones as an instrument to collect users' subjective responses about and in space.

In our current project EmoMap, we will use this new approach to gather emotional responses evoked by the environment. Using smartphones enables people to report about their perception of space anytime and anywhere. In our project, we treat affective responses to space as fundamental information approach for geo-spatial applications. We will model affective responses to space by quantifying people's perception of the affective qualities in the environment. For gathering these affective data, we aim to make affective experiences in space easily reportable, and to automatically link these responses to the physical environment. By incorporating the collected data into services for enhancing navigation for pedestrians, we will examine its usefulness in the future.

This paper will report on results from our ongoing research project, which aims to model people's affective responses to urban space, and to incorporate this affective data into navigation services for pedestrians. We

will introduce types of affective (emotional) responses and methods available to indicate them, as well as give an overview about the state of the art of cognitive and emotion mapping, and related work.

3 AFFECTIVE RESPONSES TO SPACE

Stimuli and environments, all are perceived not only according to physical features, but also in terms of a person's affective response towards them. According to Russell (2003) some affective response is always present within a person, either perceived as neutral, moderate or extreme. When affect is in the foreground – due to its intensity or due to situational cues -, it can be consciously experienced as pleasant or unpleasant and form the basis of an emotional experience (Feldman Barrett et al., 2007; Russell, 2003). When affect is milder, it influences conscious experience and behavior in a less direct way. In this case, background affect is experienced as property of the person's environment (Russell, 2003; Feldman Barrett et al., 2007). These two affective states - emotions and affective qualities - are common approaches for investigating affective responses to space. Both affective states have the same common ground, but are experienced differently. Russell (2003) aptly describes this difference as hot experience for emotional reactions, versus cold experience when perceiving affective qualities.

3.1 Emotions

Emotions are complex and multifaceted phenomena. Due to its complexity and connection with other processes, emotions are among the most challenging phenomena in psychology. Until today there is no general agreed-on definition, which can clearly mark off emotions from other affective states. Psychologist offer not one but a variety of definitions, each addressing different components of emotions. However, on its very basis, Feldman Barrett et al. (2007) define emotions as intentional states that are about something, emerging from basic processes.

Emotional reactions can be examined in multiple ways: as subjective feelings, expressive reactions, cognitive performance, motivational changes, behavioral, and physiological reactions. The fact that emotions are a complex construct and cannot be measured directly, but only be indicated through their manifestations, lead to various approaches. In general, methods for indicating a person's emotional response can largely be divided into three most common categories: (1) self reports, (2) physiological methods, and (3) behavioral observations. Feldman Barrett et al. (2007) stress that self reports are the most direct way to gather information about a person's internal state. Self reports, such as verbal descriptions or judgements (e.g. questionnaires or interviews) however are subjective by nature, with its advantages and drawbacks. Physiological recordings through sensors on the other hand, provide an objective measure to affective responses (e.g. electrocardiogram, electromyogram, galvanic skin response), with the advantage that the person does not even have to recognize the physiological changes. Recorded data is used as indicator of emotional reactions, with the drawback that high arousal may or may not be caused by an emotional experience. Behavioral observations have similar advantages and disadvantages as physiological measurements; observed re-actions may or may not be due to a person's affective reactions caused by the environment. Without any interpretation, the data collected from physiological recordings and behavioral observations may be insufficient to precisely discern a person's affective response. However, there is no one agreed-on empirical solution about the components that indicate emotional experiences best.

3.2 Affective quality of the environment

Another way to approach affective responses to space is by handling its affective qualities (cold experience). Affective qualities are experienced as properties of the external world, commonly described with affect-denoting adjectives such as hectic, exciting, or beautiful. These affective qualities are verbally attributed to a place, but have the ability to change a person's affective feeling of pleasure or displeasure (Russell & Pratt, 1980; Russell, 2003). According to Russell (2003), the perception of affective qualities is an ubiquitous process. People evaluate and judge their surroundings routinely, at any time. In contrast, emotional experiences are rather infrequent, triggered by intense or situational cues. Myrtek (2004) reports that among emotional experiences the most often reported one was the experience of no emotion (58% of females, 72% of males).

One approach to quantify affective qualities of environments is by using semantic differential scales (Osgood et al., 1957). A Semantic Differential (SD) provides a list of affect-denoting adjectives on a bipolar rating

scale, designed to measure the connotative meaning (subjective associations) towards a given object, event or concept.

4 FROM COGNITIVE MAPS TO EMOTION MAPPING

In 1948 the concept of cognitive mapping was first introduced by the psychologist Edward C. Tolman. His experiments with rats indicated an ability for memorizing locations and spatial orientation. Tolman (1948) concluded that not only rats, but also humans may be able to develop an inner picture of the external world (a cognitive map), which help guide the individual in space. Researchers from various fields started to explore cognitive processes, such as the cognitive representation of spatial content, which until then were believed to be sealed within the individual (in a black box). In the 1950s this development mounted in the so called Cognitive Revolution.

In 1960 the urban planner Kevin Lynch introduced first ideas on how people perceive and organize spatial information as they navigate through space. According to Lynch's research (1960), key elements of the cognitive representation of space are paths, boundaries, districts, nodes, and landmarks.

About 20 years later Downs and Stea (1982) examined people's mental representation of space and found various distortions of mental maps. Downs and Stea (1982) conclude that cognitive maps do not show realistic images of the external world, but indicate how people believe the world is like. Potential factors which deviate cognitive maps from reality may not only be physical barriers, and semantic unity, but also emotional involvement and attitudes (Carbon & Leder, 2005). These subjective, emotional attitudes towards space were examined by Matei et al. (2001). On the basis of cognitive maps from individuals about the perception of comfort and fear in the city on Los Angeles, one aggregated, cognitive map was generated (Matei et al., 2001). Matei et al. (2001) were not only among the first who added this kind of collective, subjective layer to maps, but they also created one of the first digital map visualizations of feelings. Even though the map reports on the emotional perception (comfort and fear) of Los Angeles, it can only be considered to be a mental or cognitive map, but not an emotion map. Due to the method of retrospective self reports, the data collected may provide more insights into people's perception, in terms of opinions and prejudices, about space than about how people feel in space when they are physically there.

Among the first, the artist Christian Nold (2008) explored emotional responses in space. In his art project BioMapping participants are instructed to re-explore their local area, carrying mobile devices with them. One of the device measures the participant's galvanic skin response (GSR), indicating a person's emotional arousal. Additionally, a GPS device automatically refers the participant's position to a geographical location. As a result, an emotion map visualizes points of high and low arousal experienced in space, and reporting on the contributions of each participant (see Fig.1). However, to generate meaningful maps, the physiological data collected automatically, must be interpreted retrospectively (not every arousal indicated an emotional experience).

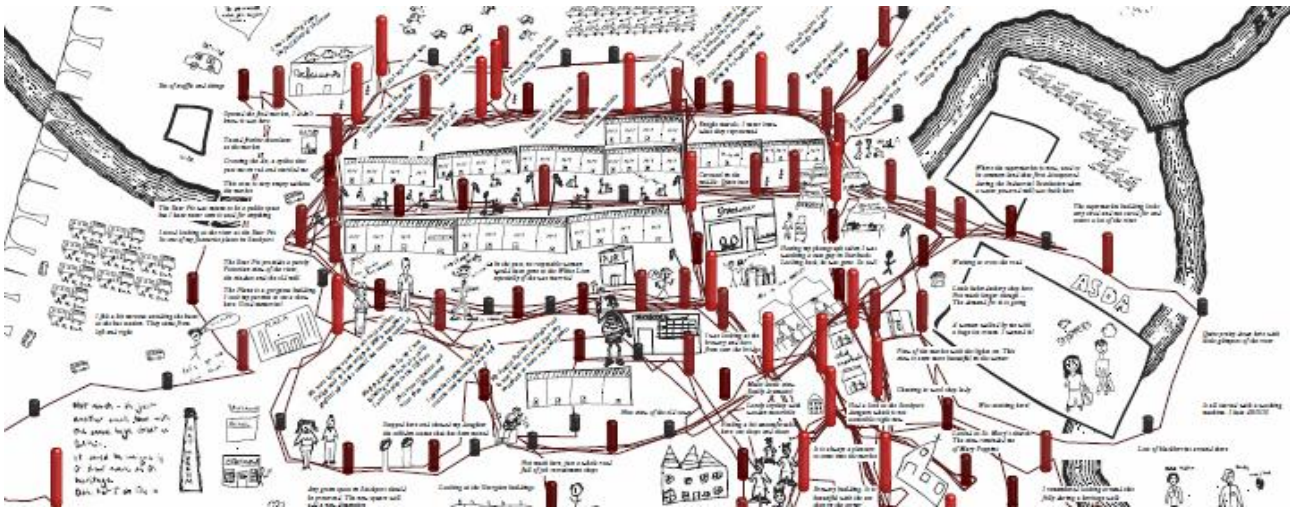

Fig. 1: Stockport emotion map by Christian Nold (2008). The higher the bars the higher arousal was measured. Textual descriptions and drawings were added retrospectively by the participants.

Recently, with the ubiquity of smartphones and increasing interests on Web 2.0, researchers start to explore using smartphones to capture users' self-reported affective responses. With smartphones the contributions can be easily linked to a person's geographic location. Current services, which ask for the user's feelings by using smartphones, as well as safe information about a persons location (by asking the user about the location or by storing the geographic information automatically), are:

- The service "Mappiness" developed by MacKerron and Mourato (http://www.mappiness.org.uk) is part of a research project, asking its users via smartphones to rate how happy, relaxed, and awake they are (on an eleven-point Likert scale). Some additional questions are asked (e.g. for current company and activities). The user's current position is stored automatically. The collected data are based on self reports. However, the benefit of using smartphones for gathering affective data, seems to be a quite promising one. Until today 48274 participants are reported on their website, indicating that a large number of contributions may be gathered easily.
- The smartphone application "Glow" (http://glowapp.com) asks the users to rate how they feel on one to five stars. The user's location is stored automatically. Personal results as well as the aggregated data of all users are displayed as heat maps with a color range from blue (awesome) to red (not so awesome).
- "Track Your Happiness" (https://www.trackyourhappiness.org/) is a research project by Killingsworth from Harvard University that aims to investigate causes and correlates of happiness. This research aims to understand what factors affect people's happiness in their daily lives. Information is gathered (on a webpage via smartphone) about a person's current happiness, and related to current activities, location, company, time of day, etc.
- "CaptureEmo" (http://www.capturemo.com/) is an instrument, which aims to assess people's emotional experiences about environments. A picture, sound recordings or a video of environments can be labelled emotionally (such as happy, interested, disgusted, etc.). However, the instrument is not a location based service. The only reference of the location is the picture or recording itself.

Present location based services for collecting emotional experiences in space tend to focus on various affective states of the users, but not necessarily on a momentary affective experience caused by the spatial surroundings. It can certainly be the case that the feelings reported by these services are influenced by a person's current environment, but not inevitably. To get clearer data it may therefore be necessary to address this issue by asking the user more specifically, such as "How does the environment make you feel?" instead of "How are you?", or as Russell (2003) suggests to have people evaluate an environment's affective qualities.

5 EMOMAP PROJECT

Research in one of our previous projects suggests environmental factors, such as safety, convenience, and attractiveness, to be relevant for the perceived route quality in pedestrian navigation (Schmidt et al., 2011). Although these factors are not emotions itself, they are affective evaluations caused by the environment.

In our current project EmoMap, we aim to gather emotional responses evoked by the environment. These emotional responses to space will be therefore modelled as a person's evaluation of affective qualities. We will ask users to evaluate the environment by ratings instead of asking them for their emotions directly. By doing so, we will direct a person's attention to the environment. We expect the collected data to be – at least to some extent - "cleaned" from non-spatial feelings of the person. According to Russell (2003) affective qualities are routinely evaluated anytime. We therefore expect to collect data, which is easily reportable by anyone, and present at any time (contrariwise to emotions, which occur rather infrequent, and which are evoked by intense external and internal cues).

For gathering this affective information, we will use a crowd sourcing approach to get a high volume of data. Self reports are the most promising method, since people can simply and freely contribute via their own mobile application any time and anywhere. People's perception of affective quality will be measured by implementing a Semantic Differential (SD), invented by Osgood et al. (1957), into a mobile application. This approach provides a list of affect-denoting adjectives on a seven-point rating scale. Using SD for our research, integrated into smartphones, brings several advantages:

- Subjective data: SD bases on self-reports and therefore no additional retrospective interpretation of data is needed.
- Simple integration: The instrument can be easily integrated in mobile phone devices. Anyone with a smartphone can contribute.
- Geo-referenced data: Contribution will automatically be stored geo-referenced. with a coordinate, obtained from GPS, and according to time of the day.
- Equipment: A smartphone is the only device needed. It can easily be carried, and is not an additional burden or creates an "unnatural" test setting for the user.
- Time-efficiency: SD provides a quick measurement for evaluating affective quality in space.
- Comparability: Different environments, as well as one place at different times can be compared.

By gathering affective responses in space with mobile devices, we expect an efficient, real-time collection of data, evoked by realistic scenarios, and therefore leading to results with high ecological validity. Within this project, this data will be used to create an emotional city layer, which will depict people's perception of space. This affective data will be the basis of a navigation service, which aims to better suit and predict people's behavior in space.

5.1 Inventory of affective qualities

In order to measure people's affective experiences in space, we first had to collect and specify affective parameters relevant to space. By using a multistage method, we obtained affective experiences related to space through several iterations:

Focus group

In a first step, a set of 39 affective qualities was compiled from affect-denoting terms found in literature. A focus group of non-experts (N=9; 5 females, 4 males) selected all relevant terms from the sets, as well as amended missing or inaccurate ones, resulting in a new sample of 67 affective qualities related to space (34 positive and 33 negative terms).

Online questionnaires

In a next step, online questionnaires were carried out, with the aim to reduce the affective parameters complied in the focus group to the most important ones. Participants were invited by social media and mailing lists. In the online questionnaire, participants were asked to select all of the parameters experienced in the urban environment of Vienna.

Among the 102 subjects (MeanAge= 34.4, SD=12) who completed the online questionnaires, exactly half of them were females, respectively males (n=51). Chi-square analyses showed a highly significant difference in the selection of positive affective qualities (χ^2= 309.007; df= 33). The standardized squared residuals indicate seven parameters, which were selected significantly more often: divers, lively, interesting, safe, upkeep, atmospheric, and beautiful. For negative affective qualities, chi-square analyses indicate a highly significance of the five parameters busy, noisy, hectic, stressful, and dirty (χ^2= 550.578; df = 32; $p < 0.001$).

Data aggregation

To reduce redundancies, the 12 parameters selected in the online questionnaire were further aggregated according to their synonyms, resulting in six environmental attributes (traffic, people, noise, attractiveness, diversity, safety). We added one more factor to our model, even though it has not shown to be significant. We added the attribute "smell" to our preliminary emotion model to find out whether smell was an important environmental aspect, which may had not been selected due to the fact that the questionnaires were conducted indoors. The resulting 7 aggregated parameters form the elements in our hierarchical preliminary emotion model, which is the basis for the geo-referenced collection of affective responses in space.

Preliminary emotion model

The hierarchical structure of the model considers people's emotional granularity, which are interindividual differences in the ability of characterizing affective experiences as broad affective or discrete terms

(Feldman Barrett et al., 2007). On two levels, the model serves as the basis for the geo-referenced collection of affective responses in space:

(1) Level of broad affect. On the first level, people can rate how pleasant or unpleasant the environment is experienced. This broad affect is considered to be reportable by any individual, independent of culture and age (Feldman Barrett et al., 2007; Wierzbicka, 1999; Russell, 2003).

(2) Level of distinct affective environmental qualities. This level asks for ratings about the current environment, regarding the categories of traffic, noise, smell, people, safety, attractiveness and diversity (on a seven-point scale, ranging from -3 to +3). This level of distinct environmental qualities provides more detailed information about characteristics of the environment.

5.2 Location model

In order to link people's affective responses to space, a location model was needed. For providing a suitable location model, we analyzed different check-in applications, such as Foursquare and Facebook Places. They link users' check-ins to place labels, each of which basically has a latitude/longitude pair (i.e. a point) and a name. However some places are hard to be named. In our current location model we link reported experiences as points to a location, which will be automatically obtained from GPS devices. In the future, we may also allow users to link their emotions to points, lines (along street network), and polygons. For each object, only the geometry is stored.

6 WORK IN PROGRESS AND CONCLUSION

After implementing the preliminary emotion model into a prototypical mobile application, the usability, as well as the emotion and location model is currently examined by using the application in the study area of Vienna. First results from people's affective responses to space are visualized in Figure 2. The colored points represent the geo-coded affective responses from eight participants (4 females, 4 males), bright red indicating places where people feel uncomfortable, dots in dark green indicating comfort. Depending an the zoom level, the data will be displayed as aggregated content with numbers of contributions provided, or as individual contributions.

Preliminary results from user's responses and correlations between the parameters suggest to aggregate, and further reduce the number of parameters. Due to the relatively small screen of smartphones, the information being displayed is limited. Consequently, a further aggregation of the parameters to their core will not only allow an even faster and non-redundant contribution, but will avoid the information overload.

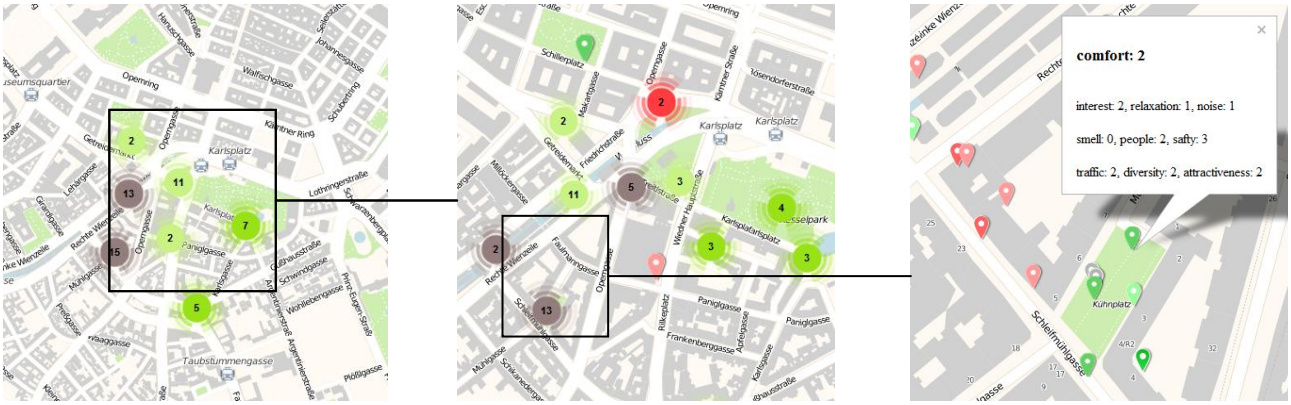

Fig. 2: Emotion maps of Vienna. Depending an the zoom level, the data is displayed as aggregated content (with numbers of contributions provided) (left and center) or as individual contributions (right). Red dots indicate discomfort, dark green dots represent comfort. Map source: cc-by-sa OpenStreetMap - contributors, 20.02.2012.

In the future, we will use the option of volunteered geographic information to collect affective responses to space. In order to illustrate the importance of affective experiences in space, the data collected in the current project will be aggregated, resulting in a collective affective map-layer, and further be used for enhancing navigation systems for pedestrians. Route suggestions based on subjective information about space will be provided, and its usefulness as well as users' satisfaction evaluated.

However, applications will not be restricted to navigation services only. The data will be stored in an open online database (OpenEmotionMap.org), which will be open for other usages and disciplines. We expect the

inclusion of this affective layer will bring benefits to different disciplines, not only in Information and Communication Technology, but also Urban Planning, Architecture, and Policy Making.

7 ACKNOWLEDGEMENT

This article is part of the research project EmoMap, which is funded by BMVIT and managed by the Austrian FFG's ways2go program. Collaborative partners are Vienna University of Technology, Salzburg Research Forschungsgesellschaft m.b.H. and Rittberger + Knapp OG.

1 EINLEITUNG

Im Forschungsverbund Verlust der Nacht, der vom deutschen Bundesministerium für Bildung und Forschung seit 2010 für drei Jahre gefördert wird, setzt sich ein interdisziplinäres Forscherteam aus den Natur-, Technik-, Geistes- und Sozialwissenschaften mit den Ursachen und Folgen der zunehmenden künstlichen Beleuchtung des Außenraums auseinander. Vor etwa 200 Jahren wurde die erste öffentliche Gasbeleuchtung in London installiert. Seitdem hat sich die Nutzung der städtischen Nacht, die erst durch künstliches Licht in der Breite möglich wurde, massiv verändert. Im Rückblick wurde nicht nur dem Leben im öffentlichen Raum und der Industrialisierung mehr Dynamik verliehen, sondern schlussendlich der Weg in die 24-Stunden-Gesellschaft geebnet. Die heutige Form der Urbanität in hochentwickelten Gesellschaften ist ohne Straßenbeleuchtung, Lichtwerbung und Lichtinszenierung kaum zu denken, gerade in der jüngeren Vergangenheit hat sich das Ausmaß privaten und gewerblichen Lichts im Außenraum massiv erhöht. Das wurde in den letzten Jahrzehnten auch von den planenden Professionen erkannt. So sind seit den 1990er Jahren in zahlreichen Städten Lichtmasterpläne und Lichtkonzepte entwickelt worden. Der soziale und ökonomische Fortschritt im Zuge von Modernisierungsprozessen ist jedoch meist auch mit sozialen und ökologischen Kosten verbunden. In diesem Sinne werden in unterschiedlichen Zusammenhängen zunehmend die negativen Folgen der Lichtverschmutzung diskutiert. Im Rahmen des Forschungsverbundes werden nun einzelne Aspekte des Verlusts der Nacht in insgesamt vierzehn Teilprojekten aus unterschiedlichen Blickwinkeln vertiefend betrachtet. Diese reichen von der historischen Genese künstlicher Beleuchtung im Raum Berlin-Brandenburg bis zur Untersuchung der Auswirkungen auf einzelne biologische Spezies.

Das Teilprojekt, dem das vorliegende Papier entstammt, geht der Frage nach, wie sich die positiven und negativen Auswirkungen der nächtlichen Erhellung des Außenraums ökonomisch bewerten lassen. Dabei zeigt sich, dass nur sporadisch Vorarbeiten geleistet wurden, auf die sich das Projekt berufen kann. Aufgrund der verhältnismäßig geringen externen Kosten, die als Folge von Lichtverschmutzung vermutet werden, fand das Thema in umwelt- und wohlfahrtsökonomischen Untersuchungen bisher kaum Beachtung. Bei grober Betrachtung stehen der Nutzen der Ermöglichung wirtschaftlicher und gesellschaftlicher Aktivität und der Inszenierung des Stadtraums den Kosten der Beeinflussung biologischer Rhythmen und des Verlusts der Sichtbarkeit des nächtlichen Sternenhimmels gegenüber. Die Komplexität der Aufgabe besteht zunächst darin, ein disperses Feld mit ebenso heterogenen Erkenntnisständen zusammenzuführen. Die genauen Folgewirkungen der nächtlichen Beleuchtung sind dabei noch weitestgehend ungeklärt. Die ökonomische Bewertung selbst steht darüber hinaus vor nicht unerheblichen methodischen Herausforderungen. Offensichtlich ist daher, dass zumindest zum jetzigen Zeitpunkt die einzelnen Nutzen- und Kostendimensionen des Verlusts der Nacht keinesfalls abschließend monetarisiert werden können. Vielmehr ist ein notwendiger erster Forschungsschritt, die einzelnen positiven und negativen externen Effekte zu benennen, zu ordnen und zu präzisieren. Diese Taxonomie der wichtigsten Nutzen- und Kostendimensionen soll eine fundierte Grundlage für eine ökonomische Bewertung des Verlusts der Nacht schaffen. Schlussendlich sollen die Analysen im Rahmen des ökonomischen Teilprojekts einen Beitrag zur Entwicklung von Empfehlungen für einen zielgerechteren Einsatz von nächtlicher Außenbeleuchtung leisten.

In diesem Beitrag wird der derzeitige Forschungsstand im Rahmen der Erstellung der Taxonomie vorgestellt. Grundlage der vorliegenden Überlegungen ist eine strukturierte Literaturrecherche, die in eine Datenbank mit über 2000 Einträgen aus der einschlägigen deutschsprachigen und internationalen Fachdiskussion mündete. Auf der Basis der Literaturauswertung werden der aktuelle Wissensstand diskutiert und weitere Forschungsbedarfe aufgezeigt. Der Aufbau des Beitrags orientiert sich dabei weitestgehend an der vorläufigen Gliederung der Taxonomie. Zunächst werden die Nutzendimensionen der künstlichen Beleuchtung des Außenraums besprochen und ihre Bewertungsmöglichkeiten diskutiert. Anschließend werden in der gleichen Form die relevanten Kostendimensionen besprochen. Das Papier schließt mit einem

Ausblick auf die weiteren geplanten Forschungsschritte und einer zusammenfassenden Problematisierung der Möglichkeiten einer ökonomischen Bewertung des Verlusts der Nacht.

2 NUTZEN DER KÜNSTLICHEN BELEUCHTUNG DES NÄCHTLICHEN AUßENRAUMS

Die Verwendung künstlicher Lichtquellen hob in den Städten den starken Kontrast zwischen Tag und Nacht auf. Der Nutzen der künstlichen Beleuchtung des nächtlichen Außenraums spiegelt dabei im Wesentlichen die Funktionen der einzelnen Lichtquellen wider. Auer (1997) unterscheidet als Quellen der nächtlichen Außenbeleuchtung in der Stadt die fünf elementaren Lichtmarken Ordnungslicht, Werbelicht, Festlicht, Wohnlicht und Arbeitslicht, die er „den fünf Stadtfundamenten“ (S. 8) Zitadelle, Markt, Tempel, Wohnquartiere und Arbeitsstätten zuordnet. Erst in den 1990er Jahren entwickelte sich zur systematischen Ordnung dieser Lichtquellen das Planungsfeld der Lichtplanung. Als Ordnungslicht lässt sich aus heutiger Perspektive das gesamte Feld der öffentlichen Straßen- und privaten Verkehrsbeleuchtung betrachten, Werbelicht dient als Denkmalillumination heute auch der Stadtwerbung und Festlicht zeigt sich zunehmend in Formen der Lichtkunst, Lichtfestivals und sonstigen temporären Lichtinstallationen. Zuvorderst dient nächtliches Kunstlicht der Ermöglichung nächtlicher Aktivität, die 24-Stunden-Gesellschaft ist nur mit künstlichem Licht denkbar. Dieser Zusammenhang muss aber anhand ausgewählter Indikatoren konkretisiert werden. Vor allem zum Beitrag der nächtlichen Außenbeleuchtung zu Sicherheit und Sicherheitsempfinden liegt eine größere Zahl an Untersuchungen vor. Von steigender Bedeutung, aber bisher nicht (wirtschafts-)wissenschaftlich untersucht, ist der Beitrag der Lichtinszenierung zur Wertschöpfung (Lichtplanung, touristische Attraktion, Werbung, etc.). Methodisch aufwendig, aber ebenso denkbar, ist eine ökonomische Untersuchung des Beitrags des künstlichen Lichts im Außenraum zur Festigung der Stadtidentität und zur Verbesserung der ästhetischen Qualität des Stadtraums. Im Folgenden wird den Möglichkeiten der ökonomischen Bewertung dieser Aspekte nachgegangen.

2.1 Ermöglichung von wirtschaftlicher Aktivität in der Nacht

Künstliches Licht im öffentlichen Raum - insbesondere die öffentliche Straßenbeleuchtung - ist ein ermöglichender Faktor für viele wirtschaftliche Betätigungsfelder in der Nacht (Henckel 2009, The Royal Commission on Environmental Pollution 2009). In ökonometrischen Analysen lässt sich ein eindeutiger Zusammenhang zwischen dem Ausmaß der Lichtverschmutzung und Formen der Landnutzung, der Höhe an Direktinvestitionen und dem Bruttoinlandsprodukt pro Kopf feststellen (Gallaway et al. 2010). Obwohl bei steigendem Pro-Kopf-Einkommen auch die Beleuchtungseffizienz steigt und daher der Zusammenhang zwischen Lichtverschmutzung und dem Bruttoinlandsprodukt nicht linear ist, zeigen empirische Analysen doch eindeutig, dass Wertschöpfung und nächtliches Licht eng miteinander korrelieren und beides räumlich in großen Städten konzentriert ist (Elvidge et al. 1997a, Elvidge et al. 1997b). Erst künstliches Licht schafft die Voraussetzungen für die 24-Stunden-Gesellschaft, also Produktion, Konsum und Verkehr rund um die Uhr. Gerade mit dem Wandel von der fordistischen Massenproduktions- und Massenkonsumgesellschaft zu flexibleren postfordistischen Gesellschaftsformationen hat sich die Struktur und Organisation der städtischen Wirtschaft massiv verändert. In traditionellen Industrie- und Dienstleistungssektoren bedingten technologische Innovationen und die Internationalisierung der Wirtschaft eine Ausweitung der Arbeitszeiten. Daneben kam es zu einem Boom neuer freizeitorientierter Dienstleistungen, neuer Einzelhandelsstrukturen und gastronomischer Angebote, die insgesamt den Event zu jeder Tageszeit in den Vordergrund rücken, sich gut mit dem Wachstum des Städtetourismus fügen und auch entsprechende Planungen der Stadtverwaltungen hervorrufen (Lovatt/O’Connor 1995, Roberts/Eldridge 2009, Henckel 2009). Dies führte zu einem fundamentalen Wandel der Raum- und Zeitstrukturen des städtischen Alltagslebens. Daneben verstärkt die Ausweitung beleuchtungsintensiver Orte wie Infrastrukturknoten (Flughäfen, Bahnhöfe etc.), Stadien und Gewächshäuser den Zusammenhang zwischen ökonomischem Wachstum und Lichtverschmutzung.

Insgesamt führen die neuen Zeitrhythmen der städtischen Wirtschaft zu einer Steigerung der Wertschöpfung. Obwohl die nächtliche Beleuchtung des Außenraums dafür als conditio sine qua non verstanden werden kann, scheint eine Zurechnung der nächtlichen Wertschöpfung überaus komplex. Produktionsaktivitäten müssten zu diesem Zweck nicht zuletzt auch zeitlich erfasst werden, was in den aktuell bestehenden Systemen der Volkswirtschaftlichen Gesamtrechnungen nicht vorgesehen ist. Gleichzeitig stellen sich in diesem Zusammenhang auch Fragen der Abhängigkeit der Produktivität von Tag-Nacht-Unterschieden, die bisher nicht abschließend geklärt werden konnten (Moore-Ede 1993, Levitt/List 2009). Daher muss vorerst zusammenfassend festgestellt werden, dass der aus der nächtlichen Beleuchtung des Außenraums

gewonnene gesellschaftliche Nutzen zwar allem Anschein nach immens ist, sich derzeit aber Möglichkeiten der ökonomischen Bewertung entzieht bzw. dafür noch erhebliche Vorarbeiten geleistet werden müssten.

2.2 Wertschöpfung durch Lichtgestaltung

Künstliches Licht in der Nacht ermöglicht nicht nur Wertschöpfung. Mit der nächtlichen Beleuchtung des Außenraums sind auch unmittelbar Wertschöpfungaktivitäten verbunden, die selbst als Teil des gestifteten Nutzens betrachtet werden müssen. Mit der zunehmenden Bedeutung von Lichtinszenierung und -planung, Lichtfestivals und Lichtwerbung (FSU/KPK 2009, Cuttle 2009, van Santen 2006, Schmidt 2007) müsste dieser Sektor erfasst und seine Wachstumsdynamik beschrieben werden. So haben seit den Vorreitern Zürich und Lyon nicht nur zahlreiche Städte weltweit professionelle Lichtkonzepte und Lichtpläne erstellen lassen, Lichtplanung wurde in den letzten Jahren als Disziplin auch an Fachhochschulen und Universitäten akademisch verankert (bspw. FH Dortmund, Donauuniversität Krems). Viele Städte versuchen gleichzeitig, sich durch spezielle Architekturbeleuchtung und teilweise auch temporäre Lichtevents im Städtetourismus zu positionieren. Diese modernen Formen des Festlichts sind aber nicht nur auf öffentliche Initiative zurückzuführen, sondern sind vielfach auch privaten Ursprungs – wie beispielsweise die durch Einkaufstraßenvereine organisierten Weihnachtsbeleuchtungen. Zusätzlich hat Lichtwerbung eine lange urbane Tradition, Plätze wie der Londoner Picadilly Circus oder der Times Square in New York sind ohne großflächige Leuchtreklame heute kaum vorstellbar (siehe auch Wurm 2009, Beckmann 1986, Behar 2005).

Im Unterschied zu den indirekten Effekten scheint der direkte Wertschöpfungsbeitrag der künstlichen Beleuchtung des nächtlichen Außenraums im Falle der Bereitstellung entsprechender Forschungsressourcen relativ klar zu beziffern. Die Kosten der Straßenbeleuchtung sind nicht zuletzt durch die kommunalen Sparzwänge in den letzten Jahren stark in den Blickpunkt der Politik geraten (NABU o.J., siehe unten). Anders verhält es sich mit jüngeren Aspekten der öffentlichen Lichtplanung und der Wertschöpfung durch private Initiativen, wie event- und ortsbezogene Festbeleuchtungen oder private Lichtwerbung. In den bisher gesichteten Quellen spielen Fragen der ökonomischen Bewertung kaum eine Rolle. Möchte man die Wertschöpfungsleistungen erfassen, müssten Primärerhebungen in einschlägigen Unternehmen erfolgen. Erste Hinweise zur wachsenden Bedeutung der entsprechenden Branchen und Professionen könnten eventuell Expertengespräche mit Planern, Mitarbeitern von Stadtverwaltungen und Werbefachleuten bringen. Die „Lighting Urban Community International“ (LUCI) hat jüngst einen Bericht zum wirtschaftlichen Nutzen von Lichtfestivals erstellt. Anhand von zehn Fallstudienstädten auf unterschiedlichen Kontinenten wurden Besucheraufkommen und -ausgaben, Veranstaltungskosten, Wahrnehmung durch die Medien, Beitrag zum Stadtimage und geschaffene Arbeitsplätze erhoben. Dabei zeigte sich, dass die Festivals in sämtlichen Städten überaus positiv bilanzieren, die Einnahmen pro Besucher sind bis zu 35 mal höher als die Kosten (LUCI 2012). Insgesamt ist offensichtlich, dass Licht als Bestandteil stadtökonomischer Strategien verstanden werden muss, der durch entsprechende Planwerke zunehmend professionell gestaltet wird.

2.3 Effizienzgewinne durch gleichmäßigere Auslastung von Infrastrukturnetzen

Indirekt könnte die Ausweitung der städtischen Aktivitätszeiträume sowie der Energiebedarf der Lichtkörper selbst zur gleichmäßigeren Auslastung von Verkehrsinfrastruktur- und Energienetzen beitragen und somit die Effizienz der Leistungserbringung erhöhen. Die kontinuierliche Ausdehnung der nächtlichen Produktion, des nächtlichen Konsums und des nächtlichen Handels könnte insofern durch die Entzerrung sogar Produktivitätsfortschritte bringen. Tatsächlich zeigt sich im Falle Deutschlands, dass sich die Spitzen der Verkehrsbelastung in den letzten Jahren etwas abflachen und verschieben (Lenz et al. 2010). Da das weitergehende Ansteigen der Mobilität primär auf die Verkehrsmittel des Umweltverbundes entfällt, ist zumindest bei gleichbleibenden räumlichen Verteilungsmustern von einem Rückgang der Staus im motorisierten Individualverkehr auszugehen und mithin auch von einem Sinken der damit verbundenen volkswirtschaftlichen Kosten. Aus verkehrsplanerischer Perspektive können damit unterschiedliche positive Folgewirkungen verbunden sein: Zunächst sinken bei gleichmäßiger verteiltem Verkehrsaufkommen die notwendigen Straßenbreiten und damit auch die verbundenen Erhaltungsaufwendungen. Gleichzeitig scheinen auch eine Reduktion von Lichtsignalanlagen und die Steigerung der Effizienz von Schaltsystemen möglich. Inwiefern diese Zusammenhänge allerdings monetär quantifiziert oder auch nur belegt werden können, wurde in der bisher ausgewerteten Literatur nicht diskutiert. Wie im Falle der ermöglichten Wertschöpfung in der 24-Stunden-Gesellschaft ist jedoch davon auszugehen, dass die Komplexität nur mit erheblichem Aufwand bearbeitet werden kann.

Ähnliches gilt für den Bereich der Energienetze. Tatsächlich wird erst jüngst im Zeichen der bevorstehenden Energiewende stärker über die ökonomischen und technischen Aspekte der Energiegewinnung aus alten und neuen Energiequellen diskutiert (bspw. Wissel et al. 2008). Bei konventionellen Formen der Energiegewinnung aus Kohle und Kernenergie stehen aufgrund der bedingten Speicherfähigkeit von Elektrizität noch Fragen der Nachfrageverteilung und der Grundlast im Vordergrund. Da die geringste Belastung des Stromnetzes regelmäßig in der Nacht auftritt, sollte die Straßenbeleuchtung in dieser Hinsicht einen Beitrag zur Stabilisierung des Stromnetzes leisten. Mit der Energiewende rücken aber unter dem begrifflichen Deckmantel des Smart Grid zunehmend Fragen der intelligenten Steuerung und Abstimmung von Nachfrage und Angebot in den Vordergrund (bspw. Knab/Strunz/Lehmann 2010). Inwiefern sich in diesem Zusammenhang ein positiver Beitrag der Straßenbeleuchtung ergeben wird, muss in den in naher Zukunft folgenden Forschungsschritten erörtert werden.

2.4 Objektiver und subjektiver Sicherheitsgewinn

Zumindest in Großstädten wird Straßenbeleuchtung mit Sicherheitsgewinn und sinkenden Kriminalitätsraten assoziiert, Sicherheit kann historisch als eine ihrer zentralen Funktionen betrachtet werden (der Geschichte der Stadtbeleuchtung widmet sich Teilprojekt 3). Heute wird die Frage, ob sich unter den institutionellen und sozialen Voraussetzungen in den modernen Großstädten der hochentwickelten Welt mit bestimmten Beleuchtungsqualitäten ein Zugewinn an Sicherheit im öffentlichen Raum erzielen lässt, meist im Zusammenhang mit der angestrebten Modernisierung der Straßenbeleuchtung gestellt. Richtungsweisend sind in diesem Zusammenhang britische Studien, in denen zur Begründung der Verteilung von Fördermitteln Kosten und Nutzen der Modernisierung in ausgewählten Zielräumen verglichen wurden (Painter 1996/1999, Painter/Farrington 2001, Loukaitou-Sideris et al. 2001). Obwohl die genauen Wirkungen vom räumlichen Kontext abhängen, zeigen Painter und Farrington (2001), dass die Einsparungen bei der Kriminalitätsbekämpfung die Kosten der Modernisierung regelmäßig übersteigen. Unklar ist allerdings, ob diese Effekte nicht auch den baulichen Verbesserungen der Wohnumgebung insgesamt zugerechnet werden müssten (z.B. Farrington/Welsh 2002). Pease (1999) argumentiert darüber hinaus, dass die Beteiligung der Bevölkerung an der Modernisierung der Straßenbeleuchtung das Verantwortungsgefühl stärkt und somit ebenfalls zur Reduktion von Kriminalität beiträgt. In manchen Quellen wird daher ein direkter Zusammenhang zwischen bestimmten Beleuchtungsformen und Kriminalitätsraten angezweifelt (bspw. Atkins et al. 1991, Marchant 2004), eine Studie für das US Department of Justice hält bei bestimmten kriminellen Handlungen sogar gegenteilige Effekte für denkbar (Clarke 2008).

Relativ unumstritten ist demgegenüber, dass Straßenbeleuchtung das subjektive Sicherheitsempfinden fördert. So belegen bisher ausgewertete Studien – meist durch Zahlungsbereitschaftsanalysen – den Nutzen von Straßenbeleuchtung für das Sicherheitsempfinden der Stadtbevölkerung (bspw. Atkins et al. 1991, Willis et al. 2005, Knight 2010). Die Verbesserung der Beleuchtung würde demnach zur Reduktion von Ängsten beitragen und die Bereitschaft, die eigene Wohnung zu verlassen, erhöhen. Allerdings scheint der empfundene Sicherheitsgewinn, der mit einer Verbesserung der nächtlichen Beleuchtung des öffentlichen Raums verbunden wird, im Vergleich mit anderen das Faktoren eher gering (Willis et al 2005) und stark vom räumlichen Kontext und den genauen Maßnahmen abhängig. Bei Detailbetrachtungen müssen daher auch Fragen der Lichtqualitäten und Beleuchtungssysteme berücksichtigt werden. Im Extremfall könnte eine durch schlechte Beleuchtung verursachte Blendung die positiven Effekte zunichte machen. Zusammenfassend kann man daher festhalten, dass Straßenbeleuchtung – wie in der Geschichte meist vermutet – zumindest im Regelfall einen Beitrag zum subjektiven Sicherheitsempfinden leistet. Ob sich der Zugewinn an Sicherheit allerdings auch an objektiven Daten der Kriminalitätsstatistik festmachen lässt, ist bisher nicht eindeutig geklärt.

2.5 Verkehrssicherheit

Ein offensichtlicher Zweck von nächtlichem Licht im öffentlichen Raum, der spätestens mit dem Beginn der Massenmotorisierung offensiv verfolgt wurde, ist die Förderung der Sicherheit im Straßenverkehr. Tatsächlich steigt das Unfallrisiko nachts immens an, wobei dies nicht nur von den Sichtverhältnissen, sondern auch von Faktoren wie Müdigkeit, Alkoholisierung und der Verkehrsgeschwindigkeit abhängt. Auch wenn die anderen Faktoren tendenziell schwerer ins Gewicht fallen, zeigen zahlreiche Untersuchungen, dass Beleuchtung einen wesentlichen Beitrag zur Reduktion von Unfallwahrscheinlichkeiten leisten kann (für einen Überblick siehe Elvik 1995, Beyer/Ker 2009). Die Wirkungen hängen allerdings auch in diesem Fall

vom räumlichen Kontext und der genauen Wahl der Beleuchtungsmittel ab (bspw. Meseberg 1997). Vor allem an Kreuzungspunkten im städtischen Umfeld können die Unfallkosten durch zweckdienliche Beleuchtung sicherlich reduziert werden. Die vor kurzem erfolgte Abschaltung der durchgehenden Autobahnbeleuchtung in Belgien wurde hingegen damit begründet, dass sich die Beleuchtung an den meisten Stellen nicht positiv auf die Verkehrssicherheit auswirkt (bspw. Region Wallonie 2003). Demgegenüber zeigte das Texas Transportation Institute schon in den 1980er Jahren, dass die Unfallwahrscheinlichkeit an zeitweise unbeleuchteten Straßenabschnitten zunimmt (nach Hasson /Lutkevich 2002). Ein positiver Effekt lässt sich folglich dann erzielen, wenn eine nach Lichtfarbe und Intensität adäquate Beleuchtung an einer geeigneten Stelle installiert wird. Wie diese genau ausgestaltet sein muss, bleibt eine wichtige Fragestellung der lichttechnischen Forschung. Dabei ist zu berücksichtigen, dass Verkehrsteilnehmer in Abhängigkeit von der Beleuchtungssituation ihr Fahrverhalten anpassen (für einen Überblick siehe u.a. Willis et al. 2005, The Royal Commission on Environmental Pollution 2009). Im Sinne einer ökonomischen Bewertung konkreter Formen der Straßenbeleuchtung können auf der Basis dieser Erkenntnisse Kosten-Nutzen-Analysen durchgeführt werden. Die Kosten der Straßenbeleuchtung werden dabei – gemessen an den Gesamtkosten des Verkehrs – als verhältnismäßig gering eingeschätzt. Diesen können die volkswirtschaftlichen Kosten von Unfällen, die sich aus dem materiellen Schaden und den direkten, indirekten und intangiblen Gesundheitskosten ergeben (siehe unten), gegenübergestellt werden.

