Firstly, one must consider the civilisational and cultural background, which produces values that influence our perception of cities and our "making" (or "creating"?) the cities. These values are not absolute, they are a product of our social development, and that, in turn, is obviously conditioned by our cultural, technical and economic development. If Jacqueline Beaujeau-Garnier and George Chabot can be agreed with (and we tend to do so) when they claimed the city to be an image of the civilisational system and its representation, then there is little doubt left that planners ought to not only recognize, but also anticipate civilisational trends. Without them the city is nothing but a body of buildings and infrastructure. If culture and, more broadly speaking, life as such is not behind them, then it is not a city that is in question, but some other spatial entity. An example of such phenomena are the abandoned ancient cities in South America, which can now be labelled as a sort of "witnesses of history". By the way, it may be worth noting that perhaps due to the lack of the civilisational background the functioning of the ideal cities – all the way from the Renaissance to the New Towns – is burdened with some hard to define, but easy to see, disability.

Secondly, we must describe and understand the state of the city as it is. In many modern ideas of urban studies/planning, it is difficult to tell whether they are a description of facts or a scenario of development. A diagnosis is an important element in searching the solution for the future, even if we understand that it had happened in history that good solutions were found without a deep understanding of the functioning of a city (but always with good anticipation of the trends). Unfortunately, taking into account the complexity of modern urban systems, we should not be counting on such luck. We should also not be discouraged by the fact that in the future cities will be different than today. If there is one stable feature of cities, it is their constant changing, the transformation. We should rather build knowledge and search for tools to help us

create possible scenarios for the future. These, in turn, require understanding not only the physical from, but especially the processes and phenomena, which shape them. Additionally, we should take into account the fact that it is not easy to conduct an experiment – we have no choice but to work the living body of the city and touch on the everyday lives of its residents and all kinds of "users". Our responsibility is great. We cannot return the lost time or life to anybody, nor can we return the worsened quality someone experienced due to a bad urban decision. In other words, we do not have the comfort to be wrong very often.

Thirdly and finally, there is the context of planning as such. What does our profession and we planners, see as opportunities and limitations? What role do we see for ourselves in the changing world? How do we react to reality and what tools do we have to influence it?

Each of the three frameworks of reference is crossed by the axes of phenomena or processes, which influence and/or shape it in a way. These processes and phenomena are an important determining factor and a background for the broad civilizational/cultural context, for the cities, and for planning itself.

If we imagine that framework of reference (civilisation, cities, planners) as columns in a table, and processes and phenomena as rows, we will get a matrix, in which planning ideas and its broader context are included. The described backbone will also allow us to trace the context and the meaning of planning ideas more easily against the background of more general phenomena, which in fact shape them.

3.1 Axis 1: Time

On the civilizational/cultural level we can see the clash of two opposite trends. On one side there is the ever-present in the second half of the 20th century tendency of "do it faster", "make it better", "earn more", "reach a higher level". For example, with the life expectancy extending we try to get to subsequent thresholds of education and career earlier than ever in history (PhD for 26 years old researchers). Meanwhile, a bottom-up movement of "live slower, enjoy life", concentrated on quality, not quantity, is growing and gaining strength. Some cultures have that incorporated in their model of life.

The first of these tendencies has obvious repercussions in cities. The process of transformation of cities has accelerated. City structures are changing dynamically; the model of a city as a whole is changing. That latter process is slower, but still has a dynamic never present before in history.

At the same time, the means of managing cities is focused on quick results. The authorities try to satisfy investors and to present as soon as possible (preferably before the next election) to the citizens the spectacular outcomes of their activity. In other words, the pressure of time creates in cities very unstable and often questionable values – nevertheless, ones that are "shiny" and "easy to sell". One can say, that a symptom of this race against time is a sort of pop-urbanism, concentrated on awing the audience, and not on the search for an optimal or – more modestly – rational solution.

The second of the aforementioned trends is manifested – so far in a not very popular, but already making its presence known – in a movement focused on searching for quality, and not only quantity. In many cities independently, alternative initiatives demand actions concerning the quality – such as changes in transportation, social or residential policies. The citizens themselves take up initiatives of a new kind – banks of free time, "days of neighbours" or common pro-social actions like "guerrilla gardening". People sacrifice their time, effort and financial means to work for their communities, without expecting a financial profit, but an improvement in the quality of life. More and more movements supporting the "slow cities" idea are created; that concept of city which rejects the race for profit and ever higher career positions, and celebrates tasting the everyday joy of life and the inner development of a person. That movement definitely reaps what it had sown and will reap the change in the perception of space – instead of isolation and the manifestations of differences, integration and cooperation. That, obviously, will translate onto the structure of cities. The movement also seems important because it is not "planned" – it was not "designed" by planners and "implemented" as a strategy, but is a symptom of the vitality of cities, a proof that cities have not yet lost their nature and still reflect the culture that creates them.

For planning, all of these processes mean that we are constantly one step behind the reality, that planning in institutional forms as we know it has a reactive character and thus has to always be somewhat late. Modern plans do not anticipate the civilisational trends, trying to find a spatial dimension for them. Modern plans answer current demands, concerning spatial development here and now. The investors can hardly be blamed, by the way – be it companies, institutions or private persons – that they are driven by particular interests; it is

a planner's job to see further and predict consequences. It seems, then, that strategic planning is bound to play a bigger role, as it anticipates the directions of development and setting a distant perspective, rather than concentrating on very local decision about land use. It seems more probable as we continue to observe how far removed from reality these decision prove to be after a couple of years, sometimes months. It is also important to be able to find tools that will not react to such changes in a hysterical way, but ones that would have the dynamics of the changes somehow implemented in its mechanism. The concept of dynamic planning has many references, but it seems that its most important determinant is time.

3.2 Axis 2: Knowledge, information and education

Nowadays the availability of information is remarkable. Anything can be found out in no time. The availability of information, however, does not always mean expanding of knowledge; more often it causes "information noise" – the gained information has no value, but only serves to kill time. That is the situation with much of the pop-cultural or pseudo-scientific information. An additional element of that process is the fact that virtually anyone can produce and spread information, which results in much of them being unreliable or quite simply false. As a source of knowledge, this information is not only useless, but even counter-productive, wrong, leading to a misrepresentation of reality.

Therefore, education is absolutely crucial, providing everyone with a chance to acquire a backbone of knowledge, which then allows to filter out the useful information from the useless and to segregate information due to their correctness, as sources of knowing and understanding reality.

Another civilisational aspect of that axis is the fact that the technological progress has made even the educated people ignorant. The very advanced specialization of knowledge and technology has excluded us from the possibility of understanding and interpreting all phenomena that happen. Each of us, on a daily basis, uses devices, the functioning of which we do not know and most probably would not understand, just like many of us owe their life or health to medicine, which is far beyond the intellectual grasp of nearly all patients.

There is also the concept of the "learning society", which is true, too. Without doubt, as a society, the level of our knowledge, especially in Europe, is at its highest in history. Institutional education has allowed us to reach a very high level of understanding and interpreting reality. That, however, causes a raised (compared to the past) level of expectations towards the quality of life. Modern communities in the rich world want not only to live long, but also live pleasantly. Not only the basic demands concerning work have to be met, but also expectations of our health, cultural life, recreation, entertainment and perspectives for children.

When the term "learning society" is used, one thinks of a combination of all these phenomena, amplified by the dynamics of changes.

That has huge consequences for cities. Firstly, the expectations of the quality of life directly translate to the expected spatial developments. For example, a whole new sector of services for retirees has emerged. These people cease to be "toothless, ill old people" and become people in great shape, expecting entertainment and attractions for the next 20-30 years of life. They are interested in self-development, they have a lot of free time; they are a growing group of city users. Secondly, a well-educated society can no longer be treated as a "component" of planning; it demands to be the real subject of processes and of the influence on the future. We observe how the sun sets over some half-a-decade old concepts of cooperation with and within the society, such as public participation or collaborative planning, as no longer reflecting the modern needs, which have advanced and require new institutional solutions.

At the same time, from the point of view of an individual wanting to satisfy their growing quality of life needs, rational spatial behaviour does not always translate to rational and valuable spatial development, also for that individual. In other words, there is a great need of urban education of the society. Just like everybody understands smoking is bad for your health, everyone should be aware that certain spatial behaviour has its consequences. Here a frequently discussed notion is the self-organisation of cities, which has other aspects, too. Without an understanding of that process one cannot, it seems, seek reasonable tools for planning, or in a broader sense – of managing the future.

All the mentioned phenomena pose new challenges for planning.

The knowledge of planning, as any other discipline of knowledge, is gradually more complex and acquires new internal specialisations. Some elements of that science are so complicated – prognostic models or some

issues of city infrastructure are good examples – that they invoke distrust even among planners. On the one hand, there is a natural limit of competence for the professionals, and on the other it is hard to communicate with the subject of planning – the society – using complicated mathematical formulas describing processes and phenomena that happen in urban structures. The means of communication are urgently needed though, because in planning, like in medicine, the patient must be aware of the procedures run on him or her, otherwise the probability of failing grows.

There is also the other aspect of that new urban knowledge. For example, much is spoken about "new urbanism", a movement especially active in the United States, promoting breathtaking and revolutionary discoveries of rules absolutely basic – if not classic – for urban design, which in Europe are taught to students around the second year of studies in planning. Additionally, the famous ten rules of that concept constitutes a fantastic mixture of very locally implemented elements of urban design with much broader ideas of nearly civilizational/cultural character. It produces a funny blend of knowledge and fashions, which claims to be a discovery of an innovative way of urban designing. That is an example of pop-urban knowledge, an attempt to find simple – if not trivial – rules, which would shape very complex phenomena. Rephrasing, it is an example of anti-knowledge in planning.

Unfortunately, there is one more great problem from the professional point of view. The huge amount of data available for planners does not necessarily influence the quality of decisions made – sometimes it is responsible for not making any decision at all. To put it differently, planning has its own "information noise". For example, there are amazing methods of organizing, segregating and analysing data thanks to the GIS technology; things are done to connect and use the various existing databases (e.g. Plan4All in Europe); institutional actions are taken to present these information (such as INSPIRE). All that is happening while planning is paralyzed with institutional crisis and has little more to offer than reactions. Information sometimes initiate actions that require a vision and new tools; they may also encourage – not always with a positive effect – to sustain some existing methods. Another aspect of that process is the fact that modern tools (like all advanced technologies) are very complex. This means that specialists who deal with these state-of-the-art technologies tend to focus on the advancement of only these tools and planners are left without understanding the possibilities of uses of what is new. The technological gap within the profession is widening. Modern, advanced tools, which let us describe parts of reality in a more detailed way, not necessarily bring us closer to the ability to make long-term decisions; neither do they guarantee the proper and true understanding of these long-term phenomena, which, at the end of the day, will have the most important influence on our future. This is so because the most influential processes happen in the social and cultural sphere, which is the most difficult one to fit into any measurements or frameworks.

3.3 The paradigm shift

On the one hand, every human activity has a tendency to continue its current trend or direction as far as to the level of absurdity. On the other hand, when the absurd is reached, mostly a revolution comes along, which, however, had grown in a minority movement of contestation. This rule applies to both social and scientific trends. Archives are full of foresights (totally false) of the future, based on an estimation of current trends. For example, many serious works on demographics predicted critical overpopulation of the Earth, based on phenomena that happened after WWII. Some of these prognostics assumed that some time by now we would be suffocating with our own breaths due to the amount of carbon dioxide produced by people. The revolution in the birth control has mightily changed the course of things and made that forecast only a historical fun fact. Perhaps, however, the "alarm scenarios" influence reality by intensifying human activity in threatened areas.

That paradigm shift has great importance for cities. We have a tendency to understand or, more frequently, unjustified glorification of past models of cities and to attempt to copy the solutions of the past to modern reality. A good example is the affection to medieval urban structures, which are inadequate to the modern lifestyle. It is enough to compare one factor: life expectancy in medieval Europe was, depending on the source, around 25 years (or less, especially for women). The vast majority of people lived and worked in conditions that would today be deemed as horrifying. At the same time, for unknown reasons, we believe we should have as a ideal urban concept the model of cities from the times when, as Jacques Le Goff reminds, the biggest civilisational challenge was to fend off the constant fear of hunger. That is not to mention that we

are trying to apply a model of cities inhabited by a maximum of a several dozen thousands of people to structures of multiple hundreds of thousands residents.

Sometimes the difficulties concerning the paradigm shift seem to come from the inertia of functioning. Let us consider, as an example, the growing needs of infrastructure. The growing cities require more and more complicated networks, including ones delivering the most basic amenities, such as water or energy. Answering those needs we create not the most efficient system, but the one meeting the current demand. If a specialist was presented with a plan of a city district with a request to design a network of infrastructure of any kind, it would surely be different from the one existing at that moment. There are only a few examples of radical, abrupt reorganisations of urban fabric and structure of functioning cities. Probably the best known large-scale project was the reconstruction of Paris by Georges-Eugene Hausmann. Smaller scale project, however, are still being implemented, such as the Spina in Turin or the famous (for the social protests) Stuttgart 21. To sum it up, the change in the way of thinking about reality and the redefining of our own approach to it are very difficult, but at the same time – which may seem paradoxical – unavoidable. It is not certain if we understand the happening changes correctly or if we describe the phenomena in a proper way, because our perception is distorted by a set of beliefs concerning the structure of cities. It is for certain, however, that the model of cities, which has been developing for the last two hundred years is different from all that had come before, and that our understanding of it is not full. Moreover, we are limited by our perception paradigm; and to make things even more complicated, we do not have very effective tools that would control these changes. Our influence on the human urban environment is, in fact, very limited. Putting it in an even more concise way, it is rather certain that the current transformations in the model of the city, relying heavily on spatial self-organization, are still very elusive to us, but that in no way changes their dynamics and scale.

An unbelievable challenge for planning appears here – how to include that dynamic into planning processes? How to distinguish the trends and anticipate the future? How the planning system should take these phenomena into account? How to manage changes rather than plan them, as we do it today? What tools may serve that purpose?

Perhaps this element of the paradigm shift presents the most important challenge for 21st century planners. Conversations about that happen on numerous meetings, conferences and seminars. On the one hand, the sectoral model of thinking is still in force – the division between architects, urban designers, landscape architects, transportation engineers – who are responsible for (and sometimes fight for) various elements of the city structure; that set also gradually grows with new specialists. On the other hand, more and more professionals understand the need to revaluate the models that have been dominant and to look for an integrated approach and tools to apply it. One of the proposed answers is the so-called integrated planning, operating with a wide set of tools and aiming at many aspects. The change, however, must include the new model of planning as such, and must not mean only enlargement and integration of tools existing today. The analogy to aforementioned infrastructure systems is all too obvious here. A new framework for planning is not only necessary, but also unavoidable, but its outline is still unclear.

That new intellectual paradigm may even include the conditions of spatial planning. As an example, should we not – in the context of environmental and economic threats – start considering a decrease in the number of the Earth's population as a scenario creating positive, interesting possibilities and not threats? A consequence of adopting such assumption would be the creation of a model different to the one we are building around now. Perhaps we should redefine the very notion of development, which has so far been focused on quantity.

What is certain is the fact that models from the past have very limited application today and general rules need to be revised, instead of only updating the planning inventory.

3.4 Axis 4: Complexity

In every discipline, at some point the quantity transforms into quality. In social life, however, apart from the quantitative measurement, there are also great cultural and technical changes. The former are caused by both social and economic changes, while the latter derive from the development of knowledge and technology.

We observe not only cultural transplantations and adaptations, but also demonstrations of cultural difference. In any way, we see how global trends influence local lifestyles, and while simultaneously how these global

trends accept and adapt local values. For many communities that process is extremely difficult to familiarize with and to accept. On the other hand, there is a big and growing group of "world nomads", who use every coming opportunity to expand their style of thinking and to get to know other cultures.

The idea of "cultural purity", understood as a set of firm values, have always been a myth to some extent, and is definitely a thing of the past from the perspective of today.

No one has tools to control or shape these phenomena, and their intensity and quantity make the available terms to describe it insufficient, let alone predicting and influencing them.

The unbelievable technological progress has contributed quite a lot to that situation.

In relation to city structures, the growth of the last two centuries itself would have caused changes in quality in an unprecedented scale and generated an unprecedented complexity. If we are able to talk about megacities, metropolisation, region-cities or global cities, then it is only an aspect of that complex reality. More processes and phenomena have appeared, however, the same as it happened with the general civilisational background.

The multitude alone of models and styles of life of people living in a city would be complex enough to grasp and understand, and if we add to that the economic factors and complicated technological transformations, we get an image which poses a great challenge to even describe. Additionally, the complexity has different dimensions, which create another level for it. Well, and it changes constantly.

For a planner the problem is not only in perceiving that whole complexity, but also in the obvious lack of tools for diagnosis or for foresights, which means for planning. Let us add that even if we create simplified models describing chosen aspects of reality, and we do that knowing we are simplifying, then we are still in the stage of searching for means of describing reality. Things get worse when we have the impression that we have found a wonderful, simple model of "everything" and we are able to describe and plan reality without a problem. It seems that the worst thing that can happen to a planner is to be sure they are in the know what is the "right" model of the city and how cities should look now and in the future. In other words, the main challenge would be to constantly see the complexity and to include it in visions, strategies and plans. There is no more use for the approach of simplifying reality, as it is prone to lead to very serious distortions in the functioning of societies. That is why all tools that allow to estimate the outcomes of actions are becoming so valuable. They should become one of the most important components of the new inventory of planning tools. A separate question is how new plans could include that complexity; what sort of plan in general would be able to give justice to it? For sure not the traditional one, focused on physical aspects of urban structures, and most probably not the lately popular "policies", which only reflect the approach of authorities to various fields. We are searching for a model that would not only integrate specialist knowledge, but also the various subjects and aspects of reality.

The model of the "smart city", discussed recently, is perhaps one of the first attempts to find a framework to include the complexity of urban structures into the future planning scheme.

3.5 Axis 5: Uncertainty

Theoretically, it is clear to everyone that future was never certain. However, the social peace and welfare that has been installed in the decades after WWII have given birth to an impression that every future generation will live longer, safer and better than the previous ones. The lack of logic in such assumption seems to be clear as day, but logic has little to do with social expectations. The unavoidable result, therefore, is that a fast growth of "everything" cannot be kept up: demographic growth which would support comfortably both the leaving and the coming generations, economic growth, the quality of the environment or of employment... What is not known is whether one of these will collapse permanently or if a new model will appear.

Social security, the mirage of which we have experienced for the last half a century, ceases to be; no one can be ensured of economic or political stability. We can no longer "buy things we don't need for money we don't have". The unpredictability of natural disasters or social trends is indisputable. The political protests of the year 2011 all over the world are good proof of that.

We cannot even know if we are heading towards growth or decline in any possible understanding of these words.

In cities, this unpredictability manifests itself in thousand, hundreds of thousands and millions of independent, and often opposing or contradicting spatial decisions which people, institutions and businesses make. They produce not only surprising, but also unpredictable effects in space. That is the spatial self-organization referred when speaking of "spontaneous cities" or "resilient cities". These last words are, too, a planning concept of sorts of how to construct cities in the future.

Planners have a growing difficulty in finding accurate tools of diagnosing what the "urban quality" would be all about; there is more to it, as it is increasingly difficult to reach a consensus what the spatial quality was in general, especially in the larger scale.

On top of that there are doubts whether planners have the tools to influence growth or decline, even if they have anything to say about that. And even if we optimistically assume we have an inventory to create that spatial quality, which would even at the same time contribute to growth, then there is always the issue of changes left. In other words, we are not able to construct anything perfect, applicable always and in every place; we can only search for accurate tools at a certain stage, keeping in mind their temporariness and the need to constantly look for newer ones. Which brings us again to the dynamic planning model.

A very realistic suspicion emerges that the model of managing cities as we have known it is ceases to be valid, and urban designers and politicians should work hard to devise a new mode of operation. The ideas of flexible planning or even soft planning begin to find their way into the minds of planners, who more frequently see their work as a continuous process and not a delivery of a ready-made product set for implementation; as defining the framework of operation for many stakeholders and not a restrictive struggle to define one final layout.

In comparison to our predecessors from a century ago (who were very quick to offer a new "perfect" city model) we need to be much more modest, we cannot be arrogant to the extent of offering a new model of life; we really need to focus on discovering as accurate and effective frameworks for civilization as possible. Whatever that might come to mean.

3.6 Axis 6: Networks

Human life has always been playing out in many parallel "worlds". We belong to multiple networks and connections – family, professional, friendship, hobby, accidental. Our life is multidimensional in many ways. The last years, which brought the technological shift, have multiplied the opportunities to experience the many levels of our existence. Technology has also allowed the existence of new dimensions of imagined worlds, created by each of us. If we add the fact that there are various frameworks of reference for these networks, we will not only return to the aforementioned issue of complexity, but also generate a completely new vision of reality.

In relation to cities, these multi-level networks manifest in more and more complicated matrixes of connections, which in reality shape the structure of the city. They decide about the city's blood flow – movements, intensity and dynamics – they are to a large extent responsible for whether we see an urban structure as functioning well or not. For example, the models describing city flows that were in force only fifty years ago have no longer any validity, because they no longer fit to reality. There are less clear rush hours, all movement is in general more fuzzy, new categories of connections appear very often, a growing number of work connections does not have a "from-to", but a "between" character. It is much more difficult to extract "pure" spheres of our routine activities, because they exist simultaneously in many networks.