2.6 Stadtidentität und Ästhetik

In einem vorhergehenden Punkt wurde schon angesprochen, dass das an Bedeutung gewinnende Feld der Lichtplanung, Lichtinszenierung und Lichtwerbung prinzipiell als Beitrag zur Wertschöpfung verhandelt werden kann. Neben diesem objektiv zu erhebenden Aspekt der ökonomischen Bedeutung von Lichtgestaltung im nächtlichen Stadtraum wird Lichtplanung als Beitrag zur Förderung der Stadtidentität, zur Schaffung sozialer Räume sowie als Element der architektonischen Gestaltung und Ästhetik diskutiert (bspw. FSU/KPK 2009, Senatsverwaltung für Stadtentwicklung 2011). Seit jeher gilt die Stadtbeleuchtung als Zeichen von Modernität, Wohlstand und städtischen Lebensstilen (Auer 1997). Licht trägt entscheidend zum Image einer Stadt bei, durch künstliches Licht wird das nächtliche Stadtbild erst erzeugt (Köhler 2009). Städte wie Las Vegas scheinen als Bild eines lichttechnisch inszenierten Raums bekannter als bei Tag. Tatsächlich wurde der seitens der Stadtbevölkerung gefühlte Nutzen von Aspekten wie Anmut und verbesserte Straßengestaltung schon mittels Zahlungsbereitschaftsanalysen erhoben (Willis et al. 2005). Daneben wäre auch denkbar, den Wert der Stadtbeleuchtung an Immobilienpreisdifferentialen festzumachen (Henke 2008). Zu berücksichtigen ist allerdings auch hierbei, dass die entsprechenden Wirkungen in engem Zusammenhang mit dem sozialräumlichen und baulichen Kontext betrachtet werden müssen.

3 KOSTEN DER KÜNSTLICHEN BELEUCHTUNG DES NÄCHTLICHEN AUßENRAUMS

Wie im Falle des Nutzens, für den keine Gegenleistung erbracht werden muss, spricht man von externen Kosten, wenn beim Produktionsprozess Kosten entstehen, die nicht vom Hersteller getragen werden und entsprechend bei Dritten anfallen. Im Fall der nächtlichen Außenbeleuchtung bzw. Lichtverschmutzung lassen sich die indirekten Kosten bei grober Betrachtung als negative Auswirkungen auf die terrestrischen und aquatischen Ökosysteme (ecological light pollution) und die Abstrahlung in den Nachthimmel (astronomical light pollution) beschreiben (Longcore/Rich 2004). Detaillierter werden die indirekten Kosten der künstlichen Beleuchtung des Außenraums in der Literatur in den Dimensionen glare (Blendung), light trespass (Lichtübertretung), sky glow (Himmelsleuchten), light profligacy (Lichtverschwendung), cost to the environment und absence of darkness (The Royal Commission on Environmental Pollution 2009; ähnlich Mizon 2002) gefasst. In sämtlichen Fällen ist eine gesamtwirtschaftliche Betrachtung schwierig, sind doch weder die negativen Folgen der Lichtverschmutzung noch Fragen ihrer ökonomischen Bewertung abschließend geklärt. So ist bisher nur eine geringe Zahl an Auswirkungen der nächtlichen Außenbeleuchtung auf die terrestrischen und aquatischen Ökosysteme gut erforscht. Auch die Untersuchung der Auswirkungen auf Krankheitsbilder steckt noch in den Kinderschuhen, in den meisten Fällen bestehen nur Vermutungen. Und selbst bei Kenntnis der naturwissenschaftlichen Zusammenhänge scheinen lediglich die Gesundheitsfolgen für den Menschen relativ zuverlässig – wenn auch unter ethischen Gesichtspunkten nicht unumstritten – quantifizierbar (siehe Zweifel et al. 2009, Deutscher Ethikrat 2011). Die ökonomische Bewertung negativer Effekte auf die Ökosysteme stellt die umweltökonomische Forschung hingegen vor das Problem ihrer anthropozentrischen Weltsicht (siehe Polasky 2002, Marggraf et al. 2005, Hein 2010).

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

Kleinere Kostendimensionen, wie jene der Lichtverschwendung, der mangelnden Sichtbarkeit des Nachthimmels oder der Blendung, lassen sich hingegen besser eingrenzen und – zumindest abstrakt – einfacher bestimmen. Im Folgenden werden die einzelnen Kostendimensionen kurz diskutiert.

3.1 Licht- und Energieverschwendung

Fragen der Energieverschwendung durch Lichtverschwendung und mangelnde Effizienz scheinen vor dem Hintergrund des zunehmenden Bewusstseins für Umweltfolgen und Ressourcenknappheit an Bedeutung zu gewinnen (bspw. NABU o.J.). In einer japanischen Studie zur Lichtabstrahlung in die Atmosphäre konnte anhand von Satellitenbildern von fünf Städten gezeigt werden, dass der Energieverlust der privaten und öffentlichen Beleuchtung zwischen 1993 und 1996 um 10 bis 20 Prozent zunahm (Isobe/Hamamura 2000). Diese Verschwendung ließe sich durch eine stärkere Nutzflächenorientierung der Beleuchtung reduzieren. Die wichtigste Quelle der Lichtverschwendung ist dabei die Straßenbeleuchtung, noch vor Werbeflächen und privaten Haushalten (Hänel 2000). Hält man sich die Kostenstrukturen der Straßenbeleuchtung vor Augen, ist das Bemühen um Effizienzsteigerungen seitens der Kommunen verständlich. In Deutschland belaufen sich die Anteile der Straßenbeleuchtung auf 0,1 Prozent am gesamten Energieverbrauch und auf 0,7 Prozent am Gesamtstromverbrauch (VDN/LiTG 2009), jedoch auf bis zu 45 Prozent an den kommunalen Stromkosten. Auch wenn das nur 0,4 Prozent des kommunalen Haushalts entspricht, ist der Anteil der Energiekosten an den Gesamtkosten der Bereitstellung von Straßenbeleuchtung von rund 30 Prozent zu Beginn der 1990er Jahre durch den technologischen Fortschritt, der Wartungs- und Instandsetzungskosten erheblich gesenkt hat, auf 50 bis 65 Prozent im Jahr 2010 gestiegen. Die Anstrengungen, durch die Umrüstung auf effizientere Systeme Energiekosten einzusparen, ist daher in den letzten Jahren forciert worden. Laut einer Publikation des Leuchtenherstellers TRILUX (2009), der auch die angeführten Zahlen entnommen sind, könnten in Deutschland allein durch die Erneuerung der Anlagen der Straßenbeleuchtung aus den 1960er und 1970er Jahren 400 Millionen Euro bzw. 2,7 Mrd. kWh und 1,6 Mio. Tonnen CO2 jährlich eingespart werden. Zusätzliche Einsparungspotenziale lassen sich durch die Anpassung der Nutzungszeit an den Bedarf erschließen (Höhne/Schröter 2002). Zusammenfassend sind Daten zur Licht- und Energieverschwendung für die Straßenbeleuchtung vergleichsweise gut zugänglich. Lediglich regionale Unterschiede der Kostenstrukturen wurden bisher kaum systematisch erhoben. Zur Effizienz der privaten Beleuchtung im öffentlichen Raum ist hingegen bisher insgesamt wenig veröffentlicht worden.

3.2 Mangelnde Sichtbarkeit des Nachthimmels

Lichtverschwendung beeinträchtigt in Form der Lichtverschmutzung auch die Stellung des Sternenhimmels als Kulturgut und Orientierungshilfe. Von Urzeiten an entwickelte die Menschheit eine metaphysische und eine praktische Beziehung zum Sternenhimmel, bis heute werden viele Kunst- und Kulturschaffende und Wissenschaftler von ihm inspiriert. Durch Lichtverschmutzung ist die Beziehung des Menschen zum Nachthimmel jedoch zunehmend gestört. Vor allem die Lichtkuppeln großer Städte strahlen weit aus, in hell erleuchteten europäischen Städten hat die Sichtbarkeit der Sterne von 3.000 möglichen auf 100 abgenommen (Hänel 2010). Um den Sternenhimmel als Kulturgut zu schützen, beschloss die UNESCO im Jahr 2009, astronomische und archäoastronomische Stätten als Weltkulturerbe anzuerkennen. In manchen Regionen der Welt wurden bereits eigene Dark Sky Parks eingerichtet (Kolláth 2010), der Astrotourismus zwecks Sternenbeobachtung nimmt seit Jahren zu (Ruggles/Cotte 2010). Kosten der mangelnden Sichtbarkeit des Nachthimmels wurden bisher jedoch kaum analysiert. Gallaway (2010) beklagt, dass die traditionellen Methoden der neoklassischen, aber auch der institutionellen und ökologischen Ökonomie mit passiven Vergnügungen nicht umgehen können. Allerdings wurden schon Zahlungsbereitschaftsanalysen zur Bewertung des Sternenhimmels als Kulturgut durchgeführt, die zeigen, dass zumindest in einschlägigen Kreisen die Bereitschaft besteht, für Dunkelheit zu zahlen (vgl. Simpson/Hannah 2010, Willis et al. 2005). Daneben müssten auch die Kosten, die der astronomischen Forschung durch die eingeschränkte Funktionsfähigkeit, Stilllegung oder Verlagerung von Sternwarten entstehen, sowie die mangelnde Nutzbarkeit des Sternenhimmels für Zwecke der Navigation berücksichtigt werden. Studien dazu sind jedoch bisher nicht bekannt. Ebenso wenig ist bisher geklärt, ob die Fragen nach der Verlagerung von Sternwarten und der Sternennavigation heute unter technologischen Aspekten überhaupt noch relevant sind.

3.3 Auswirkungen auf die Ökosysteme

Die Wirkungen der Lichtverschmutzung auf Fauna und Flora erwecken zunehmend die Aufmerksamkeit der Biologie. In der Tierwelt können sich die Veränderung des Lebensraums und die Störung biologischer Rhythmen verhaltens- und populationsökologisch auf die Orientierung, Anziehung, Reproduktion und Kommunikation auswirken, gemeinschaftsökologisch kann die Balance von Konkurrenz und Prädation aus dem Gleichgewicht kommen (Longcore/Rich 2004, Health Council of the Netherlands 2000, The Royal Commission on Environmental Pollution 2009). Bisher wurden besonders die Folgen für Vögel (bspw. Evans Ogden 1996, Jones/Francis 2003), Fledermäuse und andere ausgewählte Säugertierarten (bspw. Boldogh et al. 2007, Stone et al. 2009, Bedrosian et al. 2011), Meeresschildkröten und andere Amphibien (bspw. Perry et al. 2008, Baker/Richardson 2006), Fische (bspw. Brüning et al. 2011) und Insekten (bspw. Eisenbeis 2009) beforscht (zu sämtlichen genannten Spezies siehe auch die Beiträge in Rich/Longcore 2006). Säugetiere sind vor allem von veränderten Tageszyklen und Artenrivalität betroffen, Folgen für das Immunsystem, die Thermoregulation und die Fortpflanzung sind möglich. Bei Vögeln kann es zu veränderten Zeiten der Nahrungssuche und einem veränderten Brut- und Zugverhalten kommen, das künstliche Licht führt zu Ablenkung, Entkräftung und steigendem Risiko, gefressen zu werden. Bei Amphibien und Fischen sind vor allem die Fortpflanzung, das Wanderungsverhalten und die Schwarmbildung betroffen. Insekten drohen, entweder an heißen Lampen zu verbrennen oder im Licht zu entkräften und gefressen zu werden. Fehlen Insekten infolge der Lichtverschmutzung als Bestäuber, sind auch Folgen für die Landwirtschaft denkbar.

Im Vergleich zur Tierwelt ist jedoch zu den Auswirkungen auf die Pflanzenwelt insgesamt noch relativ wenig Wissen vorhanden. Die Lichtstärke von Straßenlaternen dürfte nicht ausreichen, um das Wachstum von Pflanzen zu beeinflussen (Health Council of the Netherlands 2000). Manche Bäume werfen jedoch als Folge der nächtlichen Beleuchtung ihre Blätter nicht oder verspätet ab, wodurch sie dem Winterwetter unmittelbar ausgesetzt sind (Briggs 2006). Daneben werden auch negative Auswirkungen auf die Luftverschmutzung vermutet, weil bestimmte Stickoxide, die bei Dunkelheit zur Reinigung der Luft beitragen, durch die Helligkeit nicht mehr wirken können (Castelvecchie 2010). Zusammenfassend lässt sich also festhalten, dass sich Lichtverschmutzung aus ökologischer Perspektive auf Fauna und Flora sowie die Luftqualität negativ auswirken kann. Ungeklärt ist allerdings die Frage nach Möglichkeiten der ökonomischen Bewertung dieser Effekte. Biodiversität wird prinzipiell als öffentliches Gut betrachtet, das als Stabilitätsfaktor in ökologischen Systemen, als Ressource für genetische Information, als Rohstofflieferant sowie zur Befriedigung ästhetischer, kultureller und wissenschaftlicher Bedürfnisse Nutzen stiftet (Klauer 2001). Schwierig ist die Bewertung von Biodiversität deshalb, weil die Zusammenhänge einerseits überaus komplex sind, Biodiversitätsverluste aber andererseits irreversibel sind, stark eingeschränkte Substitutionsmöglichkeiten bestehen und die Auswirkungen eines starken Verlusts größtenteils unbekannt sind. Aus diesem Grund wird vielfach anstelle von Kosten-Nutzen-Analysen die Gewährleistung eines "safe minimum standard" vorgeschlagen. Auf dieser Grundlage kann die ökonomische Bewertung einen Beitrag zur Diskussion effizienter Schutzstrategien und zur Schaffung von Anreizsystemen liefern (bspw. Loomis/White 1996, Montgomery et al. 1999, Stevens et al. 1991). Die Bewertung der Luftverschmutzung aus gesamtwirtschaftlicher Perspektive erfolgt prinzipiell in den Umweltökonomischen Gesamtrechnungen (Statistisches Bundesamt 2010). Kosten für die Landwirtschaft könnten bei Kenntnis der genauen Zusammenhänge auch sektoral betrachtet werden.

3.4 Physiologische Blendung

„Von physiologischer Blendung spricht man bei Blendungsereignissen, die eine messbare Herabsetzung der Sehleistung oder des Sehvermögens verursachen. Ursächlich hierfür kann eine Minderung der Unterschiedsempfindlichkeit, der Sehschärfe, des Form- und Gestalterkennungsvermögens, der Tiefenwahrnehmung und der Wahrnehmungsgeschwindigkeit sein" (IFA 2010: 3). Kosten physiologischer Blendung sind vor allem ein Thema der Verkehrssicherheit, insbesondere im Fall von großflächiger Lichtwerbung, aber auch von entgegenkommenden oder hinterher fahrenden Fahrzeugen oder Grundstücks- und Gebäudebeleuchtung. Studien zu den verursachten Unfallkosten sind bisher nicht bekannt. Insgesamt dürfte die Zahl an Unfällen, die auf Blendung zurückzuführen sind, eine vergleichsweise nachrangige Rolle spielen und darüber hinaus in den meisten Fällen durch Sonnenlicht und nur in Ausnahmefällen durch künstliches Licht in der Nacht verursacht werden (vgl. Rönsch-Hasselhorn 2003). Neben der Gefährdung der

Verkehrssicherheit kann Blendung auch kriminelle Handlungen begünstigen bzw. selbst als kriminelle Handlung betrachtet werden, beispielsweise wenn Piloten bei Abflug oder Landung mit Laserpointern gezielt geblendet werden. Zu diesen Aspekten sind aber bisher keine wissenschaftlichen Untersuchungen bekannt.

3.5 Lichtüberschreitung durch psychologische Blendung

„Im Gegensatz zur physiologischen Blendung ist die psychologische Blendung messtechnisch weder quantifizierbar noch optisch-visuell nachweisbar. Sie kommt häufig in Innenräumen vor und liegt dann vor, wenn ein aufgrund des qualitativen Urteils eines Beobachterkollektivs ermittelter Grenzwert von gerade noch annehmbarer hin zu gerade unannehmbarer Blendung überschritten wird. Es muss betont werden, dass es sich um rein subjektive Eindrücke handelt“ (IFA 2010: 5). Lichtüberschreitung durch psychologische Blendung soll hier also verstanden werden als Fall, in dem die Beleuchtung des nächtlichen Außenraums unbeteiligten Dritten Nutzeneinbußen verursacht. Bisher sind keine Studien bekannt, die versuchen, diese Lichtkonflikte ökonomisch zu bewerten. Denkbar wären auch hier Zahlungsbereitschaftsanalysen. Daneben können in Deutschland die Lichthinweise der Lichttechnischen Gesellschaft, mit denen das Bundesimmissionschutzgesetz für Fragen der Lichtverschmutzung konkretisiert wird, erste Hinweise zur Bewertung von Lichtüberschreitung und mögliche Kompensationen geben (siehe LiTG 2011).

3.6 Auswirkungen auf die menschliche Gesundheit

Bekannt ist heute aus der medizinischen Forschung, dass sich verschobene Zeitrhythmen auf die menschliche Gesundheit auswirken (Zulley/Knab 2009, Griefahn 2009), Nacht- und Schichtarbeit werden als Störgröße der zirkadianen Rhythmik angesehen und gelten als potentiell krebserregend (Straif et al. 2007). Der ‚shiftlag‘ bei Schichtarbeit kann zu Schlafschwierigkeiten, Stimmungsschwankungen bzw. Depressionen und Herz- Kreislauferkrankungen beitragen (Thorne et al. 2010). Insofern müssten die Kosten der 24-Stunden-Gesellschaft anteilig der nächtlichen Beleuchtung zugerechnet werden. Neben direkten Gesundheitswirkungen entstehen dabei auch gesellschaftliche Kosten durch indirekte Auswirkungen auf zwischenmenschliche Beziehungen und die individuelle Konzentrationsfähigkeit (Moore-Ede 1993). Die Zusammenhänge sind jedoch – wie im Fall der Ermöglichung wirtschaftlicher Aktivität – keinesfalls trivial. Inwiefern sich die Erhellung des Außenraums direkt auf den Rhythmus der Einnahme von Mahlzeiten, Alkoholkonsum, Schlafverhalten und Stress auswirkt, muss allerdings erst erforscht werden. Der am meisten diskutiert direkte Zusammenhang zwischen nächtlichem Licht und Krankheitsbildern betrifft derzeit die Wahrscheinlichkeit an Brustkrebs zu erkranken (Stevens et al. 2007, Stevens 2009). Nächtliches Licht dürfte demnach hormongesteuerte Krebsarten besonders stark beeinträchtigen. Allerdings sind den Studien zufolge vor allem Schichtarbeiterinnen betroffen, eine Korrelation mit Licht im Außenraum wurde bisher eher selten nachgewiesen (Kloog et al. 2010, Chepesiuk 2009). Ein Zusammenhang von Licht und Körpermasse konnte bereits bei männlichen Mäusen nachgewiesen werden, die sowohl bei dauerhaftem Einwirken von Licht als auch bei ständiger Dunkelheit ihre Nahrungsaufnahme ändern und Gewicht zulegen (Fonken et al. 2010).

Sollten die Gesundheitswirkungen der Lichtverschmutzung in naher Zukunft besser erforscht sein, lassen sich prinzipiell auch die gesellschaftlichen Kosten gesundheitsökonomisch ermitteln. Dabei bestehen unterschiedliche Zugänge. Direkte Kosten lassen sich aus den Ausgaben für Medikamente und die Gesundheitsdienste ermitteln, indirekte Kosten ergeben sich volkswirtschaftlich durch die Krankentage und mögliche Verdienstausfälle bei den Betroffenen, bei intangiblen Kosten müssen die verminderte Lebensqualität und eventuelle Schmerzen bewertet werden. Zur Bewertung der indirekten Kosten kann der Humankapital-Ansatz herangezogen werden, intangible Kosten werden mit dem QALY-Ansatz als Ausdruck der in einer bestimmten Qualität verbrachten Lebensjahre qualifiziert (bspw. Zweifel et al. 2009). Allerdings sind bisher keine einschlägigen Studien bekannt. Erste Gedanken zur ökonomischen Betrachtung von Licht und Gesundheit machte sich Henke (2008) in einem Vortrag, in dem er sich primär mit der Heilkraft von Licht und direkten Gesundheitsschädigungen beschäftigte.

4 SCHLUSSFOLGERUNGEN

Die Diskussion der Nutzen und Kosten des Verlusts der Nacht hat gezeigt, dass die Forschung zu vielen der besprochenen Dimensionen noch in den Kinderschuhen steckt. Die ökonomische Betrachtung erfordert dabei prinzipiell ein kreatives Vorgehen, das zumindest zu Fragen der Auswirkungen auf die Ökosysteme nicht ohne eine (ergänzende) qualitative Beschreibung oder Bewertung in physischen Einheiten auskommen wird (siehe TEEB 2010). Grundlegender Forschungsbedarf besteht noch zu Kosten und Nutzen der meisten

privaten Beleuchtungsquellen im öffentlichen Raum, zu den Folgen für die Infrastrukturnetze und zu den Folgen für die Pflanzenwelt. Ob eine Bewertung der Ermöglichung der 24-Stunden-Gesellschaft letztendlich möglich sein wird, muss aus heutiger Sicht bezweifelt werden. Unabhängig davon kann die Taxonomie aber Hinweise zu einer nüchterneren Betrachtung der künstlichen Beleuchtung im Außenraum liefern.

1 ABSTRACT

Overriding trends like globalization, differentiation of life-styles and an increasing personal mobility lead to rapid growth of central located cities and shrinkage of remote areas with no significant economy. The Transnational Alpine Space Region includes large cities like Grenoble, Lyon, Munich and Salzburg as well as small villages. Consequently there are many different settlement structures ranging from low to high density. Planners are confronted with the challenge of offering equivalent living conditions for all inhabitants including those located high within the Alps. The limited space for qualitative settlement development and the different demographic dynamics intensify these trends. In the end this development leads to high residential prices in city centres with good infrastructure and to lower prices in suburban and rural areas. Hence, people move to the countryside where they can rent or buy cheaper real estates, without reflecting on the resulting induced costs for longer travel distances. The site decision has significant impacts on mobility and residential costs which differ greatly because of the dissimilar topography and settlement structure of the Alps. The results are not only raising costs for mobility but also other negative consequences like high energy demand, emissions, air pollution, time costs, reduced quality of life and others.

All these parameters influencing the amount of these costs have to be taken into account for a long term sustainable development. The "MOR€CO" project is trying to achieve transferable strategies to tackle these issues.

The EU co-funded Alpine Space project "MOR€CO – Mobility and Residential Costs" is a cooperation of 10 project partners located in Austria, France, Germany, Italy and Slovenia. MOR€CO started in July 2011 and runs until July 2014. The general aim of the project is to force good governance for a sustainable regional settlement pattern in the pilot sites with respect to mobility and residential cost transparency including a simulation of a potential increase of these costs.

2 CONDITIONS IN THE ALPINE SPACE REGION

The Alpine Space Region extends over nearly 200.000km2 and eight countries. There are big differences in altitude between the valleys and the mountains and various settlement and traffic conditions existing in the area.

One example of extremely changing conditions in the last years is the city and region of Munich. The metropolitan area which is located in the Alpine foothills received a major population growth and a correlated demand for houses. In the Pilot Site "City of Munich and Munich Transport and Tariff Association Area" live more than 2.6 Million people on 5.470km2. This is an average population density of 475 inhabitants per km2. However the situation in the City of Munich is another one: on an area of 310 km2 live nearly 1.4 Million people which generates an average density population of 4500 inhabitants per km2. The major part prefers to live in the city centre and this trend will increase in the future. The real estate prices rise enormously, additionally the most of the people use their car for their daily ways (37% in the City of Munich, see Figure 1). This leads to massive costs for housing and mobility for private households.

In dense areas like the Munich Region it is very important to provide an effective technical infrastructure for reducing long trips, especially when the settlement structure is already strained.

On the other hand there are regions in the Alps like the Val Belluna, a valley for which the population forecasts predicts a shrinking trend till 2029. Here approximately180.500 inhabitants live on 2.454 km2 (see Figure 2) which makes an average population density of approximately 74 people per km2. Even in the City

of Belluno the density is just about 250 people per km2 (Source: www.demostat.it). The problem in areas like this is first of all to maintain the quality of the public infrastructure and also to develop and structure the settlement.

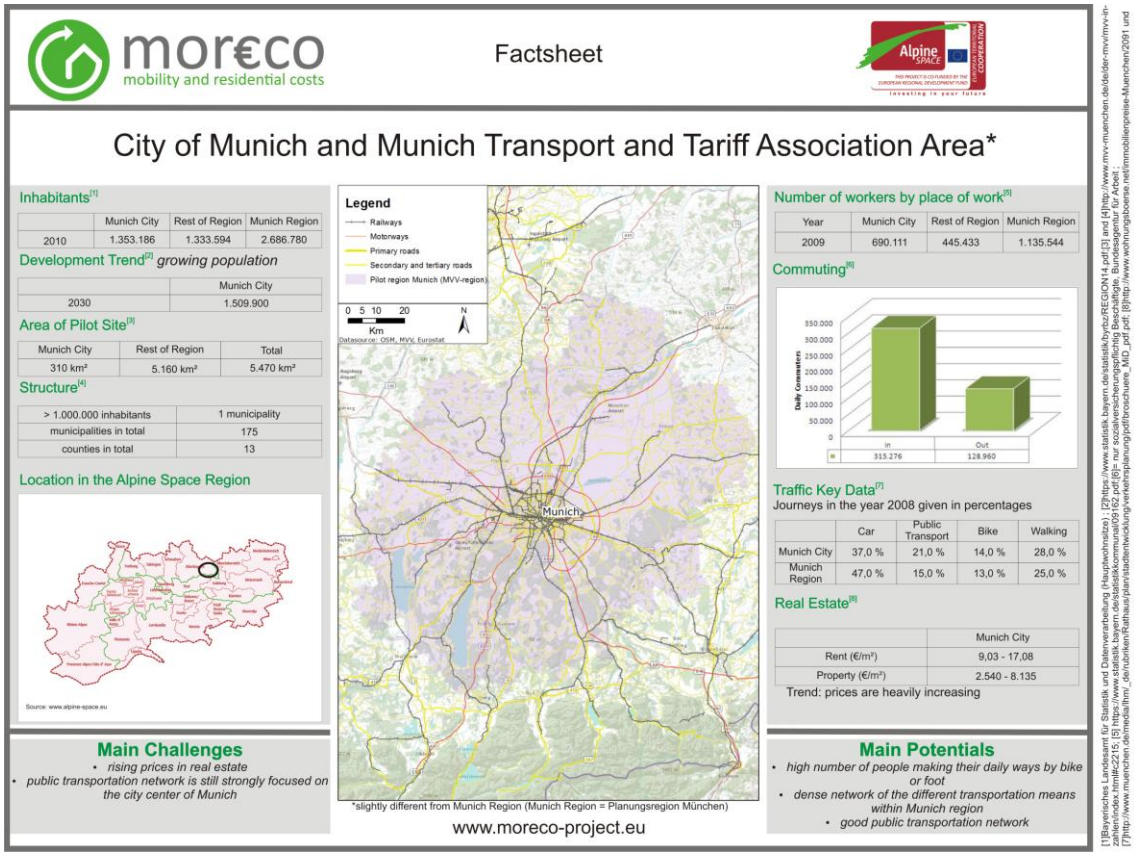

Fig. 1: MOR€CO Factsheet "City of Munich and Munich Transport and Tariff Association Area"

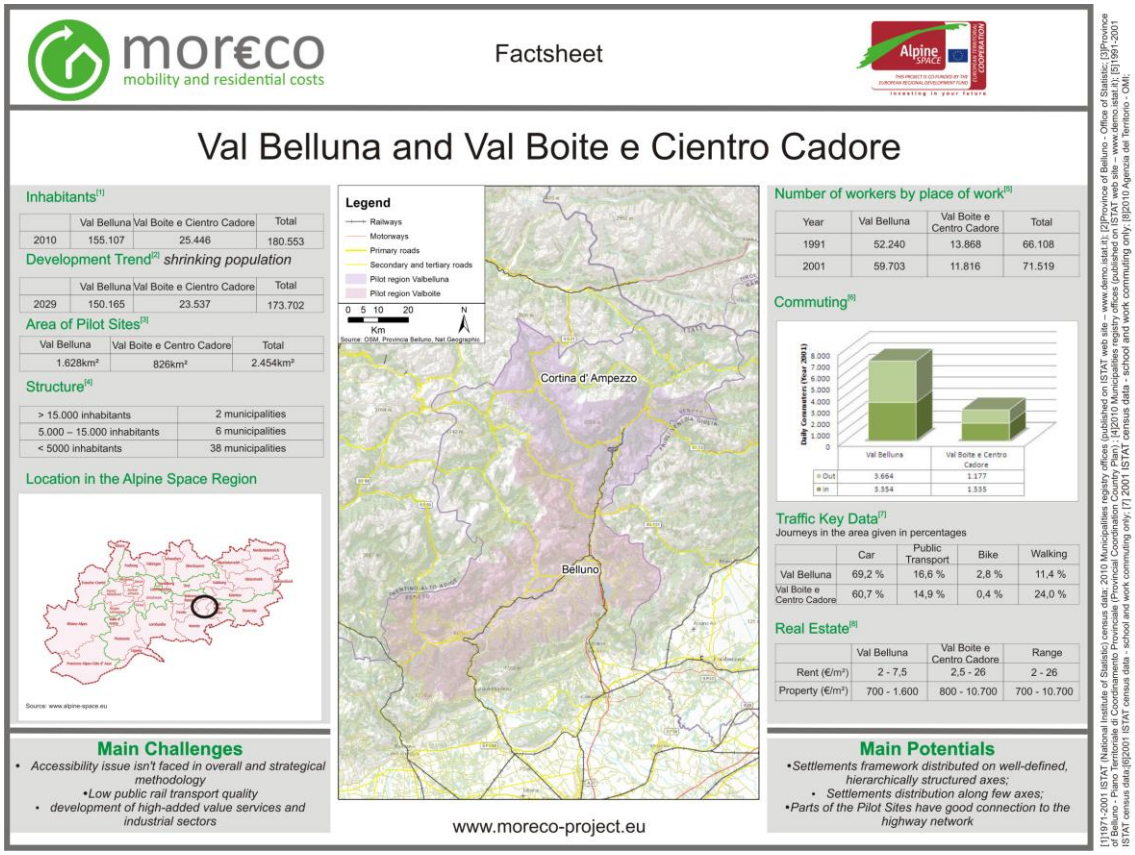

Fig. 2: MOR€CO Factsheet "Val Belluna and Val Boite e Cientro Cadore"

The pressure to tackle these challenges is very urgent in growing areas, but to accomplish equivalent living conditions it is important to serve the needs of all regions in the Alpine Space Region. MOR€CO tries to provide solutions for all kinds of these challenges. This paper is focused on the Munich area because the strategy and further approach is already very advanced.

3 THE INTENDED MOR€CO TOOL KIT

To make the induced long-term costs of site decisions transparent, several tools and strategies will be developed during the MOR€CO project time for special target groups.

Because site decisions are made by different groups of stakeholders, the project will address the following three main target groups:

3.1 Househunting citizens and other private households

When it comes to changing residential location, most people consider first of all the rent or purchase price for real estate. They rarely calculate the mobility costs they will incur by choosing a particular location and especially not the long-term costs. However, the major part of private trips start and stop at home and this implies in most cases:

- The more the residential location lies in the countryside (less costs for real estate), the longer the daily trips are (higher mobility costs)
- The more the residential location lies in a city centre (higher costs for real estate), the shorter the daily trips are (lower mobility costs)

This simple principle works in the major settlement structures but it is not very easy to transfer this to an individual private household, particularly in the Alpine Space Region whit its specific infrastructure. This is the reason why it's essential for citizens to understand the context between residential location decision and induced following costs for mobility.

The general aim of the calculation tool for private households is to give an overview about the mobility and residential costs for an inhabitant of the Alpine Space Region per month based on the individual residential site decision. The tool should help forcing the relation between residential living situations and the induced (long-term) follow-up costs for mobility more transparent.

Fig. 3: User interface of the Munich Residential and Cost Calculator (http://womo.mvv-muenchen.de/)

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

Because the cost calculator should be usable in the whole Alpine Space Area, it needs to be a simple tool free for everybody to download in the internet. The tool follows a similar approach as realized in the Munich Residential and Mobility Cost Calculator (see Figure 3) but transformed into a Windows Excel based Tool which then can be used in the whole Alpine Space Region. There are already several existing tools for this topic, but in the most cases these tools are only partially usable for special regions. The development of the MOR€CO tool will include - where possible – the results and approaches of these existing tools.

3.2 Planners and public transport organisations

The relations between residential location and induced mobility costs are not only important to know for private households but also for spatial and traffic planners, regional developers, public transport organisations and others. These stakeholders should be especially conscious of the consequences of their planning decisions. By knowing the needs of the population and customers the persons responsible for planning could determine more effective and sustainable plans when it comes to questions like mobility behaviour in relation with the settlement structure.

Within the MOR€CO Project a GIS-based tool will be developed to analyze planning decisions concerning future settlement and traffic development. The tool will consist of three main parts:

- Regional Analysis
- Settlement Assessment
- Mobility Planning

These tools will create a combination of maps, diagraphs, interpretation texts and other visualisations. The outputs will help the stakeholders to find qualified settlements for further (re-)developments.

3.3 Politicians, decision makers and municipalities

Politicians, decision makers, municipalities and other authorities at the local level are responsible for zone planning, quantitative targets in settlement development and other formal determinations. They also have to be aware of mobility effects to make sustainable decisions.

Another important group, in addition to the the main target group, includes banks and building societies, housing subsidy institutions, investors and others.

For this target group it is most efficient to develop “soft” tools like

- governance and cooperation strategies
- consulting material
- workshops and seminars

The most important aim for this target group is to provide complicated information in an easily understandable form and to give effective recommendations and instruction for sustainable development.

3.4 Tool practicability and enhancements

By this means private households as well as municipalities/political stakeholders are able to fulfil their current needs. Nevertheless an examination of the current status quo will not solve future issues. Therefore sustainable long-term strategic planning needs to take possible future scenarios into account.

For this reason so-called stress tests will be simulated within the Munich Metropolitan Region combining a mobility cost calculator with a GIS-based accessibility instrument. In the near future sharp increases of mobility costs due to the scarcity of fossil fuels are expected. Therefore simulating drastic future scenarios is a must in order to test the resilience of sub-regions as well as of individuals and households. By means of the vulnerability assessment methodology, several stress tests including different shock scenarios (e. g. triple of gas prices, budget of emission…) will be simulated within the case study.

4 MUNICH CASE STUDY

For the region of Munich the described tools have already been developed and are used in planning practice. Therefore the Munich Region will be highlighted as a case study in the following chapter. The data that will be displayed originated either from the models itself or from the Bavarian statistical database.

4.1 Stress tests on a municipal scale: methodology and first results

To see which region is in danger of increasing mobility costs a so-called vulnerability assessment has been performed for each municipality in the Region Munich.

Kelly and Adger (2000) defined the concept of vulnerability as "the ability or inability of individuals or social groupings to respond to, in the sense of cope with, recover from or adapt to, any external stress placed on their livelihoods and well-being"; while Kasperson et al. (2006) stated that vulnerability refers to "the degree to which a person, system, or unit (such as a human group or place) is likely to experience harm due to exposure to perturbations or stresses".

The vulnerability assessment is divided into the following three dimensions (Kasperson et al. (2006):

- Exposure is the contact between system and stress.
- Sensitivity is the degree to which something/someone is affected by exposure to stress.
- Resilience is the ability of something/someone to absorb perturbations or stresses without changes in its fundamental structure or function that would drive it into different state).

Measuring vulnerability is a crucial issue. As underlined by Leary and Beresford (2007) "… because vulnerability is a complex, multi-dimensional concept that is not directly observable, researchers have experimented with a variety of methods to develop proxy indicators".

The following maps show a selection of key indicators for measuring different levels of exposure, sensitivity and resilience.

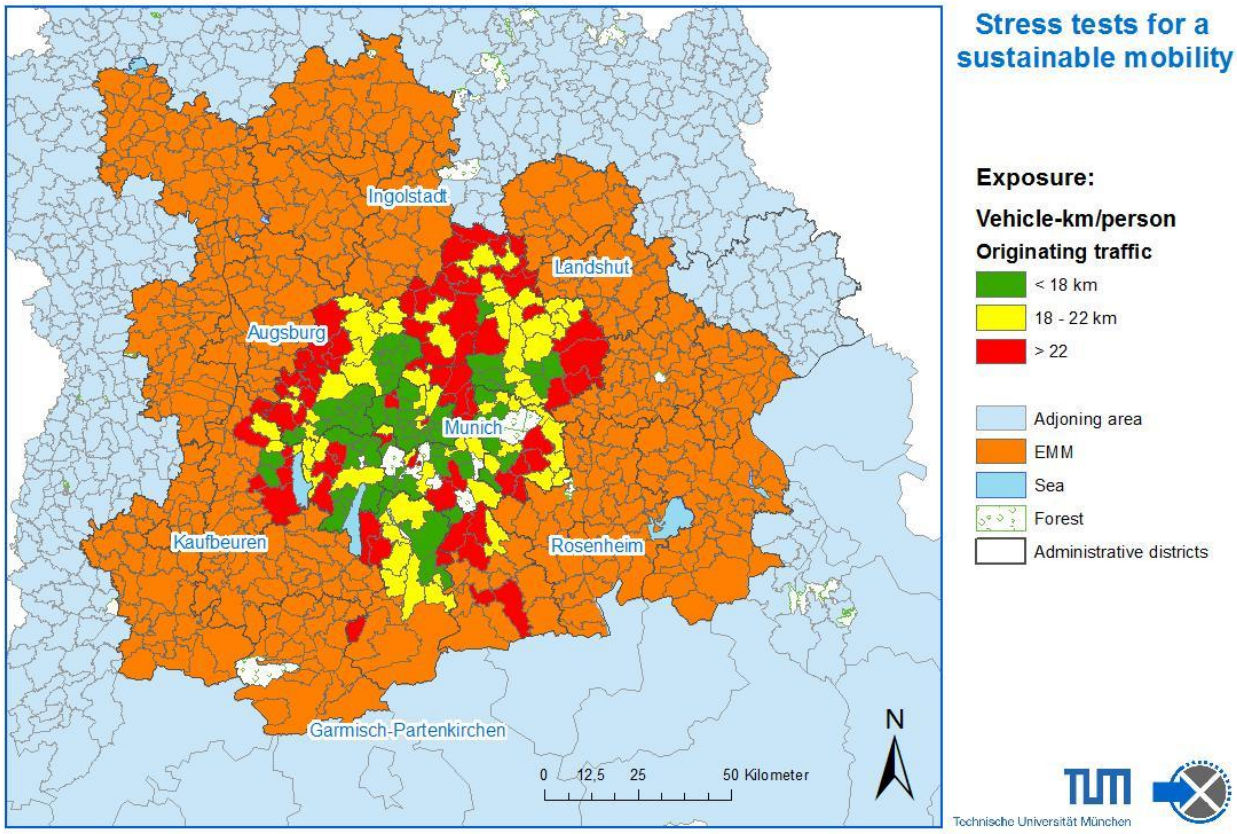

Figure 4: Exposure indicator: Average driven vehicle-km per capita for the municipalities within the Munich Region

The red municipalities have an average driven vehicle-km per capita of more than 22 kilometres daily. Hence these regions are very car dependent and are highly exposed to a sharp increase in fuel costs.

Other possible indicators for exposure are for instance car ownership rate or commuting distance.

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

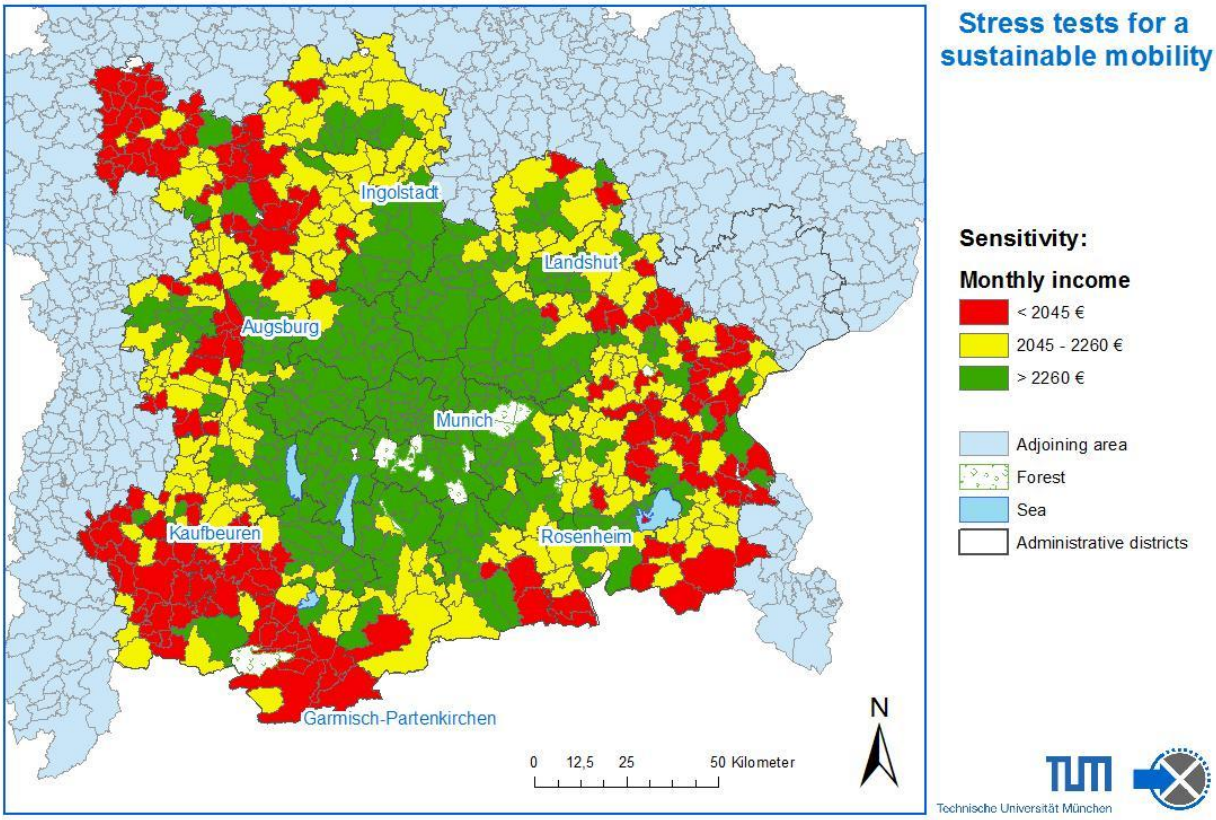

Figure 5: Sensitivity indicator: Monthly average income for each municipality within the Munich Metropolitan Region

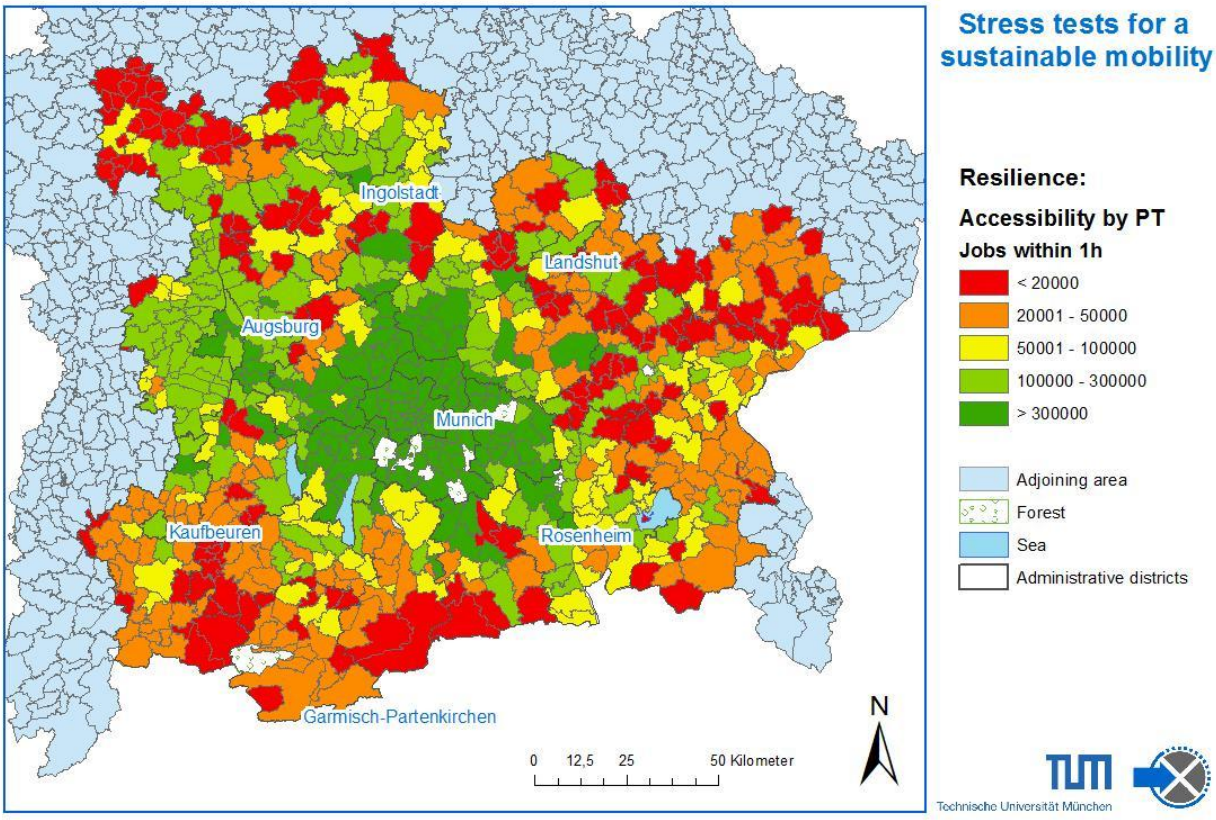

Figure 6: Resilience indicator: Accessibility of the number of jobs by public transportation for each municipality within the Munich Metropolitan Region

The average monthly income is visualized for the Munich Metropolitan Region. In the red municipalities the average income is below 2045 €. Most of them are located in rural locations. The southern regions are close to the Alps and increasing mobility costs will hit the inhabitants in the rural regions very hard; in many cases alternative modes of transport are lacking and therefore their resilience is quite low (see Figure 6).

Other possible indicators for sensitivity are for instance unemployment rate or the share of mobility costs on the household budget.

Figure 1 shows the accessibility of jobs by public transportation for the Munich Metropolitan Region. From the red municipalities less than 20000 jobs can be accessed by public transportation within one hour. Combing accessibility for public transportation with activities (e. g. jobs) will give an idea about need for improvement in the affected regions. Different sorts of accessibility indicators can and should be used for a wide range of thematic analyses.

Other possible indicators for resilience are for instance alternative locations/activities, modes and strategies (e. g. carpooling).

A combination of different indicators for the three dimensions is needed to complete the vulnerability assessment. Nevertheless an examination of the current status quo will not solve future issues. Therefore sustainable long-term strategic planning needs to take possible future scenarios into account. For this reason so-called stress tests will be simulated within the Metropolitan Region Munich combining a mobility cost calculator with a GIS-based accessibility instrument. In the near future sharp increases of mobility costs due to the scarcity of fossil fuels are expected. Therefore simulating drastic future scenarios is a must in order to test resilience of sub-regions as well as of the individuals and households. By the means of the vulnerability assessment methodology several stress tests including different shock scenarios (e. g. triple of gas prices, budget of emission…) will be simulated within the case study.

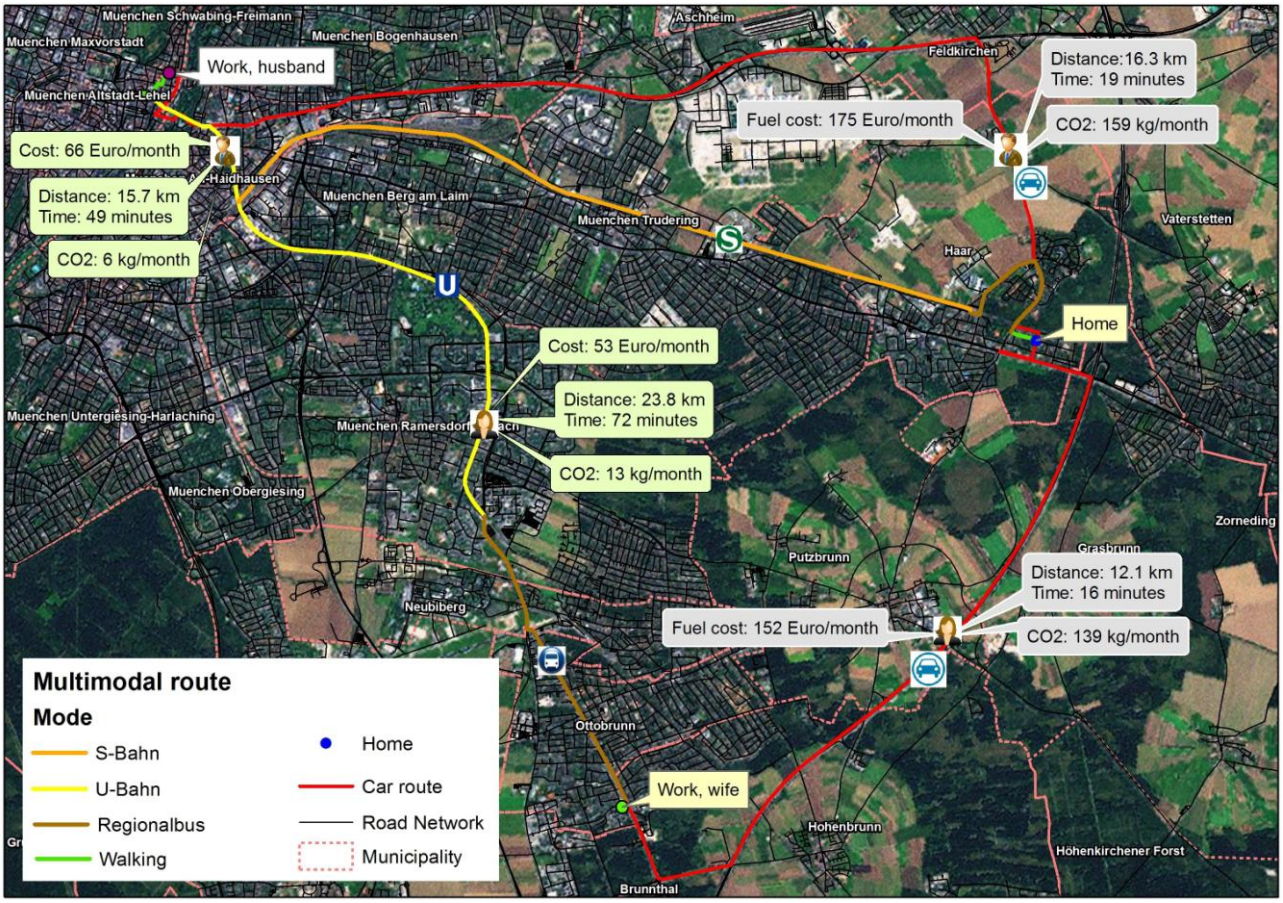

Figure 7: Current mobility costs for trip purpose working in the suburban municipality “Haar” with good access to public transport

4.2 Calculating mobility costs for households

The vulnerability assessment on a regional scale is important to stress test the municipalities regarding the future development. Nevertheless it is of high importance to include site and mobility decisions by

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

individuals and households, which cannot be highlighted in average numbers for each municipality. Wilbanks and Kates (1999) state that research on multiple scales (e. g. household and municipality) is needed.

With respect to this matter, fictional yet realistic storylines for synthetic households (based on regional data and survey) have been developed by the means of a residential and mobility cost calculator provided by the Munich Transport and Tariff Association (MVV). For three different settlement structures including a compact urban city, a suburban municipality and a rural municipality the different mobility behaviours have been analysed and the current costs for individuals and households have been calculated.

Figure 4 visualizes the route choices for different modes of transport for the suburban municipality Haar to the place of employment. The exemplary household consists of a wife and a husband; both of them are travelling to work each day. Other household members and activities like a son doing sports and going to school are included. The travel time, mobility costs as well as CO_2 emissions are calculated for each trip. In that way different activities for different members of the household are calculated, visualized and tested for their respective sustainability. Afterwards these numbers are listed and compared, and they provide guidance for improving the mobility behaviour.

5 CONCLUSION AND OUTLOOK

Visualizing the current and the even more important future costs exposes the high importance of the location choice (residential and activity based) and mode choice; this will ultimately help households and decision makers to lead to more sustainable short and long term choices. The MOR€CO tools in combination with stress testing the study regions concerning price shocks will ultimately lead to a more sustainable way of transport and spatial planning in the Alpine Space Area.

If all future project steps will be successfully finished, the project serves the needs from growing and from shrinking structures in the Alpine Space Region as well as support transnational cooperation.

Multi-Channel-Konzepte als Chance für eine nachhaltige und zukunftsfähige Entwicklung der Innenstädte?

Martina Hengst, Gerhard Steinebach

(Dipl.-Ing. M.Sc. Martina Hengst, TU Kaiserslautern, Lehrstuhl Stadtplanung, Pfaffenbergstr. 95, 67663 Kaiserslautern, Martina.Hengst@ru.uni-kl.de)

1 KURZFASSUNG

Einzelhandel und die Entwicklung der Innenstädte stehen in den Städten seit jeher in einem besonderen Verhältnis. Als eine Leitfunktion der Innenstadt trägt der Einzelhandel neben der Versorgungsfunktion maßgeblich zur Zentrumsbildung, Stadtgestaltung sowie Urbanität und damit zur Attraktivität und dem Image der Innenstadt bei, wovon wiederrum innerstädtische Dienstleistungen und innerstädtisches Wohnen profitieren. Andererseits bieten die Innenstädte mit den Wohn-, Arbeits- und Freizeitfunktionen die notwendige Geschäftsgrundlage für den Einzelhandel.

In den vergangenen Jahren ist der Einkaufsstandort Innenstadt jedoch durch äußere Einflüsse verstärkt gefährdet. Neben der Konkurrenz durch die Ansiedlung großflächiger Einzelhandelsunternehmen und Shopping-Center auf der ‚Grünen Wiese' sowie der Eröffnung von ‚Factory Outlet Centern' besteht derzeit eine zunehmende Konkurrenz durch das Online-Shopping. Während sich der Interneteinkauf immenser Wachstumsraten erfreut, leidet der stationäre Einzelhandel in der Innenstadt vielerorts unter sinkender Nachfrage. Ursächlich dafür ist u.a. das veränderte Einkaufsverhalten. Vor dem Hintergrund zunehmender digitaler, vor allem mobiler, Endgeräte und der Nutzung des Online-Shopping wollen die Konsumenten heute möglichst bequem, schnell – das heißt in Echtzeit, ortsungebunden, günstig und ohne sich zum Kauf verpflichtet zu fühlen einkaufen. Diese Anforderungen kann der stationäre Einzelhandel alleine nur bedingt erfüllen.

In Reaktion auf diese Entwicklungen kombinieren daher immer mehr Einzelhändler ihr Ladengeschäft mit einem Online-Shop. Diese Multi-Channel-Konzepte können dazu beitragen, die Versorgungsinfrastruktur in der Innenstadt aufrecht zu erhalten, sind aber auch nicht frei von Risiken. Im günstigsten Fall stellen sie durch die Verknüpfung von stationärem und Online-Angebot ein attraktives Einkaufsangebot dar, welches zu einer zukunftsfähigen und nachhaltigen Entwicklung der Innenstadt beiträgt.

Ziel des Beitrags ist es, nach einer grundlegenden Betrachtung der gegenseitigen Bedeutung von stationärem Einzelhandel und Innenstadt, der aktuellen Situation des innerstädtischen Einzelhandels und den veränderten Anforderungen der Konsumenten, die Chancen von Multi-Channel-Konzepten zur Unterstützung einer nachhaltigen und zukunftsfähigen Entwicklung der Innenstadt zu durchleuchten.

2 WECHSELSEITIGE BEDEUTUNG VON STATIONÄREM EINZELHANDEL UND INNENSTADT

Einzelhandel und die Entwicklung der Innenstädte stehen seit jeher in einer großen wechselseitigen Beziehung. „Städte ohne funktionierenden Handel sind ebenso undenkbar, wie ein Handel ohne Städte mit einer entsprechenden Wohn- und Lebensqualität sowie Infrastruktur" (Steinebach 2002: 45).

2.1 Die Bedeutung des stationären Einzelhandels für die Innenstadt

Rückblickend auf die Zeit des frühen Mittelalters – in jener Zeit bildete sich der Handel als dauerhafter und regelmäßiger Austausch von Waren und Dienstleistungen an einem Standort heraus – kam dem Handel vor allem eine Versorgungs- und Stadtgründungsfunktion zu, da das Marktrecht Voraussetzung für das spätere Stadtrecht war. Der Handel war demnach wesentlich für die Entwicklung der (Innen-)Städte. Ursprünglich auf den Marktplatz beschränkt, dehnte sich der Handelsraum im Laufe der Jahrhunderte weiter aus. Heute hat sich die gesamte Innenstadt als Zentrum des Einkaufens etabliert. Dies wirkt sich in vielfältiger Weise auf die Innenstadt aus:

Als eine Leitfunktion der Innenstadt weist der innerstädtische Einzelhandel eine „besondere zentrumsbildende Magnetfunktion" (Heinritz et al. 2003: 201) auf. Bei entsprechender Qualität und Angebotsvielfalt und daraus resultierenden Attraktivität wirkt er sich positiv auf die Frequentierung und damit die Belebung der Innenstadt aus, welche wiederum für die urbane Qualität von Bedeutung ist, die das

Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

Wesen einer Stadt ausmacht. Der Einzelhandel ist folglich ein wesentlicher Garant für den Charakter, die Bedeutung und das Image der Innenstadt. Davon profitieren auch die anderen innerstädtischen Leitfunktionen wie Dienstleistungen, Gastronomie und Wohnen.

Daneben prägt der innerstädtische Einzelhandel die Baustruktur und damit das Stadtbild. „Seit der Antike waren Handelsbauten auch immer repräsentative Bauten, die eine besondere Stellung in der Stadt einnahmen (Mayer-Dukart 2010: 50).“ Heute mischen sich kleinteilige Ladenlokale mit den dominanten Bauten von Passagen, Markthallen, Warenhäusern und Stadtgalerien. Letztere lösen die seit einigen Jahren von Insolvenz und Umsatzeinbrüchen betroffenen Warenhäuser zunehmend als Frequenzbringer ab. So werden leerstehende Warenhäuser neben der Umnutzung als Hotels, Museen, Verwaltungsgebäude oder Loftwohnungen immer öfter in Einkaufsgalerien umgewandelt oder ausgebaut (Köhler 2010). Wesentlichen Anteil an der Vielfalt der Handelsbauten haben die verschiedenen Nutzungen und die veränderten Anforderungen der Konsumenten (Walzel et al. 2011: 481) (s. Kap. 3.2).

Abschließend sei die soziale Funktion des innerstädtischen Einzelhandels für die Innenstadt genannt. Zum einen als Arbeitgeber und zum anderen als Treffpunkt und Ort der Kommunikation. Er bringt Menschen zusammen, da viele Besucher das Einkaufen in der Innenstadt mit anderen Terminen verknüpfen, sich zum gemeinsamen Shopping verabreden oder ohne Kaufabsicht Bummeln gehen und dabei auf Fremde und Bekannte treffen.

2.2 Die Bedeutung der Innenstadt für den stationären Einzelhandel

Neben der großen Bedeutung des stationären Einzelhandels für die Innenstadt profitiert andererseits der stationäre Einzelhandel bis heute von der Innenstadt. Historisch boten die dauerhaften und regelmäßigen Marktsiedlungen des frühen Mittelalters, aus denen viele der heutigen Städte hervorgingen, mehrere Vorteile. Durch die starke Abgrenzung von Stadt und Umland durch Befestigungsanlagen der Städte wie Stadtmauer und Stadtgraben waren nicht nur die Bewohner, sondern auch die Händler vor Plünderungen geschützt. Die räumliche Trennung hatte jedoch nicht nur eine schützende Wirkung, sondern führte auch zu einem Abhängigkeitsverhältnis, welches eine Kooperation der Stadt- und Landbewohner erforderte. Während die Stadt vom Umland Nahrung und Rohstoffe bezog, versorgte sie andersherum das Umland mit handwerklichen Erzeugnissen und Dienstleistungen. Daher kamen die Kunden nicht nur aus den Städten selbst, sondern vor allem aus dem Umland, ein großer Absatzmarkt für die Händler war damit gegeben. Überdies stellte die Versorgung mit Informationen einen großen Standortvorteil für die Händler dar. Vor dem Einsatz von modernen Informations- und Kommunikationstechnologien konnten Neuigkeiten auf dem Marktplatz am schnellsten in Erfahrung gebracht werden (Wietzel 2007: 23f.). Ein zusätzlicher zeitlicher Vorteil für die Händler waren die kurzen Transportwege, da sich die Produktionsbetriebe in unmittelbarer Nähe zum Marktplatz niederlassen konnten.

Auch aktuell bieten die Innenstädte eine wesentliche Geschäftsgrundlage für den Einzelhandel. Ihre Attraktivität resultiert dabei vor allem aus der großen Multifunktionalität und Nutzungsmischung, welche mit Einschränkungen in den meisten Innenstädten vorhanden ist. Die Wohn-, Arbeits- und Freizeitfunktionen tragen zu einer hohen Aufenthaltsqualität bei, ermöglichen die Verknüpfung von Einkäufen mit anderen Tätigkeiten, welche vor dem Hintergrund des knapper werdenden subjektiven Zeitbudgets immer wichtiger wird, und erhöhen somit die Frequentierung der Innenstadt und folglich auch der Ladengeschäfte. Allerdings ist die Innenstadt als Einkaufsstandort in Folge des ökonomischen Strukturwandels zunehmend gefährdet.

3 AKTUELLE SITUATION UND HERAUSFORDERUNGEN FÜR DEN INNERSTÄDTISCHEN EINZELHANDEL

3.1 Gegenwärtige Entwicklungen im innerstädtischen Einzelhandel

Der innerstädtische Einzelhandel befindet sich seit vielen Jahren in einem ökonomischen Strukturwandel, der auf handelsexogene und handelsendogene Faktoren zurückzuführen ist (Heinritz et al. 2003: 40ff.). Die Veränderung der Nachfrage stellt neben den allgemeinen politischen und wirtschaftlichen Rahmenbedingungen sowie politisch-administrativen Entscheidungen eine der wichtigsten handelsexogenen Ursachen des Strukturwandels im Einzelhandel dar und ergibt sich u.a. aus den veränderten Anforderungen der Konsumenten an das Einkaufen. Diese veränderten Konsumentenanforderungen werden, auch weil Multi-Channel Konzepte im Wesentlichen auf diese zurückgehen und in Kapitel 4 als mögliche Chance für

die Innenstädte thematisiert werden, in Kapitel 3.2 detaillierter behandelt. Zu den wichtigsten handelsendogenen Einflüssen, d.h. internen Veränderungen, zählen die kapitalbedingte Selektionswirkung bei der Umsetzung von Innovationen, da diese meist sehr kostenintensiv sind, der verschärfte Wettbwerbs- und Preisdruck infolge der Kapitalkonzentration und Internationalisierung sowie die Nachfragemacht der Großunternehmen (Heinritz et al. 2003: 42; Mayer-Dukart 2010: 59).

Vor dem Hintergrund der beschriebenen Einflussfaktoren stellt sich die Situation des innerstädtischen Einzelhandels derzeit wie folgt dar:

Zunehemende Konkurrenz

Der innerstädtische Einzelhandel ist in den vergangenen Jahrzehnten einer verstärkten Konkurrenz ausgesetzt. Auf der ‚Grünen Wiese' haben sich konkurrierende Handelsstandorte wie ‚Factory Outlet Center', Shopping-Center und Fachmarktzentren herausgebildet und auch das Online-Shopping etabliert sich zunehmend. In Konsequenz sind innerstädtische Geschäfte mit reiner Versorgungsfunktion immer seltener vertreten, während der Erlebniseinzelhandel dominiert (Fahle et al. 2008: 71).

Filialisierung – Verdrängung inhabergeführten Einzelhandels

Der kleinteilige, inhabergeführte Einzelhandel wird aufgrund seiner mangelnden Konkurrenzfähigkeit gegenüber den Filialisten zunehmend in die abgewerteten Nebenlagen der Innenstädte verdrängt und ist immer häufiger zur Geschäftsaufgabe gezwungen. So ist heute die Mehrheit der deutschen Innenstädte von Filialisten geprägt. Dies führt einerseits zu einer zunehmenden Fremdbestimmtheit, zu einer Uniformität des Stadtbildes sowie zu Niveauverlusten durch die Banalisierung, Vereinheitlichung und Verflachung des Angebots, die sich in einem sinkenden Erlebniswert und Qualitätsverlust niederschlägt (Fahle et al. 2008: 65ff; Heinritz et al. 2003: 44; Kiepe/ Thielen 2011: 7). Andererseits tragen die Filialisten jedoch über ihren positiven Wiedererkennungswert und Funktion als Ankermieter zu einer Belebung der Innenstadt bei (Fahle et al. 2008: 65).

Zunehmende Leerstände vor allem in Nebenlagen

Innerstädtische Leerstände sind aufgrund von strukturellen Veränderungen als auch individuellen Standortfaktoren wie überzogenen Mietpreissteigerungen „schon lange nicht mehr ein vereinzeltes, sondern ein alle Stadtgrößen und Standorte betreffendes Problem" (Mandac 2011: 11). Vor allem die Nebenlagen erfahren eine zunehmende Abwertung, da sich die Filialisten auf die 1A-Lagen konzentrieren (Bundesministerium für Verkehr 2011: 35), aber auch gut gelegene Ladenlokale sind in den vergangenen Jahren zunehmend von Leerstand bedroht. Je länger und je mehr Ladenlokale leerstehen desto schwerwiegender sind die Folgen. Der Branchenmix und das Image, welche die Attraktivität des Einkaufsangebots und damit auch der Innenstadt garantieren, werden nachhaltig gestört, ganze Straßenzüge veröden, da auch benachbarte Ladenlokale hinsichtlich Frequentierung und Umsatz beeinträchtigt werden und das soziale Leben in den Innenstädten verändert sich, weil die von Leerstand betroffenen Straßen deutlich seltener besucht und auch hinsichtlich Gestaltung und Sauberkeit vernachlässigt werden (Mandac 2011: 11; Bormann/ Siegel 2007: 28; Kippig 2004).

Verkaufsflächenwachstum

Ungeachtet sinkender Umsätze und des demographischen Wandels haben die Anteile der Verkaufsflächen im innerstädtischen Einzelhandel in den vergangenen Jahren massiv zugenommen; von 55 Prozent 1990 auf 63 Prozent im Jahr 2010 (Handelsverband Deutschland (HDE) 2010). Die wesentlichen Gründe für das Anwachsen der Verkaufsflächen sind die Einführung der Selbstbedienung, die Erweiterung des Sortiments (Heinritz et al. 2003: 43), rückläufige Betriebszahlen sowie die generelle Marktsättigung, die dazu führt, dass eine immer weitere Vergrößerung der Verkaufsflächen in Verbindung mit einem massiven Preiswettbewerb als einziger Ausweg gesehen wird Konkurrenten vom Markt zu drängen und dadurch die eigenen Umsätze wieder zu steigern (Bormann/ Siegel 2007: 5). Für die Innenstädte ist die Nachfrage nach größeren Verkaufsflächen insofern problematisch, als dass sie vor dem Hintergrund ihrer historischen Struktur der Gebäude oftmals lediglich über sehr kleine Verkaufsflächen verfügen und damit nur eingeschränkt konkurrenzfähig sind.

„Gastrofizierung“

In vielen Innenstädten ist seit einigen Jahren ein stetiger Zuwachs an Gastronomieeinrichtungen zu beobachten. Diese ‚Gastrofizierung‘ resultiert zum Einen aus der Verlagerung des Einkaufs lebensnotwendiger Güter auf die Grüne Wiese, während die Innenstadt eher für den meist spontan stattfindenden ‚Kann-Kauf‘ vor dem Hintergrund des Trends zum Erlebnisshopping (s. Kap. 3.2.1) genutzt wird, der ein entsprechend ansprechendes Umfeld benötigt. Zum Anderen ist die zunehmend älter werdende, gesättigte Bevölkerung weniger am Erwerb von Waren als an einem geselligem Beisammensein in der Innenstadt interessiert. In Konsequenz auf diese Entwicklungen haben nicht nur die gastronomischen Angebote in der Innenstadt selbst, sondern insbesondere die Außenbestuhlung stark zugenommen sowie die Einkaufcenter ihre Gastronomieanteile von ehemals fünf Prozent in den zweistelligen Bereich erhöht. Dies wirkt sich auch auf den innerstädtischen Einzelhandel aus, da der Passantenlauf von den Ladenlokalen weggeführt wird und somit die Kundenfrequenz in den Geschäften sinkt (Domino Immobilien Dienstleistungen GmbH 2011).

Gutes Komsumklima trotz stagnierender Kaufkraft

Nach einem stetigen Rückgang der Kaufkraft seit den 1950er Jahren, werden die Deutschen 2012 erstmals wieder mehr Euro pro Kopf für ihre Ausgaben zur Verfügung haben. Aufgrund der steigenden Preise – die Bundesbank prognostiziert derzeit eine Inflation von 1,8 Prozent – wird die reale Kaufkraft jedoch stagnieren (Lindcom Group 2011; Lichtner 2011). Dennoch ist das Konsumklima insbesondere auch vor dem Hintergrund der derzeitigen Finanz- und Wirtschaftskrise wiedererwartend gut; der Konsumklimaindex ist im Februar angestiegen (SPIEGEL online 2012). Damit steigen auch die Wachstumschancen für den Einzelhandel, ob der innerstädtische Einzelhandel profitiert bleibt abzuwarten.

Sinkende Umsätze

Die Umsätze im Einzelhandel sind seit Jahren rückläufig. Auch wenn sich seit dem vergangenen Jahr mit dem größten Umsatzanstieg seit der Wiedervereinigung eine Trendwende andeutet, zählt der innerstädtische Einzelhandel nicht zu den Profiteuren. Er büßte in der vergangenen Dekade jährlich etwa 1,5 Mrd. Euro Umsatz ein mit der Folge dass die Besucherfrequenzen vielerorts rückläufig sind (Mandac 2011: 10). Besonders erfolgreich war hingegen der Online-Handel; von 2000 bis 2010 wuchs sein Umsatz um über 1000 Prozent (Handelsverband Deutschland (HDE) 2011).

3.2 Anforderungen der Konsumenten an das Einkaufen

Die Anforderungen der Konsumenten an das Einkaufen, welche im Wesentlichen für die Veränderung der Nachfrage verantwortlich sind, haben sich deutlich verändert. Ursächlich dafür ist die Kombination aus sich wandelndenen demographischen und sozioökonomischen Rahmenbedingungen, dem Wertewandel, der zunehmenden Polarisierung zwischen armen und reichen Bevölkerungsschichten, Einflüssen der Einzelhandelsunternehmen sowie dem technologischen Wandel.

Die veränderten Anforderungen der Konsumenten schlagen sich in drei zentralen Trends im Konsumverhalten nieder; dem Erlebnisshopping, dem Convenience Shopping und dem Preiskauf, welche nachfolgend näher erläutert werden. Weiter ausdifferenziert und dynamisiert werden die Konsumtrends durch die zunehmende Nutzung digitaler Medien (Hassenpflug/ Tegeder 2004: 88f.) (s. Kap. 3.3).

<u>Erlebnisshopping</u>

Das Hauptmerkmal des Erlebnisshopping, welches vor allem auf den Wertewandel zurückgeht, ist, dass „nicht die Bedarfsdeckung mit lebensnotwendigen Gütern, sondern der Vergnügungs- und Freizeitaspekt im Vordergrund“ stehen (Mayer-Dukart 2010: 58). Dies färbt auch auf den Sprachgebrauch ab. Sowohl im allgemeinen Sprachgebrauch als auch in der Literatur lässt sich zunehmend die begriffliche Differenzierung zwischen dem klassischen ‚Einkaufen‘ als reinem Akt der Versorgung mit Waren und Dienstleistungen sowie dem ‚Shopping‘ als dem Erwerb von Waren und Dienstleistungen als Freizeitbeschäftigung beobachten. Kennzeichnend für das Erlebnisshopping ist weiterhin die Verknüpfung des Einkaufens mit weiteren Tätigkeiten, wie einem Gastronomiebesuch und dem Treffen von Freunden, welche auch vor dem Hintergrund des knapper werdenden subjektiven Zeitbudgets erfolgt (Wirtz 2008: 48).

Damit das Einkaufen zum Vergnügen und Freizeiterlebnis werden kann, sind ein guter Branchenmix und eine hohe Beratungsqualität wesentliche Voraussetzungen (Planungsverband Ballungsraum Frankfurt/Rhein-

Main 2011: 4). In Konsequenz bietet der Einzelhandel besondere Serviceangebote wie spezielle (kulturelle) Events, Gewinnspiele und Autogrammstunden an. Weitere Maßnahmen des Einzelhandels und der Planung, um auf die Erlebnisorientierung der Verbraucher zu reagieren, sind die Schaffung von Erlebniswelten, beispielsweise durch die Integration von Erlebnisparzellen in die Verkaufsräume sowie die Aufwertung der Fußgängerzonen (Fritz/ Lang 2008: F.46; Mayer-Dukart 2010: 58). Diese Maßnahmen sollen zu einer Belebung der Innenstädte auch außerhalb der Ladenöffnungszeiten beitragen. Die Ausrichtung des Einzelhandels auf Erlebnisorientierung scheint sich zu rechnen. Mehrere Studien bestätigen, dass Erlebnisse, Emotionen und Atmosphäre den Umsatz und die Kauffreude der Verbraucher erhöhen (Kroeber-Riel/ Weinberg 2003: 436ff.).

Als Angebotsformen für das Erlebnisshopping eignen sich insbesondere innerstädtische oder innenstadtnahe Galerien und Passagen, Megastores, Themenkaufhäuser, Einkaufszentren sowie Urban Entertainment Center (Planungsverband Ballungsraum Frankfurt/Rhein-Main 2011: 3). Demnach können Innenstädte wesentlich mehr vom Trend zum Erlebnisshopping profitieren als der ansonsten boomende Online-Handel.

Convenience Shopping

Ein weiterer, sich aus den demographischen und sozioökonomischen Rahmenbedingungen ergebender Trend im Konsumverhalten ist das Convenience Shopping. So werden vor dem Hintergrund der zunehmenden Überalterung der Bevölkerung, der wachsenden Anzahl an Single-Haushalten, der vermehrten Erwerbstätigkeit von Frauen sowie des subjektiven Eindrucks der Zeitknappheit durch berufliche und private Verpflichtungen, verstärkt Convenience-Angebotsformen nachgefragt, welche zu Bequemlichkeit und Zeiteffizienz beitragen (Mayer-Dukart 2010: 57; Wirtz 2008: 48; Planungsverband Ballungsraum Frankfurt/Rhein-Main 2011: 4). Typische Angebotsformen sind Kioske, Trinkhallen, Tankstellenshops und Bahnhofsmärkte, die sich bevorzugt in Transiträumen an Verkehrsknotenpunkten befinden, sowie indirekt auch Online-Shops. Sie zeichnen sich, mit Ausnahme der Online-Shops, durch eine wohnungsnahe Lage und damit gute Erreichbarkeit, verlängerte Öffnungszeiten, ein übersichtliches Angebot, welches insbesondere älteren Menschen zugutekommt, und die Möglichkeit des ‚One-stop-shopping' aus. Letzteres bedeutet, dass mehrere Tätigkeiten bzw. Konsumwünsche kombiniert werden können, wie zum Beispiel der Erwerb einer Zugfahrkarte mit dem Kauf einer Zeitschrift in der Bahnhofsvorhalle. Von Vorteil sind ferner der persönliche Kontakt sowie die Beratung und die Bedienung, welche an frühere Vertriebsformen wie den Tante-Emma-Laden angelehnt sind (Fritz/ Lang 2008: 42; Mayer-Dukart 2010: 57; Ahlert/ Hesse 2003: 5). Vor dem Hintergrund der gewünschten Entlastung beim Einkaufen werden zudem besondere Serviceangebote, wie Bring- und Abholservices, Kinderbetreuung und Online-Dienste, angeboten. Dieses Mehr an Service spiegelt sich im vergleichsweise hohen Preisniveau gegenüber anderen Einkaufsmöglichkeiten wieder. Dennoch ist gemäß HEINRITZ widererwartend kein Zusammenhang zwischen dem Haushaltseinkommen und der Convenience-Orientierung feststellbar (Heinritz et al. 2003: 160ff.).

Preiskauf

Der Preiskauf gliedert sich in zwei Verhaltensformen; das Discount Shopping und das Smart Shopping. Beide Ausprägungen gehen auf den Wertewandel zurück, das Discount Shopping ist zusätzlich Folge der Einkommensentwicklung. Discount Shopping bedeutet, dass die Verbraucher eine hohe Preisorientierung aufweisen und bevorzugt bei discoutorientierten Betriebsformen einkaufen, in denen „Konsumgüter des Massenabsatzes bei einfacher Ladenausstattung zu günstigen Preisen angeboten werden" (Ausschuss für Definitionen zu Handel und Distribution 2006: 31). Die Niedrigpreisorientierung spiegelt sich vor allem an den Ausgaben für Lebensmittel am privaten Verbrauch wieder. Innerhalb von knapp 60 Jahren haben sich diese von 44 Prozent (1950) auf 11 Prozent (2009) verringert (Frankfurter Rundschau online n.b.). Zu den Konsequenzen dieser als ‚Aldisierung bzw. Discountierung der Gesellschaft' (Horx 1995; Fritz/ Lang 2008: 38) beschriebenen Entwicklung zählt insbesondere die wachsende Verödung der Innenstädte (Fritz/ Lang 2008: 39).

Der Trend zum Smart Shopping, der sich mittlerweile zu einem regelrechten Lifestyle entwickelt hat, ist seit Mitte der 1990er Jahre zu beobachten (Heinritz et al. 2003: 156). Wesentlich, neben einer wachsenden Qualitätsorientierung, ist auch hier eine starke Niedrigpreisorientierung, die jedoch unabhängig von der sozialen Schicht und dem Einkommen auftritt (Ausschuss für Definitionen zu Handel und Distribution 2006) und aus einem steigenden Anspruchsniveau sowie einer wachsenden Professionalität und gestiegenem

Selbstbewusstsein der Verbraucher resultiert (Pangels 2011). Viele Konsumenten agieren dabei nach dem Motto ‚weniger ist mehr'. D.h. sie kaufen insgesamt weniger, legen dafür aber umso mehr Wert auf Qualität.

Eine Handelsform die dem Trend des Smart Shopping besonders entgegen kommt, ist das Factory Outlet Center, welches seine Attraktivität aus der Kombination von Discount-Preisen und hohem Erlebniswert generiert (Blank 2004). Auch die Teilnahme an Internetauktionen und die Nutzung von Coupons, Bonus- und Kundenkarten, welche auch die innerstädtischen Einzelhändler zunehmend einsetzen, sind Ausdruck des smarten Kaufverhaltens (Mayer-Dukart 2010: 57).

3.3 Einfluss digitaler Medien

Durch die zunehmende Nutzung digitaler Medien, wie Internet, Mobiltelefon und E-Book, und die Möglichkeit des Online-Shopping werden die beschriebenen Trends weiter ausdifferenziert und dynamisiert und damit schwieriger handhabbar. Nachfolgend werden die wesentlichen Einflüsse auf das Einkaufsverhalten im Einzelnen dargestellt.

Adaption des Online-Verhaltens auf den Einkauf im stationären Einzelhandel

Verbraucher, die regelmäßig im Internet konsumieren, gewöhnen sich allmählich an die Schnelllebigkeit und ständigen Neuerungen sowie die ausgeprägte Service- und Convenienceorientierung und erwarten diese auch im stationären Einzelhandel (Tegeder 2004: 114). Die Bereitschaft, für zusätzlichen Service und Beratung höhere Preise zu akzeptieren ist allerdings weniger ausgeprägt. Da der stationäre Einzelhandel zusätzlichen Service und Beratung zudem bei weitem nicht so kostengünstig anbieten kann wie der Online-Handel, ist er nur eingeschränkt konkurrenzfähig.

Durch die zunehmende Nutzung von Medien, die zu einem beschleunigten Zugang zu Informationen und einer Vereinfachung der Kommunikation beitragen, werden die Kunden „sprunghafter, spontaner und in ihrem Kaufverhalten immer weniger vorhersehbar. Damit wird die Prognostizierbarkeit der Nachfrage immer schwieriger" (Neidberger 2011: 619f.). Diese Entwicklung wird häufig im Begriff ‚Multioptionales Kaufverhalten' zusammengefasst. Ausdruck dieses Verhaltens sind das ‚Varity Seeking' und das ‚Channel Hopping'. Variety Seeking steht für das Bedürfnis von Kunden nach Abwechslung. Das Verhalten zielt darauf ab „reizmonotone Situationen, also Zustände zu geringer Abwechslung bzw. Langeweile, durch Reizvariationen, also aktive Suche nach neuen Reizen bzw. Reizwechsel, auszugleichen" (Schramm-Klein 2003: 39f.). Es stellt folglich ein starkes Motiv dar verschiedene Produktmarken und Einkaufsorte zu nutzen (Wirtz 2008: 47). Das Channel-Hopping, der kundenseitige Kanalwechsel innerhalb einzelner Transaktionen, eignet sich besonders gut, um dem Bedürfnis nach Abwechslung gerecht zu werden (Ahlert/ Hesse 2003: 11f.). Im Vordergrund steht dabei aktuell vor allem der Wechsel zwischen stationären Einzelhandelskanälen und internetbasierten Kanälen (Müller-Lankenau 2007: 47).

Fragmentierung des Einkaufvorgangs

Jeder Einkaufsvorgang setzt sich aus vielen Einzelelementen zusammen, die bei einem herkömmlichen Einkauf an einem Ort, dem Ladengeschäft, stattfinden. Dazu zählen: das Einkaufsbedürfnis bzw. der Einkaufswunsch, das Sammeln von Produktinformationen und Erfahrungen, die Auswahl und Kaufentscheidung, der Bezahlvorgang, der Erhalt des Artikels sowie die Rückgabe bei Nichtgefallen (Mokhtarian 2003: 213). Die Möglichkeit, sich im Internet zu informieren oder online einzukaufen verändert den Einkaufsvorgang. Es kommt zu einer „Fragmentierung früher ganzheitlicher Aktivitäten und eine neue Wiederverknüpfung (Rekombination) ihrer Einzelteile" (Mokhtarian 2003: 213).

Internetnutzer als Konsumexperten

Durch die wachsende Zugänglichkeit und Nutzung des Internets im privaten Bereich wird das Warenangebot zunehmend transparenter. Der Internetnutzer kann eigenständig nach Angeboten und Testberichten recherchieren und sich in Foren über einzelne Produkte und Angebote austauschen (Tegeder 2004: 113). Er ist folglich wesentlich umfassender über die Produktangebote des Handels informiert als früher. Das Internet macht Preis- und Qualitätsvergleiche dabei nicht nur einfacher und schneller, sondern auch kostengünstiger (Kromer 2005: 103).

Aufgrund der gestiegenen Informiertheit erlangen die Konsumenten einerseits eine wachsende Souveränität. In Verbindung mit dem seit dem Fall des Rabattgesetzes im Jahr 2001 erlaubten Feilschen im Einzelhandel,

kann zunehmend auf Augenhöhe mit den Anbietern der Waren und Dienstleistungen verhandel werden. Andererseits sind die Konsumenten durch ihren erweiterten Informationsstand auch wesentlich kritischer und den Anbietern gegenüber weniger loyal (Tegeder 2004: 121). Werden die Bedürfnisse nicht erfüllt, wird der Anbieter gewechselt.

Online-Shopping als Alternative

Neben der Übertragung des Online-Verhaltens auf den Einkauf im stationären Einezlhandel und der Nutzung des Internets als Informationsmedium für das Einkaufen, nutzen mehr und mehr Menschen die Möglichkeit direkt im Internet einzukaufen. „(…) shopping no longer needs to be a physical, time-consuming activity. The entire shopping process from product information search, communication and selection, transaction, delivery (of digital goods) to after sales can literally be conducted on the Internet" (Weltevreden/ van Rietbergen 2007: 68). Insgesamt 68 Prozent der Deutschen haben im Jahr 2010 Einkäufe über lokales oder mobiles Internet getätigt (Schneller 2010), wobei vor allem Bücher, Bekleidung, Veranstaltungstickets, Tonträger und Hotelübernachtungen nachgefragt wurden (Statista GmbH 2011). In Konsequenz wuchs der Umsatz im Online-Handel von 2000 bis 2010 um über 1000 Prozent, während der stationäre Einzelhandel im selben Zeitraum lediglich um 1,6 Prozent zulegte. Trotz dieser beeindruckenden Zuwächse liegt der Anteil des Online-Handels am gesamten Einzelhandelsumsatz bisher lediglich bei knapp fünf Prozent (Handelsverband Deutschland (HDE) 2011). Insbesondere die positiven Tendenzen beim mobilen Online-Shopping – jeder dritte Internetnutzer in Deutschland kaufte 2011 online per Smartphone ein, 2010 war es nur knapp jeder zehnte (Mohr/ Sauthoff-Bloch 2011: 20) – lassen jedoch erwarten, dass sich der Anteil in den nächsten Jahren weiter vergrößern wird.

Die Gründe für die zunehmende Beliebtheit des Online-Shopping sind vielfältig. Ein Grund ist zweifelsohne, dass Online-Shopping zwar weniger dem Erlebnisshopping-Trend jedoch sowohl dem Trend zum Convenience Shopping und als auch dem Trend zum Smart Shopping entspricht. Der Konsument kann anders als im stationären Einzelhandel, welcher häufig von uneinheitlichen Öffnungszeiten, schlechter Erreichbarkeit durch mangelnde Parkplätze bzw. ÖPNV-Angebote sowie der Verringerung von Breite und Tiefe des Angebotes durch Billiganbieter betroffen ist (Helmer-Denzel 2004: 26), bequem von jedem Ort und zu jeder Tageszeit zielgenau auf ein nahezu unbegrenztes und aktuelles Angebot an Waren und Dienstleistungen zurückgreifen. Der „Vorgang der Raumüberwindung [entfällt] für den Kunden völlig" (Becker 2000: 133). Die Zeit- und Wegeersparnis empfinden vor allem Frauen als bedeutsam, da „der E-Commerce (…) ein mögliches Mittel zur Alltagsbewältigung" (Lenz 2003: 73) darstellt. Auch der Nachfrage nach maximaler Qualität zum niedrigsten Preis wird das Internet durch seine umfassenden Vergleichsmöglichkeiten gerecht.