Another symptom of existence of that multi-level networks is the metropolisation. Cities have been connecting "overhead" regions in which they lie for a long time now, perhaps always, but nowadays, thanks to the accessibility of means of transport that phenomenon has grown to a huge scale, becoming a major support factor, or maybe even the basis for globalization.

In planning, the lack of understanding for these multi-dimensional networks may result in preserving sectoral planning, which by the natural course of things needs to be limited as it does not reflect the needs derived from the network functioning, both within cities and between them. The search for an efficient model of integrated planning is one of the obvious challenges of the future. That does not mean, though, that it is an easy notion to define.

3.7 Axis 7: Resources, infrastructure and technology

The limitation of the resources requires us to cut down on the use of them; at least because some of them are non-renewable. This does not have to mean "rationing" or other restrictions – this may mean innovations or education.

It seems to be clear to everyone, that cities, constituting only a very small part of the Earth's surface, use a very large part of its resources, especially energetic resources. These, including the climate, which is also "used" by us in a way (some claim it is actually abused), are an essential fuel for the functioning of cities. The use of resources requires infrastructure, and that in an obvious way conditions the development of not only city, but also regional structures. The notion of infrastructure-led development is a good description of city structures which rely completely on supplies.

The recently popular, and – in our opinion – fitting the category of pop-urban, concepts of "low-carbon cities" belong to the sphere of dangerous simplifications (mentioned earlier inside the talk about complexity), similarly to its basis, i.e. the widely discussed issue of climate change. Basically, every human being is aware of the fact that climate changes constantly and that mankind – despite its great powers – does not influence to a really crucial extent. It is enough to mention the natural disasters that people would have avoided if they had been able to do that. The problem of climate change touches upon us because it concerns economies (damages) and threats it poses for us personally. That is way it is more responsible to discuss environmental limitations for man – as there undoubtedly are many – than to get excited over slogans concerning the climate. The matter is much more complex, and fragmentary actions deprived of the understanding of the ins and outs of the issue are more likely to harm than to do good. The climate is an important, but not the only component of the environment, which determines spatial development. Emissions are important, but not to the extent to cut them down by priority, without regard to the costs and detached from other factors. For example, fully natural volcano eruptions emit enormous amounts of carbon dioxide, let alone other dangerous substances. That is why the term "environmental limitations of development" seems to me more responsible and more accurate; it includes the whole of the issue of "using" the planet, without which our species will quite probably not survive.

From the perspective of planning everybody uses (and again probably abuses) the concept of sustainable growth, the understanding of which relies on the awareness of the limitations rooted in the environment. The next step is to understand that the free market, which regulates economic relationships (including the use of the environment) requires control, especially in that aspect. Otherwise it will not be possible to solve the riddle between the nature conditioning our lives and the economy regulating them. The answer – or at least one of the possible answers – may be the technical and technological progress, which will not release planners, though, from the responsibility for strategic decisions. The answer may also lie in a change of the model of life coming from changes in values. It is impossible to change millions of people, but it is possible to use the fact they want to change.

3.8 Axis 8: Concentration and intensity

The notion of concentration, or of density of phenomena, and their intensity does not only apply only to space, although is manifested the strongest in it. We could also locate it in ideologies, religions or preferred lifestyles. The growing professionalization is also one of its symptoms.

In cities, however, the juxtaposition of the compact city vs. urban sprawl is not only a technical question about their spatial structure. It also touches on the intensity of city life and the processes that happen in it – cultural, economic and technical ones.

Does the question whether planning today should be directed towards creating frameworks for the rising intensity of city life and development possibilities stay a valid one?

3.9 Axis 9: Mobility and accessibility

Mankind has achieved progress, i.e. cultural and technical advancement, together with gaining "transport freedom". With each push for more such freedom the scope of possibilities enlarged in every thinkable aspect. It does not seem possible that the ability to travel individually could be reverted; the means of transport, which allow for that freedom, may change, though.

Cities have always been magnets which attracted those freer movements, but they were also places where mobility manifested itself in inner movements. It should be remembered that mobility and accessibility is closely connected to the need to ensure contacts, dictated by our set of needs. Therefore both mobility and accessibility belong in a way to fundamental city freedoms. However, dark sides of that issue can easily be seen: traffic congestion, air pollution, growing difficulties, all leading to a negation of the very notion of mobility due to excessive mobility (or rather to the means that provide for it).

Perhaps the crucial task for planners is not to plan transport, but to plan contacts, which would manifest not only in physical structures providing flows, but also in an influence and the structure itself, in which the contacts are realized. That leads us once more to the search for tools allowing for integration and coherence of the process of planning.

3.10 Axis 10: Locality and globality

Perhaps the opposition of locality and globality in the civilisational dimension relies more on our paradigm, not necessarily in the planning aspect, but the civilisational one. It would be wrong to ascribe values to these notions; the important thing is to see their overlapping on various levels.

On the one hand there is a very clear global trend which shapes local behaviors; we tend to complain about that trend, seeing the same stores all around the world while forgetting freedom movements that lead to the improvement of the quality of lives of many people and which have started precisely thanks to the global trends.

It is impossible to say that the quality of life depends only on global or local trends, but it is possible to say for sure that the local context will have key meaning in reinterpreting and adapting these global trends. Nothing here can be decreed or implemented – just like with any other cultural phenomena. It is even impossible to predict the final success or failure of these trends.

The "prêt-à-porter" policy, which pastes solutions into structures without considering that context, can be seen in cities with growing frequency. Sometimes such policy is successful, and sometimes it is an utter failure. The same urban solutions, delivered by global design companies and implemented in Hong Kong and Mexico, in Southern Africa and Poland, in Australia and Greenland, on the one hand terrify professionals, and on the other sometimes happen to be desired by local communities as a sign of their prestige and globality. In other words, the description of the phenomenon is simple, but a diagnosis not so much.

For a planner, the danger of using the "copy and paste" procedure is made worse by the illusion of the importance of physical planning, and not the planning of processes and policies. Still many of us is certain that a good drawing creates a good space, and then a good life. That does happen, but not always, though.

At the same time there are many concepts which we, as planners, not only support, but which we have generated ourselves, and which are a kind of attempt to bring locality and globality closer together. The concepts of spatial cohesion and social cohesion definitely belong in that category. The word "cohesion" means that there are insignificant differences in a set of elements, but the concept of cohesion does imply important local aspects, such as relying on local resources. That shows, again, that ascribing value naively ("I am against globalism" – as if it was at all possible!) does not bring us any closer to the understanding of reality or to effective solutions.

3.11 Axis 11: Political systems and power

In Poland, a country which regained autonomy only twenty years ago, half of the citizens does not participate in elections. It may seem that something is fundamentally wrong about the citizens or about the system of power which a modern democracy offers. If that critical situation troubles only Poland, one could assume that the first hypothesis could be correct, but because that problem touches all countries of the world to a varying extent, and the free Western democracies to a large extent, the second hypothesis needs to be seriously considered.

The system of political representation seems to drastically stand away from the social reality. Political parties look like dinosaurs among primates. Social and economic concepts expressed by parties do not match the aspirations of the citizens and do not reflect values represented by them. Many citizens vote "out of despair" (or for the "lesser evil") or refuse to cast their vote, which all too often offer them nothing they would wish to have.

Politicians who fall for seducing the voters with empty promises lose not only their own credibility, but also the credibility of the democratic system as a whole. The crisis of power and of political systems is becoming clear.

On the other hand, the citizens are becoming active in demanding a more direct influence on the decision-making process and on the solutions that concern their lives, both in the short and the long term.

These two opposing trends demand some proposal of solution, which does not seem to be there yet.

In cities – in which power and politics came to be – we observe a strongly technocratic tendency. Managing is an activity for professionals who know very well what is "right" and what is "wrong". They know, for example, that a private car is "wrong", and a bicycle is "right"; they know the old town is "lovely" and new business centres are "repulsive", or "pretentious" at best; they know the compact city is "ok" and that urban sprawl is not, etc. Such beliefs are very often quite rational, but planners and local authorities have a tendency to ignore social needs while telling their citizens what is best for them. That technocratic-paternalistic approach, unsurprisingly, does not meet much enthusiasm. The search for new ways of cooperation is again shown in a light of urgency. Traditional planning tools, such as law, are too often tools of neglect, control and corruption, and of development and quality improvement.

New forms of managing cities are at the gates. What we do not know is whether they resemble sweet dreams of freedom or the nightmares of slavery.

4 CONCLUSIONS AND ACKNOWLEDGMENTS

By presenting chosen planning ideas in the form of a matrix we intended to somehow organize the variety of descriptions, concepts and reference frameworks of urban issues that are discussed in the literature of the discipline and at professional meetings. We do not claim it to be a perfect format, or even a good one, but it allows us to achieve intellectual order. On the one side there are many people dedicated to planning, who see the complexity of the situation, while on the other side there are many who still conform to the "fashions" in planning. That is also supported by the fact that it is still much easier to receive funding if the research is about "climate change" or "smart cities" than when we are trying to describe the complexity of a phenomenon which does not have one clear, measurable dimension. For us, building that matrix meant a significant step in search of at least a description of the state of knowledge in which planning is at the moment and of its relation to our planning skills and chances to intervene.

The first outline of this construct was conceptualised in August 2011 and then discussed with many persons.

Most probably, we have failed to present in this paper all planning ideas, but we tried to show what many people in Europe, interested in the state of cities, have been talking about in the recent years. They comment reality using their own experience, but remain open to new ideas and new trends which hang in the air.

That is why we owe words of gratitude to many of them for many hours of conversations and the exchange of experiences. We will not be able to name all of them, but we will mention those whose thoughts are reflected in this text (and the shortcomings of which are only our responsibility). They are: Pedro Gadanho, Jan Gehl, Anna Geppert, Nikos Karadimitriou, Stephen Marshall, Diogo Mateus, Gustavo Ribeiro, Modjtaba Sadria, Ulysses Sengupta, Tadeusz Zipser.

1 KURZFASSUNG

Städtebauliche Mischung und Stadtentwicklung in integrierten Lagen scheitern häufig an Nutzungskonflikten, die mit dem (erwarteten) induzierten Verkehr der (vorgesehenen) Nutzungen zusammenhängen. Neben kurzen Wegen und einer guten Infrastruktur für alternative Verkehrsmittel zum Kfz (Nahmobilität, Öffentlicher Personennahverkehr) kann Mobilitätsmanagement als Baustein einer Mobilitätsstrategie den Kfz-Verkehr bestehender und neuer Nutzungen reduzieren und somit zur Lösung dieser Nutzungskonflikte beitragen. Bislang fehlen allerdings anerkannte Verfahren, die Minderungswirkungen von Mobilitätsmanagement abzuschätzen. Um zu bewerten, ob eine auf Mobilitätsmanagement basierende Strategie Erfolg haben kann, ist es erforderlich, die Verkehrsfolgen von bestehenden und geplanten Nutzungen an einem Standort in Abhängigkeit von Nutzungstyp und Erreichbarkeiten möglichst zuverlässig abzuschätzen und die zusätzlichen Einsparpotenziale durch die Maßnahmen des Mobilitätsmanagements zu quantifizieren.

Grundlage für die Standortbewertung bildet ein Ansatz aus „effizient mobil“, dem Aktionsprogramm für Mobilitätsmanagement der dena (Deutsche Energie-Agentur GmbH), der zur Kopplung mit Verkehrsmodellen und GIS weiterentwickelt wurde. Die auf der Unternehmensstruktur am Standort, der Erreichbarkeit sowie den Pendlerverflechtungen beruhenden Indikatoren werden zu einer groben Eignungsbewertung zusammengeführt.

Über Erreichbarkeitsanalysen werden für die Standorte Erreichbarkeitspotenziale für die verschiedenen Verkehrsmittel bewertet und gegenübergestellt. Gleichzeitig werden Charakteristika der ansässigen Betriebe erfasst und aufbereitet. Ziel des Projektes ist es, zu unteruchen, ob das Verfahren geeignet ist, um Standorte dahingehend zu beurteilen, welche Maßnahmenbündel vor Ort besonders erfolgreich sein können und ob es Effekte der anvisierten Maßnahmen abschätzen kann. Dabei soll auf aufwändige Detailbetrachtungen verzichtet werden. Dies hilft den beteiligten Akteuren dabei, ihre Aktivitäten im Mobilitätsmanagement auf aussichtsreiche Standorte zu konzentrieren.

2 AUSGANGSLAGE UND ZIELE

2.1 Ausgangslage

Mobilitätsmanagement als Baustein einer Mobilitätsstrategie

In der Praxis hat sich gezeigt, dass unter Mobilitätsmanagement – sofern überhaupt bekannt – unterschiedliches verstanden wird. Im Rahmen des Programmes „effizient mobil“ (ILS, ISB 2010) wurde es definiert als „[...] Ansatz zur Beeinflussung der Verkehrsnachfrage mit dem Ziel, den Personenverkehr effizienter, umwelt- und sozialverträglicher und damit nachhaltiger zu gestalten. Mobilitätsmanagement bietet den Verkehrsteilnehmenden durch „weiche“ Maßnahmen aus den Bereichen Information, Kommunikation, Motivation, Koordination und Service Optionen, ihr Mobilitätsverhalten und ihre Einstellungen zur Mobilität insbesondere dahingehend zu verändern, ihre Mobilitätsbedürfnisse mit möglichst geringem Aufwand an Pkw-Verkehr zu befriedigen“. Im an Betriebe und Einrichtungen sowohl der Privatwirtschaft als auch der öffentlichen Hand gerichteten betrieblichen Mobilitätsmanagement übernehmen die Betriebe Verantwortung für den von ihnen verursachten Verkehr und kooperieren mit Kommunen, Verkehrsbetrieben und -anbietern. Betriebliches Mobilitätsmanagement kann z.B. Maßnahmen aus den Bereichen JobTicket, Parkraummanagement, Kampagnen oder Radverkehrsförderung umfassen.

Mobilitätsmanagement kann als Baustein einer kommunalen oder regionalen Mobilitätsstrategie in Ergänzung zu verkehrsplanerischen sowie verkehrslenkenden und –steuernden Maßnahmen mit vergleichsweise geringem Aufwand den Kfz-Verkehr bestehender und neuer Nutzungen reduzieren

(BMVBS 2004). Zunehmend finden sich Maßnahmen des Mobilitätsmanagements auch als Bestandteil in Aktionsplänen und Plänen zur Lärmminderung und Luftreinhaltung wieder.

Planungs- und Entscheidungsgrundlagen für Mobilitätsmanagement

Während die in der Planungspraxis verwendeten Verkehrsmodelle für infrastrukturelle und angebotsseitige Maßnahmen eine Abschätzung der verkehrlichen Effekte und Wirkungen und, in Kopplung mit Umweltmodellen, die Abschätzung der daraus resultierenden Emissionen und Immissionen erlauben, fehlt vor allem eine Methodik, mit der die Wirkungen und Effekte von Mobilitätsmanagementmaßnahmen in einem flächenhaften und netzweiten Kontext abgebildet und hinsichtlich verkehrlicher, ökologischer und ökonomischer Aspekte bewertet werden können (BMVBW 2004). Allenfalls wurden die Wirkungen von Mobilitätsmanagementmaßnahmen durch Evaluationen nur auf Einzelmaßnahmen bezogen nachgewiesen und quantifiziert (Hamann 2001). Die Wirkungen in Bezug auf das Verkehrsgeschehen im gesamtstädtischen oder regionalen Kontext sind, ausgehend von einzelnen Betrieben, jedoch in der Regel nicht mehr nachweisbar. Erst durch die Überlagerung mehrerer Einzelmaßnahmen, indem sich zum Beispiel eine gewisse Anzahl an Unternehmen im betrieblichen Mobilitätsmanagement engagiert, werden gesamtstädtische/regionale und netzweite Effekte messbar (BMVBW 2003).

In der Region Frankfurt RheinMain werden derzeit in verschiedenen Städten und Kommunen verstärkt Mobilitätsmanagementmaßnahmen auf der strategischen Ebene z.B. in Form von Verkehrs-managementplänen oder Mobilitätsmasterplänen verankert und auch im Rahmen von Aktionsplänen zur Lärmminderung und Luftreinhaltung diskutiert. Trotz einer breiten Wissensbasis zu den Umsetzungspotenzialen und Voraussetzungen des Mobilitätsmanagements in der Region fehlt eine abgestimmte, anerkannte und valide Methodik zur Abschätzung der Wirkungen.

2.2 Ziele

Das Projekt steht im Zusammenhang mit einer Reihe von Aktivitäten in der Region Frankfurt-RheinMain, die darauf abzielen, den Ansatz des (betrieblichen und standortbezogenen) Mobilitätsmanagements im Rahmen einer strategischen Weiterentwicklung systematisch und flächenhaft umzusetzen. Gemeinsam mit dem Rhein-Main-Verkehrsverbund, den Städten und Landkreisen in der Region Frankfurt Rhein-Main sowie den Lokalen Nahverkehrsorganisationen werden dabei über verschiedene Aktivitäten und Programme Unternehmen und öffentliche Einrichtungen gezielt angesprochen und bei der Erarbeitung von nachhaltigen Mobilitätsmanagementkonzepten unterstützt. Um die Ansprache und Umsetzung zielgerichtet vornehmen zu können, und um bereits vor Beginn zu einer Abschätzung der potenziellen Effekte der Mobilitätsmanage¬mentmaßnahmen zu kommen, wird im Rahmen dieses Projektes von der ivm, das aus dem Programm Staufreies Hessen 2015 vom Land Hessen gefördert wird, eine Methodik entwickelt und erprobt, die die Bewertung von Standorten hinsichtlich ihrer Voraussetzungen für die Umsetzung von Maßnahmen des betrieblichen Mobilitätsmanagements ermöglicht und, darauf aufbauend, die Abschätzung der Wirkungen auf Verkehr und Umwelt erlaubt. Ein besonderer Fokus liegt dabei auf der Untersuchung der Voraussetzungen für eine gezielte Förderung der Nutzung des öffentlichen Personennahverkehrs (auch über die Einführung von Jobtickets).

Im Rahmen dieses Projektes wurde ein Ansatz zur Bewertung und Abschätzung von Mobilitätsmanagement ohne die Nutzung von Befragungsdaten in der Praxis erstmals erprobt. Weitergehendes Ziel des hier beschrieben Projektes ist es, eine Entscheidungsgrundlage für die kontinuierliche Implementierung von Mobilitätsmanagementmaßnahmen zu etablieren. Perspektivisch soll eine Einbindung von Mobilitätsmanagement in die kommunale und regionale Verkehrs- und Mobilitätsplanung ermöglicht werden, die dem gegenwärtigen Stellenwert von Verkehrsmodellen für infrastruktur- und angebotsseitige Maßnahmen gleichkommt. Städte und Kommunen sollen ein handhabbares Verfahren erhalten, welches eine stärkere Verankerung von Mobilitätsmaßnahmen im Rahmen der Luftreinhaltung und Lärmminderungsplanung sowie in den Aktionsplänen fördern kann. Bisher ist Mobilitätsmanagement nicht in den formellen Verfahren verankert; diese sind v.a. auf angebotsseitige Projekte ausgelegt (ILS, ISB, ivm 2009) Zudem soll das Verfahren Aufgabenträgern und Verbänden Grundlagen des öffentlichen Personennahverkehrs (ÖPNV) für die zukünftige Angebotsgestaltung liefern.

3 ANSÄTZE ZUR BEWERTUNG DER EIGNUNG VON STANDORTEN FÜR MOBILITÄTSMANAGEMENT

3.1 Entwicklung eines standortbasierten Bewertungsansatzes

Der hier entwickelte Bewertungsansatz basiert unter anderem auf Ergebnissen, die im Rahmen des Programmes „effizient mobil“ (dena 2010) erzielt wurden. In diesem wurden für Einzelbetriebe die Einflussgrößen auf die potenziellen Wirkungen von Maßnahmen des Mobilitätsmanagements zur CO2-Einsparung bei den Beschäftigtenverkehren untersucht. Als wesentlich wurden dabei neben bereits umgesetzten betrieblichen Aktivitäten die Standort- und Umfeldbedingungen sowie die Mobilitätsmöglichkeiten und Mobilitätsverhalten der Beschäftigten identifiziert. Es wurde ein standardisiertes Bewertungsschema zur Beurteilung der örtlichen Mobilitätsvoraussetzungen - differenziert für die wesentlichen Verkehrsmodi Motorisierter Individualverkehrs (MIV), ÖPNV und Nicht-motorisierter Individualverkehr (NMIV) - entwickelt, weiterhin wurden die Mobilitätsmöglichkeiten und Mobilitätsverhalten bei den Beschäftigten der untersuchten Betriebe mittels Befragung erhoben und die Wohnstandorte der Beschäftigten ermittelt.