Als weitere Vorteile des Online-Shopping gegenüber dem stationären Einzelhandel werden die größere Angebots- und Preistransparenz, der geringere Einkaufsstress, Spontanität und Lebensgefühl sowie das Umgehen von unfreundlichem Verkaufspersonal genannt (Lenz 2003: 71; Heggmaier 2003: 102). Viele Konsumenten schätzen zudem den persönlichen Zuschnitt der Produkte und Dienstleistungen. MOKHTARIAN spricht in diesem Zusammenhang von einer „massenhaften Maßanfertigung" (Mokhtarian 2003: 209).

3.4 Herausforderungen für den innerstädtischen Einzelhandel

Wie vorausgehend dargestellt, fällt es dem innerstädtischen Einzelhandel infolge der gegenwärtigen Trends im Konsumverhalten sowie dem zunehmenden Einfluss digitaler Medien, die sich zudem als neuer Absatzkanal etablieren, immer schwerer, den Anforderungen der Konsumenten gerecht zu werden und somit für die breite Masse attraktiv zu bleiben. Viele, insbesondere alteingesessene, inhabergeführte Geschäfte tun sich aufgrund mangelnder digitaler Kompetenz, fehlender finanzieller Mittel sowie mangeldem Interesse an Neuerungen schwer, mit der notwendigen Flexibilität zu reagieren. Das häufig verfolgte Prinzip der Ignorierung bzw. Totalverweigerung gegenüber den durch die Digitalisierung ausgelösten Anforderungen ist jedoch wenig zielführend und beschleunigt den Trend zunehmender Geschäftsaufgaben, wachsender Leerstände und sinkender Umsätze vermutlich eher.

Ein hohes Zukunftspotenzial wird dagegen dem sogenannten ‚Multi-Channel-Retailing', d.h. der Verbindung mindestens eines ‚klassischen' Vertriebskanals, wie dem stationären Ladengeschäft, mit dem Internet-Vertriebskanal (van Baal/ Hudetz 2005: 139), unterstellt. Nach Meinung des HDE-Hauptgeschäftsführers

STEFAN GENTH werden die Multi-Channel-Retailer die weitere Entwicklung der Branche signifikant prägen. Insbesondere die Verknüpfung von innerstädtischen Ladenlokalen mit Online-Shops ist äußerst vielversprechend, weil dieselben Nutzergruppen angesprochen werden (Tegeder 2004: 117). So besteht gemäß einer niederländischen Studie eine signifikante Korrelation zwischen dem Genuss des Online-Shoppings und dem Einkaufen in der Innenstadt; je größer das Vergnügen am Online-Shopping ist, desto größer ist es auch beim Einkaufen in der Innenstadt (Weltevreden et al. 2004: 15).

15 Prozent der stationären Einzelhändler – wobei die Hälfte von ihnen mittelständische Facheinzelhändler sind – kombinieren bereits ihr Ladengeschäft mit einem Online-Shop (Handelsverband Deutschland (HDE) 2011). Vor allem diejenigen Branchen, „die einen hohen Anteil digitalisierbarer sowie standardisierter Güter und Dienstleistungen umfassen“ (Adrian 2003: 322) vertreiben ihre Waren verstärkt zusätzlich online. Insgesamt generierten Multichannel-Anbieter im Jahr 2010 ein Umsatzplus von 14,7 Prozent, d.h. das Umsatzvolumen stieg auf 6,7 Mrd. Euro und liegt damit über dem Online-Handels-Gesamtvolumen der Internet-Pure-Player (Schmidt 2011: 3). „Fast 60 Prozent der Einzelhändler, die neben ihrem Ladengeschäft auch einen Online-Shop betreiben, erwarten höhere Umsätze (Handelsverband Deutschland (HDE) 2011).“

Die wesentlichen Vorteile des Multi-Channel-Retailing liegen für die Einzelhändler in:

- Der Verbesserung der Wettbewerbsposition und Steigerung der Marktanteile,
- Umsatzsteigerungen durch von Multi-Channel-Retailing ausgelöste Zusatzkäufe,
- der Sicherung des stationären Ladengeschäfts,
- steigender Kundenzufriedenheit durch besseren Service,
- besseren Möglichkeiten der Kundenansprache,
- größerer Bekanntheit und besserem Image sowie
- der Möglichkeit der Verkaufs- und Lagerflächenverkleinerung.

Insgesamt können demgemäß viele Nachteile eines stationären Geschäfts gegenüber dem Online-Handel durch die Verknüpfung beider Kanäle aufgehoben werden, wenn gewisse Spielregeln beachtet werden. Dazu zählen die Ähnlichkeit zwischen den Absatzkanälen hinsichtlich der Gestaltung und des Warenangebots, eine möglichst optimale Verknüpfung von virtuellem und realem Geschäft sowie die Schaffung eines Mehrwerts für die Konsumenten.

Inwieweit sich das Multi-Channel-Retailing auch für die Innenstädte als Chance herausstellt, soll nachfolgend betrachtet werden.

4 MULTI-CHANNEL-KONZEPTE ALS CHANCE FÜR DIE INNENSTÄDTE?

Die innerstädtischen Einzelhändler können unter gewissen Voraussetzungen in vielfacher Hinsicht von dem Umstieg auf Multi-Channel-Konzepte profitieren (s. Kap. 3.4). Drei dieser Vorteile stellen zugleich eine Chance für die Innenstädte dar:

Sicherung der stationären Ladengeschäfte

Da die Umsätze, die über das Internet erzielt werden können, die Umsatzmöglichkeiten des stationären Einzelhandels häufig übersteigen, trägt der Online-Shop als zweiter Absatzkanal insbesondere bei kleinen und mittelständischen Unternehmen zur Sicherung des Ladengeschäfts bei (Sigge 2011). In Konsequenz kann die Versorgungsinfrastruktur – zumindest im Bereich des Erlebniseinzelhandels – in der Innenstadt aufrechterhalten und zugleich Leerstände vermieden werden, da die Geschäfte mit einem erfolgreich umgesetzten Multi-Channel-Konzept seltener von Insolvenz betroffen sind. Beides, ein vielfältiges Angebot an Geschäften als auch geringe Leerstände, trägt zum Erhalt einer attraktiven Innenstadt bei.

Erhöhte Bekanntheit und Imageverbesserungen

Es ist denkbar, dass sich das durch das Multi-Channel-Retailing hervorgerufene verbesserte Image der Ladengeschäfte sowie ihre größere Bekanntheit auch auf die Innenstadt übertragen. Insbesondere von multi-channel-affinen Konsumenten – Studenten, Azubis und gut verdienenden Alleinlebenden – könnten die Innenstädte dann als innovativer und damit attraktiver wahrgenommen und häufiger aufgesucht werden.

Verkaufs- und Lagerflächenverkleinerung

Wenn zukünftig immer mehr Waren über das Internet verkauft werden, könnten sich die Ladengeschäfte zunehmend zu Ausstellungsräumen wandeln, die dem Wunsch des Anfassens sowie des An- und Ausprobierens der Waren nachkommen, das Abholen oder die Reklamation von Waren ermöglichen und nur noch untergeordnet dem Verkauf dienen. In Konsequenz würden weniger Verkaufs- und Lagerflächen benötigt. Dies würde den Innenstädten insofern entgegenkommen, als dass sie in ihrer historisch bedingten, kleinteiligen Baustruktur gerade diese nachgefragten kleinen Ladenlokalen zu bieten haben, welche derzeit vor dem Hintergrund des anhaltenden Verkaufsflächenwachstums noch eher ein Hemmnis darstellen.

Im günstigsten Fall kann die verstärkte Nutzung von Multi-Channel-Konzepten der innerstädtischen Einzelhändler folglich zu einer Unterstützung und Aufwertung der Innenstädte beitragen und sie damit zukunftsfähig machen. Neben den beschrieben Chancen bestehen jedoch auch Risiken. Es ist nicht ausgeschlossen, dass einige stationäre Einzelhändler durch die guten Erfahrungen mit dem Online-Handel oder aufgrund der fehlenden Nachfrage nach stationären Geschäften durch die Konsumenten langfristig ganz aus dem lokalen Einzelhandel aussteigen und ihre Waren und Diestleistungen, insbesondere wenn es sich um digitalisierbare und standardisierte Produkte handelt, nur noch ausschließlich online vertreiben. Leerstände, der Bedeutungsverlust der Innenstädte als Einkaufsstandort, Engpässe in der lokalen Versorgungsinfrastruktur und damit ein Attraktivitätsverlust der Innenstädte insgesamt wären die Folge. Problematisch bei beiden möglichen Entwicklungsrichtungen ist, dass die Einflussmöglichkeiten der Planung äußerst begrenzt sind.

Negative Space and Positive Environment: Mapping Opportunities for Urban Resilience

Mirko Guaralda, Magdalena Kowalik

(Magdalena Kowalik, Queensland University of Technology, Brisbane, Australia, m.kowalik@qut.edu.au)

1 ABSTRACT

Cities have long held a fascination for people – as they grow and develop, there is a desire to know and understand the intricate interplay of elements that makes cities 'live'. In part, this is a need for even greater efficiency in urban centres, yet the underlying quest is for a sustainable urban form. In order to make sense of the complex entities that we recognise cities to be, they have been compared to buildings, organisms and more recently machines. However the search for better and more elegant urban centres is hardly new, healthier and more efficient settlements were the aim of Modernism's rational sub-division of functions, which has been translated into horizontal distribution through zoning, or vertical organisation thought high-rise developments.

However both of these approaches have been found to be unsustainable, as too many resources are required to maintain this kind or urbanisation and social consequences of either horizontal or vertical isolation must also be considered. From being absolute consumers of resources, of energy and of technology, cities need to change, to become sustainable in order to be more resilient and more efficient in supporting culture, society as well as economy. Our urban centres need to be re-imagined, re-conceptualised and re-defined, to match our changing society.

One approach is to re-examine the compartmentalised, mono-functional approach of urban Modernism and to begin to investigate cities like ecologies, where every element supports and incorporates another, fulfilling more than just one function. This manner of seeing the city suggests a framework to guide the re-mixing of urban settlements. Beginning to understand the relationships between supporting elements and the nature of the connecting 'web' offers an invitation to investigate the often ignored, remnant spaces of cities. This 'negative space' is the residual from which space and place are carved out in the Contemporary city, providing the link between elements of urban settlement.

Like all successful ecosystems, cities need to evolve and change over time in order to effectively respond to different lifestyles, development in culture and society as well as to meet environmental challenges. This paper seeks to investigate the role that negative space could have in the reorganisation of the re-mixed city. The space 'in-between' is analysed as an opportunity for infill development or re-development which provides to the urban settlement the variety that is a pre-requisite for ecosystem resilience. An analysis of the urban form is suggested as an empirical tool to map the opportunities already present in the urban environment and negative space is evaluated as a key element in achieving a positive development able to distribute diverse environmental and social facilities in the city.

2 INTRODUCTION

2.1 Background

Cities have long held a fascination for people – the appeal of the melting pot of cultures, lifestyles and opportunities has drawn humanity to create ever more complex iterations of urban centres teeming with life, movement and energy (Karp, Stone, & Yoels, 1991). Yet the demands of cities are growing even now – the pace of life, the demands of new technology, resultant social changes and perhaps most urgently, the growing awareness of environmental consequences of Western lifestyles are causing cities to draw more, consume more and become more (Zukin, 2010).

Complexity is one of the main characteristics of a consolidated urban environment; mixed uses, social heterogeneity, sensory stimulation at multiple levels, economic transactions and cultural exchange are all variables that contribute to the development of a town's own complexity, a town's own identity (Allen, 2004; Tung, 2001). The balance between these different components has been assumed as a key element in the success of an urban environment based on demographic and population growth (Mumford, 1989). Several approaches have attempted to explain urban complexity and especially its contradictions; cities have always been less healthy than the countryside and historically their citizens have always had a shorter life

expectancy; nevertheless for the last 200 years people have been leaving villages in rural areas to cluster in slums, generate suburban sprawls and engage with the persistent urban congestion (Hall, 1998).

2.2 Understanding Cities

Cities have been evolving and adapting to changes in lifestyle, economy and production processes from their beginning. Elements which were central during a historic phase and that have required consistent investment in order to be built, like city walls, have been quickly demolished when more than keeping enemies out they were restraining the growth of the bourgeois society (Benevolo, 1980). Palaces and temples have been built, promoted as cultural icons of civic identity and then torn down; activities which were keeping town centres alive were removed, isolated or segregated on the outskirt of the urban stage (Norberg-Schulz, 1979).

Traditional methods of introducing urban changes have tended to fall into three categories: razing the city in order to start again; annexing new areas beyond existing city boundaries; and the more moderate approach of 'change from within' making use of infill opportunities to slowly upgrade the urban system to meet new requirements, whether social or economic (Kowalik & Guaralda). Given the small number of new cities constructed globally, and understanding the intense resource consumption of urban construction as well as more general environmental concerns, it is reasonable to suggest that the means implementing urban change has been narrowed down to the third option in the vast majority of cases (Allen, 2004).

Approaches to the Urban Environment

Cities have been described as over-scaled residential buildings, an analogy pointing out how the different components of urban life mirror that of dwellings; a room to sleep, one to work, and one to meet people became districts to live, work, shop and relax in. In other cases towns have been compared to forests or gardens (Patetta, 1986). Perfect designs have been proposed to celebrate princely power, divine intervention or social structures. In order to make cities more efficient they have been compared to machines and they have been reinvented as a rational system where every component has a specific role, every activity a specific space (Kostof, 1991).

A different approach has proposed the study of cities as organism, with a defined centre of control, green lungs, veins to move people and goods; every element in a close relationship with each other, every element contributing to the good health of the system (Hough, 1984). This comparison to organisms is still central in popular culture and cities are diagnosed with several diseases which affect the social fabric, the structure of the economy and especially the health of citizens as well as the environment (Blakely & Ellin, 1997).

While these approaches have typically been aimed at improving efficiency of urban centres and streamlining processes of delivery of urban services, there now exists a different motivation for the better understanding of urban behaviour (Newman & Jennings, 2008). Growing awareness and concern over the environmental cost of cities (Girardet, 2008) has become a driver of new urban theories and models (International New Town Institute, 2009). Recognising that on the whole, we are unlikely to abandon the city in order to pursue simpler and "more sustainable" lives, concern has shifted to the issue of urban sustainability.

Urban Sustainability

Sustainability, as a concept, has changed and developed in the last 40 years moving from being the priority of a minority to one at the centre of debate in every political arena at every level. The building industry and cities in general have been recognised as the major pollution factors which are compromising the fragile ecosystem of our planet. Several solutions to environmental issues have been proposed; being green is the new trademark of commercial companies and local governments, however the exact means of implementing large scale sustainable solutions without adverse effects is not clear (J. Birkeland, 2008); cities are inherently complex, layering meaning, history and cultural memory (Tung, 2001). As manifestations of shared cultural values they do not allow a 'tabula rasa' approach of blanket solutions (I. Birkeland, 2008).

Being sustainable is a priority, but being sustainable just means containing the damages, not repairing damage done in the past. A relatively recent attempt to counter this sustainability fault, is the theory of Positive Development by Janis Birkeland (2008). To sum up, the theory puts forth the argument that the built environment needs to have an overall net positive impact, essentially returning land to a level of ecological health that was present prior to urbanisation. Arguing that current ideas regarding sustainable development are based on a negative presumption that damage to the environment is unavoidable and

therefore 'standard' and acceptable, it calls for a paradigm shift in the planning, design, retrofitting and management of the built environment. Rather than accepting the damage that the built environment causes and believing that the best we are capable of is to remediate or restore 'inevitable' environmental degradation, Positive Development (J. Birkeland, 2008) advocates a shift to a design-based (positive) approach in our built environment. Ecological remediation, restoration and regeneration are considered to be insufficient as we have already exceeded the Earth's ecological carrying capacity; and offsetting ecological losses with social gains, typically unrealised in the final design, is a zero-sum game. Arguing that development which does not 'pay its own way' ecologically is no longer acceptable, Positive Development (J. Birkeland, 2008) calls for a built environment which has a net positive ecological and social impact. In practical terms, it argues for the retrofitting urban sites to increase the net ecological carrying capacity as well as natural and social capital, expanding both the ecological base and the public estate of cities. New buildings need to reverse the damage caused by previous development in absolute terms (J. Birkeland, 2008).

The positive development theory then, aims not only to minimise built environment impact, but also to improve the general condition of the environment (J. Birkeland, 2008), where buildings are proposed as agents to modify the context in order to provide a gain at the multiple levels that urban complexity requires: social, cultural, economic and environmental. The way this theory could be implemented in the actual design process is still debated, but this approach suggests a different way to look at cities.

Cities as Ecosystems

In the XXI century cities could be discussed as ecosystems (Chiesura, 2004); ecosystems allow a dynamic approach and the different components change in response to interactions with the others and the general context (Fuller et al., 2010). In a machine or in an organisms some elements are assumed to be central and not subject to alteration or modification, but this has been proved erroneous in the case of urban complexity, where functions move, areas grow and shrink, and shared memories and values morph (Hough, 1984). The ecological value of some urban elements, mainly green spaces, is expansively debated in literature (Smith & Levermore, 2008). Planted areas have a recognised value for the environment, contributing to absorb pollutants, mitigate the heat island effect and increase carbon sequestration (Smith & Levermore, 2008). The role of vegetation has also been discussed in terms of social structure; green areas affect the perception of the environment and also human behaviours; from the ecological point of view they support biodiversity (Fuller, et al., 2010). Vegetated areas affect the economy through impact on real estate values (Bowman, Thompson, & Colletti, 2009), but also in terms of welfare; it is recognised that an active lifestyle has a role in reducing the Government's investment in healthcare (Willis & Crabtree, 2011). Current studies are investigating how the provision of parks and gardens relates to active lifestyles of residents (Willis & Crabtree, 2011). Additionally, the growing number of dwellings in urban centres adds import to the creation and maintenance of urban retreats in the form of parks and green space (Phillips, 2003). Enhancing this connection to nature through the creation of urban habitat for native wildlife contributes to humanise the overwhelming scale of the city (Hoevan, 2006).

Approaching to the city as an ecosystem is still fragmented and focused on the provision of singular elements or defined corridors between green spaces (Pickett & Cadenasso, 2008). On the other hand sustainable buildings are proposed to respond the local environment, but usually these do not address the problem of the wider city (J. Birkeland, 2008); green roofs, green walls or other green elements to reduce the impact of new construction on the environment do not relate to the city in terms of a system, just in terms of local a environment. Looking at cities like ecosystems means that every new development could be a cluster which contributes in some way to the general positive performance; buildings, parks, and street plantings can all be seen as biotopes that interact in a dynamic way. Buildings could be developed not as isolated elements, but as 'cells' providing an environmental function to the wider ecosystem; negative space could be designed not as an in-between medium, but as the tissue connecting the different cells. Through a negative space connective tissue, buildings in urban centres could 'spread the load' and 'share the gain' simultaneously. Individual positioning and design of buildings presents a range of possible opportunities for retrofitting a myriad of environmental solutions to existing building stock. These solutions already exist and offer opportunities for energy generation, air and water filtration, carbon sequestration and food production (Birkeland, 2002). For example: equatorial facing elevations of high-rises could harness solar energy in a collective grid and 'share' it amongst the city, lessening the overall energy burden of the city. Retrofitting a

series of green roofs and walls can create wildlife corridors which would be 'safe' from human degradation without any loss of valuable urban land. This approach suggests the possibility of the city as a whole becoming a 'living' system, allowing a non-linear shift of the whole city into a new state (Newman & Jennings, 2008). The interaction of the various building 'cells', each with a shared communal social or environmental function, may result in an emergent state of urban sustainability. This proposed strategy could also suggest possible alternative developments to the recent visions of new eco-cities, which while solving some of the recent environmental issues, do not solve the question of the existing urban environment and how to retrofit it (Kowalik & Guaralda).

3 MAPPING NEGATIVE SPACE

In order to promote this vision, an initial step is proposed of the mapping of opportunities in the urban environment (Holt-Damant & Wyeld, 2005). Studies on the green space or on the blue space are consolidated in urban design and planning, what is suggested in this paper is that this kind of mapping also includes the opportunities offered by urban development in implementing the vision of cities as ecosystems (Cho, Poudyal, & Roberts, 2008). Traditionally open spaces are recorded on the basis of their use or presence of greeneries (Varon, 1998a). Parks are programmed within the urban environment to provide retreats for local residents or as main recreational precincts for the city users (Shaftoe, 2008). The planning approach takes into consideration the distribution of green areas as the provision of facilities, not in terms of an ecological system. In particular situations, especially alongside creeks and rivers, corridors are maintained; in some cases there are environmental principles behind the protection of these kinds of spaces, more often consideration of floods risk or difficulties in the development of these landscapes are the real factors which force their preservation (Hough, 1990). In some instances also the space of creeks has been urbanised, cities in Italy, Brazil and Spain made the decision to cover or channelize water bodies, having then to pay damages in the case of overload of these systems (Pavia, 1996).

In parallel to the functional or economical study of open space, a typological one has been proposed by Varon (1998b) who initiated a possible categorisation of these urban areas on the basis of their character, closely related to the one of the surrounding elements. The proposed methodology is not limited to publicly accessible areas, but has a more holistic approach taking into consideration private gardens streetscape. The studies of Varon are based on the development of pedestrian networks, potentially using open spaces within blocks to gain missing connections (Varon, 2004). On the other hand ecological studies promote the creation of interconnected systems where natural areas are connected through corridors in order to allow the movement of fauna and the creation of complex biological networks (Allen, 2004). Merging these two theories is proposed in order to create an urban system operating as an ecosystem, where all the elements can contribute to the positive development of the urban area. For this kind of approach the typological element is not central, but clearly the possibility of interconnections has to be taken into consideration.

3.1 Mapping Opportunities

Based on the studies on typologies of open space, ecological systems as well as urban planning, the following elements are suggested as a framework to map positive development opportunities:

Public Parks

These elements usually play a central role in providing cities with a social space as well as environmental relief (Vapaa, 2002). Larger parks can accommodate leisure facilities and can be key elements in the identity of a city, for example being located in strategic areas or hosting high profile festivals (Platt., 2006).

Gardens

These these are not always publicly accessible, but can be taken in consideration in the creation of an ecological network. These elements have an important social role providing a personal sanctuary where to rejuvenate within the busy urban environment (Griswold, 1996)

Pedestrian Areas

The role of walkable networks is extensively discussed in literature for their social importance, especially in terms of public health (Guaralda, 2006). Apart from being a significant element for a sustainable lifestyle, pedestrian areas are usually the outcome of a process of refurbishment of the urban environment (Newman &

Jennings, 2008). These spaces could provide opportunities to include sustainable technologies for the production of electricity or gathering of water, as well as to manage weather extremes. Some greenways projects have been including this kind of elements alongside artworks or shelters.

Street Planting

The provision of trees in the urban environment is discussed as a potential elements to improve the local environment in terms of air quality and climate control (Lee, Jang, Wang, & Namgung, 2009). Plants in the urban environment can also support a variety of life forms, provide biodiversity to the urban environment and also mitigate the presence of pest (Cowan & Steward, 2007). Cities are an ideal habitat for this kind of biotopes, especially because they do not provide space for their natural predators (Fuller, et al., 2010)

Laneways

The potential of laneways in building pedestrian networks is quite widely recognised in literature (Varon, 2004). These urban spaces can be vibrant social places, but also provide informal connections between different kinds of more structured elements, like private gardens or main streets.

Accessory Spaces

Driveways, accessways, internal manoeuvre spaces or commercial courtyards are spaces often used temporarily during the day or the week (Varon, 1997). Management of this temporality can provide different social uses and the introduction of elements to set up different kinds of urban networks.

Carparks

The need for car space is a central issues in contemporary cities. Large areas are devoted for provisional parking even entire structures are built for this use. In the case of accessible areas, the recognisable pattern is that of busy areas in the daytime, on weekdays and desolated wasteland at nighttime or weekends (Groth, 2005). Also in this case the management of the temporarily of use can allocate different social functions in these spaces as well as the inclusion of environmental mitigation elements (Rawlinson & Guaralda).

Infrastructures and Lost Space

Railway networks as well as motorways and road viaducts generate spaces which in some cases are not accessible or which are socially dangerous (Edwards, 2011). These elements, on the other hand, could play an interesting role providing ecological corridors or including elements for positive development of the urban environment.

Vacant blocks and Redevelopment Sites

Cities are ever-changing systems, mapping areas which are underdeveloped; under redevelopment or due for refurbishment can help in setting an ecological system which goes beyond the unbuilt environment. Green technologies are currently available and are already included in some new buildings (Keeler, 2009), the connection of these elements with the ones in the negative space has the potential to implement the proposed vision of cities as ecological systems.

In parallel to the planning of economic functions, cities could investigate environmental functions to be distributed in the urban fabric and interconnected by the considered design of negative space. Through this approach cities could evolve into Marshall's 'corporate entities' made up of complementary component parts which work together to reinforce and support the function of the city itself (Marshall, 2009). Distributing energy generation, air and water filtration, carbon sequestration and food production (known as 'eco-services') (J. Birkeland, 2008) throughout the wider city fabric, would see the city function as a collective whole in order to achieve a more sustainable state. Over time, as buildings are progressively either retrofitted or replaced, the entire city could generate surplus environmental services. Although composed of independently functioning elements, actively using negative space to connect these discrete environmental cells, the net result would be a city operating as a single self-sustaining unit regardless of any incremental and individual changes – a 'corporate entity' (Marshall, 2009). Identifying and using negative space in a systemic manner to drive sustainable functioning through urban infill development or redevelopment, could help meet urban environmental goals. Temporal activation of negative space could play a key role in enhancing the social interaction which is increasingly becoming 24/7 and meet evolving cultural changes

(Lofland, 1998). This approach would allow the city to evolve and change over time to effectively respond to developments in culture and society; and to progressively take advantage of technological advancements.

4 CASE STUDY

To examine the possibilities of negative space, an initial case study mapping has been carried out of Brisbane, Australia. Brisbane is Australia's third largest city and the capital of the state of Queensland with a population of 1,067,300 people. Formed around the Brisbane River it is a sprawling car-centric city with a light and mid-grained urban fabric. The mapping was carried out on the denser Central Business District which has an increasing city centre population due to a growing number of mixed use commercial and residential towers.

The initial Nolli map of Brisbane was supplemented with the use of high-resolution aerial photographs to broadly identify existing infrastructure, parks, laneways and pedestrian areas. Location visits were used to further refine the initial mapping and identify accessory spaces such as private lanes to rear parking lots.

4.1 Figure Ground

The city centre outlines a dense core which become less dense towards the rive edge. On the South-West side of the city, the connections between the urban environment and the river system is interrupted by a motorway. On the North-East side, the view from the city to the river is often blocked by high-rise buildings which follow a different settling rule in respect to the rest of the urban fabric. The figureground also shows an articulated system on open spaces.

Fig. 1: Figure ground - Brisbane, Australia.The location of infrastructure elements is shown in dark purple.

4.2 Green Space

Overlaying parks, gardens and street planting it is possible to underline a preliminary ecological network through the negative space. The pattern of green spaces is discontinuous and there are several missing links in the potential network. A connection to the river is partially regained.

Fig. 2: Green Space - Brisbane, Australia

4.3 Pedestrian Space

The inclusion of the actual and potential pedestrian areas makes evident how the system, although concentrated in the negative space, could be denser. The refurbishments of public spaces with positive technologies could implement a system which radiates from the main parks deep into the built fabric through laneways and service spaces.

Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

4.4 Redevelopment or Refurbishment Opportunities

Areas under redevelopment or refurbishment make clear how punctual elements could be nodes in the restructuring of the city as a positive ecosystem. In some cases new connections could be gained and the existing system in the negative space could be used to distribute the eventual benefit of sustainable elements included in new buildings.

Fig. 5: Complete Mapping – showing existing figure ground (black), vacant and development sites (apricot and red, respectively) green space (green), infrastructure (dark purple), pedestrian areas (light purple) and lost space (dark blue).

5 FUTURE RESEARCH

The proposed mapping is an initial approach to the investigation of cities as ecosystems (Kaika, 2005); further developments of this tool could include the recognition of elements fixed in the development of cities, such as heritage listed buildings. In some cases these cannot be heavily modified and their technological contribution to the system could be limited; however they play a key role in the social sustainability of the urban system concentrating shared memories and representing the common values of the local urban society.

Further, dismissed services, such as tunnels, old aqueducts or sewer systems could also be taken into consideration to intensify the network of connections (Coutard, Hanley, & Zimmerman, 2005). A further level of complexity could be gained introducing a time based mapping of uses and functions in order to

establish how facilities, infrastructure and spaces could be used in different ways throughout the day, optimising resources and also providing new spaces for communities (Varon, 2004).

Additionally this tool could be used to identify the best positional opportunities for retrofitting specific environmental functions in the city. Contextually appropriate technology which relies on particular environmental conditions, such as food production or energy generation, could be plotted onto the map and adjacent negative space appropriately activated. A framework for allocating suitable retrofits would need to be developed and applied.

6 CONCLUSION

Cities today are changing at fast pace and redevelopment or conversions of dilapidated areas is a common approache to the redefinition of the urban environment. These processes offer opportunities to include in our cities sustainable nodes; however mapping the available residual space from which the urban form has been created, offers an opportunity to perceive and understand the existing connecting 'web' of negative space. It is possible to then offer a structure that positively directs the progress of the urban fabric.

Cities have been oversimplified in the last 60 years, in order to regain the complexity which used to be their characteristic; the built environment should not be read as separated functional clusters, but as an integrated technological network. More than activities, planning could take in consideration opportunities; more than extreme interventions of redevelopment, urban design could work on the creation of complex ecological systems staged in time, following the pace of the urban change.

Noise Pollution Management Issues in Tirana, the Capital of Albania

Dorina Pojani

(Assist. Prof. Dr. Dorina Pojani, Epoka University, Rr. Tirane-Rinas, Km 12, Tirana, Albania, dpojani@epoka.edu.al)

1 ABSTRACT

On average, Tirana's population is exposed to daytime noise levels higher than 70 dB and nighttime noise levels higher than 55 dB. These levels are relatively high for Europe. This paper relates the results of a research project conducted in 2011 on the impact of noise on residents' comfort in two mixed-use neighborhoods in the city, and on public measures to abate the negative impacts of noise. This research found that, although noise presents a problem for exposed residents, to date public measures to abate noise levels have been very limited. Some of the negative noise impacts are due to Tirana's high density physical development pattern and laissez-faire zoning regulations, which permit noise-generating uses in residential neighborhoods. However, the author argues that the main factor is the institutional context for addressing problems related to noise, which is highly adverse to the generation of solutions, and the political culture, which dominates the government structures and the institutional forms. The weak "soundscape" management reflects larger issues of urban governance in Tirana.

2 INTRODUCTION

This paper sets forth the results of a research project conducted in the spring of 2011 on the impact of noise on residents' comfort in two neighborhoods in Tirana, the capital of Albania. In addition, the paper addresses the institutional context and public measures to abate the negative impacts of noise.

To place the noise problem in perspective, during communism Albanian cities were generally quiet, due to the absence of private cars, the dearth of entertainment and commercial services, and the peripheral location of industrial activities. However, by the mid-1990s noise levels in Tirana were already at the threshold ceilings recommended by the World Health Organization. This increase was particularly shocking in a country that had no private cars and few buses until 1990. Now, on average, Tirana's population is exposed to daytime noise levels higher than 70 dB and nighttime noise levels higher than 55 dB. Noise levels in Tirana are shown in Table 1.Overall, almost two-thirds of the Albanian population is exposed to noise levels higher than 65 dB. These levels are relatively high for Europe.

Research indicates that the majority of Tirana's daytime noise is due to motorized traffic. The noise emitted by vehicles is intensified due to: idling at malfunctioning traffic lights; drivers who impatiently hunk horns while stuck in traffic or to greet acquaintances; truck traffic within the urban area; traffic generated by youth looking to pass the time; severe shortage of parking places which increases "hunting" traffic; and the poor condition of vehicles. Other factors contributing to high noise levels, unrelated to transport, are the high volume of construction and individual diesel power generators (that many shops and restaurants use in case of power cuts) during the day, and bar and club music at night (Ministry of Environment, Forestry, and Water 2007; Institute of Public Health 2006; Cicolli 2008).

The desire to meet requirements for European Union membership is forcing legislative and administrative action in favor of environmental protection. In 2007, Albania passed a law on noise pollution management, which is based on similar legislation in Europe (*Law on the Assessment and Management of Noise Pollution*, No. 9774, 12 July 2007). The law requires the establishment of noise limits in urban areas, including noise limits for various activities and transport vehicles. The responsibility for the enforcement of this law is shared among national ministries - the Ministry of Environment, Forestry, and Water, and the Ministry of Public Health - and local governments.

However, to date public measures to abate noise levels have been very limited. Interventions to protect against noise pollution have been sporadic. They have mainly resulted from the will of key public officials rather than being produced by an accountable administrative system, which ensures continuous monitoring and enforcement.

Part of the noise pollution is due to Tirana's high density development pattern and laissez-faire zoning regulations, which permit noise-generating uses in residential neighborhoods. However, the main factor is the institutional context for addressing problems related to noise.

3 CONSIDERATION OF NOISE POLLUTION IMPACTS IN WESTERN COUNTRIES: A BRIEF LITERATURE REVIEW

The levels of environmental noise vary for a substantial part of the world population, especially in areas with a dense population and dense transportation networks. It is estimated that in the European Union during daytime approximately 77 million people (22% of the total EU population in 1994) are exposed to transportation noise levels exceeding 65 dB, a level that many countries consider to be unacceptable (Miedema 2007).

Environmental noise, like other forms of pollution, has wide-ranging adverse health, social, and economic effects. Numerous studies on the adverse health effects of noise, many of recent vintage, have been published - for a comprehensive overview, see Miedema (2007) and Goines and Hagles (2007). It has been found that noise interferes with behavior, including communication and concentrated activity, or desired states, such as relaxation and sleep. Noise exposure can lead to acute stress responses and/or chronic stress, and can even lead to cardio-vascular and mental health disturbances.

In terms of urban planning, noise has been found to interfere with home values and the cost of building and operating new construction. In US-based post-occupancy surveys, the acoustic environment, specifically the lack of adequate speech privacy and control of noise levels, has been a major complaint with respect to the ability to carry out work tasks (Jenson et al. 2005). A study conducted in Holland (Nijland et al. 2007) suggested that noise-sensitive people are less satisfied with their living environment and are more willing to move than others. Another study investigating the combined effects of noise and temperature on human thermal comfort and task performance found that thermal comfort was affected by noise levels, while ratings of building or office noise were not affected by the ambient temperature (Tiller et al. 2010).

Being able to cope with daily noise is important for human well-being and health. The effects of environmental noise depend on acoustical characteristics of the noise (e.g., loudness, time pattern), and on aspects of the noise situation that may involve cognitive processing, such as expectations regarding the future development of the noise exposure (whether will it get better or worse), lack of short-term predictability, and a feeling of lack of control over the source of the noise. People differ in their appraisal of noise situations and in their coping style (Cohen and Weinstein 1981).

However, environmental noise is not only a personal matter, but also a societal problem that is beyond the control of most individuals. Unfortunately, noise is still considered a relatively minor form of pollution and public awareness on its negative effects is lower than for air pollution.

4 RESEARCH CONTEXT AND APPROACH

This research project included door-to-door surveys of 100 households, conducted in the spring of 2011. Female, middle-aged, and well-educated individuals were slightly overrepresented in the surveys. Most respondents were long-term Tirana residents, and had lived in their present dwelling for over a decade.

Surveys were taken in two mixed-use neighborhoods: Bllok and Selvia (50 surveys in each), selected due to their contrasting settings. Bllok is a vibrant city center neighborhood, in which most high-end shopping and entertainment activities are concentrated, in addition to housing. Most housing in the Bllok is in 10-12 story condominium buildings which is relatively new. Typically, current residents belong in the upper-income strata. All surveyed individuals lived in apartments facing both on main streets and back alleys. More than one third of surveyed households included children under 10), and almost one fourth included seniors (above 70).

The Bllok's plentiful cafés, restaurants, and music venues, which generate pedestrian and car traffic until late at night, have been known to present a disturbance for residents. In the fall of 2009, one of the major newspapers in the country, "Shekulli", prompted by residents living in the center of Tirana, who were disturbed by the loud music and car traffic generated by nightclubs, led a campaign against noise pollution in the capital. This campaign drew the attention of several politicians, foreign environmental organizations, and the ombudsman. Several residents informed reporters that they were planning to change residence as the noise levels in the center were unbearable, especially at night. While almost daily press coverage of noise impact issues and complaints, over several weeks, prompted the City to issue high fines to several bars and clubs in the area, which played loud music at night, traffic-generated noise pollution was not addressed. In addition, enforcement was not consistent, and after a brief period of tranquility, club owners ignored the law. A new Mayor was recently elected in Tirana. One of his first actions after taking office was to enforce nighttime noise monitoring in the Bllok. For a few months, night clubs were forced to shut down any music at midnight. Eventually, the rules became relaxed. As of this writing, the press reports that nighttime noise levels in the Bllok are 80-90 dB, based on monitoring data from the Institute of Public Health (*Shekulli*, 23 March 2012).

The other area surveyed, Selvia, is an older, mixed use and mixed-income, neighborhood, located at a distance from the city center. It is flanked by a large open air market. Auto traffic levels are perceived as high in Selvia as well, due to its narrow and windy traditional road system inherited from earlier eras. One third of the respondents in Selvia live in single-family homes with gardens while the rest live in (mostly new) condominium buildings. About 30% of surveyed households included children under 10 and/or seniors over 70.

In the framework of the project interviews were conducted with nine representatives of public institutions, which are involved in environmental protection issues, regarding their efforts in noise abatement and prevention. Interviews were also conducted with (1) a night club employee in the Bllok on club owners' responses to resident complaints, (2) a real estate agency on the impact of noise on condominium prices, and (3) a construction firm on the use of noise insulation in new construction.

The interview with a real estate representative indicated that families are moving away from the Bllok. The area is slowly undergoing a process of transformation into an office and entertainment center. The percentage of tenants (mostly students and young adults) is increasing relative to homeowners. Selvia on the other hand is becoming a favorite neighborhood for families.

5 NOISE IMPACTS ON URBAN NEIGHBORHOODS

Resident surveys indicated that perceived noise levels are very high in the Bllok (4.2 out of a maximum of 5). Also, residents reported a high level of discomfort from noise (an average of 4.2 out of 5). Almost half of the respondents reported thinking daily about noise disturbance. In fact, Bllok's residents were more preoccupied with noise levels than other major concerns such as air pollution, car traffic, lack of parking spaces and green areas, illegal construction, and the quality of road infrastructure in their neighborhood.

Most residents said that noise levels have been on the rise in the last 5 to 10 years, a perception confirmed by public research. They pointed to car traffic as the main source of daytime noise, and the loud music from bars and night clubs as the main source of nighttime noise. The latter was considered more bothersome by the majority. Weekend evenings and nights were reported to be the nosiest and most stressful times. Respondents in households that included young children or older adults were well aware of the detrimental health impacts of noise. They cited sleep disturbance, irritation, inability to concentrate, high blood pressure, headaches, hearing problems, and stress as observed effects of noise exposure on children and seniors.

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

Some Bllok residents had been forced to sound proof their apartments. While a few had attempted to directly negotiate with night club owners, more than half had been active in appealing to the public authorities on noise management issues. They had repeatedly contacted the City, the Borrow Council, and the police. Respondents reported that authorities had attempted interventions in many, though not in the majority of, cases, but the noise problem had typically remained unsolved as of the time survey answers were collected. This outcome had led to a profound distrust of the public sector. Extreme frustration about the inability to solve a common problem that affects many was combined with a passive attitude of many residents, who were unaware of the existence of a noise management law in Albania and did not know who to contact for noise-related complaints. The principal desire of the Bllok residents surveyed was a strong regulation of the evening and night activity schedule for entertainment establishments.

In Selvia, perceived noise levels were much lower than in the Bllok (2.7 out of 5), through still above average. Although they reported a higher than average noise-related discomfort (2.9 out of 5), Selvia residents were more preoccupied with issues such as air pollution and urban amenities than noise. Residents said that they worried about noise disturbance infrequently, although they felt that noise levels had been slightly increasing in recent years. Morning car traffic was reported to be the main source of noise in this neighborhood, followed by construction-related noise. Few residents had taken any action to deal with noise pollution. A handful of residents who had contacted the police with noise-related complaints reported that the problem had remained unsolved. Selvia's residents expressed the same level of distrust in the public authorities and feeling of helplessness as the Bllok's residents.

The survey findings were in line with the finding of a larger-scale survey conducted by the Public Health Institute. It found that, citywide, 44% of the population is "very annoyed" by noises while another 28% is "annoyed". The principal reported noise source was car traffic. (Half of the survey respondents lived in flats facing traffic streets.)

6 INSTITUTIONAL CONTEXT FOR NOISE POLLUTION MANAGEMENT

The author conducted interviews with staff members of the following public institutions:

- Borough Council, Selvia
- City of Tirana, Department of Environment
- City Police
- Institute of Public Health
- Ministry of Environment, Forestry, and Water
- National Environmental Agency
- Prefecture of Tirana
- Regional Environmental Agency
- State Police

These institutions are connected to each other according to the scheme shown in Fig. 1.

In addition, the author interviewed:

- An employee of a night club in the Bllok
- A real estate representative
- An employee of a construction firm

The interviewed public officials indicated that noise-related complaints received by public institutions are numerous. Bllok's residents lead in terms of number of complaints; however, other central areas of Tirana are considerably affected by noise. Residents most affected by noise are those who live near main traffic streets, bars and clubs, schools (especially music schools), and areas with large construction activity. It must be noted that, in the last two decades, Tirana has experienced a construction boom, which turned the city into a permanent building site. However, the construction wave has recently significantly abated.

The interviews revealed that, if the noise is generated by a single source, such as a night club, the noise complaint procedure is rather complex; in some cases, public officials appeared uncertain of the steps a

complaint has to go through. Also, the procedure is relatively lenient towards businesses, granting them multiple "second chances" in case of non-compliance with the law.

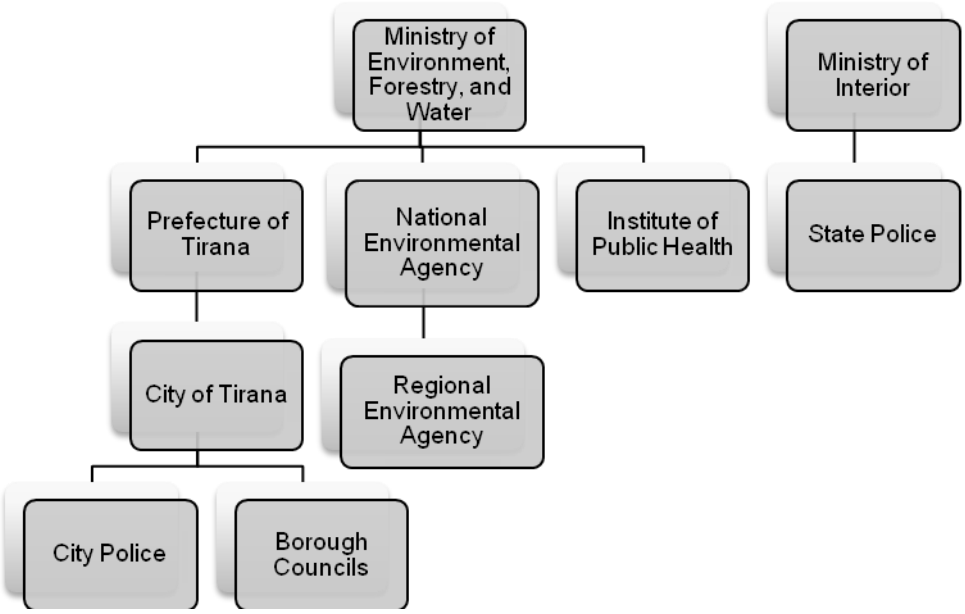

Fig. 1: Public institutions involved in noise management in Tirana.