Im Rahmen des hier vorgestellten Projektes wurde das Bewertungsschema der überwiegend verkehrlichen Standort- und Umfeldbedingungen aus „effizient mobil“ aufgegriffen. Insbesondere die Kriterien zur Beurteilung des ÖPNV-Angebotes (u.a. Gehzeit zur nächsten Haltestelle, Anzahl ÖPNV-Abfahrten in der Hauptverkehrszeit) und die der Erreichbarkeiten mit unterschiedlichen Verkehrsmitteln konnten mithilfe der Kopplung von Unternehmensdaten mit dem regionalen Verkehrsmodell VDRM („Verkehrsdatenbasis RheinMain“) sowie GIS-gestützter Erreichbarkeitsanalysen (vgl. Bohnet et.al. 2006) genau abgebildet werden. Erkenntnisse zu Zusammenhängen zwischen den Eigenschaften von Betrieben und der Mobilität deren Beschäftigter flossen in die Bildung eines weiteren Indikators ein, der auf einem den Betrieben zugeordneten primären Tätigkeitsfeld beruht. Die genannten Indikatoren wurden jeweils für Einzelbetriebe errechnet und anschließend, erneut mithilfe von GIS, für die Standorte gewichtet, aggregiert und dargestellt.

Basierend auf der Feststellung, dass der Aufwand für die Ansprache sowie die Erarbeitung und Umsetzung von Mobilitätsmanagementmaßnahmen an einem Standort maßgeblich davon abhängt, ob dort ausschließlich kleinere oder zumindest einige größere Betriebe vorhanden sind, wurde die Größenstruktur der Betriebe am Standort als weiterer Indikator eingeführt. Eine Übersicht der Indikatoren der Standortbewertung zeigt Abb.1.

Der Bewertungsansatz und die sich anschließende Wirkungsabschätzung verzichtet also auf die i.d.R. üblichen aufwändigen Vorher-Nachher-Befragungen, wie sie z.B. in Großbritannien (TfL 2009) oder den USA (NCTR 2007) zur Wirkungsabschätzung eingesetzt werden.

3.2 Datengrundlagen der Standortbewertung, -bildung und -abgrenzung

Der Untersuchungsraum im Projekt erstreckt sich auf die Städte Frankfurt am Main, Bad Homburg vor der Höhe, Offenbach am Main und Darmstadt sowie auf den Landkreis Darmstadt-Dieburg und den Kreis Offenbach. Für diese Gebietskörperschaften wurde durch die Industrie- und Handelskammer (IHK) Offenbach der Auszug aus einer Datenbank mit Angaben zu IHK-Mitgliedsunternehmen zur Verfügung gestellt. In dieser Datenbank sind unter anderem Adresse, Branche („WZ-Nummer“) und die in Klassen eingeteilte Mitarbeiterzahl der Unternehmen hinterlegt. Unternehmen aus den Größenklassen mit weniger als 50 Mitarbeitern wurden nicht berücksichtigt (vgl. Abschnitt 3.1). Die in der Statistik der IHK übermittelten Beschäftigtengrößenklassen von wichtigen Unternehmen wurden für die jeweiligen Betriebsstandorte nachrecherchiert und plausibilisiert. Ergänzend wurde eine Recherche der Beschäftigten in Einrichtungen und Betrieben der öffentlichen Hand vorgenommen. Zum Teil konnten die Beschäftigtendaten mithilfe der Beteiligten auf kommunaler Seite geprüft und ergänzt werden.

Eine weitere wichtige Datengrundlage stellte das regionale Verkehrsmodell VDRM (Verkehrsdatenbasis Rhein-Main) dar, in dem nicht nur die Straßeninfrastruktur und das ÖPNV-Angebot abgebildet sind und zur Berechnung verkehrlicher Indikatoren genutzt werden konnten, sondern auch relevante Daten zur Raumnutzung in „Verkehrszellen“ (Einwohner, Beschäftigte,…) hinterlegt sind. Da die Verkehrszellen in der VDRM zum Teil kongruent zu bestehenden Gewerbegebieten sind, wurde sie bei der Zusammenfassung von Betrieben zu Standorten ebenfalls herangezogen.

Andere Kriterien der Standortbildung und -abgrenzung waren die Standortgröße (Ausdehnung und Anzahl der Unternehmen), die Homogenität der vertretenen Branchen (z.B. Bürostandort vs. Industriestandort), aber auch die Lage relativ zu wichtigen Haltepunkten des ÖPNV oder infrastrukturelle Trennwirkungen (BAB und -kreuze, Bahngleise).

Im Zusammenhang mit Berechnungen zur Erreichbarkeit kamen auch Daten der Openstreetmap zum Einsatz.

3.3 Kriterien und Indikatoren der Standortbewertung

Eine Übersicht der gebildeten Indikatoren zur Bewertung der Standorte enthält Tabelle 1. Die dort aufgeführten Wertebereiche stellen Vorgaben dar, die noch einer weitergehenden Überprüfung unterzogen werden. Im Folgenden wird auf einige der Indikatoren näher eingegangen: Der Indikator Tätigkeitsfeld der Betriebe am Standort etwa basiert auf der Beobachtung, dass die Affinität eines Betriebes oder einer Einrichtung zu Mobilitätsmanagement, die die Erfolgswahrscheinlichkeit einer Ansprache und die erzielbaren Effekte der Umsetzung von Maßnahmen bestimmt, mit einer Reihe von betriebsspezifischen Charakteristika korreliert. Solche sind z.B. das Bildungsniveau der Beschäftigten, vorherrschende Arbeitszeitmodelle oder Tätigkeitsmuster. Anhand der Wirtschaftszweige („WZ-Nummer“) wurden die Unternehmen sieben Tätigkeitsfeldern zugeordnet. Verwaltungstätigkeiten bei der öffentlichen Hand stellen ein eigenes Tätigkeitsfeld dar. Es wird davon ausgegangen, dass als vorherrschende Tätigkeitsfelder der Betriebe am Standort

- Spezialisierte Bürotätigkeiten (für die i.d.R. ein Hochschulabschluss erforderlich ist)
- Wissenschaft und Forschung sowie
- Öffentliche Verwaltung

gute Voraussetzungen für Ansprache und Umsetzung von Mobilitätsmanagement bieten,

- Produzierendes Gewerbe (manuelle Tätigkeit in Industrie oder öffentlichen Betrieben)
- Einfache Bürotätigkeiten (i.d.R. kein Hochschulabschluss erforderlich) sowie
- Hotel und Gesundheit

durchschnittliche Voraussetzungen bieten und dass

- Handel (Einzel- und Großhandel) sowie
- Handwerk

als vorherrschende Tätigkeitsfelder die Erfolgsaussichten eher verringern. Einem Standort wird das Tätigkeitsfeld zugeordnet, dem die meisten der dort Beschäftigten angehören.

Die Tätigkeitsfelder der Betriebe und Standorte werden im Rahmen der Wirkungsabschätzung für die Modellierung der Pendelentfernungen der Beschäftigten erneut herangezogen (vgl. Kap. 4).

Indikator	Berechnungsweise	Einteilung / Wertebereiche
Betriebsgrößen am Standort	siehe rechts	gut: Mind. ein Betrieb > 500 Mitarbeiter am Standort
		mittel: Mind. ein Betrieb > 200 Mitarbeiter am Standort
		schlecht: Alle Betriebe am Standort < 200 Mitarbeiter
Tätigkeitsfeld der Betriebe am Standort:	Ableitung von „Tätigkeitsfeldern“ aus den Branchen der Betriebe, Auswahl des Tätigkeitsfeldes, dem die meisten Beschäftigten angehören	gut: “Spezialisierte Bürotätigkeiten” “öffentliche Verwaltung” und “Wissenschaft und Forschung“
		mittel: “Produzierendes Gewerbe” “Einfache Bürotätigkeiten” sowie “Hotel und Gesundheit”
		schlecht: “Handel” und „Handwerk”
Voraussetzungen für Mobilitätsmanagement aus der mittleren Entfernung zur nächsten BAB-Auffahrt	Betriebsweise Berechnung der Fahrzeit auf Basis des belasteten Straßennetzes, Bildung des über die Beschäftigtenzahlen der Betriebe gewichteten Mittelwertes am Standort. Eine gute BAB-Anbindung wird als schlechte Voraussetzung für Mobiliätsmanagement gewertet	gut: Fahrzeit > 8 min
		mittel: Fahrzeit zwischen 3 und 8 min
		schlecht: Fahrzeit < 3 min
Voraussetzungen für Mobilitätsmanagement aus Parkdruck	abgeleitet aus der Beschäftigtendichte am Standort. Hoher Parkdruck wird als gute Voraussetzung für Mobilitätsmanagement gewertet	gut: > 150 Beschäftigte / ha
		mittel: 35 -150 Beschäftigte / ha
		schlecht: < 35 Beschäftigte / ha
Gehzeit zur nächsten ÖPNV-Haltestelle (inkl. Bus)	Berechnung in GIS, Bildung des über die Beschäftigtenzahlen der Betriebe gewichteten Mittelwertes am Standort.	gut: Gehzeit < 3 min
		mittel: Gehzeit zwischen 3 u. 5 min
		schlecht: Gehzeit > 5 min
Gehzeit zur nächsten SPNV-Haltestelle (inkl. Tram)	Berechnung in GIS, Bildung des über die Beschäftigtenzahlen der Betriebe gewichteten Mittelwertes am Standort.	gut: Gehzeit < 5 min
		mittel: Gehzeit zwischen 5 u. 10 min
		schlecht: Gehzeit > 10 min
Anzahl der Abfahrten in der Hauptverkehrszeit (werktags 7-9 Uhr)	Anzahl an Abfahrten an der Haltestelle mit den meisten Abfahrten am- oder in Nähe (300m) des Standortes	gut: > 60 Abfahrten / h
		mittel: 20-60 Abfahrten / h
		schlecht: < 20 Abfahrten / h
Anzahl der Abfahrten in der Schwachverkehrszeit (werktags 20-22 Uhr)	Anzahl an Abfahrten an der Haltestelle mit den meisten Abfahrten am- oder in Nähe (300m) des Standortes	gut: > 40 Abfahrten / h
		mittel: 10-40 Abfahrten / h
		schlecht: < 40 Abfahrten / h
Konkurrenzfähigkeit der standortbezogenen Erreichbarkeitspotenziale zwischen ÖPNV und MIV	Anzahlen der Einwohner, die innerhalb einer festgelegten Zeitspanne den Standort mit dem ÖPNV und dem MIV erreichen können, werden ins Verhältnis gesetzt. (Gewichtung nach Reisezeit)	gut: ÖPNV- zu MIV-Erreichbarkeitspotenzial > 35%
		mittel: ÖPNV- zu MIV-Erreich-barkeitspotenzial zw. 20 u. 35%
		schlecht: ÖPNV- zu MIV-Erreichbarkeitspotenzial < 20%
Radpotenzial	Anzahl der Einwohner, die den Standort innerhalb von 20 min mit dem Rad erreichen können	gut: > 200.000 Einwohner in Radentfernung
		mittel: 50.000 bis 200.000 Einwohner in Radentfernung
		schlecht: < 50.000 Einwohner in Radentfernung

Tabelle 1: Standortbewertungsindikatoren, Berechnungsweise und Wertebereiche (eigene Darstellung)

Zur Beschreibung der Situation im MIV werden die mittlere Entfernung zur nächsten BAB-Auffahrt und der Parkdruck nicht unmittelbar bewertet, sondern hinsichtlich ihres Einflusses bei der Implementierung von Mobilitätsmanagement-Maßnahmen, insbesondere der Förderung der Nutzung des ÖPNV.

Der Indiaktor Konkurrenzfähigkeit der standortbezogenen Erreichbarkeitspotenziale zwischen ÖPNV und MIV beschreibt das Verhältnis zwischen der (potenziellen) Erreichbarkeit des Standortes mit dem ÖPNV und dem MIV. Zur vergleichenden Abbildung wird für jeden Standort gegenübergestellt, wie viele Einwohner diesen innerhalb üblicher (zeitlicher) Pendelentfernungen mit dem MIV bzw. dem ÖV erreichen können. Die Einwohnerzahlen zeitlich weiter entfernter Quellorte werden dabei mittels Gewichtung über die Reisezeiten (e-0,05 * t) entsprechend schwächer berücksichtigt. 100% ÖV-Konkurrenzfähigkeit würde bedeuten, dass ein Standort von der gleichen Anzahl an Personen sowohl mit dem Pkw als auch mit dem ÖV erreicht werden kann. Das Verhältnis fällt jedoch in der Regel wesentlich kleiner aus, so dass bereits ab 35 % des Wertes für den MIV von einem guten ÖPNV-Erreichbarkeitspotenzial ausgegangen wird. Der Indikator ist deswegen von großer Bedeutung, weil allein durch diesen Reisezeiten mit dem MIV und dem ÖPNV in die Standortbewertung einfließen und weil eine Entscheidung zugunsten des ÖPNV maßgeblich von dessen Konkurrenzfähigkeit gegenüber dem MIV abhängt.

Um die Indikatoren bei der Standortbewertung ihrem mutmaßlichen Stellenwert entsprechend zu berücksichtigen, wurden diese einer Gewichtung unterzogen. Diese basierte auf der Annahme, dass die Erfolgswahrscheinlichkeit von Maßnahmen des Mobilitätsmanagement in ähnlichem Maße von der verkehrlichen Situation wie auch von der Konstellation der Betriebe am Standort abhängt. Angesichts der Vermutung eines höheren Erklärungsgehaltes erfuhren die verkehrlichen Indikatoren für die vorgenommene erste Abschätzung insgesamt gegenüber den betrieblichen eine etwas stärkere Gewichtung. Eine weitergehende Überprüfung der den Einzelindikatoren zugeordneten Gewichte steht noch aus.

3.4 Ergebnisse der Standortbewertung

Anhand einer auf Basis der gewichteten Indikatoren und eines einfachen Punktesystems durchgeführten Standortbewertung im Untersuchungsgebiet und deren kartographischer Darstellung (siehe Abb. 2) lassen sich für betriebliches Mobilitätsmanagement gut geeignete Standorte im Untersuchungsraum sowie perspektivisch auch in der Gesamtregion Frankfurt RheinMain ohne detaillierte Einzeluntersuchungen ermitteln.

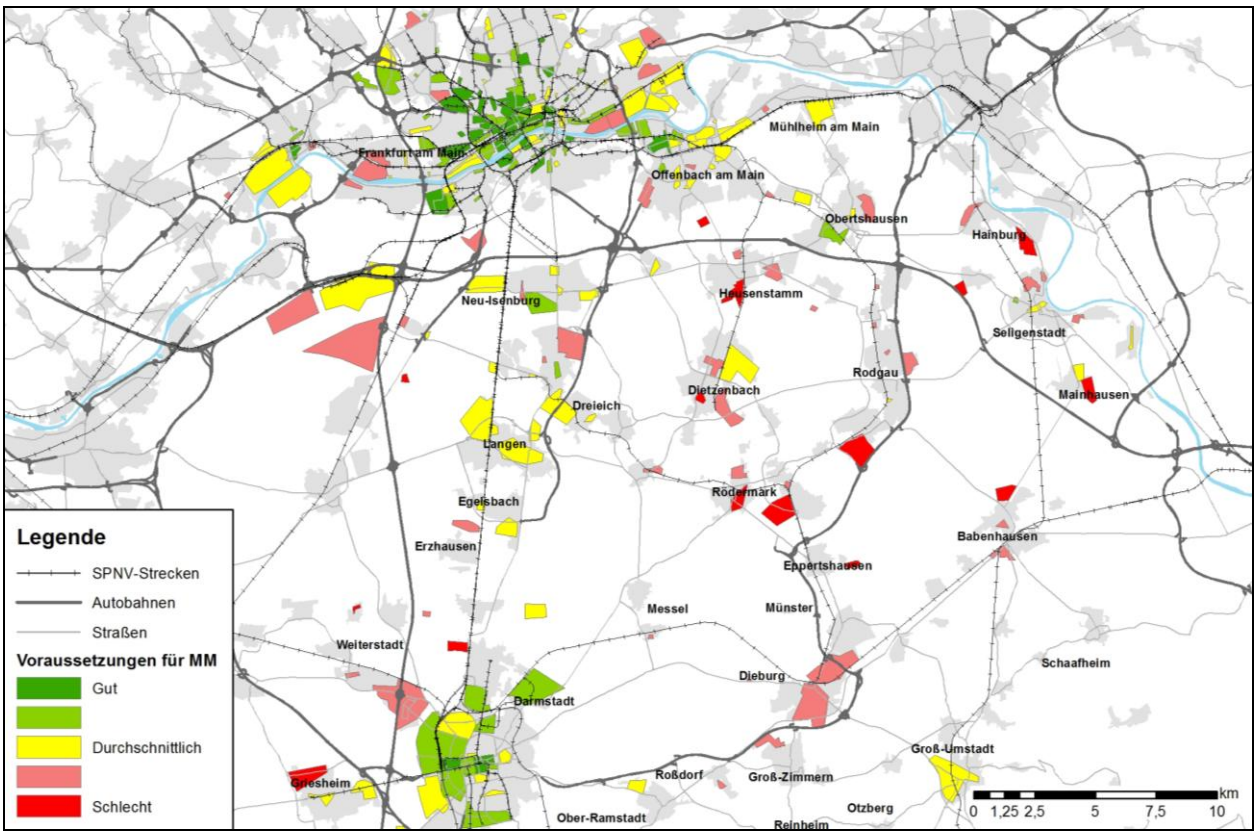

Abb. 2: Standortbewertung, Ausschnitt: Südliches Teilgebiet des Untersuchungsraumes (eigene Darstellung)

Erwartungsgemäß liegen die Standorte mit den höchsten Bewertungen in den Zentren der größeren Städte. Doch auch in Randlagen und kleineren Städten lassen sich als gut bewertete Standorte erkennen.

Bei Betrachtung der Ergebnisse über alle Standorte im Untersuchungsgebiet zeigt sich, dass sich diese über annähernd das gesamte Bewertungsspektrum homogen verteilen. Schwach repräsentiert ist lediglich der Bereich einer fast ausnahmslos schlechten Bewertung. Bei den Einzelindikatoren verteilen sich die Bewertungen bei den Indikatoren Betriebsgrößen, Parkdruck, Gehzeit zum SPNV sowie Abfahrten HVZ und SVZ auf Grundlage der festgelegten Wertebereiche zu annähernd gleichen Teilen auf die Klassen „gut", „mittel" und „schlecht". Bei den Indikatoren Tätigkeitsfeld, Entfernung zu BAB-Auffahrt, Konkurrenzfähigkeit ÖPNV/IV und Radpotenzial ist der Anteil „mittlerer" Bewertungen größer. Lediglich die Gehzeit zur nächsten ÖV-Haltestelle (inkl. Bus) wurde an knapp der Hälfte aller Standorte mit „gut" bewertet.

Mithilfe der Bewertung kann eine Vorauswahl von Standorten mit hohen Wirkungspotenzialen getroffen werden. Allerdings sind aufgrund der Zielsetzung der Standortbewertung, auf Basis von verfügbaren Datengrundlagen und erkannten Zusammenhängen (vergleichsweise grobe) Aussagen auf regionaler Ebene zu ermöglichen, deren Ergebnisse für detaillierte Standortanalysen nicht uneingeschränkt verwendbar. Daher ist es beispielsweise für die Festlegung konkreter Maßnahmen(-bündel) an Einzelstandorten erforderlich, zunächst für einige der Indikatoren eine Überprüfung der örtlichen Situation vorzunehmen. Gleichwohl sind Analysen der Schwächen von Standorten möglich, insbesondere hinsichtlich der Anbindung an den ÖPNV.

Eine Verfeinerung der Ergebnisse kann auch mithilfe der Differenzierung der Bewertung für verschiedene Wirkungsbereiche des Mobilitätsmanagement (z.B. ÖPNV-Förderung, Radverkehrsförderung, effizientere Pkw-Nutzung) erreicht werden. Für eine solche werden zurzeit entsprechende Maßnahmenbündel zusammengestellt, die später auch in die Wirkungsabschätzung einfließen.

4 WIRKUNGSABSCHÄTZUNG

Um die Wirkungen von Strategien des Betrieblichen Mobilitätsmanagements abzubilden, sind zunächst Informationen über die Pendelwege der Beschäftigten erforderlich: Wie weit pendeln die Beschäftigten? Wie gut ist das Angebot des ÖPNV im Vergleich zum Pkw für die Beschäftigten? Welche Verkehrsmittel stehen ihnen zur Verfügung und welche dieser werden heute (im Nullfall ‚ohne Mobilitätsmanagement') genutzt?