Residents must file a complaint with the nearest local government unit (the Borrow Council). The Borrow Council passes on the complaint to the Regional Environmental Agency, and in special cases, to the City Police. The City Police indicated that they are overwhelmed with filed complaints. Occasionally, the City Police collaborate with the State Police on noise management issues, if a major conflict has occurred among the parties involved. The City Police are not empowered to issue fines if a business generates noises higher than the limit; however, it can require a business to stop its activity temporarily (i.e. shut down a nightclub for one night if a neighbor has called in with a complaint).

If the issue remains unsolved, the complaint is passed on to the City of Tirana. The City is only empowered to fine a business (up to $300) should it find that it is not equipped with a proper license (i.e. to play music). If the City fails to solve the issue as well, the Prefecture of Tirana intervenes, firstly notifying the noise-generating business to reduce noise, secondly sending a written order including a compliance deadline, thirdly fining the non-complying business, and finally requesting the Regional Environment Agency to revoke its business license. The City is also empowered to request the same from the Regional Environment Agency. The Ministry of Environment, Forestry, and Water is not directly involved in noise issues; it main task is to draft action plans on noise pollution management.

The interviewed public officials admitted that often residents must file multiple complaints before any action is taken in their favor. Also, they indicated that many business owners believe that they are above the law and ignore notices to reduce noises sent by public institutions. Many residents file anonymous complaints due to fear of violent retaliation by affected businesses. Even police officials are not immune to this fear. In addition, the police are prone to corruption, as indicated by an interview with a nightclub employee. In terms of traffic or construction related noise, it is almost impossible for residents to take any steps.

In terms of noise monitoring, the institution in charge is the Institute of Public Health, which depends on the Ministry of Environment, Forestry, and Water for its funding. The collected data is owned and utilized exclusively by the Ministry. This financing arrangement limits the scope of work of the Institute. For example, the Ministry issued no funding for urban noise monitoring in 2010. The Institute does receive noise-related complaints but it is not empowered to act directly. However, it can recommend the business license revocation of activities that are found to generate noise above allowed levels.

In contrast with public perceptions collected through surveys and public research, some public officials are under the impression that noise pollution has decreased in the last few years due to stronger monitoring activities. Public officials generally agreed that, in order to reduce noise pollution, institutional capacities must be strengthened. City employees felt that they should have more legal authority to intervene in case of noise complaints. Other proposed measures included traffic calming in residential neighborhoods, use of

noise barriers (such as trees or green walls), ban of heavy and/or old vehicles within the urban area, building permit requirements to soundproof new housing construction, and zoning regulations that require wide building setbacks from traffic streets and do not allow noise sources (night clubs, bakeries, wood workshops, gas stations) in neighborhoods that are mostly residential.

Due to increasing resident complaints on nighttime noise, some clubs in the Bllok and other central locations have partially soundproofed their spaces. However, soundproofing of new housing is minimal. One construction firm has started using inexpensive soundproofing materials, such as polysterol on the internal walls. However, firm representatives say that this method blocks out only 20-30% of noises. The use of double pane glass windows (with vacuum between panes) blocks out an additional 5%. The use of triple/quadruple glass pane windows or the use of special fluid between glass panes would provide much higher sound insulation but this window technology is too expensive for widespread use in Albania. Another firm has built a pilot residential building in the Bllok, which is fully soundproof, with exceptionally high prices by Albanian standards (2000 Euro/sq.m.).

7 CONCLUSION

This research found that noise is a growing concern for residents in Tirana. While it is well known that central area residents experience serious distress due to noise pollution, even more peripheral neighborhoods are affected. However, until recently noise pollution has remained mostly untackled because the overall institutional scheme that deals with noise management issues is beset with redundancies and gaps and a lack of clear functional division among competing authorities and levels. Furthermore, corruption and favoritism are rampant at all government levels.

Within this framework, a portion of business owners, who belong to the upper income groups, resist restrictions on activities that generate nighttime noise and are able to bend the law in their favor. Any past interventions to protect residents from nighttime noise pollution have been the result of the will of individual politicians, which makes long-term rule enforcement uncertain. No clear institutional system has been set to permanently and consistently deal with noise management. In addition, Tirana's public has no belief that the citizenry can bring about public action for its benefit or much belief in the legitimacy of the law. The author speculates that this attitude is due to the legacy of the communist regime, which ended in 1990.

Solutions proposed include the creation of a single office in charge of noise management, preferably included within the city police, which can also collect and respond to complaints at night. This office must guarantee the anonimity of complaints and take immediate action, with prompt enforcement against continuing violations. Another solution would be to group night clubs in areas far from the center, in which they do not disturb residents. However, the presence of entertainment establishements gives the Bllok district its character and constitutes its major attraction. In view of this consideration, a solution would be to require club owners to sound-proof their buildings at the time of licencing, with periodic reviews afterwards. Awareness-raising is important, too. Public authorities must send notices to residents informing them that they have a right to object in case of excessive noise levels in their neighborhood.

While it might be technically easier to deal with nighttime noise, it will be more difficult to substantially improve the daytime noise situation given the growth of motorized transportation in Tirana. Given strong political will, traffic calming measures could be introduced in neighborhoods that are mostly residential or centrally located with heavy pedestrian traffic. Other effective measures would be stringent noise emission criteria for road vehicles, measures at the source (e.g., porous asphalt, speed limitation, high fines for drivers honking horns in non-emergency situations), with respect to the transmission (e.g., noise barriers, including trees), or at the receiver (e.g., dwelling insulation, dwelling layouts).

1 ABSTRACT

Architektur, deren besondere Ausstrahlungskraft ihre Besucher fasziniert, gilt in zahlreichen Fällen als Wahrzeichen von Städten und Regionen. Jährlich besuchen Tausende diese Orte, sorgen für wirtschaftlichen Aufschwung und tragen zur Imageaufwertung bei – auch in bisher unscheinbaren Klein- oder Mittelstädten.

Diese Gebäude werfen die Frage auf, welche Wirkungsmechanismen dieser Ausstrahlung zu Grunde liegen. Welche besonderen Eigenschaften lassen sich in derartigen Bauten wieder erkennen und sind diese Eigenschaften spezifisch für ihre Zeit oder auch in Gebäuden anderer zeitlicher Epochen wieder zu finden?

Bei der Betrachtung einer Anzahl ausgewählter Gebäude unterschiedlicher Nutzungen hinsichtlich ihrer haptischen Qualitäten, räumlichen und semantischen Strukturen sowie der Verknüpfung zum umliegenden Stadtraum wird deutlich, dass es gewisse Gesetzesmäßigkeiten gibt. Die beschriebenen gegenwärtigen als auch historischen Architektur- und Städtebaukonzepte sind geprägt von der Integrität und Prägnanz – der Ganzheit – der Form bei gleichzeitiger Offenheit für das Zukünftige. Beide Prinzipien sind dabei als einander ergänzend und nicht ausschließend zu begreifen. Im Sinne dieser offenen Ganzheit können architektonische und städtebauliche Entwürfe generiert werden, die verschiedene Nutzungen und Dichten kombinieren, sich den zukünftig verändernden Bedürfnissen unserer Gesellschaft anpassen und dennoch ein hohes Maß an ästhetischer Autonomie erlangen.

2 DIE EUROPÄISCHE STADT

Die Geschichte der europäischen Stadt ist die Geschichte stetiger baulicher Anpassung an veränderte soziale, politische und ökonomische Rahmenbedingungen – es ist eine Geschichte des Wandels. Aus heutiger Sicht wird deutlich, dass nicht nur das Erscheinungsbild der europäischen Stadt mittels einer historisierenden Architektur kopiert wird, sondern auch die Eigenschaften der europäischen Stadt – mit ihren Straßen, Gassen und Plätzen – werden simuliert, jedoch zumeist ausschließlich für eine nach außen hin abgeschottete Innenwelt. Viele Gebäude dabei werden so groß dimensioniert, dass eine städtebauliche Integration absehbar schwer erfolgen kann. Oft geschieht dies auf Wunsch von Investoren, die diese Strukturen als rentabler erachten.

Die traditionelle europäische Stadt besteht aus einer Vielzahl kleinteiliger Parzellen, die sich als räumliche Sequenzen gegenseitig ergänzen und zu einem Gesamtbild zusammenfügen lassen. Hierbei entsteht eine weitere kennzeichnende Eigenschaft, nämlich bauliche Dichte. Im Zusammenhang mit der Zersiedlung der Stadtlandschaft, dem Wunsch nach dem Einfamilienhaus am Stadtrand und der Entstehung von Industrie- und Einkaufsinseln “auf der grünen Wiese”, wurden die Innenstädte teilweise stark entleert.

Ebenso problematisch ist die Monofunktionalität besagter Großstrukturen einzustufen, die durch einen steigenden Filialisierungsgrad im Einzelhandel oder die gewünschte Standardisierung von Gebäuden entsteht. Die Idee der Funktionstrennung, insbesondere von Wohnen, Arbeiten und Freizeiteinrichtungen, die sich Mitte des 20. Jahrhunderts entwickelte, entspricht dabei nicht den Idealen der europäischen Stadt.

Das Wechselspiel zwischen Öffentlichkeit und Privatheit, das durch eine Verknüpfung unterschiedlicher Nutzungen beispielsweise entstehen kann, hat in der heutigen Stadt oftmals gänzlich an Beachtung verloren. Die feinsinnige Abstufung und die Ausrichtung der Stadthäuser hin zum öffentlichen Raum wird bei einer Vielzahl architektonischer Projekte wenig berücksichtigt, was dazu führt, dass das wichtigste Qualitätsmerkmal der Stadt – die öffentlichen Flächen für den Austausch der Bewohner und Nutzer – überbaut oder unattraktiv wird. Der Sozialcharakter der Stadt geht dabei verloren.

Die Qualität der europäischen Stadt liegt darin, dass sie Urbanität erzeugt, das bedeutet: Möglichkeiten des Austausches von materiellen und geistigen Gütern, Attraktivität und Identität. Historisch gewachsene Stadträume sind in ihrer Wertschätzung zwar wieder gestiegen, dennoch werden deren Eigenschaften in der

Stadtplanung noch immer nicht konsequent umgesetzt, um damit eine gebaute und gelebte Urbanität zu erzielen.

Abb. 1: Venedig

Lange war prognostiziert worden, dass eine Abwanderung der städtischen Bevölkerung ins Umland die starke Entleerung der Stadtkerne verursachen würde. Somit stand das Wachstum des Umlandes gegenüber dem Schrumpfen der Innenstädte. Heutige Erkenntnisse zeigen aber, dass dies nicht überall die erwarteten Ausmaße angenommen hat und zudem bereits eine Rückwanderung in die Innenstädte erfolgt – nicht zuletzt weil politische Gegensteuerungs¬maßnahmen getroffen wurden. Das heißt, Wachstums- und Schrumpfungsprozesse verlaufen nun zeitlich und räumlich parallel. Die simultanen Polaritäten prägen sowohl unsere Kernstädte, das Umland und die ländlichen Regionen.

Ein weiterer wichtiger Faktor ist der wirtschaftliche Strukturwandel, der eine Reihe von Brachflächen hinterlassen hat, deren Potenzial – insbesondere in innerstädtischen Lagen – zunehmend erkannt wird. Die Konversion ehemals industrieller, militärischer oder infrastruktureller Anlagen ist zum Alltagsgeschäft der Städte geworden, ebenso bietet sie Spielraum für eine Reihe innovativer Ideen und Nutzungskonzepte. Diese tragen oft innerhalb kürzester Zeit zur Aufwertung ganzer Stadtteile bei und schaffen, teilweise mit geringem Aufwand, die verloren gegangene Urbanität.

Was macht überhaupt Urbanität aus und wie muss urbane Architektur beschaffen sein, um eine langfristig nachhaltige Struktur zu gewährleisten? Welche Eigenschaften haben Städte, die als positiv wahrgenommen werden, wodurch kennzeichnen sich Bauwerke, die eine besondere Ausstrahlungskraft auf ihre Besucher haben?

3 UNTERSUCHUNG AUSGEWÄHLTER GEBÄUDE

Auf den ersten Blick haben zeitgenössische Architekten wie Frank O. Gehry, Daniel Libeskind, Zara Hadid, Jacques Herzog und Pierre DeMeuron oder Bjarke Ingels, um nur einige davon zu nennen, unterschiedliche Ansätze, um die beschriebenen Phänomene in ihren Gebäuden zu thematisieren. Aber sind diese Ansätze nur scheinbar unterschiedlich und folgen doch gemeinsamen Regeln? Um Gemeinsamkeiten oder Unterschiede ersichtlich werden zu lassen, die der Grund für den besonderen, öffentlich wirksamen Charakter der Architektur sind, werden zwei zeitgenössische Entwürfe unterschiedlicher Nutzung in Paris hinsichtlich haptischer, räumlicher und semantischer Aspekte untersucht sowie insbesondere auch deren Zusammenhang zum städtischen Umfeld hergestellt.

Die Gebäude sind ausgewählt worden, da sie sich in einer historisch bedeutenden europäischen Stadt befinden, beide der Öffentlichkeit frei zugänglich gemacht werden, jedoch sehr unterschiedliche Nutzungen und Formensprachen beinhalten. Es wird der Frage nachgegangen, welchen Bezug diese geplanten Gebäude zu Urbanität und der europäischen Stadt haben.

Fondation Louis Vuitton von Frank O. Gehry in Paris

Das Gebäude basiert auf einem Entwurf von Frank O. Gehry aus dem Jahr 2006. Es befindet sich derzeit im Bau und soll 2013 fertig gestellt werden. Das Museum gestaltet den Übergang zwischen zwei städtischen Parks und beinhaltet einen sogenannten “aktiven Sozialraum” in der Erdgeschosszone.

Forschungszentrum Universität Sorbonne von B.I.G. in Paris

Das Forschungszentrum, ein Wettbewerbsgewinn des dänischen Büros B.I.G. aus dem Jahr 2011, ist das Resultat eines urbanen Experiments auf dem Campus Jussieu in unmittelbarer Nähe zum Seine Ufer. Der gläserne Kubus thematisiert besonders den Bedarf nach Tageslicht sowie den Bezug zum urbanen Außenraum. Der Entwurf hat eine klar strukturierte, orthogonale Außenhülle, im Inneren eröffnen sich jedoch vielfältig verwobene Sicht- und Richtungsachsen, die durch die allseitige Transparenz auch außen sichtbar sind.

3.1 Wahrnehmung der Bauten

Die Wahrnehmung der untersuchten Bauwerke ist durch eine starke Betonung der haptisch-sinnlichen Aspekte der Architektur geprägt – die Bauformen sind dynamisch, oft schwellend, und appellieren unmittelbar an das Körpergefühl des Betrachters. Auch die Verwendung bestimmter Materialien trägt dazu bei, den haptischen Charakter zu verstärken. Dies erlaubt es, eine Verbindung herzustellen zwischen den dargestellten Beispielen und solchen Architekturen, die durch einen bewusst antirationalen, haptisch-sinnlich erfahrbare Merkmale betonenden Gestus geprägt sind, so etwa viele Sakralbauten des gegenreformatorischen Barock in Süddeutschland.

Eine vergleichbare antirationalistische Haltung ist ebenfalls spürbar auf der Ebene der räumlichen Struktur der untersuchten Architekturbeispiele. Anstatt dem Betrachter abgeschlossene, eindeutig interpretierbare Räume erfahrbar zu machen oder aber eine mathematisch-abstrakte Raumvorstellung architektonisch abzubilden, sind die untersuchten Beispiele stark durch topologische Raumvorstellungen geprägt. Dieses bedeutet, dass der Raum zusammengesetzt ist aus unscharf definierten Teilräumen, die in einem beweglichen und dynamischen Verhältnis zueinander stehen und die jeweils durch eine spezifische Atmosphäre oder aber eine temporäre Zweckzuweisung bestimmt sind. Die Flexibilität und Uneindeutigkeit, aber auch der anregende Charakter der so erzielten Form der räumlichen Gliederung befördern eine aktive 'nomadische' Aneignung des Bauwerks durch seine Rezipienten.

Die Bauwerke sollen weniger "gelesen" als 'erfahren' werden. Dabei ist zu berücksichtigen, dass die oft gebräuchliche Ineinssetzung von optischer Wahrnehmung und verstandesmäßiger Interpretation hier keine Gültigkeit besitzt. Von daher ist es möglich, dass auch Dinge, die 'gesehen' werden, eine ähnliche unmittelbare Wirkung auf den Körper entfalten können wie solche, die 'gefühlt' oder 'geschmeckt' werden – wie umgekehrt auch von den 'niedrigeren' Sinnen übermittelte Wahrnehmungen der kategorisierenden verstandesmäßigen Zuordnung nicht grundsätzlich verschlossen sind.

3.2 Wirkung

Die besondere Wirkung der untersuchten Architekturen ist in weiten Teilen darauf zurückzuführen, dass sie mit intellektuellen Mitteln nicht vollständig zu durchdringen sind und gerade dadurch den Betrachter in Staunen versetzen. Dies ist eine Folge ihrer hohen Komplexität sowohl auf der Ebene ihrer Bauteile, als auch ihres räumlichen Gefüges und ihrer semantischen Struktur. Sie entziehen sich hinsichtlich der einzelnen Bestandteile sowie auch bezüglich des Geflechts deren jeweiliger Beziehungen zueinander der Reduktion auf einfach zu beschreibende Grundelemente, ohne dabei den Charakter des Beliebigen oder Beziehungslosen anzunehmen. Komplexität kann im Zusammenhang damit nicht nur im herkömmlichen Sinn als formale Vielfalt, sondern auch als die Mehrwertigkeit einzelner architektonischer Bauteile, Teilräume und Bedeutung tragender Elemente verstanden werden.

Die Entwürfe scheinen dadurch gekennzeichnet zu sein, dass sie weder einen perspektivischen Punkt definieren, von dem sie vollständig zu erfassen sind, noch rationalisierenden Raumkonzepten folgen. Die Ansichten darüber sind seit der Erfindung der Perspektive einem starken Wandel unterworfen. Der in der Tradition antiker Baukunst stehenden Architektur der Renaissance liegt noch ein vorwiegend auf der visuellen Wahrnehmung von einem fest verorteten Standpunkt aus beruhendes Verständnis des architektonischen Raumes zugrunde. Demgegenüber scheint bereits die die räumliche Tiefe modulierende Architektur des Barock zur körperlichen Bewegung im Raum aufzufordern. Der Bewegung des Individuums im architektonischen Raum kommt eine wichtige Rolle zu.

Die perspektivische Wahrnehmung der Entwürfe wird ausgehebelt zugunsten eines die spezifischen Qualitäten des einzelnen Raumes oder Teilraumes herausstellenden Erlebens. Der räumliche Eindruck, den die Architektur vermittelt, entsteht mithin in der individuellen und vorwiegend assoziativen Verknüpfung von zunächst nur lose miteinander verbundenen und in kein vorgefertigtes starres Interpretationsschema gefassten Einzelwahrnehmungen. Diese werden in einer Abfolge, welche die Zeitgebundenheit des Aneignungsprozesses hervorhebt, schrittweise gesammelt: Es ist nicht möglich, mehr als einige wenige Teilräume gemeinsam zu erfahren.

3.3 Nachgiebigkeit und Gegenwärtigkeit

Betrachtet man die bisherige Darstellung der untersuchten Beispiele zur Architektur im Zusammenhang, so zeigt sich, dass diese trotz formaler Unterschiedlichkeiten gemeinsame Eigenschaften aufweisen: Deren innenräumliche Struktur kann jeweils als integriertes oder sogar 'glattes' Raumgebilde bezeichnet werden, dessen Aneignung weniger von festen baulichen Grenzen als von den Raum 'topologisch' strukturierenden unterschiedlichen Merkmalen geprägt ist, etwa einer lokal besonderen Nutzung oder einer lokal spezifischen Atmosphäre. Die haptische Unmittelbarkeit der untersuchten Architekturen und ihre semantische Asignifkanz sind weitere entscheidende Merkmale, infolge derer diese einen 'offenen' Charakter aufweisen: In den untersuchten Entwürfen werden Informationen – auch wesentliche Teile der künstlerischen Aussage – nicht allein analog der gesprochenen Sprache durch Prozesse der zeichenhaften Verschlüsselung / Entschlüsselung übermittelt, sondern auch durch direktes Vorführen, Hindeuten und Begreifbarmachen. Auf diese Weise lassen die dargestellten Beispiele, anstatt einen bestimmten Sachverhalt oder ein Selbstverständnis zeichenhaft darzustellen, diese dem Individuum intuitiv spürbar werden und erlangen auf diese Weise eine unmittelbare, alle Sinne des Betrachters miteinbeziehende Wirkung. Dadurch, dass sie das Staunen des Betrachters wecken – ebenso aber auch durch ihre "virtuellen Subjektivierungspunkte" – vermeiden sie den in den theoretischen Positionen der Postmoderne so bekämpften 'repressiven' Charakter, ohne allerdings dabei 'nichtssagend' zu werden. Architekturen wie die als Beispiele untersuchten treten tendenziell mit ihren Betrachtern und Nutzern in eine dialogische Situation ein, deren Verlauf sich ergibt durch die konkrete Erfahrung des jeweiligen Bauwerks in einer Wechselwirkung mit der konkreten Befindlichkeit des Individuums. Der Ablauf dieses Prozesses ist nicht festgelegt, sein Ende bleibt offen.

Hinsichtlich des Verhältnisses zu ihrem städtebaulichen Kontext unterscheiden sich die untersuchten Architekten von solchen, die auf der Strategie des Zitierens architektonischer Elemente basieren, im wesentlichen darin, dass im Entwurfsprozess verschiedene Strukturen – darunter auch aus dem Kontext abgeleitete Elemente – miteinander zu einer erkennbar heterogenen und dennoch unauflöslichen architektonischen Einheit verschmelzen. Im Ergebnis steht die Herkunft der einbezogenen Elemente nicht im Vordergrund und ist oft sogar nicht einmal offensichtlich zu erkennen. Durch ihre formale Offenheit legen die untersuchten Architekturen die weitere gestalterische Entwicklung ihres Umfeldes nicht fest, sondern belassen die Möglichkeit, im Umfeld flexibel auf zukünftige Veränderungen zu reagieren. Dieses bewegliche Verhältnis zwischen dem architektonischen Objekt und seinem Umfeld wird von Greg Lynn als 'Nachgiebigkeit' bezeichnet, die er als ein direktes Resultat formaler Operationen der Auffaltung, Verdrehung und Glättung auffasst.

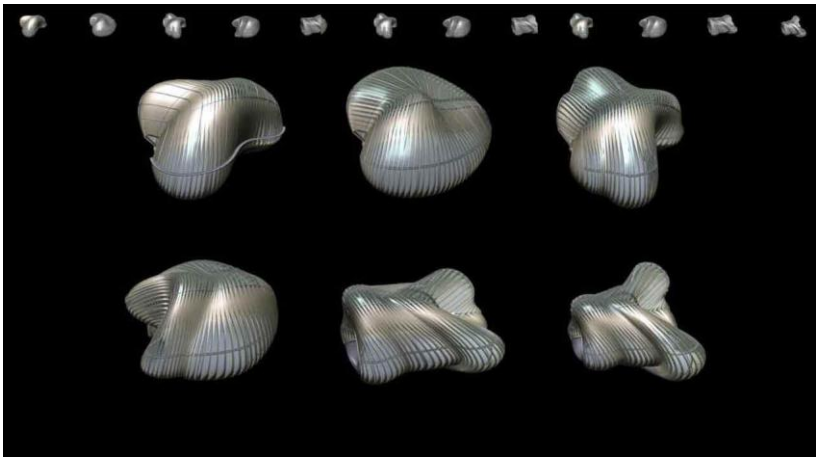

Abb. 2: Greg Lynn Embriological Housing

Der Begriff der 'Nachgiebigkeit' kann im erweiterten Sinne für die Eigenschaft eines Bauwerks gebraucht werden, bei aller architektonischer Eigenständigkeit den prägenden Bedingungen seines jeweiligen Umfeldes soweit zu entsprechen, dass Objekt und Kontext zueinander in eine frei verhandelte, nicht-hierarchische Beziehung treten. Dabei wird es möglich, sie zu einem spezifischen architektonisch-städtebaulichen Ganzen zusammenzuführen. Allerdings ist das Konzept der Nachgiebigkeit nicht so zu verstehen, dass die Entwürfe die Differenzen zwischen Objekt und Umfeld sowie innerhalb des Umfeldes ignorieren oder ver¬decken würden. Vielmehr sind nachgiebige Architekturen gerade aus diesen Differenzen heraus entwickelt. Somit kann die Eigenschaft der Nachgiebigkeit als das Resultat der spannungsreichen formalen Autonomie des architektonischen Objekts mit – oft unterhalb der Schwelle der Bewusstwerdung bleibenden – Elementen formaler Bezugnahme zum städtebaulichen Kontext einerseits in Verbindung mit einer städtebaulich verbindenden Wirkung des Bauwerks andererseits verstanden werden.

Damit verkörpern die Bauten eine Auffassung, nach der die Stadt nicht ein festes, kaum veränderbares Gefüge ist, sondern ein dynamisches und offenes Feld: Die im Umfeld vorhandenen Strukturen determinieren nicht, vergleichbar einem verbindlichen Regelwerk, die formale Ordnung der Architektur, sondern fliessen in den Entwurf in der Art von 'beweglichen Kräften' ein. Sie formen ihn zwar, bestimmen jedoch nicht sein Wesen. Die Stadt wird als ein zusammenhängendes mehrdimensionales Feld von interagierenden Kräften behandelt. Dadurch bleibt die Wirkung des architektonischen Eingriffs nicht auf sein unmittelbares Umfeld beschränkt, sondern kann weit über dessen Ort hinaus ausstrahlen. Diese Strahlkraft kann bewirken, dass die betreffenden Bauwerke den Status eines Wahrzeichens für ihr weiteres städtisches Umfeld und vielleicht sogar über die Grenzen der Stadt hinaus erlangen können.

Ingesamt ist festzuhalten, dass die dargestellten Entwürfe auf räumlicher, semantischer und nutzungsbezogener Ebene als vieldeutig und flexibel – somit als 'offen' – bezeichnet werden können. Die so erreichte Anpassungsfähigkeit geht indes nicht mit einem Verlust architektonischer Prägnanz oder des spezifischen Ausdrucks einher. Die untersuchten Architekturen sind demnach in einer Mittellage eines Spannungsfeldes angesiedelt, das definiert ist durch formale Vollendung – Eindeutigkeit, Stabilität, Harmonie, Verständlichkeit des Aufbaus – auf der einen Seite und Neutralität, Flexibilität, Unabhängigkeit vom Kontext auf der anderen Seite. Sie stehen zwischen Konzepten, die dem baulichen Ausdruck von Ganzheit verpflichtet sind, und solchen, die sich die architektonische Gestaltung von Offenheit zum Ziel gesetzt haben.

4 FAZIT: OFFENE GANZHEIT

Die untersuchten Gebäude, ein Museum und ein Universitätsgebäude, tragen zur Durchmischung der Stadt bei, an der es vielerorts mangelt. Insbesondere die Fondation Louis Vuitton als Museum mit integriertem öffentlich zugänglichen Raum mit Gastronomieeinrichtungen sowie Lehr- und Lernräumen dient als positives Beispiel für innerstädtische Nutzungsvielfalt, wie sie auch schon in der historischen europäischen Stadt in Erscheinung trat.

Die baulich-räumliche Geschichte einer Stadt ist entscheidend für die Sicherung und Entwicklung von Identität und Unverwechselbarkeit. Das Stadtbild hat eine erhebliche Bedeutung für den Imagefaktor und somit für die Wettbewerbsfähigkeit. Die Anpassung an aktuelle Veränderungen – an den Wandel – ist daher eine Daueraufgabe für die Stadtentwicklung.

Die analysierten Gebäude, wie auch andere in der öffentlichen Wahrnehmung erfolgreichen Beispiele, folgen dem Prinzip der offenen Ganzheit, sie können deshalb als positiver Entwicklungsmotor einen Beitrag zur Weiterentwicklung der europäischen Stadt leisten und dies widerum ist der Ursprung ihres öffentlichen Erfolges. Sie sind aus bestimmten zeitlich-räumlichen Zusammenhängen hergeleitet, aufgrund ihrer "Anschlußfähigkeit" kaum von ihren Kontexten abhängig und erlangen dadurch ein hohes Maß an ästhetischer Autonomie. Es ist deshalb gestalterisch nicht notwendig, dass zwischen ihnen und den anders¬gearteten Elementen in ihrem städtebaulichen und architektonischen Umfeld Spannungen und Kontraste inszeniert werden. Stattdessen ziehen sie aus ihrem Kontext einen großen Teil ihrer Prägnanz, indem sie die in ihm angelegten Zustände und Kräfte in sich aufnehmen.

Anders als die Architekturcollagen der 70er und 80er Jahre sind diese einem Ziel der Entwicklung von neuen Formen architektonischer Ganzheit verpflichtet, die sowohl verweisend als auch dynamisch und flexibel sein können. Da die untersuchten Beispiele nicht auf einer Vermengung unterschiedlicher intakter Architektur-

Sprachen beruhen, sondern in ihrem architek¬tonischen und städtebaulichen Ausdruck geöffnet sind für neue und individuelle Bedeutungszuschreibungen, erlauben sie – ohne dabei ihre formale Integrität aufzugeben – auf architektonischer, funktionaler und semantischer Ebene die Einbindung auch in Kontexte, die einem unabsehbaren und starken Wandel unterworfen sind.

Die Bestrebungen zur Entwicklung eines dynamischen, flexiblen oder verweisenden Ganzen, in der Ganzheit und Offenheit sind als einander nicht ausschließende, sondern vielmehr als einander ergänzende Prinzipien zu begreifen sind, damit nicht zu einem Ende gelangt. So entsteht ein Modell für eine geöffnete Ganzheitsvorstellung, die nicht, wie die der postmodernen Architekturcollage zugrundegelegte, auf den Mitteln der Fragmentierung und der Redundanz beruht.

Abb. 3: Gerhard-Richter-Gemälde

Aus der vorgenommenen, zwangsläufig unvollständigen Auswahl der untersuchten Projekte soll nicht der Schluss abgeleitet werden, dass nur diese oder formal ähnliche Projekte geeignet sind, einen derartigen Umgang mit dem Gegensatzpaar von Offenheit und Ganzheit Gestalt werden zu lassen. Viel eher wahrscheinlich dürfte sein, dass sie eingebettet sind in eine Entwicklung der Verbindung des Unterschiedenen, die vielleicht im Barock, vielleicht in der frühen Moderne begonnen hat oder sogar in der Architektur seit jeher angelegt ist. Es kann damit gerechnet werden, dass in Zukunft noch andere, sehr deutlich über die hier aufgezeigten Strategien hinausweisende Techniken der Aufweitung und Öffnung des Ganzen gesucht und gefunden werden, denn die Anwendung des Prinzips der offenen Ganzheit in der Architektur eröffnet den Weg für einen langfristig nachhaltigen Städtebau des 21. Jahrhunderts.

1 ABSTRACT

No matter if at home, at work or on shopping, they are always around us: the parking places. Yet, surprisingly little attention has been paid to their impact on our cities. That is perhaps because they tend to be treated as a part of the respective properties (housing projects, office parks, shopping centers etc.), and not as elements of urban structure per se. Yet, it is a parking policy what still is an important tool for the development of mobility. On one hand, the proximity of parking places to home has got a strong influence on the choice of means of transport for everyday journeys (Knoflacher 2007). On the other, parking policy in the city center may discoruage from (or encourage to) a car trip to the downtown. It is the most important "element of the push-and-pull strategy" (Topp, Pharoah: 1994). However, any limitations in access to parking space usually face opposition, as there exists a quite widespread opinion that people have a „right" to free parking. To apply this argument consequently would mean that the basic principles of urban economics do not apply to parking space. In fact, there is much evidence that free parking tends to negatively affect the functioning of the entire local economy. Shoup (2005) puts the argument right: free parking or free markets.

We approach the problem with a case study method, using the city of Poznań as in-depth case. Motorization has been on the rise in Poland in the last years, and it seems that public authorities are not able to deal with increased demand for parking, save for turning public space into space for cars. On the other hand, cities in Western Europe have been experiencing mass motorization for decades, and some of them have developed policies based on regulating parking space, which may also mean reducing supply, if necessary.

Beginning with an overview of the legal and institutional framework, we then follow to examine the parking policy, truly – the lack of an efficient parking policy – on two examples: of the city center (especially the development of a paid parking zone and its influence), and of a large housing estate (functional changes, pressure on green areas, changes in urban structure etc).

2 BACKGROUND

Poznań is one of the oldest cities in Poland. It takes the fifth place in terms of pupulation (551,627 inhabitants in 2010), and the fourth in terms of industry and university education. It is also the capital of the Wielkopolska Voivodeship. Since the 19th century the city has belonged to the richest communes in Poland. Poznań has got a relatively extensive system of public transport: normally, the city is served by 19 daytime tramway lines (mostly in 10' frequency), one night tramway line (30' frequency), 54 daily bus lines (usually in 12'-30' frequency), and 21 night bus lines (mostly in 30' frequency). Yet, the number of passengers has been slowly but systematically falling down (see fig. 1). Simultaneously Poznań has been witnessing increasing motorization. At the end of 2010 there were 525 cars per 1000 inhabitants, which was one of the highest motorization levels among Polish cities. Hence the streets of Poznań are under strong motorization pressure.

There are various reasons for the regress of public transport. Obviously the social factors play a role (keyword: post-socialist "fascination with automobile"), but there are other serious problems at the city level. The most important of them is an inappropriate network of public transit connections. Many important destinations are located far away from fast, high-frequency lines. The most spectacular example is the new university campus, which is attended by several thousands of students everyday, but does not have a tram connection. The same problem applies to new high-density residential areas. In general, the network is adjusted to old urban structures, e. g. to former heavy-industry areas, and not to the present trip matrix (see: Gadziński, Beim 2010; Radzimski 2010).

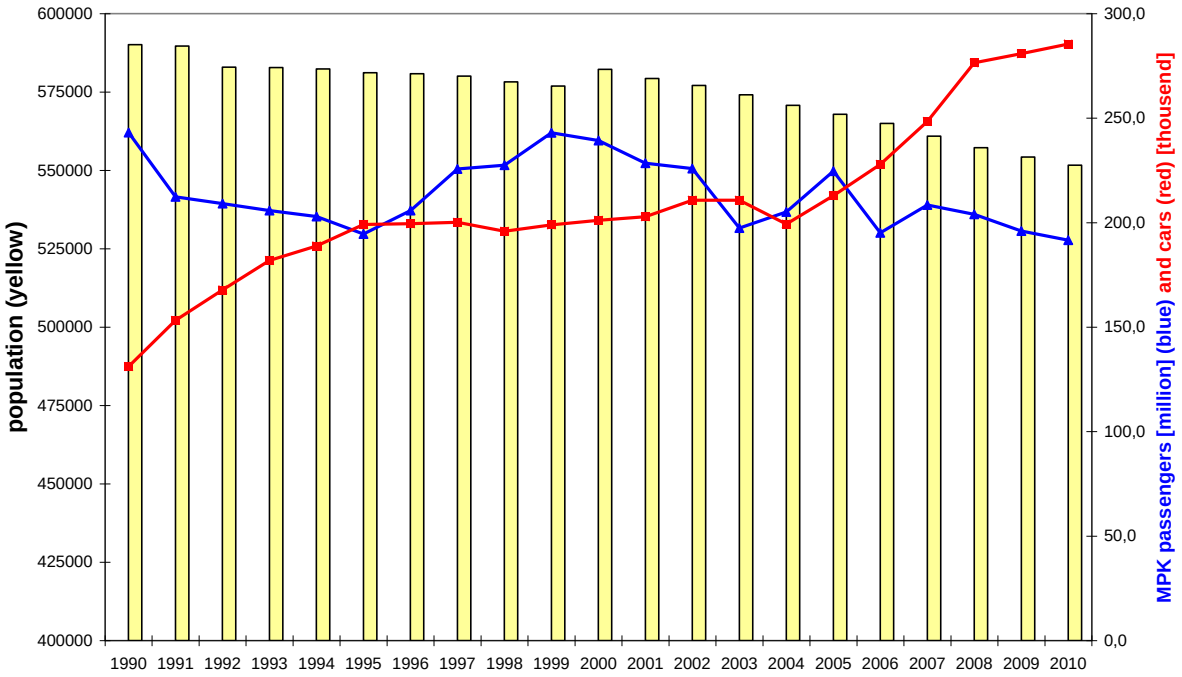

Fig. 1. Urban public transit passengers (MPK), number of cars, and population of Poznań between 1990 and 2010. Source: own compilation based on Polish Central Statistical Office (GUS).

Traffic situation has been worsened by the process of suburbanization. Since 1990 significant changes in urban development and living preferences have been observed (see: Beim 2009, Radzimski at al. 2010). Mostly due to migrations to the suburbs the city has lost about 35,000 inhabitants during that period. At the same time the population of surrounding communes (in Poznań County, powiat poznański), has risen sharply by about 95,000 inhabitants. In effect, at the end of 2010 there were 327,110 inhabitants in the Poznań County. The process of urban sprawl, both within and outside the city limits, is the primary cause of transport problems in the whole metropolitan area. But there is also a need for an efficient public transit system, which would cover both city and suburbs. However, the process of fare integration has been taking place very slowly, because the communes cannot agree on financial terms, and so only a few of them use the same tickets as the city of Poznań. Although there is an almost perfect star-shaped pattern of railway lines around Poznań, no metropolitan railway has been created so far. Most suburban communes are served only by regional trains, with various frequency. Railways are not integrated into a one fare system with urban transit, so the commuters need to buy two tickets. It is therefore not surprising that in the absence of a reasonable alternative the inhabitants become more dependent on their cars. The motorization level in Poznań County in 2010 amounted to 516 cars per 1000 inhabitants. Since the most important services like education and culture, and many workplaces are located in Poznań, the everyday commuting leads to high congestion, and strongly increases the demand for parking places.

3 LEGAL FRAMEWORKS

According to Polish law, users of public roads may be obliged to pay for parking motor vehicles on public roads in paid parking zones (art. 13 and 13b of Law on public roads; 21.03.1985). Parking fees may be introduced in specially designated areas with a deficit of parking space, desirable level of parking traffic circulation, restricted access for drivers, and also there where the local authorities want to give priority to the public transport. Fees may be charged during certain working days/hours or round the clock. Some parking spaces (envelopes) may be reserved for exclusive use.

The rates of parking fees are set by the municipal council, but they must not exceed the maximum set by the parliament. The maximum fee for parking a motor vehicle cannot exceed 3 PLN (1 EUR = ca. 4 PLN) in the first hour, and in the second and third hour it may not increase by more than 20%. In the fourth hour and later the fee must be the same as in the first hour. It means that the local road management authorities have

limited flexibility in shaping the demand for parking spaces. These solutions are a result of quite a long legal "battle".

In the mid-90s the maximal fee used to be regulated regionally, by voievode (the governor of a voivodeship appointed by the central government) and it was defined as an equivalent of the average price of 1.5 l of gasoline 98 RON (nowadays it would be about 8,80 PLN). After that, the maximum fee level was established by a governmental regulation. This solution was sentenced by the Constitutional Tribunal as not compliant with Polish Constitution (Sentence of Constitutional Tribunal; 10.12.2002). The main question was whether the parking fee is a price for service or a "local fee" (according to Polish law), thus, a special kind of tax. The Tribunal settlement proclaimed it to be a "local fee", which has to be regulated by an act passed by parliament, not by governmental regulation. Despite the fact that former law lost its power, the drivers were not allowed to have old fees refunded. Except inflation correction, the maximum fee levels have not been updated since 2002.

Furthermore, restrictive conditions need to be met in order to establish a paid parking zone. Paid parking places need to be marked by both traffic signs and road surface marking. The regulations addressed to road management are more restrictive than general parking regulations addressed to road users. According to art. 47 of law on road traffic (20.06.1997) it is legal to park a car partially on a sidewalk if at least 1.5 m for pedestrian passage was left, and the parked car does not block the traffic. However, a car may be parked entirely on a sidewalk if such parking places have been marked with the respective sign. These regulations had created until September 2000 (until changes in decree on traffic signs) a kind of a "loophole" in the law: if a car had met the above criteria, it had been parked legally. It could be parked for free, even in a paid parking zone, unless the driver had parked on a marked paid parking place. In practice these legal but free places had been the primary target of drivers. There are certainly illegally parked cars, too. Those drivers do not pay a parking fee, but they are at risk to be fined. Yet, the enforcement of parking fees in practice turns out to be much easier than the enforcement of parking fines (the first ones are "administrative fines", and so the ticket can be send by post to the car owner, while in the latter it needs to be given personally to the driver), so it actually pays off to park illegally. Furthermore, the parking tickets are not very restrictive 50 – 100 PLN. These problems concern all major Polish cities.

Government regulations of parking policy also include the law on spatial planning. A single regulation is of great importance here, namely the required number of parking places for each land use. This number ought to be specified in local development plans. To sum up, the legal system makes it very difficult for urban planners to apply a sustainable parking policy.

4 TRANSPORT AND PARKING POLICIES IN POZNAŃ

The main direction of transportation and road policy in Poznań is to support the development of ring roads. Large parts of the two inner ring roads already exist, and the third ring of approximately 7.5 – 9.5 kilometres in diameter is planned for the years to come. It is designed in a standard of a high-quality dual carriageway, and its construction costs are estimated at ca. 9.2 billion PLN. The system of ring roads within the city is intended to be linked with outer automobile bypass roads (A2, S5, S11), according to the City of Poznań Road Program for the Years 2008-2015. Directing the main traffic volume to the three ring roads, together with successive widening of existing main radial streets, is expected to cause more convenient conditions for traffic throughput. The additional advantage, according to the document, would be benefits for public transport and, indirectly, better conditions for parking program implementation (Park&Ride on the outskirts of the city; and multi-storey car parks – called in Poznań "Park&Go" – on the periphery of the centre itself).

Some general directions of parking policy are given by the Study of Conditions and Directions of Spatial Development of the City of Poznań (a general spatial planning document for the entire city area) adopted in 1999 (with significant changes in 2008). It has been recognized that in certain areas demand for parking exceeds supply, especially in the city centre. The establishment of a paid parking zone (SPP) has been positively evaluated, since it "helped to bring order into the public spaces, and the project implementation, control, operation and maintenance of the system are assessed as one of the best in the country" (Studium…, Volume 1, Part II, Section 8.9), while in other areas without similar regulations, opposite effects occurred.

According to the norms and provisions, and existing local development plans, additional parking needs (for example, those resulting from the continuing absence of a Park&Ride system) should be met by parking on

users' own plots, or commercial parking lots. Polish planning law states that local development plans should include records of the required number of parking spaces, in particular, the number of parking spaces in relation to the number of dwellings or number of employees or the surface of the manufacturing and service facilities.

Land use	Reference unit	*Studium 1999*	*Studium 2008*	Parking Policy 2008
		in city center / outside city center		
Offices	per 1000 m^2 of usable area of premise	11-24/15-30	11/30	24/30
Industrial and craftsmanship's areas	per 100 employees	8-14/15-32	8/32	14/32
Shops, shopping malls	per 1000 m^2 of usable area of premise	7-20/10-45	7/45	20/45
Restaurants, bars etc.	per 100 places	12-20/15-36	12/36	20/36
Theaters, cinemas	per 100 places	12-23/15-37	12/37	23/37
Stadiums, arenas, concert halls etc.	per 100 places	6-12/10-20	6/20	12/20
Hospitals	per 10 beds	2-3/10-20	2/20	3/20
Hotels	per 100 bed	20-30/20-50	20/50	30/50
Multifamily residential areas	per 1000 inhabitants or flats	220-260/330	1/1,5	1/1,5
Single family houses	per one house	1-1,5/1,25-2	1,5/2	1,5/2

Table 1. Evolution of parking standards (minimum number of parking places) in Poznań. Source: own compilation based on Studium 1999, Studium 2008 and Poznań Parking Policy.