Anders als im Ansatz von effizient mobil, bei dem für Einzelbetriebe Wohnstandorte der Beschäftigten ermittelt und letztere zu ihrem Verkehrsverhalten befragt werden konnten (dena 2010), liegen bei einer regionsweiten Betrachtung von Standorten diese Informationen nicht vor. Daher wurden die Wohnstandorte und die Verkehrsmittelwahl mit Hilfe eines Ziel- und Verkehrsmittelwahlmodells abgeschätzt, differenziert nach Tätigkeitsprofilen mit unterschiedlicher Akzeptanz von Reisezeiten (höhere Widerstandsempfindlich¬keit bei gering- gegenüber hochqualifizierten Beschäftigten (Bohnet und Walther 2011, S. 27) :

So wurde zunächst für alle Erwerbstätigen i eines Tätigkeitsprofils, die in 1270 Verkehrszellen der Region Frankfurt Rhein-Main verortet waren, die Wahrscheinlichkeit Pi(jm) dafür ermittelt, dass der Arbeitsplatzstandort j mit Verkehrsmittel m aufgesucht wird. Es erfolgte dann iterativ eine Randsummenanpassung, um sicher zu stellen, dass jeder Job jeweils von einem Beschäftigten eingenommen wird. In die Nutzenfunktion des Multinominalen Logit-Modells flossen Reisezeiten, Kosten für Pkw-Nutzung, ÖV-Tarife, Umsteigehäufigkeiten und die Zahl der Jobs ein. Strukturdaten und Netze wurden aus dem regionalen Verkehrsmodell ‚Verkehrsdatenbasis Rhein-Main' (VDRM) entnommen. Die dort verwendete Spezifikation des VISEVA-Modells für den Wegezweck „Wohnen-Arbeiten" war allerdings nicht für die Anwendung für dieses Projekt geeignet, sodass die Spezifikation und die Modell-Koeffizienten im Wesentlichen aus einem von der TU Hamburg-Harburg für die Region Hannover erstellten Modell (Bohnet und Walther 2011) übernommen wurden und dann anhand der Pendlermatrix und Daten zu Reiseweiten und Modal Split aus einem Datensatz zur Aufstockung der Studie „Mobilität in Deutschland" (MiD 2008) für Hessen bzw. die Region Frankfurt-RheinMain validiert wurden. Im Ergebnis liegen Matrizen nach Tätigkeitsprofil von Wohnort i nach Arbeitsort j mit Verkehrsmittel m vor.

Aus dieser Matrix können für jeden betrachteten Standort die Wohnorte einer „synthetischen Belegschaft" und deren Verkehrsmittelwahl im Nullfall ‚ohne Mobilitätsmanagement' generiert werden (Abb. 3).

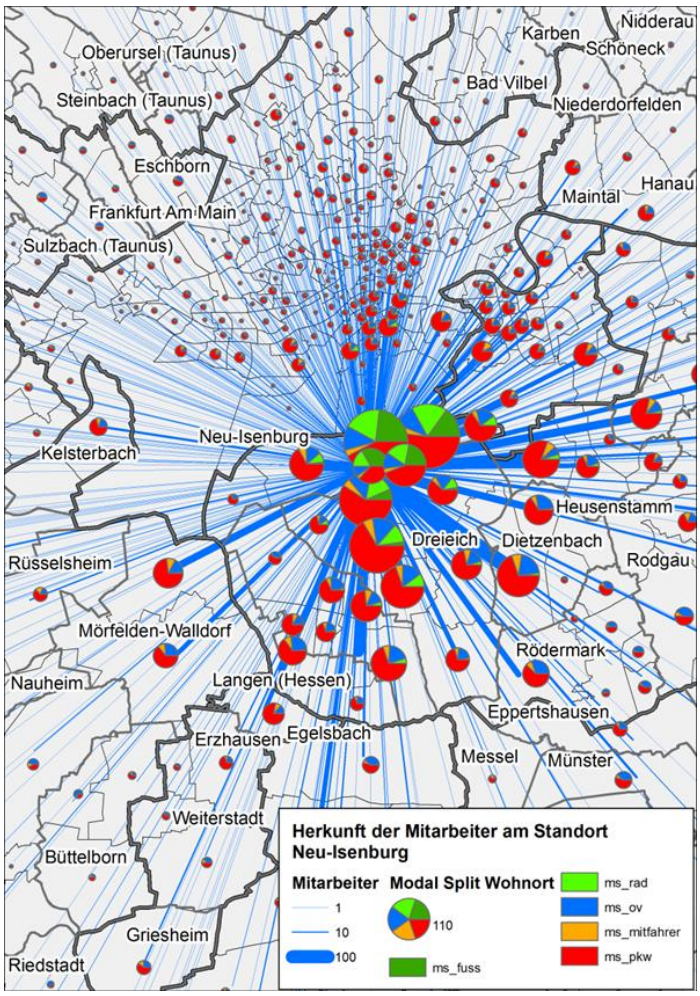

Abb. 3: Beispieldarstellung der Wohnorte und der Verkehrsmittelwahl der synthetischen Belegschaft des Standorts "Neu-Isenburg Gewerbegebiet West" (Eigene Darstellung)

Viele Beschäftigte sind über Alternativen zum Pkw nicht oder falsch informiert. Nicht-Nutzer überschätzen nach den Praxiserfahrungen der Mobilitätsberater in der Region Frankfurt Rhein-Main sowie einer Niederländischen Studie von van Exel und Rietveld (2010) die Reisezeiten des ÖPNV um mehr als 50 %. Daher wird die synthetische Belegschaft eines Standortes in nicht über Alternativen informierte „Pkw-Fixierte" und „ÖV-Informierte" unterteilt, wobei die Anteile aus den Befragungen der Beschäftigten in „effizient mobil" ermittelt werden (Fricke 2011). Die Verkehrsmittelwahl der „Pkw-Fixierten" wird dann noch einmal mit einem eingeschränkten Choice-Set bzw. unter Berücksichtigung der um 50% zu hoch wahrgenommenen ÖPNV-Reisezeit simuliert und das Modell so geeicht, dass der Nullfall ‚ohne Mobilitätsmanagement' valide abgebildet werden kann.

Daraufhin wird ein Planfall ‚mit Mobilitätsmanagement' simuliert. Dabei werden für verschiedene Standorttypen typische Maßnahmenbündel definiert. Diese umfassen verschiedene Maßnahmen, deren Wirkungen wie folgt modellmäßig abgebildet werden (vgl. Abb. 4):

- Durch das Mobilitätsmanagement werden objektive Eigenschaften von Alternativen verändert (z.B. Kosten der ÖPNV-und Pkw-Nutzung durch JobTicket-Angebote und Parkraumbewirtschaftung, Zugangshürden durch bequeme und sichere Radabstellmöglichkeiten)
- Durch individuelle Mobilitätsberatung und Aktionen wird die „empfundene" ÖPNV-Reisezeit bei der Gruppe der nicht-Informierten reduziert
- Mobilitätsmanagement generiert für einen Teil der Beschäftigten bislang nicht verfügbare Alternativen (z.B. die Alternative Pkw-Mitfahrer durch Fahrgemeinschaftsvermittlung). Daher wird das Choice-Set eines Teils der Beschäftigten um diese Alternative erweitert

- Durch Kampagnen, die Vorbildfunktion von radelnden Kollegen etc. wird die subjektive Bewertung von Alternativen (Image des Fahrrads) verbessert. Dies wird durch eine Anpassung der verkehrsmittelspezifischen Konstanten modellmäßig abgebildet.

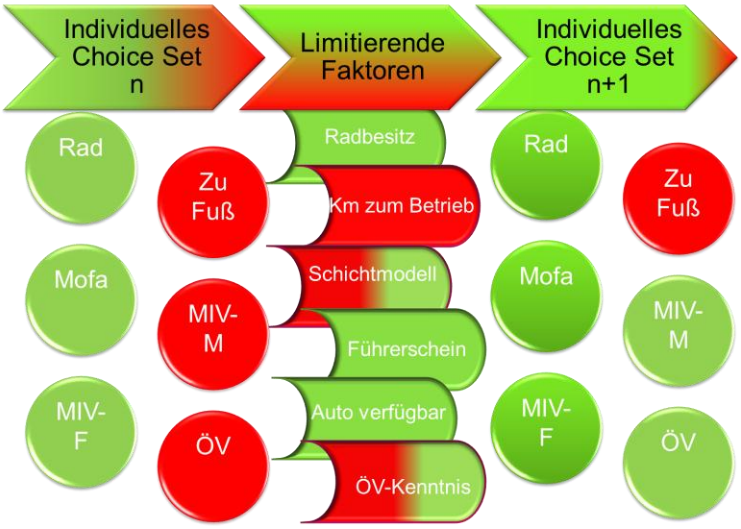

Abb. 4: Abbildung im Modell: Erweiterung wahrgenommener Verkehrsmittelalternativen durch Maßnahmen der Information über ÖPNV-Angebote und der Anpassung des Arbeitszeitmodells (eigene Darstellung)

Für eine regionsweite Wirkungsabschätzung von Mobilitätsmanagement wird für alle in der Standortbewertung als „gut geeigneten" Standorte die Verkehrsmittelwahl der synthetischen Belegschaft im Null- und Planfall ‚ohne' und ‚mit Mobilitätsmanagement' simuliert und so die Veränderungen bei der Nutzung der einzelnen Verkehrsmittel relationsspezifisch abgeschätzt.

Mit Hilfe der so erzeugten Differenzmatrizen Wohnen-Arbeiten können nachfolgend neben dem Modal Split auch weitere Kenngrößen wie CO2-Emissionen, ÖPNV-Erlöse berechnet werden.

Zudem könnten Entlastungseffekte im Straßennetz lokalisiert dargestellt werden, indem die Gesamt-Pkw-Nachfragematrix um die Differenzmatrix mit den eingesparten Pkw-Fahrten vermindert wird und auf das Verkehrsnetz umgelegt wird.

5 FAZIT, AUSBLICK

Während sich bisherige Ansätze zur Abschätzung der Umsetzungspotenziale und Voraussetzungen für betriebliches Mobiliätsmanagement primär auf die Untersuchung einzelner Betriebe konzentrierten, erlaubt das hier vorgestellte Verfahren eine flächenhafte Bewertung der Voraussetzungen für betriebsübergreifende Standorte auf Basis von Indikatoren zur Beurteilung der verkehrlichen wie auch der betriebsstrukturellen Situation am Standort. Im Ergebnis lassen sich geeignete Standorte einfach erkennen und kommunale Strategien zur Umsetzung von Mobilitätsmanagement gezielt angehen - sowohl im Bestand als auch bei der Neuansiedlung von Betrieben. Ebenfalls möglich sind Analysen der Schwächen von Standorten. Wird für einige der Indikatoren eine Überprüfung der Situation am Standort vorgenommen, lassen sich auch standortbezogene Analysen vornehmen, die detaillierte Planungen zur Ansprache der Betriebe und zur konkreten Umsetzung von Mobilitätsmanagement ermöglichen. Durch die Standortbewertung wird festgelegt, für welche Maßnahmenbündel („ÖV-Förderung", „MIV-Effizientssteigerung", „Radverkehrsförderung", „Parkraummanagement") der Standort geeignet ist und welche Entlastungseffekte daraus am Standort resultieren.Vorteil des hier beschriebenen modellgestützten Ansatzes ist, dass er auf verhältnismäßig leicht zu erschließenden Datengrundlagen basiert, was die Übertragbarkeit begünstigt und einen Verzicht auf sonst übliche Befragungen (BMVBW 2003) ermöglicht. Außerdem werden die Effekte des Mobilitätsmanagement dabei fundierter als bisher üblich abgeschätzt, da nicht eine pauschale Reduzierung angenommen wird, sondern die Effekte eines für jeden Standort passenden Maßnahmenbündels individuell geschätzt werden.

Auf Basis der Standortbewertung, der Modellierung der Wohnstandorte von Pendlern und der Auswahl von Maßnahmenbündeln können schließlich Planfälle mit- und ohne Mobilitätsmanagement vergleichend modelliert werden. Die zu erzielenden Entlastungseffekte für das Straßennetz können dann abgeschätzt,

Minderungen bei der Umweltbelastung und weitere Größen abgeleitet werden. Analog zur in der Praxis üblichen Modellierung von Infrastruktur- und anderen angebotsseitigen Maßnahmen können so die potenziellen Wirkungen der Anwendung von auf Mobilitätsmanagement basierenden kommunalen Mobilitätsstrategien vorab abgeschätzt werden.

1 ABSTRACT

Nicosia is the last divided city in Europe, which is the result of Cyprus conflict. Most important result was the necessities of population transfer between the inhabitants of the island. According to the ethnicity, Turkish Cypriots moved to northern part and Greek Cypriots to the southern part of the Island. Although the allocated land use at the edge of Nicosia buffer zone (border) in North is practically the same, because of their close proximity to the border these properties gradually either changed or lost their users, and became vacant and/or abandoned.

Brownfield definition for this study is based on widely accepted European brownfield definition which explains brownfields as the sites that previously developed and now are vacant, derelict and/or abandoned, and also these sites usually consist of real or perceived contamination which requires intervention to bring them back to effective use. Therefore the areas along the border in Nicosia are accepted as Brownfields within the concern of this paper.

These sites, which are in low quality condition of physical environment, have been affecting the overall development of the city, local economy, and also have socio-cultural consequences where those places are becoming differentiated from the rest of the city by means of physical, socio-cultural and economical aspects, including user profiles as well. Accordingly, the aim of this article is to define brownfield lands at the edge of Nicosia buffer zone, and to analyse their existing condition by means of physical, socio-cultural and economical aspects for achieving further sustainable development of those areas. The methodology of this study for data collection is site surveying and the evaluation will be through the European brownfield policies. At the summary of the paper, the findings out of the evaluation will be summarized to define the potential land use of those areas which are considered as brownfield site.

Keywords: Land Use, Mobility, Sustainability, Brownfield Regeneration, Urban Development

2 INTRODUCTION

2.1 Brownfields of Nicosia

Sustainable Brownfield Regeneration (SBR) is one of the most accepted tools in sustainable development issue, which is also a comprehensive solution for problematic lands such as brownfields. The definitions' exploration of the term "Brownfield" clearly shows that there is no exact common definition for this term. Therefore, based on British, European, and American definitions, the term "Brownfield Sites" is defined overall by this research as previously developed land which is real (estate) properties and may occupy a permanent structure in both built-up and rural locations. These sites have been affected by former uses of the site or surrounding lands. Brownfield sites are generally abandoned, derelict, idled or underused, and may have real or perceived contamination problems, where require intervention to bring them back to beneficial use (CABERNET, 2006). One of the accepted solutions for turning these deprived areas to lively, vibrant, and functional space is laid in the combination of urban regeneration and sustainable development, which is widely called as Sustainable Brownfield Regeneration (Dixon at el. 2007). SBR programs are about providing connection between technical issues and socio-economic concerns in order to give a new life to those dead lands and properties. Besides, these regeneration programs will reduce the pressure on Greenfield and prevent the urban sprawl to achieve more compact way of urban form. Awareness of the realistic dimensions of the projects is an essential, which throughout defining the role of stakeholders and managing the partnership, and also recognition and handling the potential risks, more realistic and sufficient results are expected.

Aim of this study is to provide prospects for brownfields in Northern part of Cyprus in general, and areas close to the buffer zone in particular, where no any research has been done before in this perspective. Accordingly this study aims at defining sites with potential brownfield status in northern part of Nicosia, and

particularly at the edge of Nicosia buffer zone to make an initial analysis and evaluation on their existing condition by means of physical, socio-cultural and economical aspects for achieving further sustainable development of those areas. The methodology of this study for data collection is site surveying, and the evaluation will be through the European brownfield policies. The existence of the border or by other means, the UN buffer zone which horizontally divided the entire island into two parts, and particularly the division of the city of Nicosia, caused urban decays with many dimensions at peripheral of the buffer zone.

Broadly, the study moved along a quantitative to qualitative path. Quantitatively, the components of urban changes in selected pilot area, in reference to the theoretical discussions of brownfield, are identified. This set a setting against which ranges of qualitative inputs were set. These inputs were derived from these primary research objectives of brownfield development; defining and classifying the existing setting according to different explorations of brownfield sites, developing an awareness against the issue, achieving participation of stakeholders, develop strategies to achieve regeneration of those potential sites as accepting them as assets to be activated for achieving socio-economic and physical transformation of urban space. In order to assess the existing setting and understanding the public response to certain provisions of the study, in-depth interviews with employees, residents and finally other stakeholders such as the central and local authorities have been held accordingly. Although brownfields exists on both sides (South and North) on buffer zone, it is important to define the limitations in order to be able to develop a comprehensive study for 'specific part of an area'. Therefore, areas close to buffer zone have decided to be case to develop an approach against existing 'unsustainable development'.

Though in South, through the EU accession and afterwards, several policies and programs have been developed for achieving regeneration of declined urban areas by means of brownfield development, and there have been no attempts done before on the concern of this research. Therefore, the theoretical part involves with the overall idea of brownfield regeneration that provides a holistic approach for further steps of the study where the developed strategies will be considered for the Southern part as well. Particular study of Northern part, peripheral areas to buffer-zone is accepted as 'case study' where outputs of the study will provide an input, and accordingly a complementary work should be considered by the South Cyprus as well in order to achieve integrated urban regeneration as a whole.

Generally, case studies related to Brownfield sites are defined in a framework that is formed throughout three dimensions; these three dimensions are physical/environmental, socio-economic, and economic. Each dimension has its own indicators, which all together formulate a framework for beginning of brownfield regeneration program. Also the outcome of this framework produces another framework for beginning of a holistic strategic plan. According to recent literature on brownfield issues, in each dimension there are some indicators, which act as the checklist for brownfield site analysis and evaluations. To be aware of variety in reflections of dimensions and indicators is an essential. For example, in the case of Nicosia, regeneration of residential areas will not increasing the rate of tax, therefore the indicator of tax income will not be the consideration. As a result, this research will use dimensions and indicators according to the characteristic of the area.

This study examines and evaluates the characteristics of these areas in a holistic approach. This holistic analysis takes the whole area as a mixed-use environment, with variety of users, and tries to decode and decontextualize the problems regarding to brownfield issues. Study area consists of industrial, commercial, and residential properties. In most of the literature and actual practices, the most common brownfield sites are industrial, and then commercial ones are in second place, the residential properties have become vacant and abandoned due to the result of special events, such as political/ethnical/religious conflicts, earthquake, war, and etc. The special issue about this case study is existence of the residential properties within the area, and these unique cases became brownfield as the impacts of buffer zone, which are now functioning as a barrier between two communities.

on the other hand, process of Sustainable Brownfield Regeneration (SBR) program consists of several steps, which each step is essential and foundation of another one (Shojaee Far, 2011). In fact, the beginning or the first stage of the program has an important role in whole regeneration project, which produces a general assessment and defines the problems (Table 1). This research attempts to evaluate the case of Nicosia according to the first stage, to emphasise the theme of general problems related to brownfield issues of the study area. For the purpose of this study, an initial site survey has been carried out in regards to all

dimensions. Beside exploration in existing documents and researches related to the Nicosia for finding out its physical characteristics, the questionnaires, in-depth interviews with locals and governmental authorities, decodes many problems of the area. Moreover the observations and physical evaluations of the sites, in combination with qualitative and quantitative data drew a framework to assess the problems and give the better understanding of existing situation.

Initial Stage of Process of SBR Program	
Initial Process (General Assessment and Problem Definition)	Initial Site Survey: - Physical/Environmental Site Survey - Socio-Economic Survey (Interviews, questionnaires, etc.)
	Recognition of Stakeholders to arrange a multi-disciplinary team for further stages
	Identification of theme of general problems
	Conceptual Framework out of initial analysis for SBR Program to emphasize positive and negative points

Table 1: Initial Stage of Process of SBR Program (Shojaee Far, 2011)

2.2 Nicosia, Last Divided City in Europe

Nicosia is a city where its history goes back to the early Bronze Age (3000 B.C.). From 9th century A.D. to 20th century many dynasties and kingdoms used to rule the island, such as the Byzantines, Lusignans, Venetians, Ottomans, and British governors (Gunnis, 1973). Finally after British period (1878-1960) in 1960 the people of Cyprus formed and established the Republic of Cyprus, however by the agreements between United Kingdom, Turkey, and Greece, two base areas have been reserved for Britain which are still in use and active. These two reserved base areas are located in Famagusta and Limassol regions, as it can be seen in figure 1. The life of new republic was so short, which it last only less than 14 years. Political conflict between Turkey and Greece in influential of new republic, and also the ethnical conflict between the two communities of Turkish and Greek Cypriots conclude another political conflict in 1974. Therefore Turkey intervened into the island as the guarantor for safety of Turkish Cypriots (BBC Timeline, 2011). Result of the conflict was division of island into two parts, with an establishment of a border by United Nation (Figure 1). Turkish Cypriots moved to the northern part of the island and Greek Cypriots to the southern part. The impact of this disaster also showed up in the city of Nicosia as well, which leads to division of the city into two parts (Cyprus country profile, 2011).

Figure 1: Cyprus map from CIA World Factbook, after 1974 (Source: CIA Fact Book, URL: https://www.cia.gov/library/publications/the-world-factbook/maps/maptemplate_cy.html)

2.3 UN Buffer Zone of Cyprus and Urban Decays Which It Caused in Nicosia

The border, which divided the country, consists of a buffer zone that established by UN to function as a physical barrier between the two communities. Agreeing the importance of buffer zone itself, there is another important factor about the buffer zone, which has shown in Alpar (2008) studies. In her studies it has noted that after southern part of the island have been placed to the European Union (EU), the buffer zone and northern Nicosia became one of the edges of EU, and Nicosia buffer zone transformed to the EU border. Therefore the existence of vacant and abandoned properties at peripheral of EU makes more sensitive

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

discussions about brownfield conditions. Furthermore what is perceived in buffer zone is like that the time is stopped since 1970's and all elements within the buffer zone such as houses, shops, cars, and etc. remain as how Cypriots' life style was in 1970's.

Right now the buffer zone itself has a function which is the country border, but if any time in future the conflict of Cyprus will be solve the buffer zone will not have any other function and it will turn to a huge amount of brownfield. According to this research the UN buffer zone is categorized into three parts according to where the buffer zone is located (Figure 2). The three parts of buffer zone are explained here:

(A) The part which divide the cities/settlements; these sections of buffer zone are located within the cities, and a portion of cities where many commercial, residential, and industrial functions were located, have become vacant and abandoned (e.g. Nicosia Buffer Zone, Maras District in Famagusta).

(B) The part which divide the greenfields, where now is no man land and is a huge undeveloped land where crossing horizontally all over the country.

(C) The part which is completely covered by previously functional land/buildings or facilities and now they are vacant and abandoned because of characteristic of border itself, these properties are not within the cities and they are located in suburbs or rural areas (e.g. Cyprus International Airport).

The main difference in these categories is in the locations of the buffer zone, for example although both category A and C are a built up area, the difference between them is that the category A located within the city and category C located at suburbs or totally out of the city.

As a matter of fact, the buffer zone, divided the city of Nicosia into two parts, and although before the division, the historic walled city of Nicosia was the centre of city, it turned to the edge of the city as well as the other central neighbourhoods. In the northern part of Nicosia the properties where Greeks used to live, became vacant and abandoned, and because of population transfer it started to be used by Turkish people [1]. The threat of another possible conflict, the huge vacant and abandoned area within the buffer zone, existence of army in the area, and existent of physical and mental border resulted in population crisis of original inhabitant. Besides for many years because of its strategic location, the government did not put any effective urban investment into the area. (Cyprus country profile, 2011)

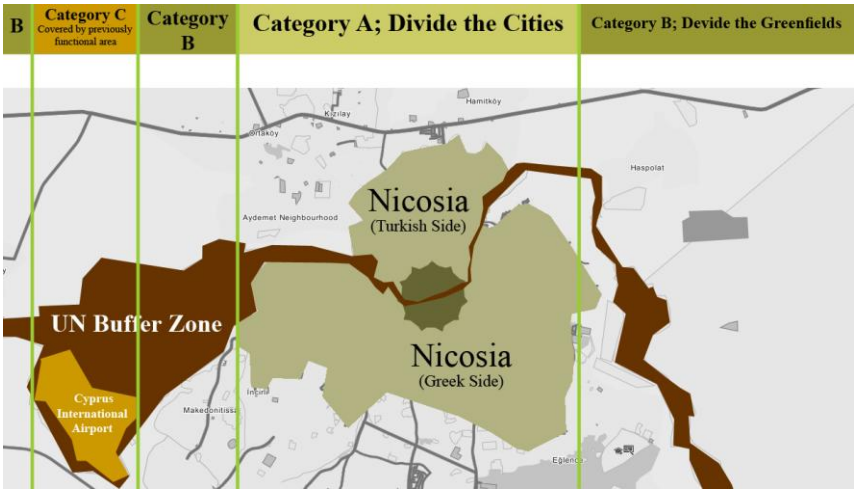

Figure 2: Categories of UN Buffer Zone According to its Location

All these situations caused urban decays in peripheral of Nicosia buffer zone. The neighbourhoods where used to be a vibrant urban space, turned down to a poor neighbourhood, which progressively caused the slum condition. It is important to know that the physical barrier was not the only reason for urban decays of peripheral of buffer zone and other older part of the city. Accordingly other several reasons were involved in that condition such as negative political and international situation, economical problems, big number of immigrants with low user's profile, and many other issues that have discussed in further sections of this study (BBC Timeline, 2011).

[1] Turkish Cypriots who were refugee from the southern part and Turkish immigrants from Turkey.

Existence of the barrier in middle of the city transferred most of economic activities toward the northern part of the city, and stayed away from the buffer zone. Many commercial and industrial buildings were shut downed in last 30 years, and left vacant and abandoned areas within the city at the peripheral of buffer zone, as well as many residential properties, for example "Sanayi Holding Binasi" which used to be an industrial building and "Caglayan" neighbourhood where used to be one of the luxury residential area. The division showed its impacts on urban structure and formed a negative socio-economic setting within the area.

In brief overview on periphery of southern side of buffer zone it can be said that although in Southern Cyprus, regards to their membership in European Union and EU Strategic Development Plan, regeneration of urban areas is one of the main concerns of their development plans, but the particular "integrated" approach to "urban regeneration" which can ensure the "integrative" effect is often missing. This missing element established fragmented and partial approaches, which have a great negative impact on the city, and produces the big obstacle for considering the city as a whole for developing strategies of a greater scope. (IUREU, 2010)

2.4 Brownfield Sites in Peripheral of Nicosia Buffer Zone

In peripheral of Nicosia buffer zone there are many previously developed lands, which are vacant, derelict, and abandoned. Although in land use policies of Northern Cyprus, there are no rules for brownfields, however according to this study, these properties are subjected to brownfield status. In these regards there are three regions of brownfields next to Nicosia buffer zone in northern part, which surrounded the historical Walled City. Although in the Walled City there are many sites with brownfield's characteristic, but because the Walled City is a historic place, then those sites are considered as historic urban quarters (HUQ) and they cannot have the status of brownfield. Therefore these regions have been marked with brownfield status according to the accepted definition of brownfield sites by this research. Within these regions there are many previously developed lands (PDL), which are vacant and/or abandoned, and also many lands are partially occupied. Many sites in the study area have one or combination of the elements of partially occupied lands, which are (1) not currently fully in use, (2) land or building currently in use and allocated by different land use in local plan, and (3) land or building currently in use with redevelopment potentials (HCA, 2011). Two of these regions have the residential land use and located at sides (east & west) of the walled city and the other one is a mixed-use area consists of commercial, industrial, and residential area, which is located on top (north) of the walled city (Figure 3).

These three areas have been suffering from an urban decline because of that huge vacant and abandoned area (Buffer Zone) which crossed the city and gradually by the time, they have lost their original users, and became vacant and abandoned. Although some restoration and conservation project were applied on a number of those properties, but still many of them remains empty with no good condition, and as a whole is seems to be far from achieving sustainability concerns in the area.

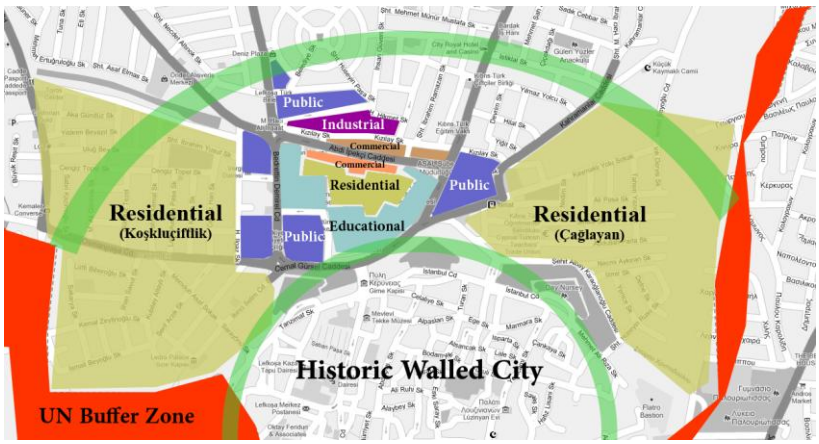

Figure 3: Study Areas, Peripheral of Nicosia Buffer Zone

With no doubt there are variety of barriers to achieve sustainable development in these areas, such as lack of professional and contemporary methods, absence of sufficient policies regarding to sustainable development, variety of visions between local government and professionals, poor attention to social sustainability, and of

course the existence of physical and psychological border. All these limitation shaped an unsustainable scheme for these areas.

3 MACRO SCALE REVIEW

Today, the urban structure of the city of Nicosia consist of three parts, (a) the historic walled city, (b) the inner part of the city, and (c) the newly developed areas in suburbs which has been attached progressively to the city. On the other hand, the shape of buffer zone, which is the dividing element in the city, formed the southern edge of the Nicosia in northern part (Figure 4).

According to this study the buffer zone has been categorized into three categories, therefore in this scenario, the buffer zone located in the category A. This section of buffer zone is located within the cities, where many commercial, residential, and industrial functions were located become vacant and abandoned. Progressively according to these situations, the peripheral areas of buffer zone which consists of mixed land use include residential, commercial, industrial, governmental, and public facilities have been faced the serious declines in urban environment.

Impacts of buffer zone have been affected its periphery and have shown up in many ways such as in functional, infrastructure, and transportation systems of the city. Not just brownfield sites within the area, also most of properties in the area as a whole need a comprehensive regeneration plan. In regard to finding a solution, Alpar (2008) argued that a holistic top down decision with combination of bottom up decision system, which is partnership of community, could resulted in more sustainable outcomes.

Although many efforts have been taken place for redevelopment of the area, such as Nicosia Master Plan (NMP) and United Nation Development Program (UNDP), the main focus of all these programs were on protection of historic and cultural heritage. These efforts achieved some good results such as NMP by winning the Aga Khan Award in 2007, which restored and regenerated some areas, however it fails in social dimension, due to lack of participation of property owners who are waiting for political settlement (Hadjri, 2008).

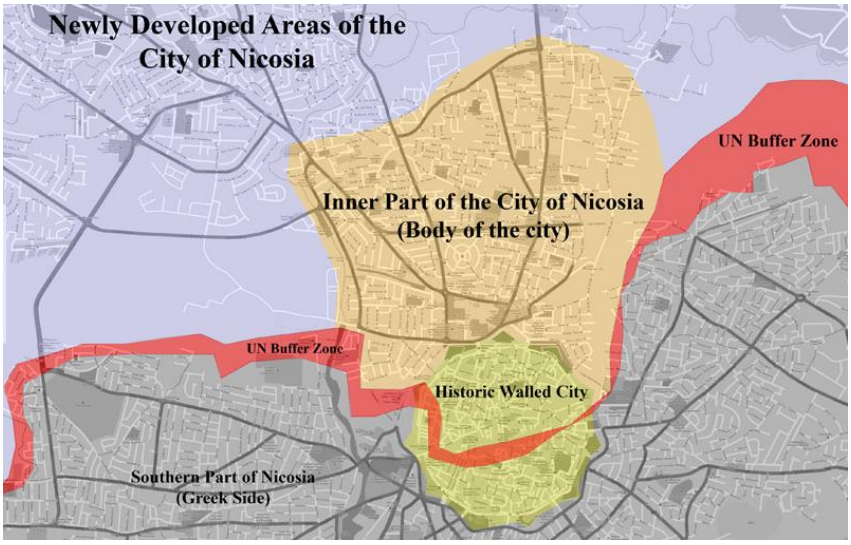

Figure 4: Urban Structure of City of Nicosia

3.1 Initial Stage; Findings Related to Periphery Area of Nicosia Buffer Zone

Based on the study of existing documents about physical characteristics of the case area, it can be said that the selected study area has variety of land use; previously industrial activities and accordingly vacant industrial buildings are located at the heart of the area, which surrounded with vacant commercial buildings and warehouses (Figure 5). Existence of some functional daily activities such as governmental offices (parliament, ministry buildings, and Turkish embassy), public high school and historic walled city brought some daily life to the area. However these activities are not enough to change the social structure of the area and did not help the improvement of urban settings. On the other hand, the residential areas (e.g. Caglayan

neighbourhood [2]), which are one of the oldest neighbourhoods in Nicosia, are suffering from abandoned properties and lack of sense of belonging form owners, users, and public authorities (Figure 6).

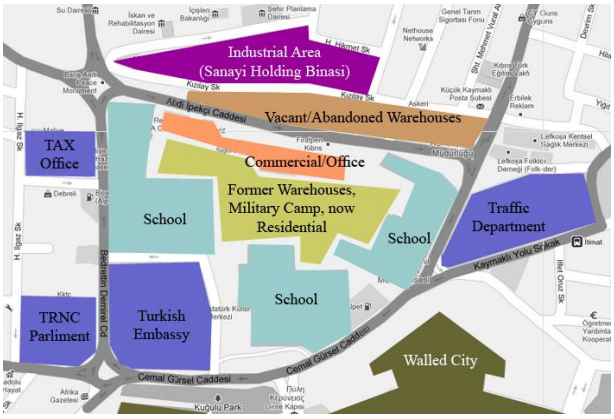

Figure 5: Study Areas, Mix-used Environment

Figure 6: Vacant and Abandoned Houses in Caglayan Neighbourhood

To realize the sole of challenge a site survey has been done with Turkish Cypriots community who lives or works in that area. The initial site survey formed throughout three dimensions, which are physical/environmental, socio-economic, and economic.

3.2 Physical/Environmental Dimension

During the study it was realized that there is a level of contamination in whole neighbourhood, and there is no statics and analysis about that. The industrial building (Sanayi Holding Binası) has been vacant for many years and municipality does not have any authority and rights [3] about that building (Figure 7). This building which was performing industrial activities, for sure has been contaminated the soils and water base, however there is no action about this and rather than applying brownfield regeneration program, which leads to un-contamination and regeneration, the government decided to demolish the building and built the new one.

In challenge between demolition and regeneration option a questionnaire shows that more than 50% of the people who live in the area were strongly agreed to regenerate that building and any buildings with same situation rather than demolition option. Towards resident's opinion, also people who work in municipality were strongly agreed with the regeneration. In this regard, deputy town clerk of Nicosia noted everything in that area are suffering from lack of a holistic strategic plan and for sure the partial planning and fragmented decisions will not help any of these problems.

The bigger disaster was about another neighbourhood just in front of that industrial zone, the neighbourhood has a long history, it was a graveyard and then it turned to industrial warehouses and British soldiers' camp, and then the function has changed to UN camp. In 1964 Turkish Cypriots [4] who forced to leave their properties, moved to this neighbourhood and some other refugees and immigrants moved there after 1974. This area was never un-contaminated (graveyard, military camp, copper warehouses), and people live in the

[2] Caglayan neighbourhood used to be a rich environment, and mainly with the high profile users, still some villas with yellow stone façade can be seen there, however the overall condition of those buildings and whole neighbourhood is in decline.

[3] Before municipality of Nicosia built its new building, municipality asked for that industrial building to regenerate and change it for use of the new municipality building, however they never succeed in their request and they built a new building somewhere else.

[4] The verbal story from an old man who actually moved there in 1964 and still living there in poor condition.

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

warehouses, where now transformed to residential area, however the physical condition is more look like a slum neighbourhoods (Figure 8).

In centre of study area there are two sides, the main street and the back street side where most of properties are located. Thanks to Nicosia Master Plan, the main street side is improved and somehow it is gentle by means of physical environment; however the back street side is suffering from serious urban declines. In those back street areas (Figure 9) there is no utilized infrastructure (e.g. street lights, proper roads, pedestrian, and etc.), rain water runoffs in the road during the winter time, garbage and waste materials are everywhere. Unfortunately as a matter of fact, in governmental departments and municipality there is no policy and regulation regarding to brownfield issues, and more sadly nobody knew about it, from top to down level, include professionals and decision makers were unfamiliar with the term "Brownfield". Accordingly, since there is no policy, then nobody knows about the risks of brownfields and the benefits of regenerating them, moreover it is a policy disaster that there is no action about that. This is the foundation of problems regarding to SBR program in North Cyprus.

Figure 7: Abandoned Industrial Building

Figure 8: Warehouses, which were transformed to residential

Also physical existence of UN buffer zone and military area in nearby all civic functions in study area are affecting the physical environment of the area. The shadow of restricted areas prevents any further efficient development in nearby sites.

Figure 9: back street areas

3.3 Socio-Economic Dimension

The people who live and work in the industrial, commercials (e.g. vacant warehouses) and residential areas (e.g. Caglayan neighbourhood and residential nearby industrial zone) do not have any sense of belonging to the area and as what perceived there, it resembles refugee camps rather than urban environments. There are just some conservation projects about historical heritages, which act as a gentrification scenario, and there is no actual regeneration. Most importantly people lost their belief in government for any further changes, therefore according to quantitative surveys there is a high level of user's un-satisfaction.

In series of interviews at Nicosia municipality many thoughts and believes has been demonstrated the professional opinions about the area. In this regard, an architect from project department believes that many components should get together to succeed the regeneration program, and especially in the case of brownfield sites it needs specific knowledge and policies that are not exist in North Cyprus. He believes what they are doing is only the restoration program, and because it fails in social aspects, it will be only a gentrification. In the city-planning department there is a progress to produce a new master plan, but unfortunately as he mentioned there is no specific consideration about brownfield issues.

Although most of people are not satisfied with existing situations and they do not believe the local government will share the decisions with community, but then again more than half the people who answered the questionnaire have the willing to participate with any future regeneration programs. This willingness is an opportunity for further development plans.

Opinions about participation of community in regeneration programs have two sides; people within the community wish to participate and open a new page of healthy urban environment and in other side government and in particular the municipality believes that there is no community to partnership. Accordingly deputy town clerk noted that the community in Nicosia changes a lot and people are behaving privately and not like a community. It is because of many changes in texture of community during less than a century. Each week the municipality has a council meeting for public, to let them share their opinions, but as the long term results, these discussions will not affect the decision processes, and it is a top down decision system. Deputy town clerk sharply defends this situation by referring to lack of existence of permanent community, and then he raised this question that "when we don't have a permanent community how can expect the community shares the ideas and be a part of the projects?"

Although there is no regulations regarding to brownfield regeneration, and both sides of community and government lost their beliefs in partnership, municipality still believes that the problem can be solve by partnership with private sectors with economically feasible strategic plans. This Public-Private Partnership (PPP) idea can open new chapter in governmental decisions and leads it to the community partnership.

According to the in-depth interviews, it is perceived that there is not much partnership between these actors. In this regards municipality believes that everything will come to the political issues, and since politic is the part of holistic approach, there is an essential needs for a holistic strategic plan. Therefore, if a holistic strategic planning happens, then it can be expected the partnership of all stakeholders, and particularly the community, which leads the project to succeed. Also, uncertainty about political situation will produce uncertainty in public, private, and community decisions.

3.4 Economic Dimension

Unfortunately, there are no defined incentives or grants for propose of regeneration plans or SBR program, therefore mostly it is too costly for private sectors to handle these types of programs in their development plans. In this regards private investors are not interested in those areas and the investment will goes to greenfields rather than brownfields, therefore more pressure will be on natural environment. The main source of this situation is lack of feasible financial strategic plan for brownfield regeneration, which means there is no holistic management for economic and strategic development. Also, as the start point of economic analysis to produce initial analysis for SBR program, the opinion of community is an essential.

According to the questionnaire surveys, which has collected the data from community about their opinion related to economic issues, most of the people in community were agreed that the regeneration programs bring new job opportunities and new investment to the area and if the government provides some grants and incentives as a catalyst, then the private sector and community have the willing of partnership. Therefore if the area is regenerated they might not be complaining for any possible future new tax systems and more tax payments.

According to the findings of this research, the existing stakeholders are mainly from public sector. Stakeholders in regards to brownfield issue have been categorized into four categories. In physical environment this is the top down decision system, which start from ministry of interior, parliament, city planning department, and municipality, and these are the main actors in this category. For environmental issues there is an environmental office department, and ministry of tourism and environment, which are the main stakeholders. For community support and social issues, working and social security department, NGOs, and associations are the main stakeholders. Finally, for economic issues the government and department of economy are the main actors. As a matter of fact, most of these stakeholders act separately and unfortunately there is no efficient partnership between them.

4 EVALUATION OF THE INITIAL STAGE FINDINGS

In order to provide a better understanding of existing situation, and according to initial qualitative and quantitative data analysis, for future decisions and holistic plans, this research categorized the positive and

negative issues related to the study area. It examines the area's strengths and weaknesses, which identified the opportunities for further improvements and threats where needed to be controlled and managed.

4.1 Positive Issues

The study area is located in heart of the inner part of the city and there are many public buildings and facilities in that area, which are giving the impression of daily life activities. Also the existence of historic walled city and tourists who come to see the historical heritages is a great advantage to the area. On other hand, the overall structure of most of buildings is suitable for restoration and then regeneration. Moreover, as an environmental advantages the area has a good air quality.

Another positive point of the area is that the people who works in municipality are mainly Turkish Cypriots who experienced and seen the advantage of cooperation with other society (Greek Cypriots) throughout NMP, and they have a strong willing for improving the quality of life of people who lives in their community. Also existence of infrastructure within the area is an economic advantage for government, which they do not need to invest for new ones.

Throughout de-contextualization of existing situation within the site, the study shows some opportunities for further developments, which also should be considered as positive issues. These opportunities are the access to the UNDP resources, being at the peripheral of European Union, which provide the possible request for technical support, have chance to find a solution for contamination problem, and also because of historical and strategically location there are many optional new functions for regenerating the abandoned properties, and then development opportunities in vacant lands.

On the other hand, people who work and live in those areas are willingly participating in any possible future regeneration program and they wish for changes for better quality of life. Also another good signal of opportunities is that professionals who work in municipality are aware of most of the existing situations. Moreover since the government gave the incentives to revitalize and protect the historic heritage and have got the positive results, then there is chance for possible incentives for future regeneration programs, which increase the tax income for the government. Another positive point of study area is that municipality believes the solution is laid in private approaches, which sound like high profit for privet sectors throughout participation and investment.