The basic principles of transport policy in Poznań have been adopted by the municipal council in 1999. According to this document, the general purpose of transport policy is to "achieve a sustainable transportation system, from the point of view of economy, space, society, and ecology". Further documents which identified guidelines and described categorized areas of transportation policy are as follows:

- Sustainable Public Transport Development Plan for the Years 2007-2015 (24 October 2006);
- Poznań City Bike Program for the Years 2007-2015 (15 January 2008);
- City of Poznań Parking Policy (10 June 2008);
- City of Poznań Road Program for the Years 2008-2015 (16 December 2008).

The most severe disadvantage of Poznań Transport Policy is the lack of quantitative and qualitative objectives. The document contains a long list of policy guidelines and recommendations, but it fails to define such important terms like 'sustainability', nor does it establish a legible general goal, e. g. modal shift, reduction of travel time or CO2 emission limits. In consequence, it is hardly possible to evaluate the results of the implementation of this policy.

The overall purpose of Poznań Parking Policy is to define general directions of management and development of public parking spaces. However, it is not a statutory obligation of the local government in Poland to supply parking space. Therefore, the Parking Policy is not an operational program (i.e. it does not include technical and legal aspects, parking rules, financial sources of funding, time framework or measurements for evaluation). It is rather a non-binding "declaration of intent". According to the this document, the parking policy should be mainly driven by the need to reduce demand in individual car traffic, rather than by the obligation to protect the environment.

One of the aims of Poznań Parking Policy is to "encourage travel behaviour aimed at counteraction of increasing traffic congestion". This goal is to be achieved by such instruments like: traffic calming zones in

central area, support of public transport, encouraging non-automobile traffic (pedestrian and bicycle), and levelling anti-urban effects of automobile traffic, like urban barriers weakening the integrity of neighbourhoods. On the other hand, somewhat contradictory to the goal stated above, the need for more comfortable automobile traffic conditions is expressed, including improvement of traffic flow. Parking Policy concludes that most of the traffic could be (theoretically) operated by public transport (in indefinite future and under favourable urban conditions). Yet, the overall impression is that it is still the car, which is perceived as a symbol of comfort, freedom and speed, and so it should be the privileged means of transport within the city. According to the forecast, the phenomenon of giving up public transport in favour of private cars, is referred to as a 'natural' result of an increase in living standards, at least till 2020 (City of Poznań Road Program for the Years 2008-2015). To sum up, one of the official priorities is to encourage alternative means of transport. However, at the same time the conditions of driving are going to be improved via successive extending of total road network in relation to increasing car number.

5 PAID PARKING ZONE

Currently, there are approximately 300 parking lots and 59.5 thousands parking places in Poznań (Parking Policy, p. 3). Roughly a half of the parking places (53%) within the city centre are on-street places. On 1 July 1993 the city council of Poznań has established a Limited Parking Zone (Strefa Ograniczonego Postoju, SOP). The name has been later changed to Paid Parking Zone (Strefa Płatnego Parkowania, SPP). Additionally, there are about 1000 parking spaces within eight existing 'buffer' parking lots around the city centre.

SPP has been extended two times, in 1999 and 2011 (fig. 2). Also, in 1999 the parking fees have been differentiated by zones (red, yellow and green), and 'buffer' parking lots have been introduced. In 2011 the paid parking zone has been extended beyond the historical city centre to cover the district of Jeżyce, an old neighbourhood constructed at the turn of 19th and 20th century. Before that decision, there had been only some sections of streets with paid parking there.

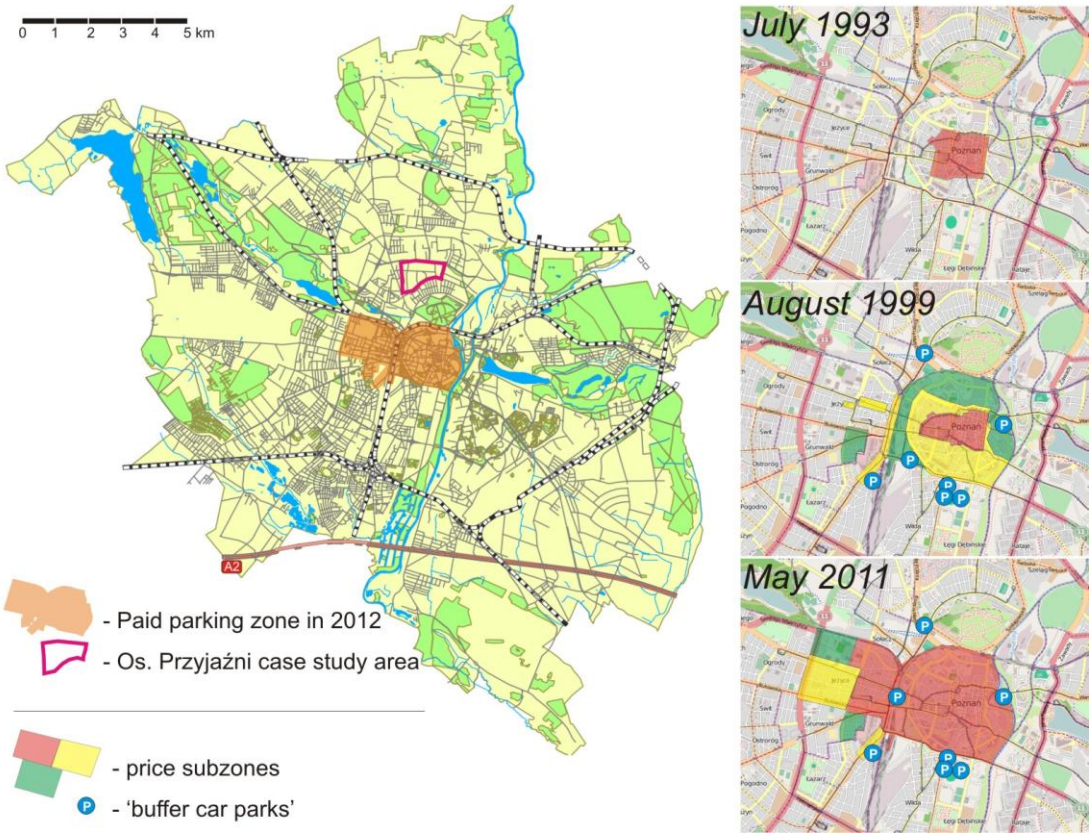

Fig. 2. Development of paid parking zone in Poznań. Source: own elaboration; maps based on OpenStreetMap.org

Paid parking zone in Poznań operates only on weekdays from 10:00 a.m. to 6:00 p.m. The most expensive sub-zone is the red one, with a base fee of 3 PLN/h, so the maximum permitted by law. In the yellow sub-zone the base fee is 2.80 PLN/h, and 2.00 PLN/h in the green one. Limits established by Polish parliament do

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

not allow to create parking policy based on supply and demand equilibrium. Therefore, during peak hours of demand (from 11:00 a.m. to 1:00 p.m.) it is difficult to spot vacant places in the city centre.

It is less expensive to use the 'buffer car parks' than to park in the zone. The price amounts to 2.00-2.50 PLN/h during SPP working hours, and 3 PLN/h in other times. The inhabitants of the area covered by SPP can buy an inexpensive ID (parking license) for a car. It costs only 10 PLN per month for the first car and 150 PLN for each additional. Other users can buy a subscription for 16 - 24 PLN per day (depending on sub-zones). There are some allowances (usually 25%) for companies and institutions located within the SPP as well as special fare for disabled persons (5 PLN per month). Parking licenses and subscriptions can be bought at the office of the operator, and short-time tickets are sold at the machines. Fines apply in the case of parking without a valid ticket, and, depending on time and form of payment, they range from 10 to 50 PLN. According to the data of the operator, 21% of places are taken up by users who have not paid the fee, and only 20% of them are fined by parking controllers (see: fig 3).

It is worth to mention that in comparison to fines for free riding in urban transport, the fines for unpaid parking are very low. A passenger caught on free riding has to pay from 100 to 200 PLN (in the past it used to be even 300 PLN). The parking fees are also low in comparison with bus and tramway tickets: a normal ticket valid for a half an hour costs 3,00 PLN, what is an equivalent of one hour parking in the red (most expensive) sub-zone. Therefore, legal limitations of parking fees have negative influence of the competitiveness of public transport.

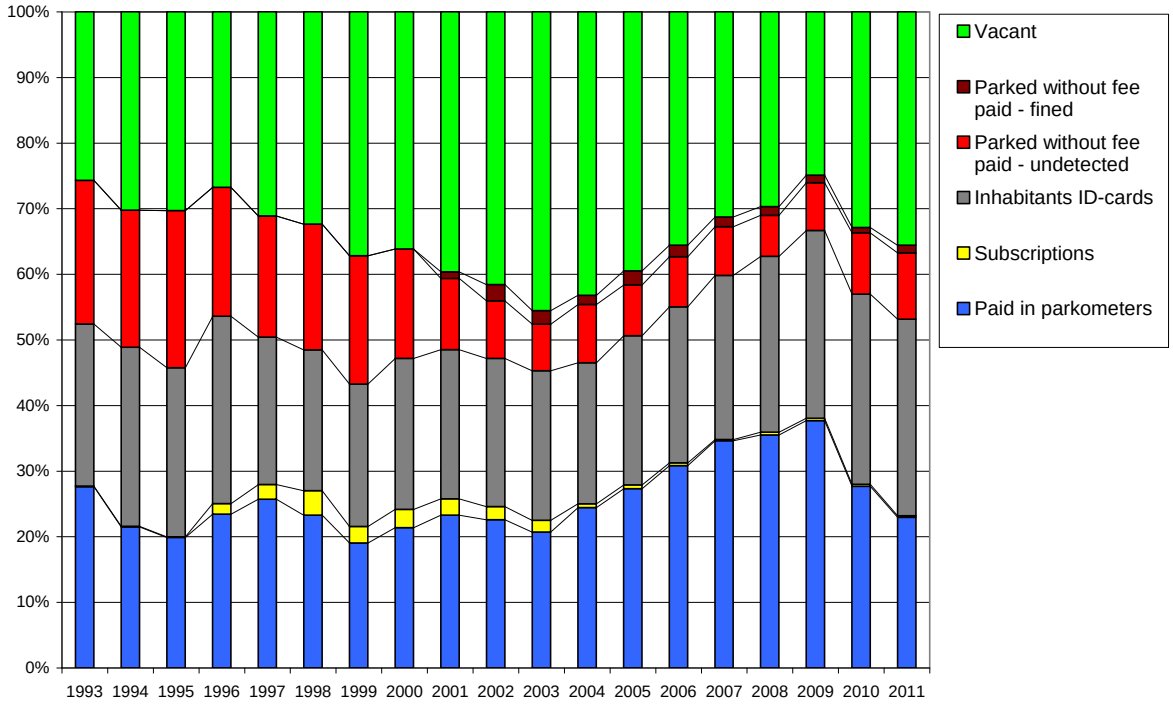

Fig. 3. Average usage of Paid Parking Zone (SPP) in 1993-2011. Source: own compilation based on data of Urban Road Management (ZDM Poznań)

After the extension of SPP in 2011, the public revenue from paid parking has increased by about 4 million PLN per year. The costs of the SPP extensions (including renewal of sidewalks and street greenery as well as some small improvements for cyclists) amounted to about 11 million PLN, and are expected to be covered within 3 years period. Estimated income for 2012 is 20 million PLN. Although there is a quite widespread opinion that public paid parking is "a repression against drivers and unjustified source of money", during last years incomes from the SPP covered only about 2-3% of general expenses on road construction and maintenance in Poznań. In Poland, parking fee is the only one collected directly from drivers by communes. Excises, fees and other taxes paid by drivers go to state budget, and in fact they have been recently lower than the spending on state roads and motorways (Beim 2011).

One of the most urging problems of the parking policy is illegal parking (see: fig. 4). This problem results, among other things, from a lack of progress in the implementation of P&R policy, the state of public

transport and demand for parking in the area. Estimated average rate of illegal parking within SPP is approximately 15%. Some cars are parked at the gates, other at a pedestrian crossing, or just before the beginning of a sign designating parking zones (and thus formally outside the zone). In order to discourage illegal parking, repressive measures are applied, i.e. installing bollards (traffic poles) on streets with most severe parking problems. Moreover, some drivers used (until September 2000) above-mentioned "loopholes" to park legally outside designed parking spaces but without fee paid.

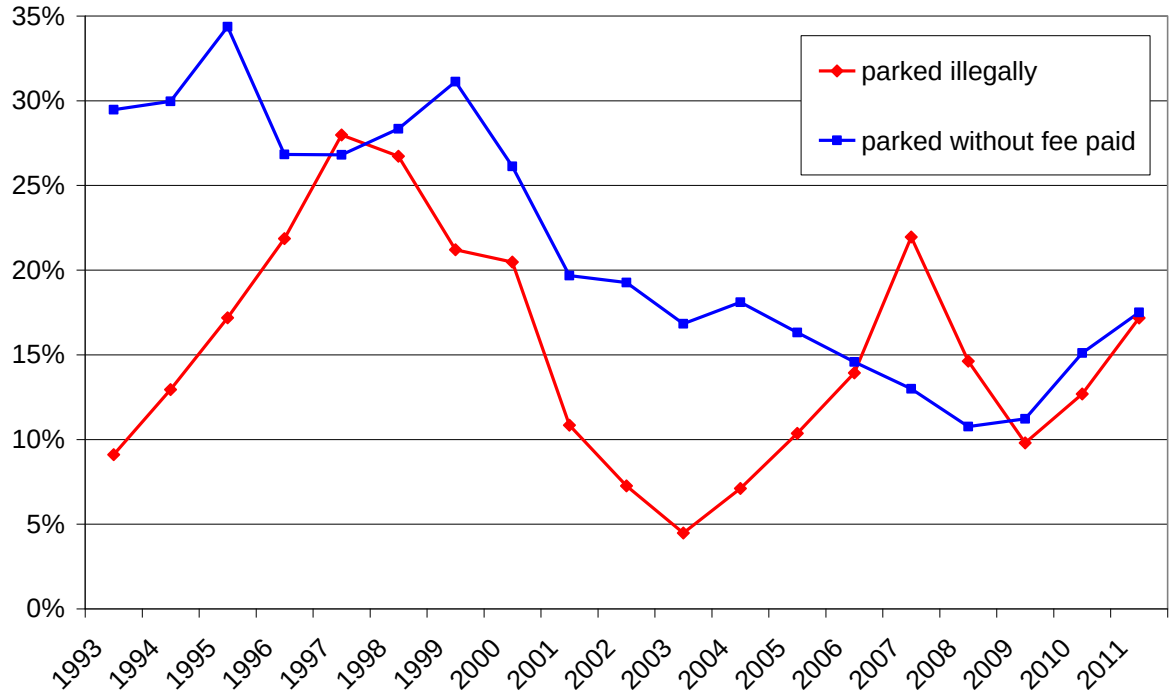

Fig. 4. Percentage of cars parked illegally and without fee paid (on designed parking spaces) the SPP (Paid Parking Zone) in 1993-2011. Source: own compilation based on data of Urban Road Management (ZDM Poznań)

Another extension of the paid parking zone is planned by the local authorities for the coming years. This time SPP should cover two another old neighbourhoods (Łazarz, Wilda). Recently, the municipal council has decided to extend paid parking hours from 8:00 a.m. on weekdays, and from 10:00 a.m. to 2:00 p.m. on Saturdays. This change should become effective in the middle of 2012.

In the absence of a sufficient amount of multi-storey parking lots, which would meet the needs of parking for cars, Parking Policy calls for 13 such facilities in the city centre. The first and so far the only one underground parking was opened at the Liberty Square (Plac Wolności) in 2006. The cost amounted to about 140 million PLN, and the capacity is 540 parking spaces. It has been developed in a build – operate – return system. Together with the opening of the new underground car park, the City of Poznań eliminated about 450 parking places on sidewalks, although the official plans stated that 540 places should be removed. After negotiations with the investor, the city lowered the number of closed places by 90 (surprisingly, on the initiative of local authorities themselves). Moreover, a significant part of the removed places is only "closed" during the operating hours of the car park (10 a.m. – 6 a.m.), so in fact they can be used for illegal parking. Not surprisingly, the occupancy of the underground car park has turned out to be below the assumed targets. Despite numerous attempts from the side of the local authorities, no potential investors for other 12 planned parking lots have appeared so far.

6 DRIVERS CONQUER SPACE. A STORY OF A HOUSING ESTATE

As the city of Poznań expanded in the post-war period, a huge demand for housing space occurred. The response of government for this demand was a large-scale project nicknamed "northern development axis". A suburban development, with large housing estates supplemented by other functions (for example, a university campus), but a linear one, with all the elements located along a rapid tram line. The plan was divided into several phases, and the first of them to be developed was the closest to the city centre – Winogrady. It was then subdivided into five housing estates, and one of them was named Osiedle Przyjaźni

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

(Friendship Estate – the Polish-Soviet friendship was meant, in accordance with the political climate of that time). The estate has been built in the 1970s by a housing cooperative, which is still responsible for management and owns most of the land.

From the perspective of urban design, the estate is a superblock. This spatial form is inseparably linked to the rule of traffic mode separation, the quasi-dogma of modernist planning. To make things clear, traffic separation was not an original idea of modernists, since it had already been applied, for example, in the famous planned community of Radburn in the U.S. state of New Jersey (1929), which bears more similarity with garden cities than with large housing estates. Yet, in the socialist "shortage economy" there was little demand for villa suburbs, but rather for mass housing.

This economy was also incapable of large-scale automobile manufacturing. Waiting time of several years for a tiny "Polish FIAT" (produced in Poland under a license) was nothing unusual. Under these circumstances the planners reasonably assumed that the ratio of automobile ownership would not exceed the range of 100 – 200 cars per 1000 inhabitants. The residents were supposed to commute mainly with the public transit, and so they did, notwithstanding that the rapid tram has not been constructed until 1997, so more than a decade after the last part of Winogrady had been finished (eventually, the original idea of "northern development axis" has been only partly realized). Moreover, the planners assumed that most basic goods and services should be provided in a walking distance. Unfortunately, the "estate centre" fell victim to financial cutbacks, and only a couple of years later shopping malls have filled the niche, certainly equipped with multi-storey car parks.

Following the rule of traffic separation, the estate was conceptually divided into three concentric zones. Car drivers should only have convenient access to the outer zone, whereas the two inner zones, with housing, schools, and leisure facilities, should be a domain of pedestrians and cyclists, with limited access for cars (Marciniak 2005). No through traffic was allowed within the superblock, and also no public transit. As the projected ratio of motorization was low, not much space was allocated for parking. The basic solution was to allow on-street parking, which to some extent collided with the idea of traffic-free internal zone, but with a relatively small number of drivers the negative effects were tolerable. Yet the conditions have changed as the wave of mass motorization reached Poland.

Rapidly increasing level of motorization, especially after the accession of Poland to the EU (2004), which allowed for duty-free import of used cars, and so made car ownership as cheap as never before, created a high demand for parking space. This caused a trouble especially for large housing estates, which as already mentioned, have been designed mainly for non-motorized mobility.

There are several kinds of parking spaces on the estate. In the two blocks of flats that have been constructed in last years there are underground car parks, which serve mostly their inhabitants. Then there are paid parking spaces with a capacity for several hundred cars, with monthly fee of about 150 PLN. Those who do not wish to pay, can park their car on the street, although in certain times they need to spend some time cruising for a free place. And if they are unable to find one, or simply want to park closer to the door, they can use another option – wild parking. It means parking the car in such a way which is either illegal (for example, does not leave enough space for pedestrians), or forces other drivers to disobey the rules (for example, to drive where it is not allowed to). Finally, there are over 500 parking places in car parks adjacent to shopping centres, mainly in the northern part of the estate.

The story of a last couple of years is a story of drivers taking more and more space of the estate. The settlement of parking places has also affected driving behaviour, which will be mentioned in the later part. The process of taking over the space has been in part spontaneous, and in part an organized one. Paid private parking lots have been created between the blocks of flats, where – according to the principles of modernism – much "social" space was left. Yet it turned out to be not enough.

Demand for parking space increased when a private developer built a new block in the north-western part of the estate. The weak system of spatial planning has been usually unable to prevent such "in-fill" developments in large housing estates that have become quite common in the last years because of the "housing boom". The building is equipped with an underground car park, but the number of parking spaces turned out to be insufficient (62 places per 188 dwellings). This led to a conflict between the residents of the block and of the neighbouring buildings, who claim that new neighbours leave their cars on a parking lot which belongs to the housing cooperative. In their opinion, as non-members, they are not entitled to do that.

To solve the conflict, the authorities of the housing cooperative have decided to turn another bit of green space into a parking lot. Yet, some residents of the nearest block protested against having cars park too close to their windows. They proposed to limit access to the existing lot to the members of cooperative only. They also demanded a change of authorities of the cooperative, but the attempt was unsuccessful. Successful on the contrary has been until now their opposition against the new parking lot.

Having learned from the experience, the authorities of the housing cooperative had planned a much larger underground car park, when they have built a new block of flats a couple of years later. They have also consequently pursued the goal of increasing parking space by taking over the green space. Recently a new parking lot for about 50 cars has been built at the very heart of the estate, in a zone that in original plans was considered as "internal", so essentially free from car traffic. However, as the construction of new blocks has already shown, the old plans are hardly obeyed.

The new parking lot is located next to Hercena street, which runs from east to west through the middle of the estate. Originally it was only allowed to drive in the eastern and western part, and the central part was only accessible for pedestrians and cyclists. This was a convenient and safe solution since a small park is located in the northern part of the street, and many people with small children go through. Because of the construction of the new parking lot, traffic rules on Hercena street have been changed (fig. 5). About 100 m long section of the pedestrian route has been converted into a street with sidewalk. In the western part, the pedestrian section separating the traffic from another street (running from north to south) is now only about 20 m long. There is no physical barrier that would stop the traffic, and it is not possible to establish one, because the street is used by emergency vehicles. And how do the drivers behave in such situation? Many of them do not hesitate to drive through the pedestrian part. A short distance, but some rule has been broken.

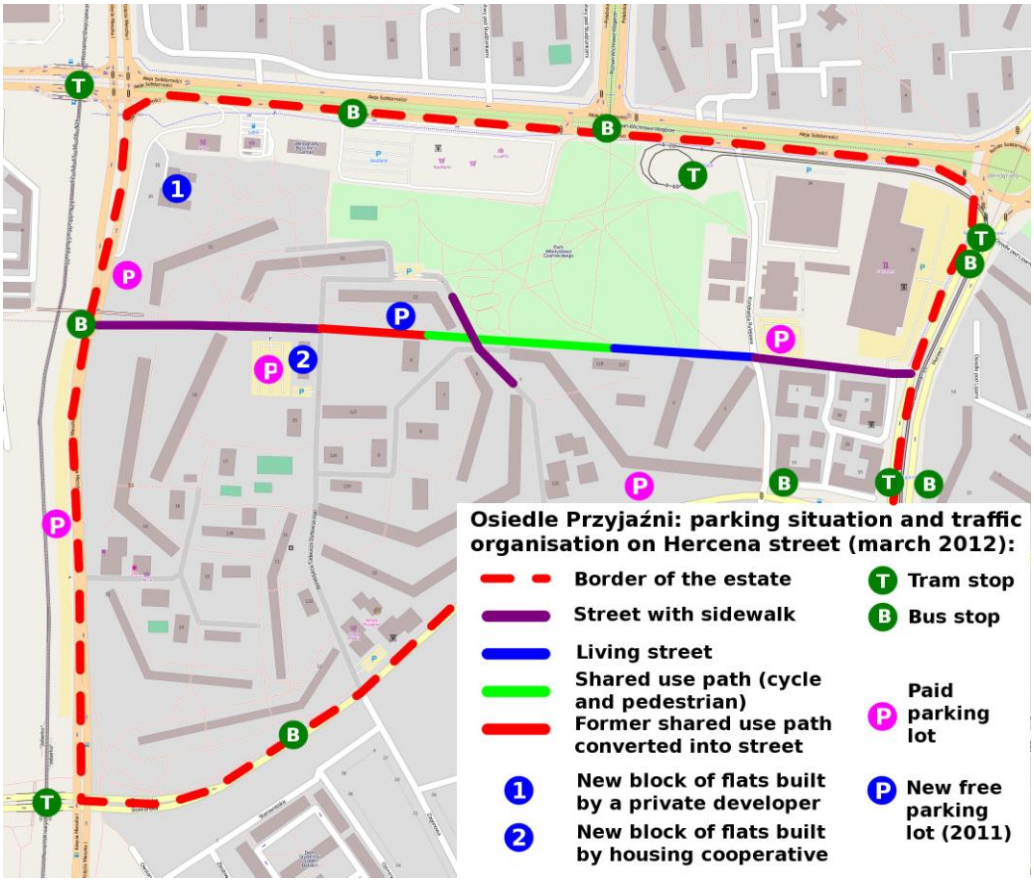

Fig. 5. Case study: changes in traffic organisation caused by a new parking lot. Source: own elaboration; maps based on OpenStreetMap.org.

And this was not the end. The changes had a psychological effect. As the drivers have noticed that many people disobey the rules, they felt encouraged to do the same. And so more drivers appeared on the longer part of pedestrian route, the one which is close to the park. First just a small step, then a bigger one. Each day several dozen of cars drive through the pedestrian route, and the number is growing. They have a very small chance to be fined, because the municipal police does not make controls frequently. The pedestrians seem to

be accustomed to the new situation, just the parents need to look after their children more carefully. Recall, many pedestrians are at times drivers and vice versa.

Some general conclusions can be drawn from this particular case. Several decades ago the rule of traffic mode separation was seen as a great progress in urban design, or even the salvation for "dying" cities. A great example of this popular belief is Hans Bernhard Reichow's work "Die autogerechte Stadt", and especially its very enthusiastic reception among planners throughout Europe (Reichow 1959). The basic idea of traffic mode separation was to divide the city into a "realm of drivers" and a "realm of non-drivers". Both "realms" should coexist peacefully, respecting each other's rights. Yet, the concept turned out not to work very well. The drivers were not only unwilling to respect the rights of non-drivers as "minority" in their own realm. They have also invaded the realm of non-drivers, as they felt that driving was not convenient enough yet. So traffic mode separation in fact turned into a "battle of realms", with one side having a huge advantage of power over the other. The positive benefits of this battle for the city are rather questionable.

7 CONCLUSION

Poznań, like other Polish cities, remains under strong automobile pressure. The dominance of cars in urban space is clearly visible, not only within the city center area, but at modernistic housing estates as well. Downtown streets are losing their representative character, while housing districts are deprived of recreational areas and walking routes. The original urban design and layout of the city is being distorted. One of the greatest obstacles to restore spatial order are the legal provisions, which, on one hand, do not protect sidewalks effectively against illegal stopover, while allow for destruction of spatial structures on the other. Lack of stringent legislation makes the construction of multi-storey car parks unprofitable. Parking chaos continually deepens. Yet, flawed legislation does not necessarily imply passivity. The city has a great potential to organize the urban space through design. But surprisingly it is not using it. Nor does it use the possibility of lobbying for improved legislation, as there is no political will. This kind of thinking is grounded in the realities of the 1990s, when it was the criterion of car accessibility what marked the fashionable investments. Nowadays, one can see that the investors interested in central locations expect primarily the improvement of pedestrian conditions. In 2011 local media reported two cases with a symbolic meaning. In the first case, a German investor withdrawn from the purchase of the "House of Books" (multistory shopping mall of 1970s.) due to insufficient volume of pedestrian traffic, even though the building is located straight in the city center. In the second case, an Irish investor, who modernizes an office complex at Ratajczaka St., explained that among the main reasons for his investments were plans for a "zone 30" and new tram line.

Poznań, without a proper parking policy, exposes itself to the risk of stagnation, which will foster the escape of people and commerce to the suburbs.

Pathology of Urban Space Based on Standard Designs for Wheelchair Users, Sari 2011

Mehdi Golestanibakht, Khadijeh Rabiei, Reza Lahmian

(Mehdi Golestanibakht, Bachelor of economy, wheelchair user, Sari, Iran, pmgolestany@yahoo.com)
(Khadijeh Rabiei, MD, Traditional and Complementary Medicine Research Center, Mazandaran University of Medical Sciences, Sari, Iran, mprabie@yahoo.com)
(Reza Lahmian, Urban planning, Payam Noor University, Sari, Iran, rlahmian@yahoo.com)

1 ABSTRACT

Purpose: In recent years the practitioners and sociologists apply all urban standard design so that all citizens can equally make use urban facilities and live in their privacy. Persons with disabilities are members of society that have limitations and don't live like normal people. Environmental conditions should be in such a way that they can increase their ability and quality of life. In this study we analyzed the urban space according to standard design for wheelchair users in Sari. This historically attractive city is located in north of Iran.

M&M: This was a cross-sectional study done in spring 2011. A checklist was developed according to governmental and international standards. Thirty restaurants, 20 streets and 20 bus stations were randomly selected. All of Public drinking-fountains, Parks, Cinemas, Libraries, Museum, Gyms and Public toilets were assessed. Content validity was obtained by consultation with experts. These places examined by experienced wheelchair users. Reliability was tested "test-re-test" method (Pearson Correlation Coefficient, r=0.78). Scales for evaluation were as; existed as standard, existed but not as standard. Data entered the SPSS (16) software to analyze.

Results: Sari has 300.000 population and 3923 square kilometer area. This city has 4 parks, 3 public toilets, 3 Public drinking-fountains, 2 cinemas, 2 libraries, 2 gyms and one museum. One hundred percent of all intended pedestrians, bus stations and restaurants and other items are inapplicable for persons who always use wheelchair in their life and relied on them.

Conclusion: This survey showed that since urban design isn't based on international standards, the disabled especially people who utilize wheelchair can't use urban facilities and have to stay at home and therefore the quality of their life reduces. It seems it is necessary to revise urban design, governing and performing of correct a fair law.

2 INTRODUCTION

Many people become physically disabled in some occasions in their lives. There are few people who remain healthy and able in whole period of their life. Enjoying life, attending and progressing in society are the right of all people. A major outcome of the "International Year of Disabled Persons" was the formulation of the World Program of Action (WPA) concerning disabled persons, adopted by The United Nations General Assembly (UNGA/GA), that was important act towards recognizing the rights of the disabled, understanding of their needs and appreciation of their capabilities on 3 December 1982, by its resolution 37/52 (1-3). The WPA is a global approach to promote disability prevention, rehabilitation and equalization of opportunities, which pertains to full participation of the disabled persons in social life and national development (3). The conference on the capabilities and needs of disabled persons in the economic and social commission for Western Asia (ESCWA) region was held in November 1989, recommended that city planning and construction legislation, should take into account the conditions that facilitate the movement of disabled persons and ensure their safety, including in the design of infrastructural services, transport and the entrances and interiors of buildings. Early in 1994, ESCWA was requested to provide Lebanon with assistance in developing construction standards and policy recommendations to accommodate disabled people. ESCWA began with an assessment of the magnitude of the issue on the national level, hoping to devise a long-term strategy and aiming at placing urgent short-term measures within an integral capacious perspective. The Lebanese company for the development and reconstruction of Beirut central district (SOLIDERE) and ESCWA provided the manual that it can also be used as a reference by designers and planners (1). A barrier-free environment is a space that allows free and safe movement, function and access for all, regardless of age, sex or condition. A barrier- free environment can be of four domains (1, 4):

- Inside buildings

- In the immediate vicinity of buildings
- On local roads and paths
- In open spaces and recreational areas.

As far as the built-up environment is concerned, it is important that it should be barrier-free and adapted to fulfill the needs of all people equally. As a matter of fact, the needs of the disabled matches with the needs of the majority, and all people are at ease with them. As such, planning for the majority implies planning for people with varying abilities and disabilities. The disabled people should be to take an active part in society and lead a normal life. To be active, a disabled person should be able to commute between home, work and other destinations (1). This research analyzed the urban area according to the international codes for wheelchair users in Sari.

3 MATERIAL & METHODS

This was a cross-sectional study. A checklist was created by consulting the experts and according to the national codes. Ten items was looked for. Thirty restaurants, 20 streets and 20 bus stations were randomly selected. All of Public drinking-fountains, Parks, Cinemas, Libraries, Museum, Gyms and Public toilets were assessed. Scales for evaluation were as; "existed as the standard" and "existed but not as standard". Content validity was obtained by consultation with experts. Examiners were experienced wheelchair users familiar with design codes. Reliability of checklist was examined by retesting the 10 random selected items in 2 weeks (Pearson Correlation Coefficient, r= 0.78). For analyzing data we used of SPSS (16) soft ware.

4 RESULTS

Sari is a historical city and locate in north of Iran. It has 300,000 population and 3923 square kilometer area. This city has 4 parks, 3 public toilets, 3 Public drinking-fountains, 2 cinemas, 2 libraries, 2 gyms and one museum. One hundred percent of all intended pedestrians, bus stations and restaurants and other items are inapplicable for persons who always use wheelchair in their life and relied on them (Table 1).

	Items	Standard No. (%)	Existed/Not standard No. (%)
1	Pedestrian	0 (0)	20 (100)
2	Bus station	0 (0)	20 (100)
3	Restaurant	0 (0)	30 (100)
4	Park	0 (0)	4 (100)
5	Public drinking-fountain	0 (0)	3 (100)
6	Cinema	0 (0)	2 (100)
7	Library	0 (0)	2 (100)
8	Public toilet	0 (0)	3 (100)
9	Museum	0 (0)	1 (100)
10	Gym	0 (0)	2 (100)

Table 1: Condition of urban facilities for wheelchair users, Sari, 2011.

Figure 1: The public drinking-fountain is located on platform. Figure 2: The ramp in the public toilet isn't standard.

Figures 3 and 4: The design of bus stations aren't standard for all people especially wheelchair users.

Figures 5 and 6: Park has stairs and bollards. There isn't any ramp for the disabled.

Figures 7 and 8: As it is shown in the pictures, the disabled couldn't walk in the pavement.

Figures 9 and 10: The junction point between pedestrian and street should be flat but in these pictures we are faced to some levels.

Figures 11 and 12: Street has a level that wheelchair users couldn't go across the street.

5 DISCUSSION & CONCLUSION

The study showed Sari has not urban design standards minimal for the disabled therefore they cannot present in society actively and their physical and mental situations deteriorate. Eleven years after the distribution of regulations of appropriateness of buildings for the disabled, few officials and constructors observed such

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

issue (5). Concept of the quality of life is multifaceted and comparative. It is affiliated to time, place, personal and social features (6). There are two approaches in the studies of urban quality of life, subjective and objective. Approaches are used often separate from each other and are rarely combined to assess the quality of life. (7). Quality of life in subjective aspects reflects people perception and evaluation of their own life. It is measured by social and material indices (8). In these recent decades many countries have emphasis on the role of people, local communities and civic society in urban management at global levels (9). The principles of the urban management include:

- urban civility and citizens' education
- continuous poll from citizens
- codified rules for informing and guiding citizens
- gaining trust of public and private sector
- verifying and revising the actions which have been done (10)

Australian Capital Territory (ACT) provides design standards for urban infrastructure. In section 13, pedestrian & cycle facilities are described. This standard aims to provide Practitioners with a suite of planning considerations and design measures to ensure a consistent approach is maintained in the provision of pedestrian and cycling facilities. Pedestrians and users of wheelchairs, including motorized wheel-chairs have right of way over cyclists and users of wheeled recreational devices including roller blades, roller skates and skateboards (11). There are lots of urban standard designs were performed in many countries especially the developed countries therefore the disabled could work and attend in the society (12-19). Each city does not belong to especial type of people. Indeed, city looks like a family. By planning the cities correctly, all members can take a good advantage in their residence. It seems necessary to revise teaching in university and performance in urban management. In order to give a chance for all to use equal value from urban facilities, historical construction should be rebuilt and the government should make sure to perform the correct laws. Because almost all cities in Iran don't have standard designs for people with disability, we recommend the international conventions to provide Iran with assistance of standards of developing construction to accommodate disabled people.

Pedestrian Crossing Behaviour in Signalized Crossings in Middle Size Cities in Greece

Athanasios Galanis, Eliou Nikolaos

(Dr Transportation Engineer Athanasios Galanis, University of Thessaly Greece, Pedion Areos, 38334, Volos, atgalanis@uth.gr)
(Assoc. Prof. Nikolaos Eliou, University of Thessaly Greece, Pedion Areos, 38334, Volos, neliou@uth.gr)

1 ABSTRACT

Pedestrian road safety is a key point of the transport road safety policy in urban areas. Pedestrians are vulnerable road users and despite their limited representation in traffic events, pedestrian involved injuries and fatalities are overrepresented in traffic collisions. This paper presents the findings from the examination of the pedestrian crossing behaviour in signalized crosswalks. The study took place in the city of Volos, Greece, in peak traffic hours, during the summer of the year 2010. The target of the study was to count the pedestrian crossing time and velocity for each crosswalk. Furthermore, the target was to identify the illegal pedestrian crossing with red traffic light, criticize their behaviour and propose remedial actions.

More than 1300 pedestrians were recorded using a video camera in twelve signalized crossings located in the center of the city, across main arterials. The pedestrians were categorized according to their sex in men and women and their age in three age groups: 0-20, 20-50 and over 50 years old. The analysis of the pedestrian video data was achieved with the use of a state of the art tool, the Captiv L2100 (TEA). The researcher entered the video data in avi format and created the project, the description protocol and the video configuration. The researcher tested each video, marking each pedestrian crossing in the video sequence window, with great accuracy in a short period of time. After the data analysis and the creation of the post coding file, the results were exported in excel format, where they were following analyzed.

Some of the results of the study were that the 17% of the pedestrians crossed the streets with red traffic light. The velocity of the younger pedestrians was 1,32m/sec and of the older ones was 1,19m/sec. Men walked faster (1,32m/sec), than women (1,25m/sec). Furthermore, the pedestrians walked faster crossing the streets with red traffic light (1,34m/sec), than with green one (1,28m/sec). Finally, this study criticizes the lack of pedestrian road safety education and illegal crossing behaviour.

2 INTRODUCTION

2.1 Pedestrian road safety

Pedestrian road safety is a key point of the transport road safety policy in urban areas. Pedestrians are vulnerable road users and despite their limited representation in traffic events, pedestrian involved injuries and fatalities are overrepresented in traffic collisions. Crosswalks are sites where pedestrians face lower levels of road safety, because they have to cross the street and must be aware of the incoming traffic. Intersections with high vehicle flows should be signalized in order to prevent accidents and raise the level of road safety for both pedestrians and vehicle drivers.

The pedestrian illegal crossing behaviour is a major fact in the road safety issue. The main concerns are the following:

- Pedestrians cross the streets without noticing the incoming traffic, usually because their attention is distracted.
- Pedestrians usually miscalculate the traffic gaps.
- Pedestrians walk across the street, usually due to lack of space on sidewalks.
- Pedestrians cross the streets in midblock location or out of designated crosswalks.
- Pedestrians do not follow the indications of the traffic lights.

2.2 Objective of the study

This study examines the pedestrian crossing behaviour in twelve signalized crosswalks located across main urban arterials in the city of Volos, Greece with the use of a new tool that analyzes video data: Captiv L2100 (TEA). The pedestrians were categorized according to their age and sex. The main questions of the study were the following:

- How much is the pedestrian crossing time.

- How much is the pedestrian crossing speed.
- Do pedestrians cross the street with red or green traffic light.

3 LITERATURE REVIEW

3.1 Pedestrian crossing behaviour

Many studies have examined the pedestrian crossing behaviour analyzing several factors. Rosenbloom (2008) analyzed the behavior of 1392 pedestrians in signalized crosswalks. The first hypothesis was that pedestrians' behavior waiting to cross the street depends on the factor of being alone or in group. It was expected that the pedestrians would be more optimistic of crossing the street with red traffic light if they were accompanied. Furthermore, the second hypothesis was that he pedestrians would be more optimistic of crossing the street with red traffic light if another pedestrian crossed before him. The first hypothesis did not come true, but the second did so. Moreover, men were more optimistic to cross the street with red traffic light than women. At last, the longer waiting time in red light phase and the less waiting pedestrians increases the possibility of a pedestrian crossing the street with red traffic light.

Hill and Holland (2008), analyzed the factors that influence the pedestrians' crossing behavior. Using video data they checked the crossing decisions of 213 pedestrians. They counted safe or not traffic gaps for every person, according to their walking speed. The most unsafe choices were taken from men and especially the older ones. Factors like the pedestrians' driving experience, their physical skills, walking speed, sex, age and understanding of the traffic characteristics, were important in order to decide where and when to cross the street.

Pedestrian risk decreases as pedestrian flow is also decreased (Leden, 2002). He made that conclusion after studying pedestrian accident data from 300 signalized intersections in Hamilton, Ontario, during the years 1983-1986. Pedestrian safety at semi-protected schemes, where left-turning vehicles face no opposing traffic but have possible conflicts with pedestrians, was compared with pedestrian safety at normal non-signalized approaches, where right-turning vehicles have potential conflicts with pedestrians. Pedestrian safety seems to be affected much more by the traffic pattern (left or right-turning traffic). At low vehicular flows, right turns and semi-protected left turns tend to be equally safe for pedestrians, but right turns are safer for pedestrians than semi-protected left turns at high vehicular flows. If risk for pedestrians is calculated as the expected number of reported pedestrian accidents for pedestrian, the risk decreases with increasing pedestrian flows. One explanation could be increased driver alertness with increasing pedestrian flow. However, an increased pedestrian flow might lead to more pedestrian accidents if promotion is not accompanied by appropriate safety measures.

Ekman (1996) examined 95 non-signalized intersections in Malmo and Lund in Sweden and concluded that the rate of pedestrian conflicts per pedestrian was not influenced from pedestrian flow. According to Ekman the individual pedestrian does not seem to benefit from the presence of other pedestrians. Another explain is that the motorists expect the presence of pedestrians (at least if pedestrian flow exceeds 30 pedestrians per hour. Ekman also found that if risks for pedestrians are calculated as the expected number of reported pedestrian accidents or conflicts for pedestrian, the risk increases as traffic flow is also increased.

Signalized intersections should consider signal phases for pedestrians which do not significantly delay them. Wang et al (2008) concluded that with high delay, pedestrians are likely to violate the signal. From field observations, most pedestrians searched for traffic gaps and crossed the street without following the traffic signal indications. Furthermore, pedestrian intervals should adjust to the vehicle crossing phase, based on the rule that no conflicting phase should be on together.

Pedestrian road safety depends on their exposition on traffic flow. Many studies have concluded that about 25% of the pedestrians cross the streets illegally (Mullen et al, 1990). Keegan and O'Mahony (2003) reported that 35% of the pedestrians cross during the red light phase. Pedestrians usually cross the streets in sites they consider as more convenient or located across their desire route in order to achieve minimum time delay of physical effort.

Many studies have used video data in order to examine the pedestrian crossing behaviour (Hao et al, 2008; Jiangang et al, 2008; Eliou and Galanis, 2009). Some of them use state of the art equipment. Ismail et al (2009) used a real time video data analysis system, which registers vehicle and pedestrian tracks and

recognizes traffic conflicts. Relative equipment can examine bicyclists' behaviour. Constant et al (2010) used an "Intelligent Video Analysis System" (IVAS). Connecting an internet protocol (IP) with a video camera in a building above the tested street they could track the bicyclists' route and count their speed.

4 METHODOLOGY

4.1 Data collection

The crosswalks where located across the Benizelou St. and Kartali St, which are main arterials located in the center business district of the city (Fig. 1). The crossing streets were the following:

- Gallias St. (collector arterial)
- 28 Oktovriou St. (collector arterial)
- Dimitriados St. (main arterial)
- Iasonos St. (man arterial)

The data collection took place in June 2010, during peak traffic hours (12:00-14:00). A video camera was put in the opposite of each crosswalk in order to have a complete view of the pedestrians waiting and crossing the street in both sides. The time duration of each video record was 30min for each crosswalk. After the video data collection, certain amount of photos of the crosswalks were collected and the crosswalks' length was noticed in order to count the pedestrians' speed.

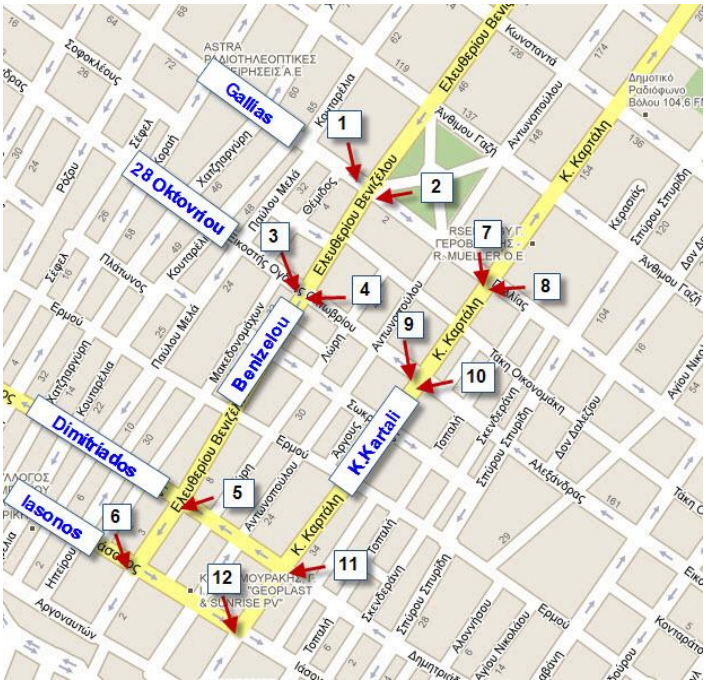

Fig. 1: Study area

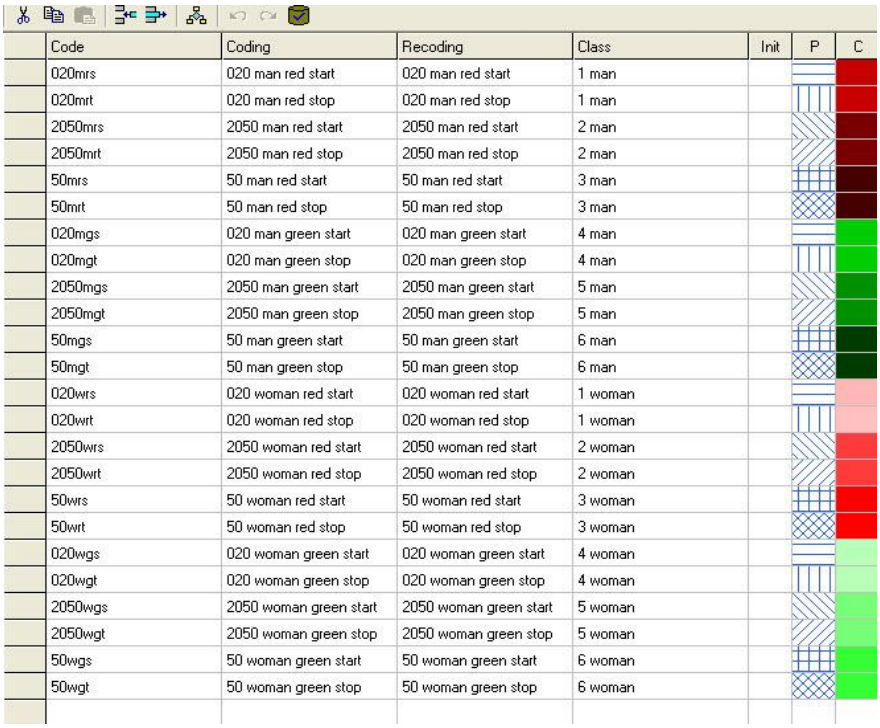
4.2 Data analysis

After the video data collection, the video was exported from the camera to the pc in avi format in order to be compatible with the Captiv L2100 software. The first step of the analysis was the creation of the project in the site: C:\Program Files\Captiv L2100\Project. The second step was the formation of the "Description Protocol", which is the most important step of the analysis because the researcher forms the coding (Fig. 2). The pedestrian crossing behaviour was analyzed according to their sex and age. The columns of the description protocol were the following:

- Code: 020mrs (abbreviation of the characteristic)
- Coding: 020 man red start (analytic presentation of the characteristic)
- Class: 1man
- C: Color of each code

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

12 classes and 24 codes were formed because in order to notice the time when the pedestrians start and finish crossing the street. So, the coding "020 man red start" describes a pedestrian in the age group of 0-20 years old who starts crossing the street with red traffic light and the coding "020 man red stop" describes the pedestrian in the age group of 0-20 years old who stops crossing the street with red traffic light. For each coding line a proper colour was selected. With red color was marked the coding referring to pedestrians who crossed the street with red traffic light and with green colour the ones who crossed with green traffic light. Darker colours referred to men and brighter to women.



Code	Coding	Recoding	Class	Init	P	C
020mrs	020 man red start	020 man red start	1 man

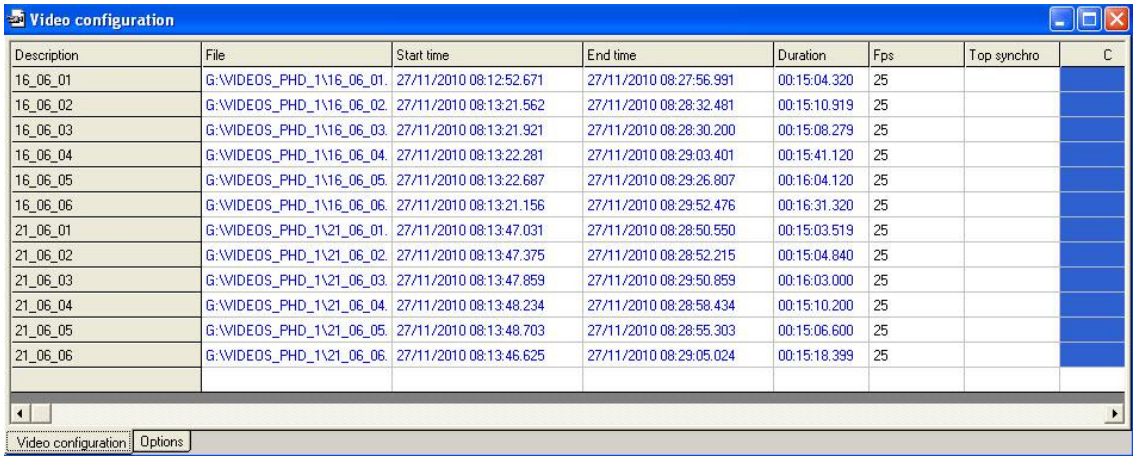
Fig. 2: Description Protocol (Captiv L2100)

After the formation of the description protocol, was formed the "Video Configuration" file (Fig. 3). This file was created when the videos were entered in the project. Each video was characterized from its description name, the file where it was saved, the start and end time and its duration (about 15min).



Video configuration

Video configuration | Options

Fig. 3: Video Configuration (Captiv L2100)

The next step was the formation of the "Video Sequence" file, which was the basic tool for our analysis (Fig. 4). Each button referred to a coding and its one colour (Fig. 2). We run the videos and marked each pedestrian start and stop time, based on our coding. We were able to stop the video (pause), play it back or synchronize it in a selected time when a pedestrian crossed the street. All the registrations were saved in a "Post Coding" file, which refers to the start and stop time of the pedestrian crossing according to the coding.

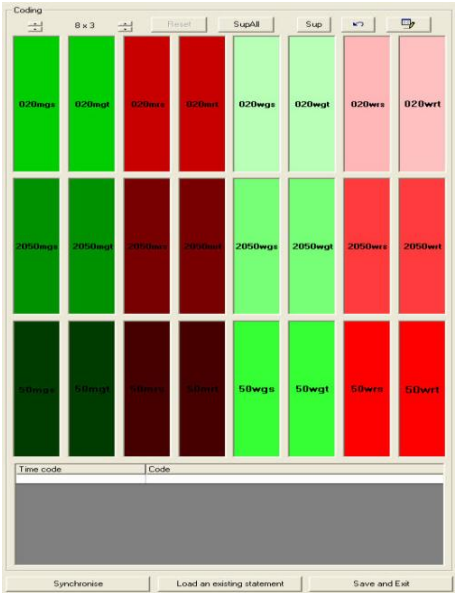

Fig. 4: Video Sequence (Captiv L2100)

After the creation of the post coding file, all the data were exported in the excel software for further analysis. The basic benefit of this analysis procedure was the speed, convenience and reliability of the process, comparing to the manually video analysis.

5 RESULTS

5.1 Pedestrian and traffic flow

The first result of the data analysis was the counting of the traffic flow (Table 1). The highest traffic low were noticed in crosswalks No5-6 and No11-12, located in Iasonos St and Dimitriados St, which are main urban road arterials.

The traffic flow is those streets was about 300% higher than the other crosswalks No1-4 and No7-9, located in Gallias St and 28 Oktovriou St, which are collector arterials. The duration of the traffic signal phases in each crosswalk is presented in Table 2. Higher percentage of green traffic light was noticed in the crosswalks located across the collector streets.

Traffic (1hr)	**1**	**2**	**3**	**4**	**5**	**6**	**7**	**8**	**9**	**10**	**11**	**12**

Table 2: Traffic signal phase (sec)

In Table 3, are presented the pedestrians who crossed the streets during the data collection time (30min for each crosswalk) and their percentages according to their age, sex and traffic light (Table 4). The crossing behaviour of 1322 pedestrians was analyzed. Separating them by age, 304 pedestrians were under 20 years old (23%), 664 between 20 and 50 years old (50%) and 353 over 50 years old (27%). Separating them by sex, 529 were men (40%) and 793 women (60%). Analyzing their crossing behaviour, 185 pedestrians crossed the street during the red traffic light phase (15%) and 1137 during the green traffic light phase

(85%). The highest illegal crossing behaviour was noticed in collector streets (8%-28%) and the lowest in main arterials (4%-16%).

Pedestrians in the age group of 20-50 years old were more optimistic to cross the street with red traffic light (55%) and also women (63%) than men (37%), (Table 5), comparing to the sample percentages (Table 4).

Table 5: Pedestrians crossing with red traffic light (%)

In Table 6, is presented the pedestrian crossing time in each crosswalk according to their age, sex and crossing behaviour. Due to the difference of the crosswalks' length it was better to count the pedestrian crossing speed (Table 7). The pedestrian crossing speed was analyzed according to their age (Fig. 5), sex (Fig. 6) and traffic light (Fig. 7). It is clear that pedestrians under 50 years old cross the streets faster (1,30m/sec) than pedestrians over 50 years old (1,18m/sec). Furthermore, men walked faster (1,31m/sec) than women (1,25m/sec). Finally, pedestrians realize the danger for their road safety and cross the streets faster during the red traffic light phase (1,35m/sec) than during the green traffic light phase (1,26m/sec). The speed profile was relative smooth and steady in all categories (Fig. 5, 6 and 7).

6 CONCLUSION

The implementation of the Captiv L2100 (TEA) software was a very useful tool to analyze the pedestrian crossing behaviour with convenience, reliability and speed, using video data. The main conclusions of our study were the following:

- The quantum of pedestrian data collection using this age scale was representative. The 50% of the pedestrians were aged between 20-50 years old, 23% under 20 years old and 27% over 50 years old.
- The 60% of the pedestrian sample was women and 40% men. We noticed a significant dominance of women walking in the center of the city during morning time.
- The 85% of the pedestrians crossed the streets with green traffic light and only 15% with red traffic light. More pedestrians crossed the streets illegally where the traffic flow and speed are lower.
- Older pedestrians crossed the street with lower walking speed (1,18m/sec) than pedestrians 20-50 years old (1,30m/sec) or under 20 years old (1,31m/sec).
- Men crossed the streets faster (1,31m/sec) than women (1,25m/sec).
- Pedestrians walked faster when they cross the streets with red traffic light (1,35m/sec) than green traffic light (1,26m/sec).
- The highest walking speed (1,55m/sec) was noticed when the pedestrian crossed main arterials during the red light phase when the traffic flow gaps are minimized.
- The most illegal crossing behaviour was noticed in women and pedestrians 20-50 years old.
- Pedestrians usually respect the traffic light indications, crossing the street when they judge that there is a safe traffic gap, according to their physical skills and traffic road safety education.

The conclusions of our study can help engineers and local authorities to understand better the pedestrian crossing behaviour and promote remedial actions in urban road network. Furthermore, we propose the implementation of a road safety training program to older citizens in order to improve their walking behaviour.

1 ABSTRACT

People's safety and security in urban space has a high priority for planning decisions. Especially at major events pedestrian planning aspects play a decisive role for associated evacuation scenarios. A well-developed urban design of spatial environments, with its escape routes and infrastructure on-site, is consequently most important for a fast evacuation.

The research project REPKA (Regional Evacuation: Planning, (K)Control, and Adaptation), funded by the German Federal Ministry of Education and Research, focuses on open space evacuation of major events, especially in case of national soccer matches. The soccer stadium of the 1st FC Kaiserslautern/Germany (up to 50.000 visitors), located in the inner city with a difficult topography, is centered in the project. First project results show that there are two determining factors to be regarded in context of pedestrian evacuation planning: a) urban design of escape routes in the event's surroundings and b) human factors, like socio-psychological mechanisms on the behavior, environmental perception and orientation of crowds under stress. The combination of these two factors, missing in research on open space evacuation until now, is discussed in this paper. Hence, in the research project REPKA, a spatial analysis was done to identify physical characteristics of escape routes and infrastructure. In addition, research in literature, standardized interviews (with visitors and security services) and observations concerning human factors were conducted. It became evident that different guidance systems (guidance staff, signage, new technologies) are essential for effective use of existing escape routes and a fast evacuation. Totaling, the results reveal that a well-regulated evacuation depends on a well-developed urban design combined with a guidance system including human factors. By this, evacuation time is reduced and thereby people's safety is improved.

This paper aims to make a contribution to a new holistic approach in the field of pedestrian evacuation planning. Moreover, the findings have consequences for interdisciplinary approaches like modeling of pedestrian flows in computer evacuation simulation.

2 INTRODUCTION

At present, mass events are continuously becoming more popular and take place more frequently. Security of attendees is of prime importance, but often not assured. Perilous situations can arise at any time when many people get together in a narrow place. Referring to the Hillsborough Disaster in Sheffield 1989, for example, or recently the Love Parade in Duisburg, Germany 2010, when too many people surged into a place already overcrowded. As a consequence, many people died and hundreds were injured because of too much pressure. There are a lot of other risks and accidents, which necessitate the breaking off or even the evacuation of a mass event. These may be a fire, bomb threat, technical faults or health hazards because of climatic conditions (heat, storm). There is a lot of research on evacuation of buildings, because the planning of escape and emergency routes are part of preventive fire protection and corresponding regulations. Furthermore, various simulation models regarding flight behavior during evacuation of buildings have already been developed (e. g. Shi et al. 2009, Waldau et al. 2003 or Xiaoping et al. 2008).

It is not assumed that visitors are out of danger after they have left the building in which the event was taking place. Not every venue of a mass event is outlying a city center and easy to access for arriving emergency services, such as firefighters, police and ambulance crews. Depending on the kind and extent of the threat or damage, it is necessary to bring visitors further away to safety. However, existing research on evacuation of buildings provides only first benchmarks for open-air events or crowds in public space. This is because "the movements of large number of people are distinctively different in public buildings as opposed to public event venues such as theatres, stadiums, open-air stages, etc." (Waldau et al. 2003, p. 308). For a spatially wide-ranging evacuation of mass events there is a research gap and therefore there is assumed to be a gap in security.

In case of various emergency situations or sudden break-offs of events, people have to be guided adequately for several reasons. Visitors have to be guided in order to avoid perilous situations and accidents within the mass of people, when the density of the multitude of people becomes a threat. They also have to be guided in order to get them to assembly points in a safe place. By splitting off the crowd, emergency access routes can be kept free. This is important, especially in a closely built-up environment, where evacuees stream into a public place with a lot of traffic circulation. The main stream of visitors moves towards the access route of rescue services, who get to the venue time-delayed. At soccer matches perilous situations can additionally arise when hostile fan groups meet each other.

3 INFLUENCING FACTORS ON FLIGHT BEHAVIOR

3.1 Urban design of escape routes

One dominating factor to guarantee a safe evacuation is the urban design of escape routes. Here, it is possible to take influence on the construction of the event's surroundings. So, the planning of elaborated escape routes is the precondition for a safe evacuation. In this research, the escape routes in public space, beyond the property boundaries of the event (e. g. a soccer stadium), are regarded. There are a lot of laws, standards and regulations (e. g. public assembly by-law, state building codes, fire regulations, etc.) concerning the design of escape routes inside the building and the outdoor area within the property boundaries. But what happens after the people have left the venue? People have to be guided controlled away from disaster as far as possible in order to prevent new risks arising from the crowd itself.

Important characteristics of well-designed escape routes are already known. Partly they can be transferred from the broad field of building evacuation standards to open space evacuation in combination with some extra aspects. The aim is to accelerate the pedestrian stream's speed and to raise the quantity of people getting away from disaster as safe as possible. Helbing et al. (2000, p. 489), for example, pointed out: "Improved outflows can be reached by columns [intended obstacles] placed asymmetrically in front of the exits, which also prevent the build up of fatal pressures." Also the barriere-free design of environments is often underestimated. Besides slowdown effects, handicapped people could become active hindrances in the pedestrian flow. The following table shows the most important aspects for a good urban design of escape routes and their consequences for the pedestrian flow (table 1).

Urban design aspects	Consequences for pedestrian flow
Path widths	Determinate the pedestrian flow rate
Soil conditions	Potential risk of stumbling
Barrier-free design	Handicapped people can hinder a pedestrian stream
View-shafts	Orientation and perception of the optimal route away from danger (as safe and fast as possible)
Lighting	Orientation and perception of the optimal route away from danger (as safe and fast as possible)
Intended obstacles	Intentionally positioned obstacles to avoid bottlenecks

Table 1: Urban design aspects and their consequences for the pedestrian flow.

Not only the urban design in its constructional character is an important fact to help people to get away, but also the equipment of public space with emergency signage. After identifying the constructional possibilities to accelerate the pedestrian flow, it is now indispensable to know how people exactly react and behave in case of disaster. As consequence, the question is raised how human factors determine the requirements for urban design.

3.2 Human factors

A mass of people always consists of small or large groups of people. Especially attendants of mass events mostly visit the event in company of friends or family members. They stay together during the event and even travel to, arrive at and depart from the venue frequently together. Therefore, social groups within crowds have to be considered to understand and explain the crowd behavior. Research about crowd dynamics confirms that mass dynamics cannot solely be explained by the behavior of single members of the

crowd. Individual persons in turn are influenced by other individuals and groups, e. g. how they notice and act on signpost or on other instructions and if they decide for or against the usage of a certain route.

Different factors have an impact on crowd behavior (this concerns the behavior of single members, social groups and the crowd as a whole). Helbing et al. (2000) assume "a mixture of socio-psychological and physical forces influencing the behavior in a crowd". This includes aspects like walking speeds (Helbing et al. 2002), distances kept to other pedestrians or obstacles, "clogging" (Helbing et al. 2000, p. 488), "faster-is-slower effect" (Helbing et al. 2000, p. 489) or "herding" (Helbing et al. 2005, p. 20). Herding behavior occurs in situations with low visibility or insufficient orientation, e. g. in unfamiliar environment (Helbing et al. 2005, p. 21): "People either follow other people who are believed to know the best way, or they use the exit they are familiar with (typically the main exit they have entered)." This applies to buildings, but is definitely also true for flight behavior in the event's surroundings, particularly when people have less knowledge of the place or view-shafts are limited. People will take their familiar routes and/or follow other people, especially in stressful situations, where orientation is all the more important. Because of herding effects, alternative escape routes are easily missed and therefore existing routes are not used effectively. Helbing et al. (2002, p. 23) pointed out that "pedestrians feel a strong aversion to taking detours or moving opposite to the desired walking direction, even if the direct way is crowded." To reduce people's uncertainty where to go and to guide them effectively on existing routes a well-elaborated urban design is needed.

Unlike visitors of most major events, who are relatively unfamiliar with the venue, e. g. soccer fans are characterized by high familiarity with the stadium and its surroundings and use the same paths many weeks a year. Extensive knowledge of the event's venue has an impact on the visitors' compliance with security service instructions. If some roads are blocked, it will be quite hard to prevent visitors from using their habitual routes. In many cases it will implicate uncertainty or resistance and therefore time delay for overall evacuation. Perilous situations can always arise, if single persons feel confident to find the "best way" completely on their own. This also became apparent in Love Parade 2010 immediately before the disaster occurred, when single persons started to use narrow stairs to escape and many people tried to follow.

If, e. g. a soccer stadium has to be evacuated for some reason, it is assumed that not tens of thousands of visitors are expected to flee from the building at once. As far as possible, only several sections of the building will be evacuated, not the whole stadium at once. Apart from that, it is known from evacuation of burning buildings, that people do not start leaving the building immediately. A "pre-movement time" delays evacuation for a few seconds to several minutes, in which people try to find out what is happening and to warn and gather family and friends (Proulx 2003, p. 34). The essential factor for reducing evacuation time is to optimize the time in which visitors start moving. "Design parameters such as exit width and travel distance, which have been equated traditionally with predicted escape times, are less likely to be related to overall evacuation times than is the time for people to start to move to safety" (Proulx/Sime 1991, p. 844). Definite information and concrete behavior instructions are important to implicate prompt reaction as well as to make sure that people are guided effectively and safely. Existing routes – in and outside the building – have to be able to manage the stream of people pouring out of different building exits.

Contrary to general opinion, there is little ruthless and egoistic behavior during and immediately after disasters, "panic is actually rare" (Drury/Cocking 2007, p. 9), but mutual assistance is at the very fore (see also Quarantelli 2003, p. 4). Socio-psychological research about fear and panic behavior in flight situation shows that groups of people, especially families and friends with strong ties, stay together if possible (Mawson 2005). This is even, or rather especially, in cases of emergency (Mawson 2005). In fact, making contact with affiliated persons takes precedence over individual flight (Sime, 1983). The loss of companions and uncertainty about their well-being has a destabilizing effect for people affected by disaster, whereas the presence of companions is reducing fear (Mawson 2005).

The presence of groups has great impact on crowd behavior in case of evacuation. As mentioned before, the presence of groups delays the starting point of evacuation. Mawson (2005, p. 107) emphasizes that "people in groups of familiars […] wait to assemble with their primary group before evacuating." Because of their "primacy of attachments" (Mawson 2005, p. 107), families and friends try to stay together, and if this fails, they are expected to stop or even turn back to search for lost companions. This again will hinder the stream of fleeing people and will complicate access of emergency services to the venue in the case of a large-scale

Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

accident. That fact strengthens the need for an adequate guidance system outside the building. The following table shows the most influencing human factors and their consequences for the pedestrian flow (table 2).

Human factors	Consequences for pedestrian flow
Social groups (members stay together or search for each other)	Time delay and physical obstacles
Herding and familiar routes	Existing route grid is not used effectively + Difficulties in directing people on alternative routes
Environmental perception and orientation	Basic requirement to guide people and to give instruction
Mutual assistance	Evacuation is relatively ordered, panic is rare

Table 2: Human factors and their consequences for the pedestrian flow.

4 CASE STUDY SOCCER STADIUM

The research project REPKA deals with open space evacuation of the soccer stadium in Kaiserslautern/Germany. Here, a large scaled crowd with up to 50.000 soccer fans leaves almost every second week the stadium and the area around. Especially such events are vulnerable to many potential and realistic dangers: fan riots, attacks, large scaled accidents.

The soccer stadium is located in the inner city of Kaiserslautern. It is situated 40 meters above other parts of the inner city and lies in the middle of a residential area (Fig. 1). The consequences are clear – a difficult topography with steep slopes and a close link to the residential neighborhood complicate an ordered and fast evacuation. Making things not easier, the escape routes mostly are access routes for rescue teams at the same time. Here, a high risk and conflict potential is obvious. Due to land-use type, topography, basic traffic grid and a moving mass of people, the installation of completely free access routes is very complicated. Depending on the scenario, the declared safety areas are far away from the stadium, because of the high building density in the stadium's surroundings. Declared safety areas need an open ground to serve as assembly points for injured people and to set up emergency equipment.

Consequently, it is not enough only to let the crowd leave the building in good order. The crowd has to be brought further away to safety. As figured out from the presented influencing factors on flight behavior, the crowd itself and the event's surroundings play a decisive role. As shown in chapter 3.2 it is relevant to reduce the time in which people start to move, but here the focus of the research is on the situation after the crowd has already left the building.

Fig. 1: View on the Fritz Walter Soccer Stadium in Kaiserslautern from the South (source: REPKA project).

4.1 Methods

Urban spatial inventory-taking and analysis

The usage of escape routes is due to the interdependency of the individual perception and the behavior of the crowd around (herding etc.). The factual perception is also guided by environmental factors. Thus, in a first step there is the need to take a closer look at the research area with the help of a spatial inventory-taking and analysis. The general traffic routing is the basic grid for escape routes outside a building. Internally it consists of streets, sidewalks and footpaths distant to the streets. These three categories have their own characteristics, which are important to be suited as good escape routes for a fast evacuation. Especially the width is linked to a fast flow of persons away from disaster. Further influencing values are soil conditions, barrier-free design, existing view-shafts, signage and routes which have to be free for rescue teams. Here, research in law literature concerning evacuation of buildings can help to identify first benchmarks for outdoor regulations. The transport connection to safe areas and the means of transport available are also important. In a next step a spatial analysis follows, where neuralgic points and routes hindering a fast evacuation are identified. Serious deficits in the field of urban planning and design are revealed, which can be improved to assure an unhindered pedestrian flow. From the results of urban spatial and socio-psychological analysis, optimized escape routes are determined.

Socio-psychological analysis

At the Fritz Walter Soccer Stadium in Kaiserslautern 328 interviews with visitors were conducted in the run-up to two home matches of the local soccer club '1st FC Kaiserslautern' (1. FCK) in spring 2010. The interviews were carried out in short face to face interviews (5 to 10 minutes) using standardized questionnaires. The interviews deal with the visitors' perception of escape routes, their knowledge of the stadium and its surroundings, their information seeking behavior and preferred contact persons in case of emergency. Also included are aspects concerning shared arrival, like group size and companions attending the event. Interview participation was voluntary and analysis was anonymized. Most visitors showed great interest in taking part.

In addition, further findings on human behavior in emergency and flight situation were explored by literature research and studies about previous disasters. This expert knowledge is applied to an evacuation scenario of the soccer stadium in Kaiserslautern with regard to the local urban design characteristics. Evaluation occurs according to own experience (several observations of visitors going home after the end of the match) and the experience of the involved local security services.

4.2 Results

Urban design of the event's surroundings

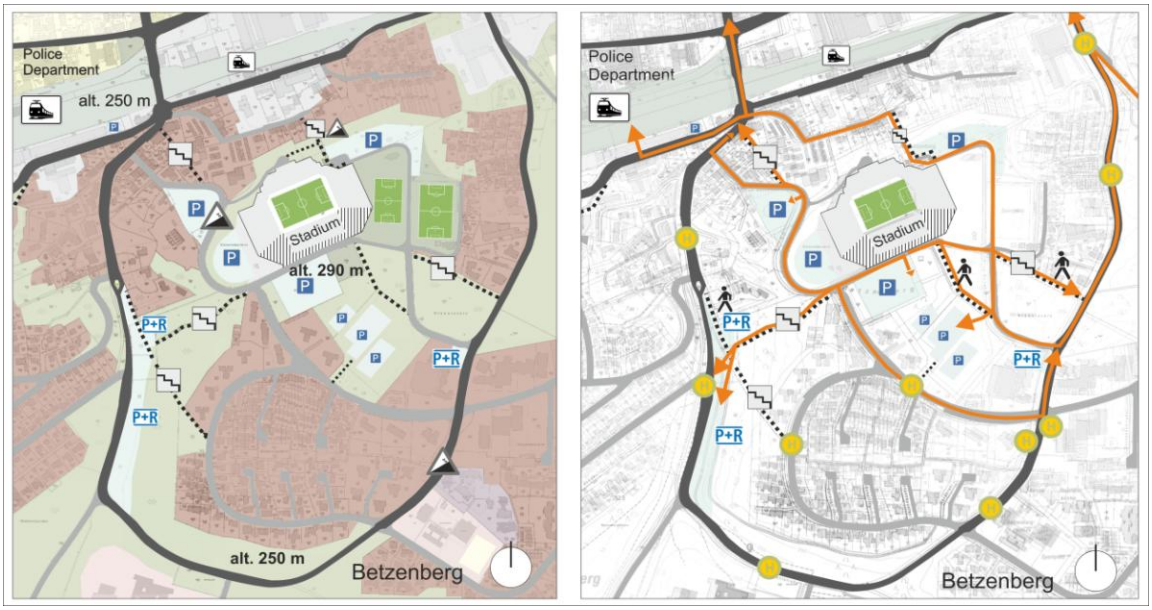

Fig. 2 and 3: Urban spatial inventory-taking and analysis (map not scaled) (own source).

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)

Main contents of the urban spatial inventory-taking (Fig. 2) are the basic traffic grid, the parking, the topography and the surrounding land-use type. The traffic grid is extremely branched, because the stadium is intimately connected with the residential neighborhood. There are no linear routes leading away from the stadium, so the existing view-shafts are limited. The different path widths, especially in the intersection from streets to footpaths, cause "bottleneck effects" (Helbing et al. 2000). Potential destination for a part of the crowd is the parking, which is widespread all around the research area. "Park & Ride" stops are also far away from the stadium (defined as pedestrian flow source), which gives the crowd a chance to disperse. That could help to prevent congestion or "clogging".

The spatial analysis (Fig.3) is geared to the situation after a soccer match and concerns itself with the terminating traffic of the pedestrians. The main destinations are the main train station, the city center in the North, the "Park & Ride" stops and also the parking in the stadium's surroundings. The pedestrians encounter many different path widths with different soil conditions. Especially in the context of stairs, there are more than a few bottlenecks. In a next step, the results of the urban spatial inventory-taking and analysis can be compared with findings in the human factor analysis.

Characteristics and behavior of the crowd

The study of crowd characteristics at the Fritz Walter Soccer Stadium reveals that most attendees of the soccer match visit the event in small groups of two to four people (63 %) or even large groups of five and more people (26 %). More than half of the interviewed visitors are accompanied by friends (58 %) and many interviewees said that they visit the soccer match in company of their partner (25 %) or other relatives (24 %).

Visitors, who attend the soccer match in company of others, predominantly travel to the venue in this group constellation (77 %). Even larger groups of five and more people travel to the stadium together (53 %; small groups: 84 %). Many visitors (48 %) solely use the car to get to the stadium, 34 % use train or bus and 10 % use a combination of car and park and ride bus. Three persons use one car on average. The quantity of people using the respective means of transport modifies the destinations for parts of the pedestrian flow. This may increase bottleneck effects at narrow places. Summing up, soccer fans rarely visit the event alone, but in small or larger groups. These groups will try to stay together if somehow possible as ties are strong and they are reliant on each other, e. g. for going home by car.

Visitors are highly familiar with the stadium and its surroundings for the most part (79 % do not need any maps or signs to get to the venue and 68 % characterize their knowledge of the place as "excellent" or "good"). Because of their high familiarity with the venue, it will be difficult for security staff to send them on alternative routes. Thus, definite instructions from the guidance staff and sophisticated urban design are all the more relevant.

The study shows that members of the event's security team obviously are the preferred contact persons if attendees have to ask for help. Present on location, clearly visible and accessible at any time (which is the case at soccer stadium), they are favored contact persons for visitors searching for help because of injuries (56 % would ask a member of event's security team for help when their companion got injured; instead of asking other visitors (16 %) or calling for help via mobile phone (26 %)). This is confirmed by Coellen (1992, p. 105), who showed that people in extreme situations look for somebody to get a better orientation. This could be a person nearby who takes over leadership of the group in the first moment. Normally, this would be an official person.

In addition, the study shows that in information seeking behavior there is clear preference in use of personal information. Being asked about an actual situation in which they have to seek shelter from their actual position, most visitors (72 %) in our study definitely prefer personal information (that means information about what to do or where to go communicated by other people) to signpost (23 %) or technical support (3 %).

Awareness of risk and potential danger is obviously increased: Many visitors (44 %) said that they pay attention to emergency exits and escape routes intentionally when they are visiting major events. The older the people the more they do so (17 to 25 year olds: 27 %; 46 years and older: 63 %). Almost as many of them (41 %) said that they stay near emergency exists as possible.

4.3 Combining analysis

After getting some insights in the urban spatial characteristics on-site and the specification of the relevant human factors, the merging of both is the next logical step. The most interesting results are identified neuralgic points and routes, where clogging effects and congestion arise (Fig.4).

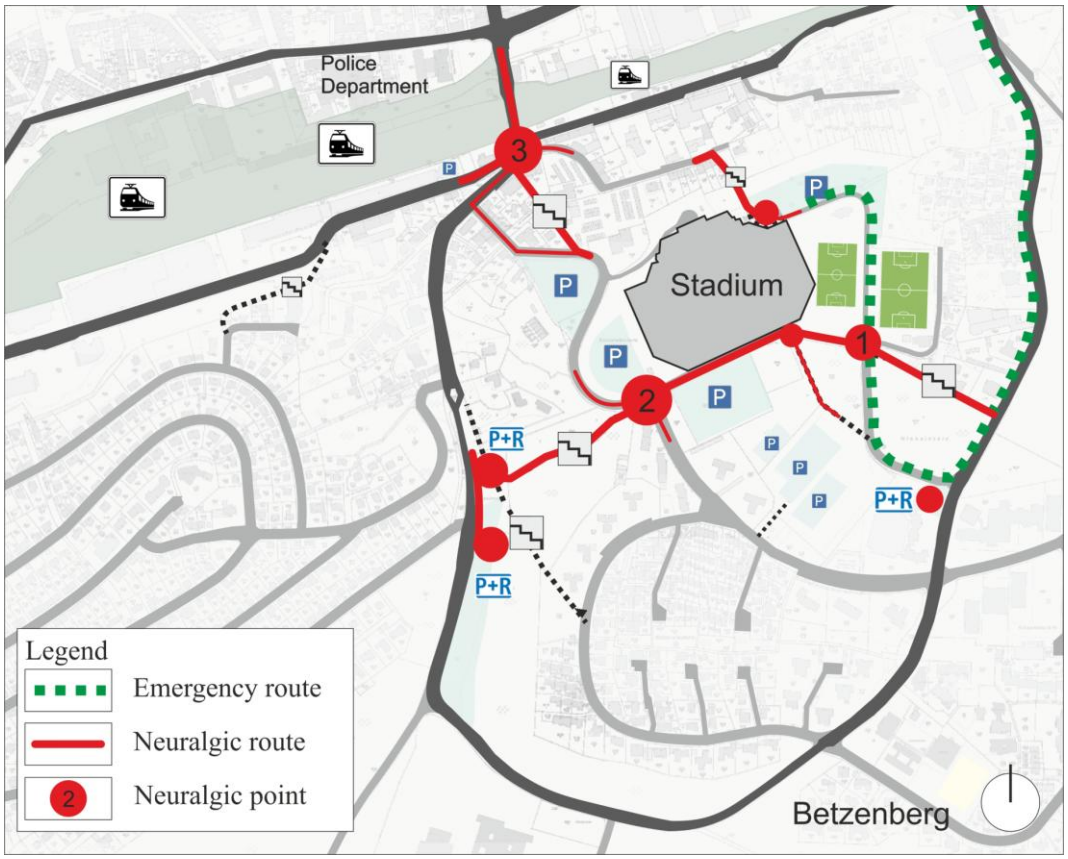

Fig. 4: Neuralgic points and routes (map not scaled) (own source).

These effects actually occur after every regular soccer match. In case of disaster, it is assumed that the effects will have much more fatal consequences. The reason is the lack of a good urban design in consideration of a large crowd moving to appointed destinations. But not only urban design plays a decisive role at these neuralgic points and routes. Also the crowd with its behavior and environmental perception, its composition of different group sizes and partly its unerring knowledge of the place is strengthening congestion and clogging effects.

A special case is the traffic routing of the emergency route, which should ensure fast access and departure of emergency vehicles. This route is crossed by a main pedestrian route in an eastward direction (neuralgic point 1). In order to keep the emergency route free of pedestrians, they have to be directed to the West. This causes more congestion at neuralgic point 2. Here is the most critical bottleneck (also at regular soccer matches) in the intersection from street to footpath. More than that, the footpath, at first slightly descending, gives way to long and steep stairs down to the Park & Ride stop. As consequence, the congestion spreads far into the adjoining streets. From the hitherto results of the influencing factors, an exemplary optimization is done (Fig. 5). With the help of guidance staff and signage the pedestrians find their optimal way to their destination. The guidance staff helps to organize an ordered pedestrian flow. More staff has to be positioned in the adjoining streets to split up the crowd. This aims for a more effective dispersion of the pedestrian stream. Furthermore, the existing foot path and following stairs can be widened without difficulty so that a higher quantity of people can take this path (green band). Consequently, the adjoining streets can be pressure reduced and balanced. Other aspects to be regarded are the visibility conditions in the evening after end of the match. Special lighting, like a traffic light system, can also be very helpful in guiding people safely away from disaster.

Fig. 5: Exemplary optimization of neuralgic point 2 (own source)

Also important is the situation at neuralgic point 3, where three different pedestrian streams come together at one choking point. In this area, where originally a traffic roundabout is situated, the streams are crossing each other, because the people are going to their main destinations: the train station and the city center.

5 INTERDISCIPLINARY APPROACH FOR OPTIMIZATION OF ESCAPE ROUTES

Essential factors influencing the crowd behavior in flight situations are identified and described in their consequences on pedestrian flow. It became clear that urban design aspects and human factors highly depend on each other. It is not sufficient to consider only one of them for a good planning of escape routes and improving evacuation. Figure 6 illustrates the combination of all identified aspects for a new approach for pedestrian evacuation planning.

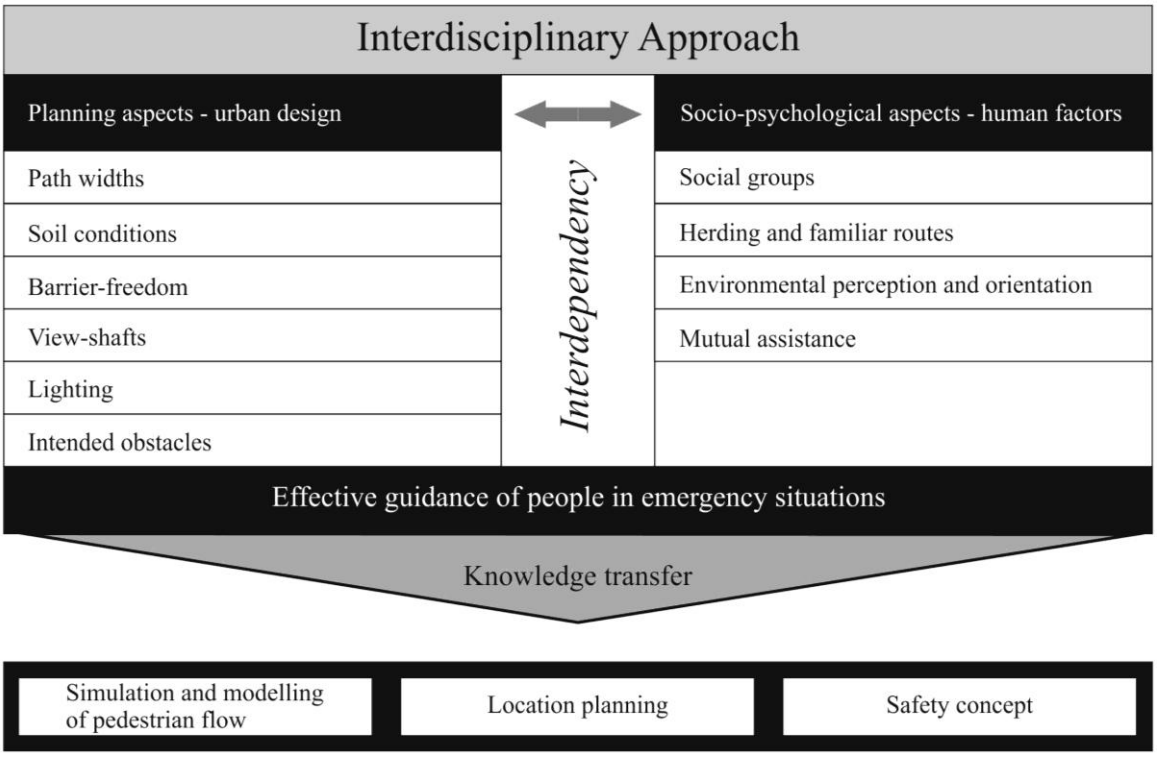

Fig. 6: Combining planning and socio-psychological aspects for interdisciplinary approach.

The combination of urban design aspects and human factors results in a definitely more effective guidance of people in emergency situations (as exemplary illustrated in figure 5). These findings can be transferred to research on modeling of pedestrian flows in computer evacuation simulation. Regarding human factors in simulation models, simulation of pedestrian flow becomes more realistic (Köster et al., 2011) and helps to identify neuralgic points, which can be optimized by urban planning intervention. Location planning of major events, including planning or modification of parking, access routes, positioning of security staff, etc. up to the elaboration of the event's safety concept, also benefits from this interdisciplinary approach.

Further research should consider more detailed the behavior of crowd and groups encountering obstacles and behavior in stress situations. Conditions of a spatially wide ranged evacuation should be regarded in events' safety concepts to more extent.

It became evident that the planning of escape routes and the effective use of these routes need a wide and holistic consideration – regarding human perception and behavior. Humans are in the focus of urban planning and design, so new approaches, including aspects of social psychology, are needed. This makes a contribution to a new holistic approach in the field of pedestrian evacuation planning.

6 ACKNOWLEDGEMENTS

We are grateful to the German Federal Ministry of Education and Research for the funding that made this work possible. We are also grateful to the event managers of Fritz Walter Soccer Stadium in Kaiserslautern for permitting interviews. We thank all attendees taking part in the interviews and last but not least all the interviewers for their help. Special thanks to Vanessa Platz for her engagement in the project.

Planning Emergence via Sustainable Partnerships in Urban Ethiopia

Tendayi Gondo

(Lecturer Tendayi Gondo, Department of Urban and Regional Planning, University of Venda, Private Bag X5050, Thohoyandou 0950, Limpopo Province, South Africa, gondotee@gmail.com)

1 ABSTRACT

The advent of Complex Adaptive Systems thinking has seen most urban planning authorities becoming relentless in adopting sustainable participatory approaches in strengthening their adaptive capacities for unforeseen events. To developing countries like Ethiopia, this view is based on anecdote rather than reliable empirical evidence. This analysis seeks to close the knowledge gap by evaluating the extent to which urban planning authorities are engaged in sustainable partnerships to boost their adaptive capacities under a climate change scenario. First a conceptual model for sustainable partnerships relevant to a developing country context is developed. Such a model is then applied. Finally, a number of factors that explain the adoption and / or non adoption of sustainable partnerships by some planning authorities are deciphered. Empirical evidence relate to a Delphi study conducted in 2009 in which 64 urban planners from 23 cities / town were surveyed. The binary logistic regression model was employed to decipher some of the factors that explained the adoption and / or non-adoption of sustainable partnerships by some planning authorities. Results reveal that adaptation efforts by most local authorities have not benefited much from forging of working partnerships at various planning scales. Both vertical and horizontal collaboration were found to be limited. Major hindrances included on one hand absence of credible participatory structures and on the other hand the general divide that exists between the environment and planning institutions. Efforts that strive to build proper participatory structures, bridge the current divide and reconcile science and practice would go a long way in fostering sustainable partnerships for improved adaptation.