4.2 Negative Issues

Throughout the analysis and evaluation of the study area it has shown that there are some risks and threats existed there, which need to be controlled and managed. The best solution for these problems is placed on a clear and professional risk assessment and management process. The level of awareness is an important factor regarding to the risks. One of the main threats to the studied site is absence of policies and regulation about brownfields and contaminated sites and no existence of statics and surveys about the level of contamination. On the other hand, existence of abandoned properties which has the ownership problem, poor urban setting which look like a slum neighbourhood, and possible contamination within soils and water bases produce the physical and environmental threats to the area.

Another negative issue is producing the high risk for the community and social aspects; these risks, which have long-term effects, can end up with another social disaster. High level of users' un-satisfaction, top-down governmental decision system, no more community believe in government and government does not share the decisions with the community are the main social negative issues. Correspondingly, because of political situations, municipality does not have enough power to make the main decisions of city and in other hands central government concerns more economical issues rather than social ones and also they do not believe in regeneration, which make them focused and invest on new developments. Since public sector does not act as catalyst for possible brownfield regeneration programs, then private sectors invest for new developments in greenfields. Furthermore the most important negative point is the absence of guideline for previously developed lands (PDL), which are vacant and/or abandoned now.

As general negative issues in study area there is lack of many things such as lack of skills and knowledge for un-contamination techniques, lack of utilized infrastructures, lack of green spaces and landscapes, lack of permanent community, lack of sense of belonging, lack of community partnership, public-private partnership, partnership of public stakeholders, lack of holistic strategic plan, lack of incentives and grants,

lack of feasible financial and economic plans, and lack of management for economic and strategic development. These missing elements draw a scheme of what does not exist.

However, there is existence of some other elements, which are the reason for other negative issues in study area such as UN buffer zone, military bases, uncertainty about political situations and settlements, and gentrifications rather than regeneration. Moreover low level of some other issues such as people's income, local's population, educational background, and low interest of investment from private and public sector make the negative points of the study area more dominant. For finding a solution for these negative issues, an intervention and in-depth studies are essential need.

5 SUMMARY AND CONCLUSION

This study initially analysed the periphery of buffer zone which is located at inner part of Nicosia by means of physical/environmental, socio-economic, and economic dimension. These analyses were based on existing situation of the city in regards to urban declines, vacant and abandoned properties, and in more complex way the brownfields issue.

Existence of physical barrier and the dead area, which has referred to UN buffer zone, set a huge pressure to the urban areas in general and in particular to peripheral of border within the island. These impacts affected the social structure, physical environment, and economics of those areas. These urban crises were shown up with the vacant and abandoned properties have been addressed as urban declines that referred to brownfield site. Unfortunately, because the issue of brownfield was a new concern within the island, there is no existing policy and regulation about it. All abandoned and vacant properties with possible contamination have been leftover in poor urban environment, which many immigrants and refugees moved there (Figure 10). The area that once used to be a vibrant urban environment has turned into a neighbourhood which looks like a run-down area or slum.

Although there are some positive points within the study area, the negative issues lead the area to serious risky situations. Contamination within the sites, which are never evaluated, can cause long-term health problems for the community, and affect the natural and environmental system in the area. On the other hand people are extremely unhappy about the existing situation and lost their belief to the government, and uncertainty about political situation adds more pressure to the situation. Also, the government does not share the partnership and this solo mentality in decision making system, which referred to the top down decision system, will produce the high risk of urban disasters for future of the city and in particular the brownfield issues.

In general overview, what are needed for the study area are improvement in state policies, transformation of abandoned and vacant properties to the functional form, transformation of military areas within the city to some other public functions which leads to contribution of those facilities and properties in city life, and enhancing the community partnership which are essential to improve the quality of life in Nicosia.

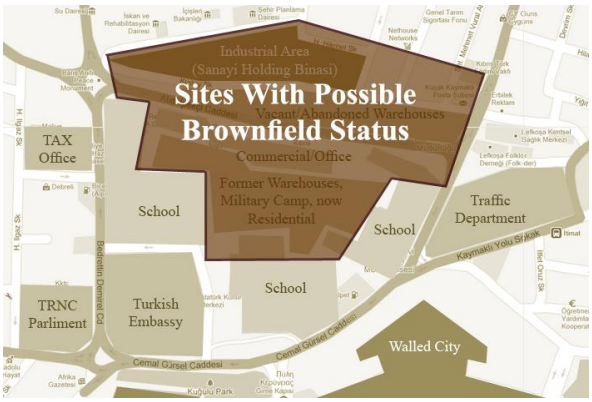

Figure 10: One of the sites with possible brownfield status at the centre of study area

Nowadays the main development issue in Cyprus has focused on Greenfields and this sprawl development will have long term negative impacts to the urban environment of the island. If this situation continues with the existing condition, approximately in next 30 years, solution for all these problems will be so expensive by means of money, time, and effort. According to these situations the main outcome of this study should be considered as a serious warning for the future of the island and particularly the city of Nicosia.

1 ABSTRACT

In the last years, advancement of digital technologies has led to the development of innovative information and communication applications. Today, geographical digital tools are closely linked to computer-based communication processes, and contemporary (Geo-)ICT is extensively used in a wide range of different applications. However, for taking full advantage of these tools across society – including special needs groups – manifold open issues still have to be considered referring to topics such as e-inclusion. Interest is rising on enabling visually impaired to make use of web map applications, especially web-based city maps. Due to demographic change – associated with the rapid aging of population and the increasing number of people with age-related visual impairment – this is particularly in recent times. Unfortunately, the access and use of currently available web map applications is difficult or even impossible for visually impaired. Hence, several questions pertaining to the appropriate design and implementation of web maps for visually impaired are still open: (1) How to design and configure user interfaces of web map applications for visually impaired? (2) Which functionalities need to be implemented? (3) Which map content is demanded by visually impaired? (4) Which kind of graphical and non-graphical map design is most useful to enhance accessibility? The AccessibleMap project aims to investigate the above mentioned questions and to develop methods to make web-based city maps more (easily) accessible and usable for visually impaired. A prototype web map application is developed.

2 INTRODUCTION AND RESEARCH QUESTION

Rapid advance of information and communication technologies (ICT) has changed the way we communicate, exchange information, and catch up on contents. Virtual globes, web mapping services, GPS, and many other geographical digital tools are closely linked to computer-based communication processes. This opens up new opportunities for E-inclusion. The concept of E-inclusion focuses on widespread web accessibility for all users, enabling everyone to benefit from ICT. It tends to support participation of everyone in all aspects of today's information society. The concept of E-inclusion is in line with the goals defined by the Digital Agenda of Europe which generally aims at "(…) to chart a course to maximize the social and economic potential of ICT, most notably the internet (…)" (EC 2010: 3). In addition, the i2010 Initiative on E-inclusion targets at "(…) to realize an inclusive information society, that is, an information society for all" (EC 2007: 2).

Hence, the concept of E-inclusion focuses on digitally including disabled users who cannot (fully) access and use web-content. This refers to persons with vision deficiency such as people with reduced, i. e. limited vision, colour-blind, and blind users. In fact, these target users are very heterogeneous as – for instance – they embody elderly people which due to age-related visual impairment experience similar difficulties in retrieving web content. Thus, demographic change and the growing number of elderly people underline the outlined demand.

In this context special interests arise in terms of web-based maps. As by studying a map, users create a mental or cognitive map and can understand space in a better way (Tolman 1948). Alike maps in general, web-based maps are crucial means in terms of helping people to orientate themselves in physical space, and to guide from place to place. By enhancing mobility skills, (web-based) maps improve the quality of life and support a more active life and aging. A person who is mobile can better perform autonomously daily-life activities, and can hold up social networks (UN Habitat 2006; WHO 2007). Thus, (web-based) maps are important assistive (Geo-)ICT-based solutions. This refers especially to the urban space, where city maps can enhance individual sense of confidence, autonomy, competence, and feeling of safety. Generally, these maps can be used for the discovery of urban space, i. e. the location and spatial relation of streets, crossings, and landmarks etc.

However, even though different types of assistive technology and visual aids (e. g. screen reader, braille display, text to speech technology) as well as guidelines and standards of accessible web design have been developed, for this special needs group it is currently difficult or even impossible to make use of the available web-based maps. Research is still needed to provide accessible graphical and cartographic information (i. e. maps) on the web for visually impaired. Several questions on appropriate design and implementation of web-based maps for visually impaired exist: (1) How to design and configure user interfaces of web map applications for visually impaired? (2) Which functionalities need to be implemented? (3) Which map content is demanded by visually impaired? (4) Which kind of graphical and non-graphical map design is most useful to enhance visual accessibility? To answer these questions major importance refers to understanding the user group visually impaired and their requirements.

The project AccessibleMap, funded by the Austrian Federal Ministry of Transport, Innovation & Technology within the Benefit program (started in April 2011), addresses the above-mentioned questions. The AccessibleMap project is based on the research results of the AmauroMap project (funded by the Internet Foundation Austria in 2010; Wasserburger & Neuschmid 2010). The main objective of the AccessibleMap project is to develop and improve usage of web-based maps according to the requirements of visually impaired people. Therefore a prototype of a web map application is developed that is executable on PCs and mobile devices.

3 ANALYSIS AND SPECIFICATION OF USER REQUIREMENTS

Within the AccessibleMap project constructive co-operations between users and target group experts as well as developers are principally seen as a fundamental precondition for and a central aspect of the application development process.

The AccessibleMap project analysis and specification of user requirement is based on a literature review as well as on a user survey, focusing on the above outlined target user groups. Therefore an online questionnaire was designed using the internet survey tool SurveyMonkey (URL 18) according to the principles of empirical social research. The survey was developed in close co-operation between the different project partners (ICT-experts, GI-experts, target user group experts).

The questionnaire design is based on the results of the comprehensive literature review which covers literature from e. g. Web Cartography, Modern Cartography, Special Needs Cartography, and Cybercartography (Hennig & Zobl 2011). From reviewing the literature available on the topic, it became obvious that detailed information on design and implementation of web map applications for visually impaired is mostly missing. Thus the questionnaire was particularly designed to get response on open questions regarding user interface design and functionalities, map design, and map content.

The questionnaire consisted of 55 open and closed questions addressing the different types of visual impairment. The questions referred to:

(1) Demographic issues (sex, age, education, profession, place of residence etc.);

(2) Aspects regarding the visual impairment of the participants (type, extent and timing of the visual impairment etc.);

(3) General characterization of internet user behavior (extent of internet use, use of digital devices, use of assistive technology and visual aids etc.);

(4) General characterization of web map user behavior (extent of use, problems, purposes etc.);

(5) User needs on map content (user group specific information, supplementary links, etc.);

(6) User preferences on the graphical and non-graphical user interface design (access and use) including functionalities;

(7) User preferences on the (carto-)graphical and non-(carto-)graphical map design (cartographic means of design, use of additional information media like photos, audio signals, verbal description etc.).

The survey was carried out in autumn and winter 2011. The study was spread across Austria, Germany and Switzerland by Email, telephone and face-to-face propaganda. The data collected by the survey was pre-processed (identifying valid and invalid responses such as responses of non-visually impaired), statistically

analyzed (e. g. frequency distribution, measures of central tendency), interpreted, and integrated in existing knowledge, experiences and other research findings.

4 TARGET GROUP SPECIFIC USER REQUIREMENTS

The AccessibleMap user survey resulted in 199 returned and 158 valid questionnaires. The valid questionnaires are grouped under three subgroups of target users as follows:

- people with reduced and limited vision: 59 %,
- colour blind: 4 %, and
- blind: 37 %.

Because of the large number of issues covered by the questionnaire, only selected items are presented in the following.

4.1 General use of the internet and web map applications

The majority of the 158 (valid) respondents indicates to make strong use of the internet. 63 % of the interviewees use the internet several times per day. To make full use of the internet, assistive technology and visual aids are required by 85 % of the respondents (Table 1). In this context voice output, screen reader, braille display, and magnification software are the most popular tools.

Assistive technology & visual aid		**Blind** (n=59)	**Limited vision** (n=99)	**All (n=158)**
Braille display	An electro-mechanical device for displaying Braille characters by use of raising dots through holes in a flat surface. This enables blind people to read text output on the computer.	88 %	10 %	39 %
Braille embosser	A Braille printer that renders text as tactile Braille cells.	25 %	3 %	11 %
Magnification software	Software for enlarging text on the computer screen (e. g. screen magnifier, ZoomText).	3 %	57 %	41 %
Optical Character Recognition (OCR)	Software used to convert scanned text into information that the computer can recognize. This software – along with PC and scanner – gives visually impaired people access to almost all printed material.	53 %	9 %	25 %
Screen reader	A software application used to identify and interpret text presented on the computer screen into spoken words. Common screen readers are Window-Eyes from GW Micro, JAWS from Freedom Scientific, etc. NVDA is an open source screen reader that gets well-known nowadays.	80 %	24 %	45 %
Voice output	A text-to-speech (TTS) system converts normal language text into speech.	88 %	31 %	53 %

Table 1: Used assistive technology and visual aids (multiple replies possible).

Even though the interviewed persons show a high level of internet usage, only 56 % point out to use web maps. Respondents mentioned different reasons therefore:

(1) Web map applications are not (easily) operable, i. e. not (easily) usable.

(2) Web map applications do not provide verbal descriptions of their content.

(3)Web map applications cannot be interpreted by screen reader, Braille display or voice output.

(4) Users lack knowledge on the existence of web-based maps.

(5) Users make use of voice-operated navigation devices instead of web map applications.

Hence, the provision of voice output and textual, i. e. readable descriptions is a fundamental requirement to enable usage of computer applications including web map applications to these users. In terms of web map applications this refers to the user interface as well as the map content. While blind users generally rely on

assistive technologies and visual aids, also 36 % of the persons with low, i. e. limited vision ask for information in audio output format, and 35 % demand for written texts explaining the map content.

4.2 Requirements on user interfaces

During the last years several graphical and textual user interfaces providing specific features focusing on the needs of visually impaired have been designed and implemented (e. g. The European GUIB: graphical and textual interfaces for blind people). As stated by GOLLEDGE, RICE & JACOBSEN (2006: 183) "… multimodal interfaces (implemented as graphical, audio, textual, and haptic user interfaces) are becoming increasingly important in many areas, including geospatial information processing". Addressing different senses enables users to access and use information according to their personal preferences and capabilities (GOLLEDGE, RICE & JACOBSEN 2006). Experiences, expertise and findings on user interface design which complies with the demands of visually impaired are also useful for the implementation of user interfaces providing web maps for visually impaired.

Thus, for instance, literature emphasizes that accessible user interfaces should only use simple visual design avoiding patterned or complex backgrounds and provide buttons and menus (most) relevant to the users to reduce the complexity of user interfaces (Hung 2001; Jacobson 1998). Therefore, the most important functionalities for the users need to be specified and implemented. Here, the survey shows that the respondents make use of web maps for several purposes: Most of the interviewees point out to use web maps for address search (44 %) and navigation (37 %). Only 18 % use web maps to discover a (city) area, i. e. finding points and areas of interest (museums, public buildings, health care services and facilities, features on public means of transport such as bus routes, stops, public parks etc.). Accordingly web map applications must enable easy searches, navigation and discovery functionalities, besides providing basic map functionalities such as zoom and pan.

	Colour & Contrast	**Annotation**	**(General) Presentation**
Buildings	Light red (buildings without annotation being e. g. residential buildings) Dark red (buildings with annotation being e. g. buildings of public interest) Alternative presentation mode: buildings in light and dark grey	Dark red characters on a white halo to guarantee contrast If at all, only the first character of a word (substantives) is written with capital letter, others are written in lower case letters	Availability of annotations depends on the level of detail, i. e. zoom level
Streets	Generally: white Important streets (e. g. major streets): yellow	Black If at all, only the first character of a word (substantives) is written with capital letter, others are written in lower case letters	
POIs	Different colours (mainly the fundamental colours, high saturation) Providing generally high contrast to the surrounding	Black with light yellow-orange background Annotation (incl. further information on the POI) is presented (information window) in the map if the user single-clicks the icon	Information is presented in the map depending on users' interests and preferences (visible/ invisible) Simplified and generally-accepted symbols
Areas	Open, i. e. green space: green water bodies: blue other areas: light brown	Black characters on a white halo to guarantee contrast If at all, only the first character of a word (substantives) is written with capital letter, others are written in lower case letters	Availability of annotations depends on the level of detail, i. e. zoom level

Table 2: Selection of preferences of visual impaired people on cartographic design of web maps (N=99); light green: representation mode of Google Maps, and light red: representation mode of digital Vienna city map.

4.3 Requirements on graphical and non-graphical map design

To specify user requirements on map design, users were asked to assess the web map application that they commonly use. While the majority of respondents indicates to use Google Maps (67 % of the respondents who use web maps), the digital Vienna city map (http://www.wien.gv.at/stadtplan) is ranking as second most popular web map (17 % of the respondents who use web maps), due to the large number of respondents living in Vienna. Other web map applications mentioned are Bing Maps, Open Street Maps and other city-specific web-based maps (such as the city map of Berlin: http://stadtplan.meinestadt.de; or the city map of Bern: http://map.bern.ch/stadtplan). Table 2 presents a selection of map design preferences of visual impaired people, based on a comparison between Google Maps and the digital Vienna city map (Fig. 1).

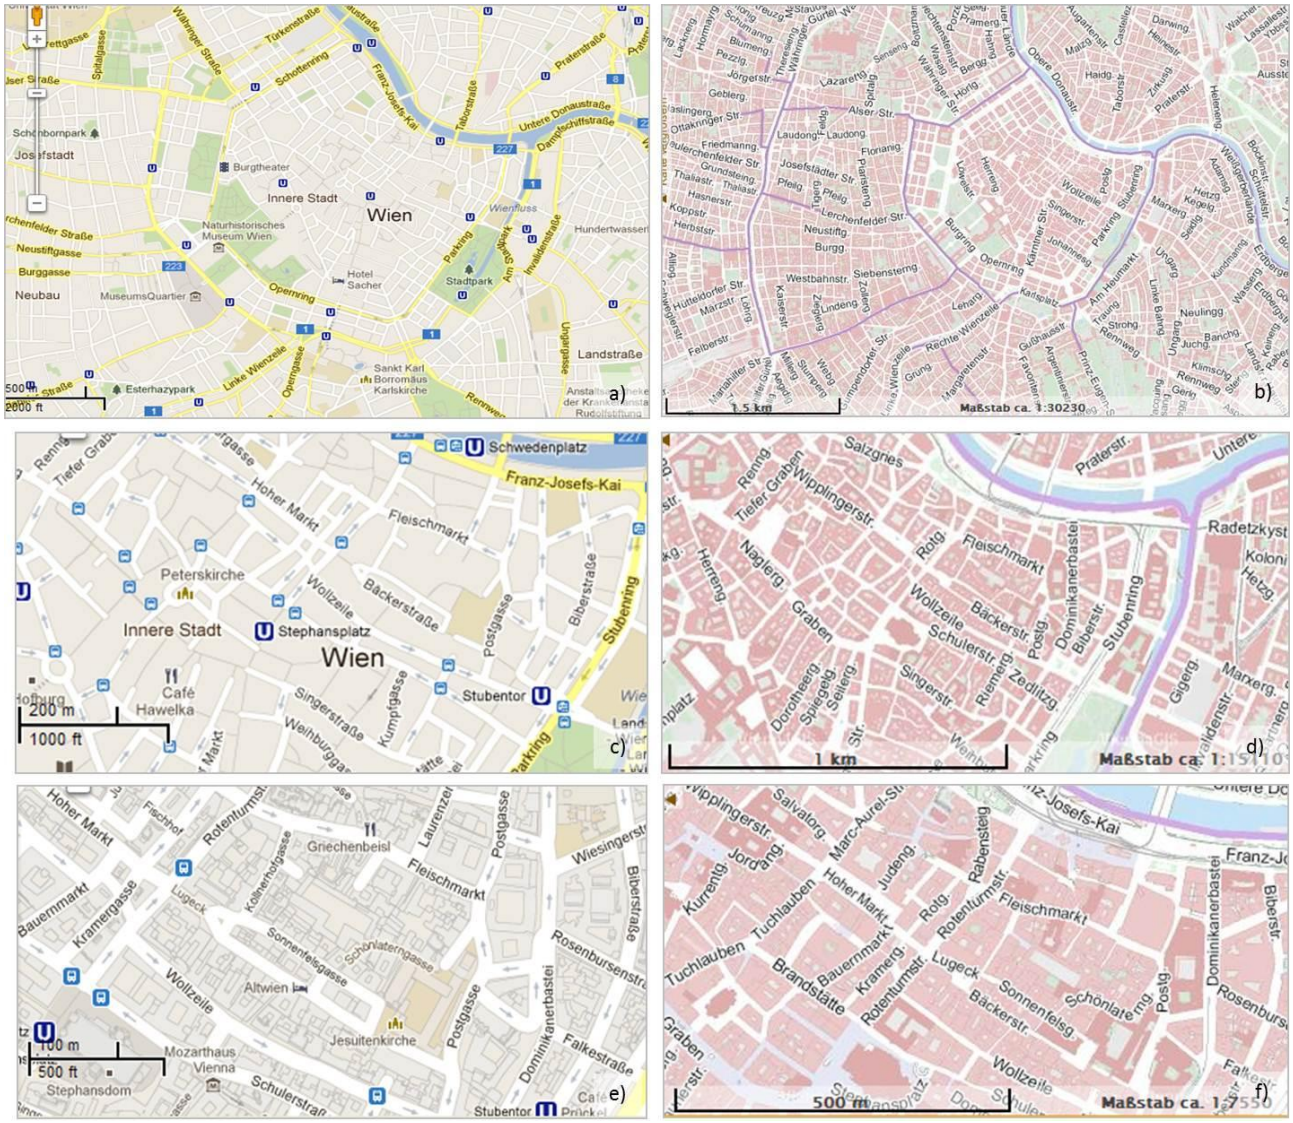

Fig. 1: Google Maps (a, c, e) and digital Vienna city map (b, d, f): selected differences on map design (focusing on the representation of buildings and streets).