2 INTRODUCTION

For years, partnerships between actors in environmental governance issues have formed a common means of providing infrastructure and services where state funds or expertise were found lacking (Forsyth, 2005). With climate change high on the agenda, recent years have seen this role expand. In addition to this traditional role, partnerships have now become sites where norms of climate change concern and political accountability are formulated and replicated. The need for such a much diversified role of partnerships has seen international groupings such as the United Nations (UN) calling for a greater adoption of partnerships in development policy through the Global Compact, Millennium Development Goals, and 'Type 2' partnerships proposed at the World Summit on Sustainable Development in Johannesburg in 2002. Perhaps the greatest and most visible manifestations of partnerships at work has been their role as means to overcoming some of the political standoffs in implementing global environmental agreements, such as the UN Framework Convention on Climate Change (1992) and its Kyoto Protocol (1997) - (Cosbey et al., 2005). Such a partnership discourse has often centred on climate mitigation at both the international and national planning scales (OECD, 2010). At the local urban scale, climate change partnership discourse has focused more on climate change adaptation issues (UN-HABITAT, 2008; Kharen et al, 2011).

The multiplicity of actors that shape and are affected by climante change outcomes has led to a renewed interest in the implementation of sustainable partnerships at the urban scale. Since climate change issues are increasingly viewed from the complex systems thinking lense – a new paradigm that sees the effects of climate change as so encompassing and far reaching, an integrated effort of governmental, non-governmental and private individuals and organizations is required (Nath and Behera, 2011). Such a partnership approach requires a comprehensive framework if coping with the effects of climate change are to become a reality. It is beleived that a much more cohesive and closely knitted approach from stakeholders is very important in underdeveloped countries where resource crunch is a major hurdle in the path to adaptation (Nath and Behera, 2011). Such a partnership stance is however underesearched and underdeveloped for most urban areas in developing countries (Mani et al. 2008). Yet most scholars agree at least in principle that a number of factors ranging from scientific uncertainty, through to the current state of technology, the availability of financial resources and short time horizons - which mostly constrain effective adaptive planning (Smit and Pilifosova, 2001; Lorenzoni et al., 2000a, b; West and Gawith, 2005; EEA, 2005; EU, 2007) can be overcome through the adoption of inclusive partnerships.

Such a limited research scope on the policy context of adaptation to climate change (Lim et al, 2005), has had a dent on efforts targeted at exporing best options aimed at enhancing longterm adaptive capacity of many urban local authorities (Lim et al, 2005; Niang-Diop and Bosch, 2005) – particularly those found in Africa. This paper assesses planning emergency via sustainable partnerships in urban Ethiopia. It specifically analyzes the extent to which urban planning authorities in Ethiopia are engaged in sustainable partnerships to boost their adaptive capacities under a climate change scenario.

2.1 Partnersips, climate change and urban planning

Partnerships for sustainable development (also called the UN-Type II partnerships) are voluntary, multi-stakeholder initiatives aimed at implementing sustainable development (Parthan et al, 2010). Most climate change partnerships are launched by governments and international governments. Such partnerships tend to be regional or global in scope and reach and are aimed at supporting the practical implementation of climate change initiatives as defined by the Intergovernmental Panel on Climate Change (IPCC), the United Nations Framework Convention on Climate Change (UNFCCC) and other related international groupings (Craik, 2011). Partnerships are considered both in principle and practice as innovative approaches that seek to overcome existing deficits in global governance regulation, implementation, and participation (Szulecki et al., 2010). The discussion of 'climate policy integration' through partnerships has however tended to focus on mitigation decisions mostly taken at the international and national levels (Urwin and Jordan, 2008). In the recent past, a number of such partnership initiatives have continued to be developed (refer to table 1) with little or no bearing on climate change adaptation decisions that are normally taken at the local scale.

Name of Partnership	Partners	Objectives/purpose
[1]The Earth Systems Science Partnership (ESSP)	A partnership that represent a concerted effort by DIVERSITAS, IGBH, IHDP, and WCRP	To enable a partnership that: (1) enables the community to identify and carry out research on scientific problems of high social and policy significance in a unified and integrative manner; (2) initiates and supports capacity building; (3) provides a high-level platform for effective engagement with stakeholders and the policy community; and, (4) facilitates efforts to ensure the continued vitality of the scientific enterprise
[2]The Renewable Energy and Energy Efficiency Partnership (REEEP)	Was established in 2002 by the United Kingdom (UK) government together with other committed governments, businesses, and NGOs	Established to deliver World Summit on Sustainable Development (WSSD) commitments made at the 2002 Johanesburg summit.
[3]The US Department of of Energy's Regional Carbon Sequestration Partnerships (RCSPs)	The seven partnerships include more than 350 state agencies, universities, national laboratories,private companies, and environmental organizations, spanning 42 states, two Indian nations, and four Canadian provinces.	The partnership was tasked with determining the most suitable technologies, regulations, and infrastructure for carbon capture, transport, and storage

Table 1. A sample of global partnerships on climate change related issues

It is therefore apparent that a more locally focussed adaptation dimension to climate policy integration has not been explored (Urwin and Jordan, 2008). There is therefore an urgent need to 'glocalise' partnerships so

[1] (Leemans et al, 2009)
[2] (Florini and Sovacool, 2009; Parthan et al, 2010).
[3] (Litynski, et al, 2009)

as to facilitate the effective implementation of adaptation decisions at the city or local scale. Such a focus on city level planning is not misplaced given that cities are (undoubtedly) centers of economic growth and population – a dominant feature that has seen them becoming a focal point of both climate change related risks and disasters and the solutions thereof. The OECD, (2009) has for instance advanced three reasons why climate change and adaptation policy should be redirected to municipal level planning. The first argument holds that climate change impacts are manifested locally, affecting city-wide systems (including, economic systems, livelihoods, infrastructure, water and so on). The second thinking holds that vulnerability and adaptive capacities are determined by local conditions. Finally, it is believed that adaptation activities are often observed at the local level and it is therefore easy to tailor actions to the specifics of a particular city (OECD, 2009; Gondo and Kori, 2012). A city based strategy therefore plays an instrumental role in shaping successful climate change adaptation practices.

Defining successful adaptation at all scales (regional, urban and local) is however complicated because the criteria for success are generally contested and context specific (Dessai and Hulme, 2007). It is however usually assumed that elements of effectiveness, efficiency, equity and legitimacy are important in judging successful adaptation (Adger et al, 2005). Many scholars however agree that a path towards sustainable partnerships can help realize such elements and subsequently smooothen the terrain for the achievement of efective adaptation (Schreurs, 2002; Mani etal, 2008; Huntjens et al, 2011; Nath and Behera, 2011). It is therefore imperative that, the workings of, and the interaction between city authorities (as an important arm of government) and other stakeholders be closely monitored if important climate change decisions are to be taken at the urban local scale. Such an expandend role of urban planning has been underscored by the Stern Review, (2008).

The Stern Review (2008) holds that market forces if left alone are unlikely to lead to efficient adaptation decisions. Public intervention is therefore necessary for many different reasons. The usually advanced aims and benefits of such public intervention include but are not limited to: (1) to protect those least able to cope by addressing the causes of vulnerability; (2) to provide information for planning and stimulating adaptation by non-state actors; and (3) to protect important public goods such as ecosystem services, public resources, land use and early warnings of extreme events (Tompkins et al, 2010).

2.2 Path to 'sustainable' partnerships

This analysis defines 'sustainable partnerships' as collaborative efforts that breeds a win-win situation for each of the stakeholders involved. If adaptation measures are to address the concerns of, and build on the latent energy from each of the stakeholders, then such measures are more likely to be sustainable. The OECD (n.d) contends that, with access to up to date climate science, impacts and vulnerability assessment, urban local authorities should work with other stakeholders to design and implement effective adaptation strategies. This according to Khare et al, (2011) can be achieved via the formulation of programmes and initiatives that benefit from the existence of an integrated continuous and long term strategy. Such conditions are however not yet present in most developing countries in Africa (Nath and Behera, 2011; Gondo and Kori, 2012).

Most programmes geared towards long term sustainability tend to be confronted by a number of significant hurdles. This is because each of the stakeholders has issues that tend to work against long term adaptive solutions (Kharen et al, 2011). To this end enlisting cooperation among climate change agents, before forging of working partnerships is crucial. Such a stance forms the hallmark of what has been referred to as 'co-operative environmental governance' (Glasbergen, 1998; Meadowcroft, 1998; Klausen and Sweeting, 2003). In climate change mitigation, co-operative governance has over the years sought to overcome the conflictual nature of negotiations through the creation of a positive negotiating space between climate change actors. At the urban planning scales, such co-operative governance may be deliberate in the sense that it permits local actors to participate in the identification and implementation of norms of climate change concern and political accountability to a variety of adaptation decisions taken (Klausen and Sweeting, 2003). Co-operative governance may make urban planning behaviours that seek to winnow the intricate, and often complex problems associated with actual and potential effects of climate change more functional. Not only will this help boost the adaptive capacities of concerned stakeholders to deal with actual and pending climate change challenges, but this could also increase the number of options by which this objective is achieved. Forsyth, (2005) beleives that co-perative governance facilitates this process by increasing local participation in deciding how investment decisions (in climate change adaptation) are made. Most partnerships based on

cooperative governance, however tend to be discurve in nature and run the risk of collapse due to challenges of fostering long term trust building processes (refer to figure 1).

Such challenges require knowledge, approaches and a much more localized understanding of the workings of such solutions that cannot be easily generated through co-operative governance, including all known forms of 'conventional' research programmes. A much more broader structure for climate change and adaptation is therefore required. Related efforts in environmental governance and / climate change issues have often identified forging of working partnerships between and among actors as the single most important approach to dealing with such challenges. Such partenerships may take avariety of forms as summarized in figure 1.

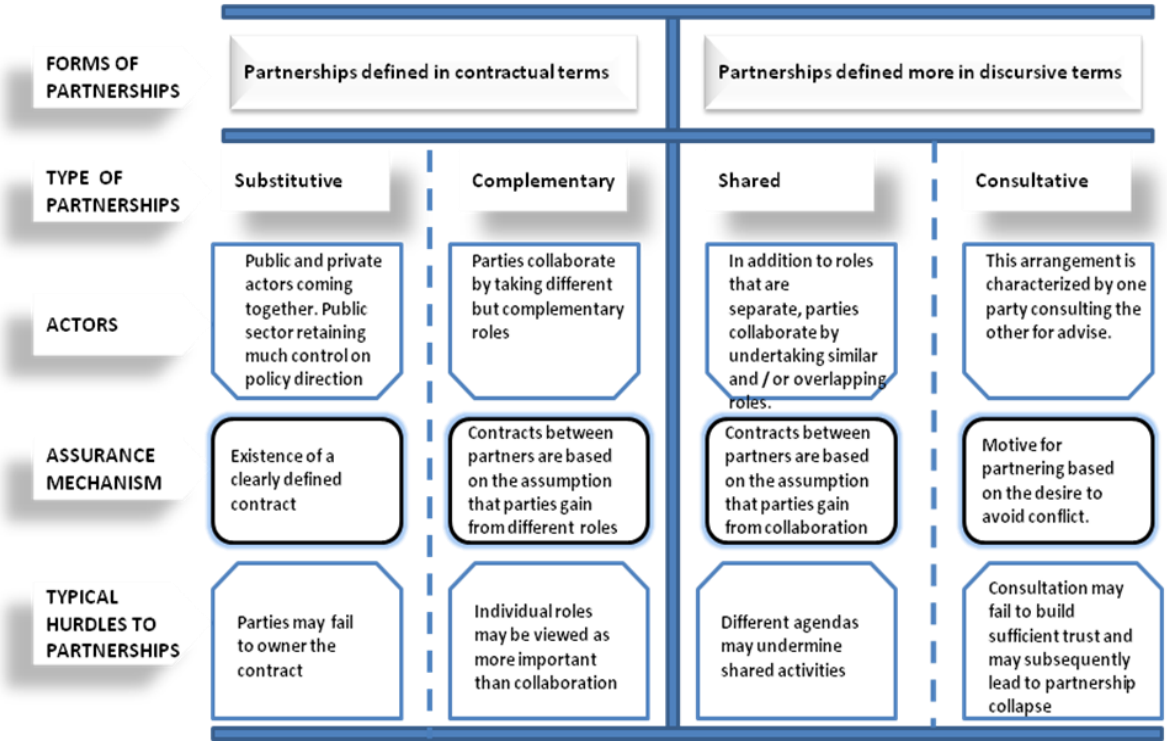

Figure 1. Forms of partnerships

According to figure 1, partnership forms are usually twofold. On one hand are discursive partnerships that often lack any contractual obligations on the part of stakeholders. Specific types include consultative and share partnerships. The other mode of partnerships include stakeholder arrangements defined by binding known contractual agreements. These are usually substitutive and complementary in nature. The path towards sustainable partnerships should be viewed as the gradual transition from consultative type of partnerships through to shared, complementary and finally substitutive types. A review of partinership discourse and practice in developing countries however reveals that such a transitional perspective is not complete. Based on a review of obstacles to climate change adaptation in developing countries, Nath and Behera, (2011) contend that adaptation policies work best when climate changes initiatives help create synergies with other goals and policies. Such a move towards integration has been mooted by policy makers and other societal actors who beleive that the policy and or partnership context in which adaptive decisions are made must also be considered (see Burton et al., 2002; Lim et al., 2005; EU, 2007). Such thinking has also been taken up by the United Nations Development Programme which recently investigated how to integrate climate change into all strands of policy making in ways that support adaptive planning (Lim et al., 2005).

Drawing on the different forms of partnerships ranging from discursive through to contractual forms of partnerships and integration, three important levels – including cooperation, co-ordination and integration may be defined as important phases that can define the path towards sustainable partnerships for city authorities in developing countries. A simplified version of this conceptual model is given in figure 2.

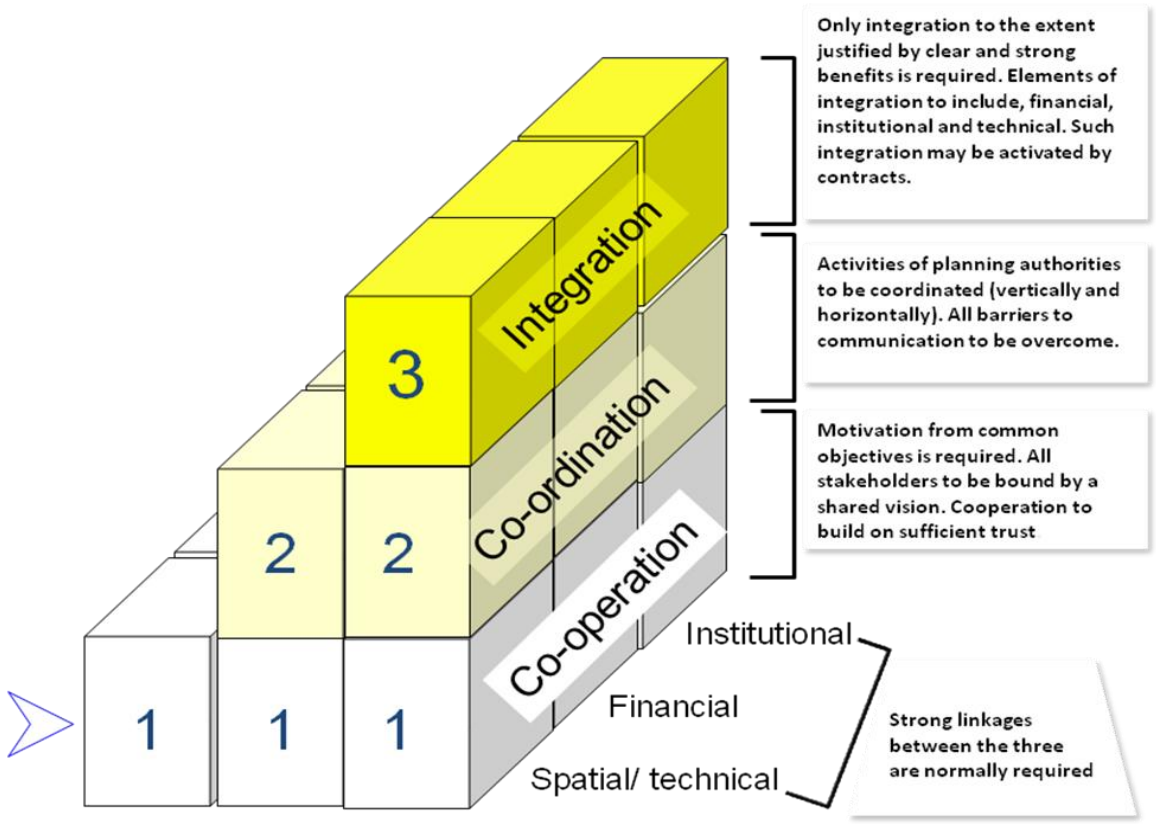

Figure 2. A conceptual model to understanding partnerships for climate change adaptation in developing countries.

2.3 Obstacles to 'sustainable' partnerships

Most urban planning authorities in the West are becoming relentless in adopting sustainable participatory approaches in strengthening their adaptive capacities for unforeseen events. As argued earlier on, such adaptation practices have been more visible at the national scales rather than the local scales. At the local scale, there exists a multutude of challenges that limit planning emergency via sustainable partnerships.

Khare et al, (2011) for instance observe that most city programmes and initiatives respond to climate change in the absence of any integrated, continuous and long-term strategy. Available empirical evidence on stakeholder involvement in environmental governance issues from elsewhere suggest that collaboration happens incrementally rather than systematically. Most research scholars have argued that most stakeholders partcipate in socially responsive activities when it serves their self centred interests (Bird and Hughes, 1997; Ferrarini et al, 2001; Pickett-Baker and Ozaki, 2008). Lack of will to engage in partnerships is one other limiting factor often mentioned. Some political scientists for instance have argued that the political implications of partnerships outweigh the potential benefits of enacting environmental policy (see Osbourne, 2000; Rosenau, 2000). Some critics have argued that forging partnerships with the private sectors poses important contadiction to the principles of climate equity. The usual line of argument is that such partnerships weaken environmental regulation through processes such as 'regulatory capture' – a situation where policy makers represent the interests of investors at the expense of poor communities (Gouldson and Murphy, 1998; Singleton, 2000).

Using partnerships as a functional means to implementing climate change and adaptation policy has been viewed by some as a neo-liberal attempt to 'hollowing out' the role of the state. This has often been viewed as a new trend towards 'New Public Management.' Such a 'new' trend has often been blamed on the grounds that it reduces public space for governing the provision of essential services – a sitiuation that subsequently erodes the democratic accountability of local governments (Rhodes, 1996; Skelcher et al, 2003; Forsyth, 2005). A much more developmental perspective to climate change partnerships at local level suggests that implementing partnerships without critical attention to questions of participation and governance may result in policy that is not pro-poor (Evans, 1996; Fischer, 2003).

2.4 Climate change In Ethiopia

Despite the economic reform made after the political change in 1991 that brought significant improvements in the economy, Ethiopia is still one of the least developed countries (LDCs) in the World (MoFED, 2006). This development status makes the country more vulnerable to climate variability and change. Climate related hazards in Ethiopia include drought, floods, heavy rains, strong winds, frost, and heat waves (high temperatures) among others (NAPA, 2007). The much broader environmental concerns that have attracted interest from government, the private sectors, Non-Governmental Organizations and international donor agencies include land degradation, soil erosion, deforestation, loss of biodiversity, desertification, recurrent drought, flood and water and air pollution (NAPA, 2007). Going into the future such concerns are likely to deepen as temperatures and rainfall amounts are projected to surge. For the IPCC mid-range (A1B) emission scenario, it is projected that the mean annual temperature will increase in the range of 0.9 -1.1 °C by 2030, in the range of 1.7 - 2.1 °C by 2050 and in the range of 2.7-3.4 °C by 2080 over Ethiopia (Figure 3) compared to the 1961-1990 normal. A small increase in annual precipitation is also expected over the country. Higher temperatures in Ethiopia have potentially serious impacts on the lenth of growing season (for crops), the aridity of the soil, the risk of deaseses such as malria and dengue, and the timing and the intesity of rainfall. At the national level.

Owing to their potentially damaging impact to both rural and urban communities climate change issues have become a high government priority through the National Adaptation Programme of Action (NAPA). The National Adaptation Programme of Action (NAPA) is a mechanism within the UNFCCC, designed to help the Least Developed Countries (LDCs) including Ethiopia to identify their priority adaptation needs to climate change and to communicate these needs to the Conference of Parties (COP) of the UNFCCC and other concerned bodies. I addition, the Ethiopia has already put in place policies, strategies and programs that enhance the adaptive capacity and reduce the vulnerability of the country to climate variability and change. Such programs include Plan for Accelerated and Sustainable Development to End Poverty (PASDEP), Environmental Policy of Ethiopia, Agriculture and Rural Development Policy and Strategy.

3 MATERIALS AND METHODS

Empirical evidence presented relate to a Delphi study conducted in 2009 in which 64 urban planners from 23 cities / town were surveyed. The proportion of the sampled officials from each city / town is shown on figure 3. The share of each city / town reflects the number of completed questionnaires that were returned.

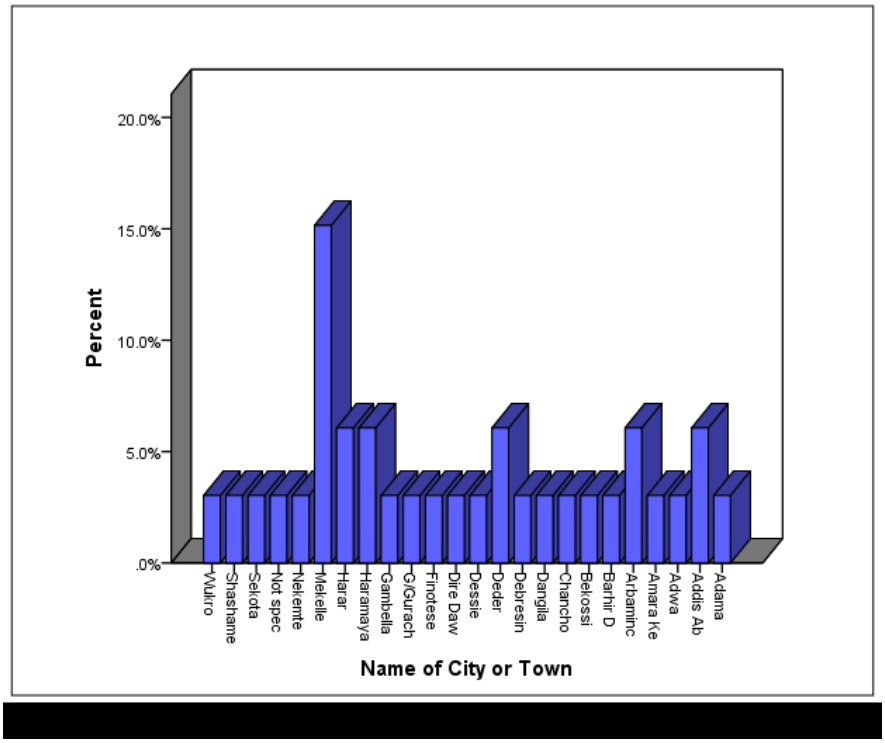

Figure 3. Sample charcteristics

The binary logistic regression model was employed to decipher some of the factors that explained the adoption and / or non-adoption of effective partnerships by some planning authorities. Data analysis was performed using the Statistical Package for Social Scientists (SPSS).

3.1 Empirical model specification

The logistic regression model was applied to determine factors that explained why some urban planning authorities engaged in sustainable partnerships in response to actual and / or potential climate change threats. When dealing with a dichotomous dependent variable - the main interest is to assess the probability that one or other characteristics is present (Peng and So, 2002; Peng et al, 2002). The logistic regression model answers the question what determines the probability that the answer is yes, or no. The special features of the model guarantees that probabilities estimated from the logistic model will always lie within the logical bounds of 0 and 1. In other words the probability that a municipality picked at random is engaged or not engaged in sustainable partnership is not a continuous variable but a discrete one. The logit regression model can be expressed mathematically as follows;

$$Y = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + \cdots + \beta_n x_n + ui$$ Where;

Y=is the dependent variable (i.e. probability that a municipality chosen at random is engaged or not engaged in sustainable partnerships to dealing with actual or potential climate change impacts).

B_0=is the intercept (constant) term

B_k=coefficients of explanatory variables

X_i=explanatory variables

The aggregate expression of the model can be summarized as follows;

$$Y = \beta_0 + \sum_{k=1}^{k} \beta_i x_i + ui$$

Any municipality that had its climate change and adaptation activities linked to other stakeholders through cooperation, coordination or integration of activities and policies was defined to be on the path towards sustainable partnerships. The selection of predictor variables is based on the review literature on major limiting factors to effective parnerships. Model variables were therefore defined as follows;

Y=Probability of an expert drawn from a municipality that is engaged in sustainable partnerships (i.e. probability Municipality / engaged in Partn.=1)

X1=Perceved level of financial capacity (1=better; 0=poor)

X2=Perceived benefits of partnering (1=Yes; 0=No)

X3=Perceived level of technical capacity (5 point likert scale: 1=poor; 5=Excellent)

X4=Perceved level of climate science integration in municipal affairs (5 point likert scale: 1=poor;5=Excellent)

X5=Level of uncertainty about climate policy context (5 point likert scale: 1=low; 5=high)

X6=A general concern for the poor (5 point likert scale: 1=lowest score; 5=highest score)

X7=Perceived level of institutional capacity (0=better; 1=poor).

3.2 Model evaluation

Parameters in logistic regression model were estimated using the maximum likelihood method. The statistical significance of each coefficient was evaluated using the Wald test. The enumerated regression coeficients represent the change in the logit of the probability from a unit change in the associated predictor, assuming other factors are constant (Gujrati, 2003). The goodness-of-fit test of the regression model in this study was analyzed using;

- The Omnibus test, which is a likelihood ratio chi-square test that test whether the coefficients of the variables in the model are all jointly equal to zero.

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

- The Hosmer & Lemeshaw (H-L) goodness-of-fit test, which examines the null hypothesis that the model adjust well to the data and
- The Cox and Snell (1989) and Nagelkerke (1991) – two descriptor measures that reveal the amount of variation in the outcome variable that is explained by the models (Long, 1997; Hosmer and Lameshaw, 2000).

The inferential goodness-of-fit test employed is the Hosmer & Lemeshow (H-L) test that yielded a Chi-square (7 degrees of freedom) of 8.474 and was insignificant ($p > 0.05$) suggesting that the model fitted to the data well. Two other descriptive measures of goodness of fit are R2 indices defined by Cox and Snell (1989) and Nagelkerke (1991). Results suggest 43.1 to 63.6% of variations in the outcome (i.e. the probability of a municipality beeing engaged in sustainable partnership) can be explained by the model predictors.

4 RESULTS

Results suggests that 26% of the sampled municipality can be characterised as being on the path towards sustainable partnerships. Such partnerships were however found to be limited to discursive arrangement that existed between the concerned municipalities and largely unorganized community groupings, the private sector, and to some extent the respective regional governments. Such partnerships were generally on the lower end of the path towards sustainable partnerships. They are mostly cooperative partnership arrangements that are based on what other scholars refer to as 'reactive' adaptation rather that 'proactive' adaptation to climate change. No evidence of contractual agreements through such means as the signing of MOUs were discerned. More disturbing to find was the general lack of collaboration between municipalities and environmental agencies such as the Meteorologiocal department, the disaster management unit, the private sector and other civic organizations. The separtion between planning and environmental planning institutions has often meant that activities of the National Urban Planning Institute (NUPI) – a professional body of planners and those of the Environmental Management Agency (EMA) have been running parallel with little or no foreseable signs of integration. This alone has been regressive to building adaptive capacity for many municipalities. Many reasons to constrained partnership arrangements between the municipalities and other chief actors were deciphered (refer to table 2).

Variable	B	S.E.	Wald	df	*p-value*	Exp(B)
Financial capacity	.091	2.408	.001	1	.970	1.095
Perceived benefits	.839	.546	2.365	1	.124	2.314
Technical capacity	-.581	.714	.662	1	.416	.559
Climate science integration	2.422	.991	5.975	1	.015	11.263
Uncertainty about the climate policy context	-.396	.546	.525	1	.469	.673
A concern for the poor	-2.617	1.172	4.987	1	.026	.073
Institutional capacity	-4.231	1.714	6.090	1	.014	.015
Constant	4.305	3.413	1.591	1	.207	74.043

Table 2. Predictor variables for engagement in sustainable partnerships

The ability of the sampled municipalities to engage in sustainable partnerships varied according to a number of variables. The positive Beta parameter on financial capacity (i.e. $\beta=0.091$) means municipalities that were perceived as finacialy better were 1.095 times (i.e Exp [B]=1.095) more likely to be engaged in sustainable partnerships than those who had poor financial capacity. Such a finding was however not statistically significant (p-value > 0.5). Perceived benefits in engaging in sustainable partnerships were also found to be another important factor ($\beta=0.839$; p-value=0.124). Municipalities that did not perceive real benefits from engaging in sustainable partnerships were 2.314 times less likely to engage in such arrangements.

The negative Beta estimate on technical capacity means that municipalities that were perceived as better equipped technically were 0.559 times less likely to be engaged in sustainable partnerships. Such results were however insignificant (p-value > 0.4). On the contrary, municpalities that had a much better level of

climate science integration in own affairs were 11.263 times likely to be engaged in sustainable partnerships. Such findings were significant ($p < 0.05$).

Although such results were insignificant (p-value > 0.1), municipalities that were characterised by an uncertain climate change policy context, were less lekely to engage in sustainable partnerships. On the other hand a general concern with the poor and the more vulnerable urban communities was found to be a significant factor in explaing municipal attitude towards sustainable partnerships. Study results revealed that municipalities exhibiting such a concern were 0.073 times less likely to engage in sustainable partnerships than those that had a much lesser concern (β= -2.617; p-value < 0.05). The negative Beta estimate on institutional capacity reveals that municipalities that have a relatively better institutional capacity are more likely to engage in sustainable partnerships than those whose institutional capacity is weak. This is because better institutional capacity was coded 0, while poor institutional capacity was coded 1. This results were significant (p-value < 0.05).

5 DISCUSSION

The ability of munipal authorities in Ethiopia to adapt to climate change, and implementing adaptation decisions (i.e. transforming that capacity into action) has been constrained by the absence of credible partnership between the planning authorities and other key actors – including environmental agencies, local community groupings and the private sector among others. Similar observations on constrained partnerships have been made in other developing countries (Mani et al. 2008; Nath and Behera, 2011).

In the absence of sustainable partnerships it is increasingly beleived that most city authorities lose out from further mutual learning between scientists and stakeholders, new opinions, sharing of technical expertise, and the the generation of compromise solutions against actual and / or pending climate change impacts (Renn, 2006; Ceccatop et al, 2011). This analysis revealed that the majority of municipalities in Ethiopia are constrained in terms of their technical, financial, institutional capacity and a general lack of access to climate science. While other studies have revealed that the existence of knowledge, capacity and resources to undertake adaptation, is not a guarantee to taking action (Hanemann, 2000; Moser, 2009; Repetto, 2008), this analysis has revealed that municipalities that are constrained by such attributes were not engaged in sustainable partnerships. On the contrary, those who were better positioned in terms of climate knowledge, technical, financial and institutional capacities were found to the on the path towards sustainable partnerships.

Lack of access to climate science, weak institutional capacity and a general concern for the poor were three most significant activities that defined whether the municipality is engaged on not engaged in sustainable partnerships. Uncertainty over climate science information interfers adaptation decsions and can stymie local authority involvement in sustainable partnerships. It is also important to note that, other stakeholder groups such as NGOs, community groupings, environmental related groups and the business community, can play a decisive role in determining climate change related policy outcomes through their interaction with policy makers and urban local authorities in a partnership environment (Broadbent, 1999; Schreurs, 2002; Mani et al, 2008). The weak institutional capacity that charcterize the bulk of municipalitiers in Ethiopia has often meant such a decisive role has never been a reality for many. Major symptoms of such weak institutional capacity include absence of credible participatory structures and weak communication lines – factors that have seen municipalities failing to harness the advantages associated with horizontal and vertical collaboration with other key climate change actors.

Most partnerships are bound together by a general concern for the poor. It is largely beleived that an active and organized civil society can play the role of driving force to lead governments and / or municipal authorities to implement responsive adaptation policies (Kelkar et al, 2008; Nath and Behera, 2011). Interestingly, this analysis revealed that municipalities that had a general concern for the poor and most vulnerable communities were not engaged in any form of partnerships. Perhaps it is the general fear of losing control over the plight of the most vulnerable groups that have seen some municipalities going solo on climate change adaptation issues.

If adaptation decisions are to be successful, there is an urgent need for municipal authorities in Ethiopia to engage in deliberative participatory activities aimed at winnowing the most complex problems associated with climate change. It is the contetion of this study that further mutual learning between scientists and

stakeholders can be promoted, new opinions can be expressed, problems can be addressed, technical expertise shared, agreements reached, and compromise solutions found if all vested interests are voiced (Renn, 2006). Stakeholders' involvement is also essential, because stakeholders hold the necessary information that could facilitate the exploitation of scientific knowledge with high social relevance (Forsyth, 199; Griffin, 2007; Reed, 2008).

6 CONCLUSION

The advent of Complex Adaptive Systems thinking has seen most planning authorities around the world becoming relentless in adopting sustainable participatory approaches in strengthening their adaptive capacities for unforeseen events. To developing countries like Ethiopia, this view is based on anecdote rather than reliable empirical evidence. The analysis has revealed that participatory decisions have largely dominated the international and to some extent national agendas, with little or no evidence of collaborative effort at the much more local urban scale where most climate change and adaptation decisions are taken.

Using a delphi study that pitted 64 urban planners from 23 cities and / towns of Ethiopia, the analysis revealed that adaptation efforts by most local authorities have not benefited much from forging of working partnerships at various planning scales. Both vertical and horizontal collaboration were found to be limited owing to weak technical, financial and institutional capacities of the concerned municipalities. Major hindrances included on one hand absence of credible participatory structures and on the other hand the general divide that exists between the environment and planning institutions. Efforts that strive to build proper participatory structures, bridge the current divide and reconcile climate science and practice would go a long way in fostering sustainable partnerships for improved adaptation.

7 ACKNOWLEDGEMENTS

The author would like to acknowledge the views shared by a smaple urban planers and / or managers drawn from 23 cities and / towns of Ethiopia. The author also acknowledges the institutional support rendered by the Ethiopian Civil Service University (ECSU) under its World Bank funded Urban Management Masters Programme (UMMP). However, the views expressed here are of the author and not necessarily of the supporting institution (s).

Planning Re-Mixed: Conceptual Framework of New Planning Ideas

Izabela Mironowicz, Derek Martin

(Derek Martin, International Federation for Housing and Planning, Binckhorstlaan 36, M04-03, 2516 BE The Hague, The Netherlands, d.martin@ifhp.org)
(Dr. Izabela Mironowicz, Wrocław University of Technology, Faculty of Architecture, 53/55 B. Prusa Street, 50-317 Wrocław, Poland, izabela.mironowicz@pwr.wroc.pl)

1 ABSTRACT

Modern planning as an autonomous research discipline, practice and education is celebrating its centenary. In 1909 the first modern legal act – Housing and Town Planning Act came into force in the UK. In the same year the first courses in planning began at the University of Liverpool and Harvard University. For the first time in history the concepts of and for the cities as the spatial response for urgent social needs emerged (garden city, ciudad linear, ville sociale). Royal axes and theoretical geometrical solution were no more relevant to the social and economic problems generated by urban growth. Interesting is that all these new complex concepts were proposed not by architects (traditionally involved in the process of urban design) but by social activists, enlightened philanthropists, progressive politicians, new professionals or even more far-sighted industrialists. Inter- and multidisciplinarity of planning as well as planning as a new profession have come into existence.

One hundred years on, cities again have to face challenges that in a number of fundamental ways are not dissimilar to when planning was first established – the liveability of cities, the quality of life, social cohesion in neighbourhoods, functional and green public spaces, healthy cities, affordable housing. The nature of the problems and the specific issues and challenges are, however, vaster, more complicated and essentially different due to not only size and complexity of the cities but also social demand for better life in the cities.

Society has become complex, is changing fast and unpredictably. Technology is speeding up. The economic and financial crisis is dominating thinking and policies. Cities have to adapt; planning has to adapt. The realisation of this major challenge amongst planners and city governments is now quite widespread. We see a variety of slogans: healthy cities, green cities, sustainable cities, intelligent cities, smart cities, resilient cities, eco-cities, low-carbon cities… Are these planning policy visions, urban concepts, diagnostics, socio-political statements, implementation strategies? Do they provide a real frame of reference to actually tackle the problems? Are they being proved useful or do we have to knuckle down and actually ask ourselves what we as planners need to do to adapt our discipline to face the challenges that face our cities.

Today planners cannot offer prêt-à-porter urban concepts – like garden city; today planners have to place the debate about new ideas in the wide cultural – social and economic – and institutional context. The crisis is evident. But the solution must be different.

How can we channel and structure this debate? How do we avoid having far-reaching intellectual debates and not reaching any particular and implementable conclusions? How do we identify and collect the good new, innovative ideas?

This paper offers an integrated conceptual framework that actually identifies the areas of new thinking necessary to adapt planning to its present-day challenges. It offers a structure, a matrix in which a number of phenomena and processes which have become so influential and omni-present in modern-day society are set against three frames of reference fundamental to the professional world of planning.

The present-day phenomena and processes are: time, knowledge, information and education, the paradigm shift, complexity, uncertainty, networks and others.

The three frames of reference are:

- the independent cultural and social background context that influences cities by the very norms and values it produces,
- space/territory itself and processes which we can observe using that space/territory,
- planning itself and planners .

If we represent the frames of reference as the columns of the table and the phenomena and processes affecting and shaping them as the rows of this matrix, we can identify the areas in which new planning ideas

need to be developed and also initiate a description and analysis of such new planning ideas in the context of processes that shape them.

The paper offers an integrated conceptual framework that actually identifies the areas of new thinking necessary to adapt planning to its present-day challenges.

There are three frames of reference we would like to consider:

- independent cultural and social background context that influence cities by the values it produces,
- space itself and processes which we can observe in the space,
- planning and planners.

Each of these frames of references is intersected by the phenomena and processes affecting and shaping them. These phenomena and processes determine cutural and social background, space itself and planning. These phenomena/processes are i.e.: time, knowledge, information and education, paradigm shift, complexity, uncertainty, networks and others. If we represent frames of reference as the columns of the table and phenomena and processes as the rows of this table we could locate planning ideas and their wider context in the matrix. This matrix would allow us to describe and analyse planning ideas in the context of processes that shape them.

2 INTRODUCTION

It is worth noting that it has been one hundred years since modern planning has been considered an autonomous discipline of knowledge, practice and education. The world saw its first coherent, modern act of law concerning planning in 1909, when the Housing and Planning Act was passed by the British parliament. In the same year, the first teaching programmes in planning were started at Harvard University in North America and the University of Liverpool in Europe.

The industrial revolution, the abrupt urbanisation and the development of transport, which all happened in the 19th and 20th centuries, gave birth to social problems unheard of before. Obviously, the problems were rooted in space, where axes of the changes crossed. The issues implied here required interventions in a scale that had never taken place earlier – interventions which were necessary and urgent. In other words, someone had to start managing the spatial processes with social and economic factors in mind, not only as "royal grand axis" designs, but with tens of thousands of people in regard.

That need became visible not only in legislation or education; it also produced a number of professional organisations, especially in Europe: Town and Country Planning Association (TCPA, 1899), Société Française des Urbanistes (SFU, 1911), International Federation for Housing and Planning (IFHP, 1913), Royal Town Planning Institute (RTPI, 1914), Towarzystwo Urbanistów Polskich (Society Of Polish Town Planners, TUP, 1923).

Holistic concepts of cities also began to appear, much removed from the ideal geometric designs of earlier times, looking for a spatial answer for various social problems (garden city, ciudad linear, ville sociale). Very interestingly, these concepts did not come from architects, but from social activists, business people or philanthropists. Inter- and multidisciplinarity of planning, and the new profession, became a fact.

A century later, our urban problems are not fewer, on the contrary: they seem larger and even more urgent. The reason for that is not only the size of cities, in which (as we are constantly being reminded) already more than half of the population of the Earth lives, but also from the complexity of the issues we are facing. That complexity is not only due to technological changes, but also social ones, ones we tend to dismiss as unimportant because we perceive them as natural and obvious. Let us remember, however, that a hundred years ago, in 1912, women had the right to vote only in five countries: the USA, New Zealand, Australia, Finland and Norway. In many European countries, which today claim to be cornerstones of democracy, such a fundamental element of citizenship was introduced as late as after World War II (e.g. France – 1944, Italy – 1945, Belgium – 1948, Greece – 1952, Switzerland 1971, Portugal – 1976). Poland, by the way, does not stand badly in this ranking, having granted women the right to vote in 1918, directly after regaining independence, a year later that it had been introduced in the Netherlands. Moreover, rights to such basic amenities as health care, education or social security, in the form that seems unquestionable to the modern, rich (despite the crisis) citizens of Europe, were reserved to the sphere of imagination. A hundred years ago, the challenge for Europe was to provide shelter and elementary level of hygiene.

Today, in spite of incredible technological progress, even in the advanced and civilized Europe illiterate and homeless people can still be found. It is not them, however, who pose the biggest challenge. Just as a hundred years ago the situation arose due to changes in quantity (population, transport modes etc), now the urgent need for intervention is caused by the changes in quality of the many facets of life.

Nowadays, people demand healthy cities, which offer opportunities for personal development and a good life. Are we – as planners – able to provide them with that? Are we able to see both the perspectives and threats in front of our profession and its public mission? Are we able to cure the disease, which troubles modern planning? And most of all – are we able to diagnose it in the first place?

We discuss many ideas for cities. Such terms as "low-carbon cities" or "resilient cities" are attempts to find solutions to some of the burning problems of modern urban reality. At the same time, a number of bottom-up ideas, such as the "slow cities", not inspired by planners, but by the citizens themselves in the drive to define their own lifestyle and their expectations for cities.

Parallel to that discussion, we are going through an institutional crisis of planning. On the one hand, politicians (and politics is a crucial component of planning) tend to reveal at present the FROG syndrome ("First Restore Our Growth"), treating planning as an obstacle on the way to grow economies and fight the crisis. They fail to ask the question, however, whether growth is identical with progress/development, or, to be more precise – with improving the quality of life. On the other hand, urban communities see little sense in heavily bureaucratic procedures in planning and tend to see it as a large set of rules, which limits their freedom to operate in space. In a way, planners lost their credibility. No one remembers that the very goal of planning is to raise the quality of life by a rational management of space; that planning concerns the spatial dimension of civilization and therefore culture. Everybody sees technocratic procedures and limitations, a façade of consultations which no one cares about and a dismissive and paternalistic (patronizing?) approach to "unprofessional ideas". Nowadays planners act frequently as surgeons do, operating on a patient regardless of whether the patient wants that or not, all while he or she is still quite conscious.

It is obvious that it is today impossible to come up with a ready-made product, like Ebenezer Howard did with the garden city a century ago. We now must locate the discussion on planning ideas in a wider territorial, civilizational, cultural and institutional context. What we have in common with the situation from a hundred years ago is the apparent crisis; its sources and character are vastly different though. Thus, the solution must be different as well.

3 THE MATRIX

In order to discuss ideas for cities today, one needs to keep in mind three frameworks of reference.