In conclusion of the survey results, to improve map design in terms of the needs of visual impaired, attention must be paid mainly to colour contrast between the different objects (areas, buildings, streets etc.), colour design, and labeling (font size). However, due to the wide range of extent and forms of visual impairment literature suggests the provision of functionalities which allow user adjustment on contrast, symbols size, line width, colour combinations and lightness etc. (JEFFREY & FENDLEY 2011). These suggestions are confirmed by the user survey results as well.

As mentioned in chapter 4.2 voice output and textual description of the map content are considered as relevant elements for visually impaired. Accordingly, verbal descriptions of the pertinent map content are needed. Its provision relies on the conception and design of non-graphical map content. On this topic a

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

number of recommendations exist (different possibilities of viewer's perspective, anchor-point hypothesis, hierarchy and order of information etc.). In the following only two aspects are explained in more detail.

Generally, when accessing verbal descriptions of maps, i. e. location of features, users prefer information being available at different levels of detail. This means – as also described by Hung (2001) and National Mapping Council of Australia (1985) – voice output and verbal description should be available:

(1) on a very general level, describing the overall situation of a city or a city area with information on e. g. districts ("Show the minimum detail!"),

(2) on a more detailed level providing information on e. g. particular streets (street names) and blocks of buildings („The content should be such that users can not only identify blocks of buildings and the streets surrounding them but also navigate their way from public buildings or facilities. In order to do this users will need to be aware of traffic lights, pedestrian crossings and other relevant facilities!") , and

(3) as in-depth information on particular houses, shops, facilities and services including entrances („It is important to show door access to buildings and businesses, using standard symbols, as well as stairways, escalators, elevator and ramp locations!").

To build a mental or cognitive map including the location or direction of single landmarks (buildings, streets etc.) as well as the relations between these elements, users prefer the usage of hour system (e. g. Sánchez & Torre 2010). For instance, the verbal description of the directions of a street or crossroad could be designed as follows (Fig. 2): „Street A diverges at 1 o'clock (respectively 20 degree) from street B. Street A diverges at 11 o'clock (respectively 340 degree) from street B, thus the crossroad looks like as Y crossroad, i. e. triple-trace crossroad."

Fig. 2: Description of location based on hour system (Source: Sánchez & Torre 2010).

Information category	Exemplary information
Tactile	surface of road and footway including changes (sewer cover, surface irregularities), texture paving blocks, curb, steep gradients
Auditory	traffic lights with audio signals, acoustic of the surroundings (water features, traffic noise, underpasses, house walls, large squares)
Olfactory	smell of gardens, stores, coffee houses, and restaurants
General information	name of streets and squares, course of the road and direction (one way street), pedestrian crossings (with layout and detailed description if they are complex, underpasses, cross walks), width of the road, number of lanes, bridges, environment around the roads, current road works, shared cycle- and footways, pedestrian area, entry and exit, walking times in minutes and meters,
Public means of transport	bus stop, tram stop, metro station, taxi ranks, railway stations
Useful buildings and landmarks (Points of Interest POIs, Lines of Interest LOIs, Areas of Interest AOIs)	public buildings (office, government agency, theatre, museum), places of interest, healthcare facility (hospital, doctors' surgeries), supermarkets, shops and stores, restaurants, hotels, parks, open and green spaces
Orientation system for blind people	fences, house walls, bushes, texture of the pavement
Route planning	detailed textual description including time and direction

Table 3: Information to display in city maps required by visually impaired (N=59; multiple replies possible).

4.4 Requirements on map content

As stated by Horstmann et al. (2006) no specifications exist on objects which – user group independent – should be presented in city maps. Generally, map publisher tend to produce product-specific standards.

Horstmann et al. (2006) provide a list of objects typically presented in city maps. It encompasses elements such as parks and gardens, water bodies (lakes, rivers, sea), different types of streets, squares and places, points of interest (museums, shops, hotels etc.), public buildings (churches, schools, city hall etc.), features referring to public means of transportation (bus routes and stops etc.), bridges and tunnels. All objects are characterized by numerous attributes such as name and number of lanes, one-way or two-way. Apart from information which should generally be available in city maps, the literature review revealed that – compared with sighted people – visually impaired ask for additional information (e. g. Ienaga et al. 2006; Jacobson 1994; Reichert, Kurze & Strothotte 1994). An overview on information to display in city maps required by visually impaired – embodying results from the literature review and the user survey – is presented in Table 3. Furthermore, Bradley & Dunlop (2005: 399) highlight that "… directions consisting of a reduced amount of textual-structural and textual area/ street information, and incorporated sensory, motion, and social contact information are more optimal for helping visually impaired people navigate." This was proved by the user survey as well.

5 SYSTEM DESIGN

The AccessibleMap (prototype) application, which is developed to be used either with PC or by mobile devices (e. g. smartphone, tablet PC, etc.), is based on open source software. The service-oriented software architecture is made up of a PostgreSQL/ PostGIS database, Geoserver, Open Layers and PHP Application Server. The use of assistive technology and visual aids – as exemplary listed in Table 1 – is supported by the application. Fig. 3 gives an overview of the basic components of the AccessibleMap application.

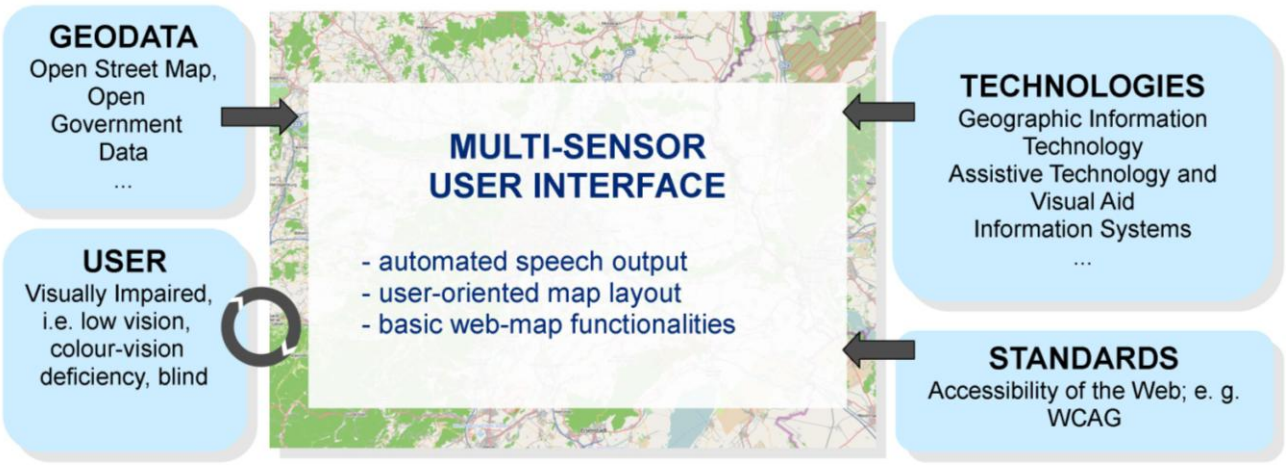

Fig. 3: Components of the AccessibleMap application.

To develop the AccessibleMap application a number of common standards as well as web-accessibility standards and guidelines can be used (Table 4). They help to guide the design and implementation of the web-based map application in association with the identified user requirements. However, despite an immense number of standards and guidelines, no specific standards and guidelines regarding the development of web-based maps for visually impaired or blind people exist.

Type of standards & guidelines	Web content & GUI	Cartographical user interface & map design	Auditory & visual signals	Map content
General, non-technical	Design guidelines, WCAG 2.0 (URL 1), ATAG 2.0 (URL 2), UAAG (URL 3), ISO/IEC Guide 71:2001 (URL 4)	ISO/IEC TR 19766 (URL 7), ISO/IEC 11581-1 (URL 9)	ISO/TR 22411 (URL 8)	
Technical	XML (URL 5), ISO/IEC TR 29138-1:2009 (URL 6)	SLD (URL 14), CSS (URL 15)		WMS (URL 10), WFS (URL 11), GML (URL 12), SVG (URL 13)

Table 4: General and technical standards and guidelines regarding accessibility of web and map content.

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

Thus, according to existing standards and guidelines the AccessibleMap user interface is developed as a multi-sensory interface. It contains a map component with an optimized cartographic design (map layout). Functionalities are implemented which allow (1) to configure, i. e. select the cartographic design depending on user abilities and preferences, (2) to access verbal descriptions (text and speech output), and (3) to perform basic map operations such as search, zoom, and pan.

Different spatial data sources are used to generate the map content: Open Street Map data (OSM; URL 16) which is created by the user community (i. e. volunteered geographic information), and open government data provided by public administration. Various reasons account therefore: This data is published under the Creative Commons license (URL 17) which targets at promoting open and shared data access and use via web services – for everybody. Due to the great variety of data and their attributes, these data sources provide a wide range of information, which meets data demanded by the respondents (Table 3). Thus, most general information (street names etc.), tactile information (surface of roads), useful landmarks, etc. is available for the users. Olfactory (e. g. smell of a bakery) and auditory information (e. g. traffic noise), particularly demanded by blind users, is currently still more complicated to provide to the users. Due to the fact that e. g. opening hours vary and traffic impact is changing, it is difficult to deliver such information being reliable and up-to-date.

To perform end-user tests and to provide to the user accurate and reliable data for a testing area in Vienna, the data – originating from the above-mentioned data sources – must be quality checked and processed according to its accuracy, completeness, up-to-dateness, and language (e. g. translation into German language). Afterwards, the data is transferred to particularly designed data models. This is a precondition to transform the data into information, i. e. to spoken or written text, and to facilitate the visually impaired users to hear or read the map content making use of assistive technologies and visual aids (Table 1). Thereby the verbal description is automatically generated. The automated approach is required in order to generate verbal descriptions of web-based maps which generally cover wide areas and are based on a wide range of different spatial data. It helps to reduce costs as there is no need for extensive manual, time consuming updates. Furthermore, the approach makes the application flexible so that it can be easily applied in different cities and regions.

For the map layout Styled Layer Description (SLD) technology is used. SLD allows creating a map rendering style according to the user requirements which includes e. g. the configuration of colour design and labeling as well as colour contrast between the different objects (Table 2). The data, i. e. the maps, are provided via Web Map Services (WMS) to the user.

6 OUTLOOK

The presented results, on how to support the access and use of web-based maps for visually impaired, can be seen as a contribution towards E-inclusion and web-accessibility. The comprehensive user requirement analysis (literature review and user survey) gives important input for design and implementation of the AccessibleMap (prototype) application. It includes (1) the optimization of the cartographic design, i. e. the map layout in terms of colour, contrast, object size and type, etc. and (2) the automatic generation of a verbal description of the map content respecting the requirement of the users asking for a multi-sensory user interface.

Anyway, especially the verbal description of maps requires a lot of efforts on semantics. To improve the audio and textual output as well as to create meaningful semantic information, spatial data needs to be preprocessed to present information on existing relationships between particular objects (e. g. with regard to distances and directions). More in depth work on semantics will be a main focus of the next tasks of the project and will be based on the results of the user requirements analysis. Ultimately, testing of the prototype application scheduled for autumn 2012 will enhance the integration of the target user group and gain user feedback.

Raum.Sicherheit.Bewusstsein – Sicherheitswirkung und Sicherheitsverständnis räumlich handelnder Akteure

Jan Abt, Josiane Meier

(Dipl.-Ing. Jan Abt, Technische Universität Berlin, Institut für Stadt- und Regionalplanung, j.abt@isr.tu-berlin.de)
(Dipl.-Ing. Josiane Meier, Technische Universität Berlin, Institut für Stadt- und Regionalplanung, j.meier@isr.tu-berlin.de)

1 EINLEITUNG

Sicherheit in Städten wird zunehmend als eine Aufgabe verstanden, die nicht mehr nur von einzelnen Sicherheitsakteuren wie Polizei und Ordnungsamt gehandhabt werden kann (vgl. z.B. Deutscher Städte- und Gemeindebund, 2003: S. 7). Eine wesentliche Rolle hierfür spielt das wachsende Bewusstsein darüber, dass verschiedenste städtische Akteure mit ihren Handlungen sowohl die (objektive) Sicherheitslage als auch das (subjektive) Sicherheitsgefühl in Städten laufend beeinflussen – ob diese Wirkungen intendiert sind oder nicht. Dabei besteht kein absoluter und meist auch kein abgestimmter Sicherheitsbegriff. Vielmehr treffen in Akteurshandlungen unterschiedliche Sicherheitsverständnisse und -ziele aufeinander, die mehr oder auch weniger gut miteinander harmonieren. Dieses Zusammenwirken verschiedenster Akteurshandlungen setzt weit reichende Rahmenbedingungen der objektiven und subjektiven Sicherheit in Städten.

Als Handlungsebene kommt dem städtischen Raum mitsamt seiner Gestalt und seinen Nutzungen eine hohe Bedeutung zu: Sicherheitseinschätzungen kommen selten ohne Raumbezug aus (Stichworte „Angsträume“, „No-Go-Areas“) und viele sicherheitsrelevante Handlungen zielen direkt auf ihn ab oder schlagen sich zumindest indirekt in ihm nieder. Mit ihren raumbezogenen Theorien zu „Defensible Space“ und „Broken Windows“ prägten Newman (1972) und Wilson/Kelling (1982) sowohl Begriffe mit erheblicher Nachwirkung, als auch ein Verständnis von Raum nicht nur als statischer Rahmen, sondern auch als planvoll veränderbares Element.

Zu den Akteuren, die sich laufend und unmittelbar mit dem Stadtraum auseinandersetzen und seine Entwicklung besonders tiefgreifend und langfristig prägen, zählen Stadtplanungsämter und Wohnungsunternehmen. Es handelt sich dabei nicht um klassische Sicherheitsakteure – aber dennoch um solche, deren Handlungen direkt und indirekt sicherheitswirksam sind: Sie sind maßgeblich daran beteiligt, der physischen Umwelt ihre Struktur und Form zu geben; ihre Entscheidungen bestimmen über Nutzer, Nutzungen und Nutzungsmöglichkeiten des Raumes mit.

Ob eine Stadt sicher ist und als sicher empfunden wird, entscheidet sich in diesem Sinne mit daran, mit welchem Bewusstsein diese Akteure ihren sicherheitsrelevanten Handlungen nachgehen: Berücksichtigen sie Sicherheitsaspekte in ihrer Arbeit explizit oder ergibt sich eine wie auch immer geartete Sicherheitswirkung ungeplant und quasi von selbst? Im Zentrum der folgenden Betrachtung steht daher die Frage, mit welchem Verständnis diese raumprägenden Akteure mit dem Thema „Sicherheit“ in ihrer Arbeit umgehen. Hierbei wird ein besonderer Schwerpunkt auf die baulichen und planerischen Aspekte der Tätigkeiten gelegt.

Die in diesem Beitrag zusammengefassten Erkenntnisse erlauben eine erste Verortung der beiden Akteure im Spannungsverhältnis von Raum, Sicherheit und Bewusstsein. Sie basieren auf Zwischenergebnissen des laufenden interdisziplinären Verbundforschungsprojekts „DynASS – Dynamische Arrangements städtischer Sicherheitskultur“, das durch das deutsche Bundesministerium für Bildung und Forschung im Zuge der Bekanntmachung „Gesellschaftliche Dimensionen der Sicherheitsforschung“ im Rahmen des Programms der deutschen Bundesregierung „Forschung für die zivile Sicherheit“ gefördert wird.

2 STADTPLANUNGSÄMTER UND WOHNUNGSUNTERNEHMEN ALS RAUMPRÄGENDE AKTEURE

Kommnale Stadtplanungsämter und Wohnungsunternehmen entfalten jeweils weit reichende Wirkungen auf den öffentlichen und öffentlich zugänglichen Stadtraum, entstammen aber unterschiedlichen Sphären mit eigenen Zielansprüchen und Handlungslogiken.

Stadtplanung wird als das „Bemühen um eine den menschlichen Bedürfnissen entsprechende Ordnung des räumlichen Zusammenlebens“ (Albers, 1996: S. 4) verstanden. Dies umfasst auch die sozialen, ökonomischen, kulturellen und ökologischen Dimensionen der Stadt, aber: „der Fokus der Stadtplanung liegt auf der baulich-räumlichen Dimension, auf die unmittelbar Einfluss genommen wird“ (Pahl-Weber, 2010: S.

491). Die Gestaltung des Stadtraums bildet damit den Kerninhalt der Stadtplanung. Die Aufgabe der Stadtplanung wird dabei im Rahmen der kommunalen Selbstverwaltung von der Gemeinde übernommen und in der Regel in eigenen Ämtern oder Fachbereichen verortet. Sie ist damit Teil der Stadtverwaltung und den jeweiligen Handlungsrahmen und Zielen der Kommunalpolitik unterworfen. Ähnliches gilt auch für verwandte Fachplanungen wie die Freiraum- oder die Verkehrsplanung, die mit ihrer Arbeit ebenfalls die Gestalt des öffentlichen Stadtraums beeinflussen, aber stärker sektoral ausgerichtet sind.

Wohnungsunternehmen sind in der Klassifikation des Statistischen Bundesamtes dem Wirtschaftszweig „Grundstücks- und Wohnungswesen“ zugeordnet. Dieser umfasst jene Akteure, die sich dem Kauf und Verkauf von eigenen Immobilien (z.B. Bauträger), der Vermietung und Verpachtung von eigenen Immobilien (z.B. Wohnungsunternehmen) und der Vermittlung und Verwaltung von Immobilien für Dritte (z.B. Makler) widmen (vgl. Statistisches Bundesamt, 2008: S. 457ff). Insbesondere die ersten beiden Bereiche dieses Wirtschaftszweiges beeinflussen durch ihre Tätigkeiten die physische Umwelt und nehmen starken Einfluss auf das Erscheinungsbild und die Nutzungsmöglichkeiten des öffentlichen Raums.

Mietwohnungen machen in Deutschland einen Anteil von 58 Prozent (das entspricht knapp 24 Millionen Wohnungen) der insgesamt auf dem Wohnungsmarkt verfügbaren Wohnungen aus. 39 Prozent dieser Mietwohnungen (ca. 9,2 Millionen Wohnungen) befinden sich im Eigentum professioneller Wohnungsunternehmen (vgl. Deutscher Bundestag, 2009: S. 21, 28). Die Wohnungsunternehmen prägen den städtischen Raum deutlich stärker als Selbstnutzer und private Kleinanbieter, denn mit ihren Entscheidungen beeinflussen sie jeweils eine deutlich größere Zahl an Objekten, die durch ihre räumliche Konzentration oder allgemein ihre kritische Masse häufig stadtbildprägend wirken. Die Bestände von Wohnungsunternehmen umfassen zudem meist öffentlich zugängliche Außenbereiche, die auch von externen Bewohnern genutzt werden.

Unter den professionellen Wohnungsunternehmen lassen sich u.a. kommunale Wohnungsunternehmen, Genossenschaften, professionelle private und kirchliche Wohnungsanbieter unterscheiden – eine Homogenität der Wohnungswirtschaft kann in dieser Hinsicht nicht unterstellt werden, Zielstellungen und Selbstverständnis können sich erheblich unterscheiden. Den Unternehmen gemein ist jedoch ein grundsätzlich renditeorientierter Ansatz, der ihre Handlungen prägt. Dies gilt, spätestens seit dem Wegfall der Gemeinnützigkeit 1990, auch für die kommunalen Wohnungsanbieter. Für Bau und Unterhalt des Wohnungsbestandes sind in der Regel eigene Abteilungen innerhalb der Unternehmen zuständig.

Die beiden Akteure Stadtplanungsamt und Wohnungsunternehmen treffen dort aufeinander, wo es um Fragen der baulich-räumlichen Entwicklung von Stadtbereichen geht. Dabei obliegt es der Stadtplanung, den planerischen Rahmen für die räumliche Entwicklung zu gestalten, dem auch die mit ihren Beständen ortsgebundenen Wohnungsunternehmen in ihren baulichen Aktivitäten unterliegen. Entsprechende Tätigkeiten der beiden Akteure sind jedoch häufig eng verknüpft – Wohnungsunternehmen bringen sich in Planungsprozesse ein bzw. werden konsultiert und gestalten damit den künftigen Rahmen ihrer Handlungen mit. Vor dem Hintergrund des Wandels von einer Angebots- zu einer Nachfrageplanung können planerische Prozesse auch von privatwirtschaftlichen Akteuren wie Wohnungsunternehmen ausgelöst werden. Während die beiden Akteure jeweils zeitlich längerfristige Perspektiven betrachten und sich in ihrer globalen Zielstellung bezogen auf die Stadtentwicklung – nämlich der gesteigerten Attraktivität – ähneln, haben Wohnungsunternehmen in erster Linie ihre eigenen Bestände im Blick, die Stadtplanung hingegen eher das „Große Ganze“. Bezogen auf das Thema Sicherheit verdeutlicht eine 2011 bei Stadtplanungsämtern durgeführte Umfrage des Deutschen Instituts für Urbanistik (Difu) die Bedeutung von Wohnungsunternehmen als Kooperationspartner: Mehr als die Hälfte (52 Prozent) der antwortenden Stadtplanungsämter gibt an, im Themenfeld „Sicherheit“ mit Akteuren der Wohnungswirtschaft zu kooperieren (vgl. Floeting/Seidel-Schulze in diesem Band).

3 ROLLE IN DER SICHERHEITSPRODUKTION

Stadtplanungsämter und Wohnungsunternehmen wirken durch die Gestaltung des baulichen Umfeldes in der Regel präventiv auf die lokale Sicherheitslage, indem sie beispielsweise Tatgelegenheiten schaffen oder vermeiden sowie durch die Gestaltung von Raumsituationen das Sicherheitsempfinden beeinflussen. Zudem prägen diese Akteure die räumlichen Rahmenbedingungen für das Handeln anderer Sicherheitsakteure. Sie erfüllen damit eine aktive wie auch eine vorbereitende Funktion für die Sicherheitsproduktion.

Sicherheit spielt allerdings nur in wenigen Fällen eine eigenständige Rolle im Tätigkeitsfeld von Stadtplanungsämtern und Wohnungsunternehmen. Insbesondere für die kommunalen Planungsakteure ist die Gestaltung des (öffentlichen) Raumes vielmehr eine ganzheitliche Aufgabe, die menschliches Leben und Zusammenleben in all seinen verschiedenen Aspekten ermöglicht und prägt. Zu diesen Aspekten gehört nur unter anderem die Sicherheit. Ähnlich streben Wohnungsunternehmen meist die Schaffung von in ihrer Gesamtheit attraktiven Wohnanlagen an, um eine hohe Nachfrage zu erzielen und Bewohner langfristig zu binden. Dass sich (potenzielle) Bewohner sicher fühlen ist ein integraler Aspekt dieser Bestrebungen – denn kaum etwas wirkt so geschäftsschädigend wie ein als unsicher in Verruf geratenes Wohngebiet. Das Thema der (wahrgenommenen) Alltagssicherheit im Wohnumfeld wird jedoch selten dezidiert behandelt und noch seltener nach außen gestellt, ganz im Gegensatz zur Sicherheit im Sinne der „Wohnsicherheit“: Sie findet in Leitsprüchen häufig Verwendung, bezieht sich jedoch vorrangig auf das Vertragsverhältnis zwischen Mieter und Vermieter oder die physische Sicherheit der Wohnungen etwa vor Einbrüchen.

Für diese wenig explizite Behandlung von Sicherheit in der Gestaltung des Stadtraums durch Stadtplanungsämter und Wohnungsunternehmen lassen sich mindestens drei Erklärungsansätze identifizieren: Zum ersten wird Sicherheitsproduktion als eine Aufgabe unter vielen anderen wahrgenommen, zum zweiten wird Sicherheit als Thema mit Überschneidungsbereichen und Synergien zu gänzlich anderen Themen begriffen und in einer dritten Verständnislinie dient das explizite Thema Sicherheit als Vehikel weiterer Ziele und Interessen.

3.1 Bewusste Breite – Sicherheit als eine Aufgabe unter vielen

Stadtplaner und Wohnungsunternehmen besitzen durchaus ein Bewusstsein für das Thema der Sicherheit im öffentlichen Raum. Dass ihm selten eine eigenständige Rolle zukommt, ist daher weniger einem „blinden Fleck“ geschuldet als vielmehr einer Bewertung „sehenden Auges“ zuzuordnen. Insbesondere bei der mit der Abwägung von Nutzungsinteressen betrauten Stadtplanung zeigt sich, dass Sicherheit als ein Thema gilt, welches gleichwertig zu anderen Themen behandelt werden muss. Eine Priorisierung wird für die eigene Arbeit abgelehnt: „Also das ist ein Aspekt unter anderen. Man muss es jetzt auch nicht nach oben hieven.“ (Vertreter Planungsamtsleiter)

Interdisziplinär zu arbeiten und thematisch vernetzt zu denken sehen Stadtplaner als eine ihrer Kernkompetenzen an. Dabei weitet sich der Blick und das Bewusstsein für Abhängigkeiten mit der Maßstabsebene: Die Tätigkeitsschwerpunkte haben sich in der jüngeren Vergangenheit weg von der künstlerischen oder technischen Tätigkeit hin zu einer moderierenden Rolle gewandelt, die unterschiedliche Interessen in Ausgleich zu bringen versucht. Grundsatzfragen des gesellschaftlichen Zusammenlebens, des demografischen Wandels und des Klimaschutzes werden als die großen Themen begriffen in die sich Einzelthemen wie Sicherheit integrieren lassen (müssen). Im Zentrum des Schaffens steht ein „großes Ganzes“ anstelle eines Einzelthemas.

Sicherheit ist für Stadtplaner wie Wohnungsunternehmen eng mit Begriffen wie „Lebensqualität“, „Wohlbefinden“, „Nachbarschaft“ und „sozialer Zusammenhalt“ verknüpft. Sie verweisen auf einen Anspruch, der deutlich über die Schaffung sicherer Orte hinausgeht. Dementsprechend sehen sich die beiden Akteure auf einer allgemeinen Ebene sehr wohl in einer eigenen Funktion als Sicherheitsproduzenten, auch wenn der Begriff „Sicherheit“ nicht immer fällt oder durch andere (z. B. „attraktive Stadt“) ersetzt wird.

Ein bewusstes und planvolles Sicherheitshandeln – nur unter anderem Namen – kann daraus jedoch nicht abgeleitet werden. Das Problem gerade für kommunale Planer besteht darin, das grundsätzliche Bewusstsein auf konkrete Arbeitssituationen herunterzubrechen: „Ich glaube, dass das in der Gesamtbetrachtung – gerade auch planerisch ausgebildeter Menschen – immer schon eine Rolle gespielt hat. Auch diese Frage ‚Sicherheit in der Stadt‘ – allerdings nicht pointiert wurde. Und indem man es nicht pointiert hat, auch an vielen Stellen also ein bisschen geschlabbert wurde, und in diesem Schlabbern dann das eigentliche Problem lag.“ (Vertreter Planungsamtsleiter)

Im Alltagsgeschäft fehlt häufig die Reflexion über das eigene Sicherheitshandeln. Aus dem sehr allgemeinen Verständnis über seine Funktion in der Sicherheitsproduktion wird im konkreten Handeln für einige Akteure dieses Typs häufig ein unbewusstes Sicherheitshandeln. Ein expliziter Zielfokus „Sicherheit“ besteht in dieser Hinsicht nicht.

3.2 Gern gesehene Synergien

Viele Wirkungen, die durch anderweitig motivierte Maßnahmen erreicht werden, haben aus Sicht von Stadtplanungsämtern und Wohnungsunternehmen, zumindest in der Nachbetrachtung, auch eine positive Wirkung auf die lokale Sicherheitslage. Bereits in dieser Reihung wird jedoch deutlich, dass Sicherheit in diesen Fällen selten der Handlungsauslöser ist. Sicherheit wird zu einem willkommenen Nebeneffekt, wenn andere Themen behandelt werden müssen: Fragen des Klimaschutzes, der Verkehrsplanung und Mobilitätsgestaltung, des Strukturwandels, des Substanzerhalts oder der Ästhetik. In vielen Gestaltungsfragen „… steht natürlich der Sicherheitsaspekt überhaupt nicht im Mittelpunkt, aber der schwingt natürlich indirekt da immer mit." (Vertreter Wohnungsunternehmen)

Für eine gezielte Sicherheitsproduktion sind solche vermutete Synergien und das grundsätzliche „Mitschwingen von Sicherheitsaspekten" in gänzlich anderen Planungsaspekten problematisch. Wirklich greifbar und bearbeitbar wird Sicherheit in diesen indirekten Bezügen nicht. Daher erfolgen bewusste Sicherheitshandlungen in der Praxis meist als Reaktionen auf konkrete Problemlagen – und das Bewusstsein endet auch mit der Findung eines Lösungsansatzes für diese Problemlagen wieder. Das Gegengewicht hierzu wäre eine planvolle Befassung mit Sicherheitsthemen in größerem Zusammenhang, die darauf abzielt, Synergien zu verstärken: Wie kann von vorneherein bei anstehenden Maßnahmen ihre Sicherheitswirkung bewusst (mit)gedacht werden?

Ein solches Verständnis findet sich bei den betrachteten Akteuren jedoch nur selten. Die planerischen und gestalterischen Projekte, die explizit als Sicherheitsthemen bewegt werden, haben daher konkreten Bezug: „Angsträume" und „Un-Orte" sind beispielsweise häufig genannte Problemlagen objektiver oder subjektiver Sicherheit im Raum, die im expliziten Bezug zu einem planerischen Handeln verstanden werden.

3.3 Sicherheit als nützliches Vehikel

Wird das Thema Sicherheit im öffentlichen Raum durch Stadtplanungsämter oder Wohnungsunternehmen explizit in den Mittelpunkt gestellt, so handelt es sich häufig um Vorhaben, die zwar mit dem Begriff „Sicherheit" betitelt, aber aus einer anderen Motivation heraus verfolgt werden. Im Kern geht es dann nicht unbedingt vorrangig um die Sicherheit der Stadtbewohner, sondern auch darum, andere Werte und Ziele umzusetzen. „Sicherheit" wird hier zu einem Vehikel beispielsweise für ein Verständnis „guter Gestaltung" von Stadtplanern und Architekten. Diese strategische Verwendung des Sicherheitsthemas zeigt sich auch dann, wenn es um die Akquise von Fördermitteln geht und kann insofern als Reaktion auf die Reduktion verfügbarer Mittel für „weichere" Themen gewertet werden.

3.4 Handlungsspielräume mit Grenzen

Insbesondere die kommualen Planungsämter sind in ihren Handlungen nicht auf den einzelnen Bürger als Subjekt ausgerichtet, sondern betreffen die Allgemeinheit als Ganzes. Dabei sind ihnen ihre begrenzten Einflussmöglichkeiten auf städtische Sicherheit bewusst.

Bei der Planung und Gestaltung öffentlicher Räume unterliegen alle Akteure der gleichen, einschränkenden Rahmenbedingung: der finanziell angespannten Situation der Kommunen. Die Kommune ist die „Inhaberin" des öffentlichen Raumes und dessen ansprechende Gestaltung ist angesichts knapper Kassen eine Herausforderung. Es herrscht unter den betrachteten Akteuren grundsätzliche Einigkeit, dass sich der öffentliche Raum aufgrund der finanziellen Situation der Kommunen in einem schlechten Zustand befindet, was sich negativ auf das Sicherheitsempfinden auswirkt:

„Also, weil, je verwahrloster die öffentlichen Räume sind, desto verlorener fühlt sich der Einzelne. (…) Es wird zu wenig Geld in die Hand genommen, um Räume herzustellen und zu wenig Geld, um sie zu pflegen." (Vertreter Architekten)

Zur zentralen Rolle der Kommune bei der Gestaltung des öffentlichen Raumes gibt es wenig Alternativen. Wohnungsunternehmen sind in besonderem Maße abhängig von der Qualität und dem Zustand des Umfelds ihrer Bestände – und sehen sich zunehmend in der Lage, die eingeschränkte Handlungsfähigkeit der Kommunen kompensieren zu müssen. Kommunale Wohnungsunternehmen – wie andere Wohnungsunternehmen verantwortlich für Räume, die häufig gleichfalls als „öffentlich" begriffen werden – sind der angespannten Haushaltslage ihrer Eigentümer häufig direkt ausgesetzt: Rediteerwartungen schränken auch ihren Spielraum ein.

Aber auch jenseits eines Möglichkeitsraumes, der finanziell definiert wird, zeigen sich strukturelle Grenzen im Handeln der Akteure. Dies zeigt sich zunächst in den verschiedenen Maßstabebenen des Planens und Bauens, auf denen sich die betrachteten Akteure verändern:

„Die klassische Vorstellung ist: ‚Wir entwickeln eine Stadt und überlegen gesamt-strukturell. Und dann wird es konkret örtlich. Und dann wird es irgendwann realisiert' – die Realisierung ist dann ja nicht mehr eine Aufgabe, die in der Regel von der Stadtplanung begleitet wird, in jeder Dezidiertheit. Also das Bauvorhaben noch weniger, als – ich sage mal – die Ausgestaltung des öffentlichen Raumes." (Vertreter Planungsamtsleiter)

Trotz gleicher Wirkweise auf die Sicherheitslage sind auf verschiedenen Maßstabsebenen unterschiedliche Einzelakteure tätig, z.B. von der Stadtenwicklungsplanung über die Stadtplanung, das Bauordnungsamt bis zum Bauherren und Architekten. Der Herstellungsprozess von Raum ist damit nicht frei von Brüchen.

Auf räumlicher Ebene schränken darüber hinaus Verfügungsrechte die Handlungsfähigkeit dieser Akteure weiter ein. Die Ausgestaltung von öffentlich nutzbaren Räumen ist originäres Handlungsfeld der Kommunen, aber ihre Zugriffsmöglichkeiten auf private Flächen sind begrenzt. Bei Flächen in Privateigentum kann die Kommune lediglich einen Rahmen setzen, Anreize schaffen, als Verstärker wirken um die Bedürfnisse der Allgemeinheit zu transportieren oder versuchen, auf dem Verhandlungswege Einfluss zu nehmen ¬– aber kaum direkt handeln. Besondere Bedeutung kommt in diesem Zusammenhang kommunalen Wohnungsunternehmen zu, mittels derer Impulse und Maßstäbe für die Entwicklung von Stadtteilen gesetzt werden können. Mit einer Verbindlichkeit für Dritte sind diese Maßnahmen freilich nicht verbunden: Akteure der Wohnungswirtschaft können ebenso nur begrenzt auf die Gestaltung angrenzender Flächen einwirken, die nicht zu ihren Beständen zählen. Jenseits von Impulsen, die in (neuen) Entwicklungsdynamiken resultieren können, beschränken sich die Einflussmöglichkeiten in diesen Fälle auf Argumentationen und Aushandlungsprozesse. Diese kommunikativen und kooperativen Elemente sind besonders für die Planung, aber auch für Wohnungsunternehmen essentiell, um ihre begrenzten Handlungsreichweiten zu erweitern.

Auf thematischer Ebene erreichen Planung und bauliche Gestaltung ebenfalls ihre Grenzen. Selbst eine Planung mit einem – oder grade aufgrund ihres – so umfassenden eigenen Wirkanspruchs wie die kommunale Stadtplanung kann nicht alles bewirken und will es auch nicht können:

„Da ist baulich gar nichts geändert worden. Da sind nur durch rechtliche Normierungen Änderungen erfolgt. Also – ich sage mal – wiederum ein Thema, was die Stadtplanung jetzt weder aktiv angegangen, noch in irgendeiner Form forciert hat, hat da zu Veränderungen geführt. Das meine ich auch damit: Da ist man dann eben auch durch stadtplanerisches Handeln einfach nicht mehr fähig, etwas zu bewältigen. Es sei denn – aber dem hänge ich nicht an – man empfindet eine Omnipotenz bei Stadtplanung und Stadtplanerinnen und Stadtplanern – habe ich nicht, und das nicht nur aus Faulheitsgründen." (Vertreter Planungsamtsleiter)

Gerade in Bezug auf Sicherheitsthemen wird von den betrachteten Akteuren die Vielschichtigkeit unterschiedlicher Einflussgrößen anerkannt – und dass viele von diesen jenseits ihrer originären Handlungsmöglichkeiten liegen. So ist zwar die Auffassung weit verbreitet, dass qualitativ hochwertige Gestaltung zu einer positiven Bindung beiträgt und einen pfleglichen Umgang mit Objekten befördert – also Einfluss auf das menschliche Verhalten hat. Ebenso klar wird jedoch herausgestellt, dass gute Gestaltung allein besonders dann nicht reicht, wenn die Probleme grundlegender sozialer Natur sind: Gestalterische Maßnahmen ohne eine Addressierung des sozialen Verhaltens werden häufig als unwirksam und gesellschaftliche Probleme auf der lokalen Ebene als nicht lösbar, sondern nur in ihren Symptomen behandelbar angesehen. Sicherheit entsteht im Verständnis dieser Akteure erst im Zusammenwirken der Faktoren. Ein Primat baulicher gegenüber sozialer Prozesse wird von Stadtplanern und der Wohnungswirtschaft in der Regel nicht gefordert, sondern die gleichberechtigte Verknüpfung beider Stränge. Als erfolgreiches Beispiel für diese Verbindung gilt das Städtebauförderprogramm „Soziale Stadt", bei dem „bauliche Investitionen der Stadterneuerung in Gebäude, Wohnumfeld und Infrastruktur (…) mit Maßnahmen zur Förderung von Bildung, Beschäftigung und Integration gebündelt" werden (BMVBS, 2011: S. 105).

4 GEMEINSAME SICHERHEITSPRODUKTION - ABHÄNGIGKEITEN

Die unterschiedlichen Raumverantwortungen zwischen kommunaler Planung und Wohungsunternehmen erfordern für ein koordiniertes Vorgehen eine gezielte Zusammenarbeit.

Für kommunale Planungsakteure sind Wohnungsunternehmen und Privateigentümer wichtige Partner. Sie erweitern die Grenzen des eigenen Handelns, denn angesichts des – im Vergleich zum Bestand – geringen Umfangs an Neubauprojekten findet Sicherheitsproduktion in der bereits gebauten Stadt statt. Hier sind es häufig die Wohnungsunternehmen, die im Umfang und in der räumlichen Konzentration ihrer Bestände Veränderungspotentiale bieten. Solche bestehen ebenso bei privaten (Klein-)Eigentümern, sie verfügen jedoch meist über Bestände von wesentlich geringerem Umfang und sind für die kommunalen Akteure in Bezug auf Ansprache und Koordination oft aufwändiger.

Im Wechselspiel ist für Wohnungsunternehmen wiederum die kommunale Planung ein wichtiges Gegenüber:

„Dann gibt es in den großen Wohnsiedlungen, wenn sie stark begrünt sind, zunehmend das Problem Sicherheit – also Beleuchtung und Zuwachsen ist so ein Thema und dann ist wahrscheinlich ein interessantes Thema, dass es oft solche undefinierten verwahrlosten Räume gibt. Also wo fängt mein Haus an oder wo fängt meine Nachbarschaft an und wie geht dann der Weg weiter bis zur S-Bahn oder zur U-Bahn, das sind manchmal noch so kritische, als unangenehm oder als unsicher empfundene Räume, wo dann die Partnerschaft mit der öffentlichen Hand ganz wichtig ist. Da geht es halt um die Wohnumfeldgestaltung.“ (Vertreter Wohnungsunternehmen)

Wohnungsunternehmen und Kommune sind sich ihrer jeweiligen begrenzten Handlungsreichweite bewusst und dementsprechend sind die Kooperationsbeziehungen zwischen diesen Akteuren häufig etabliert. Die Zusammenarbeit zwischen den planenden und bauenden Akteuren von Kommune und Wohnungsunternehmen erfolgt aus unterschiedlichen Beweggründen und wird gleichermaßen von beiden Seiten initiiert: Die planenden Akteure sind darauf angewiesen, dass die umsetzenden Akteure die Ziele ihrer Tätigkeit weiterverfolgen, ebenso wie die Umsetzenden bemüht sind, ihre Ziele bereits in der Planung zu verankern. Inhaltlich geht es um räumliche Schnittstellen und Übergänge, aber auch um grundsätzliche Nutzungskonzepte und die Zugänglichkeit von Räumen.

5 VOM WISSEN, WAS WO ZU TUN IST

Kommunale Planer und die planenden und umsetzenden Akteure aus der Wohnungswirtschaft sind in der Wahl ihrer Schwerpunkte vergleichsweise frei und setzen diese nach wahrgenommener, gesamtheitlicher Problemlage – zu der in ihrem breiten Verständnis auch die Sicherheitslage zählt. Bei der Bewertung der Sicherheitslage stützen sie sich stark auf informelle Zugänge: auf eigene Beobachtungen und direkte Erfahrungsberichte.

Eigene Beobachtungen sind für Stadtplaner und Wohnungsunternehmen durch keine anderen Informationen substituierbar. Sie haben jeweils zahlreiche Anforderungen an den Raum zu koordinieren. Dies erfordert einen direkten Kontakt mit der Situation vor Ort. Entsprechend ist gerade für eine wirksame Prävention die Ortskenntnis der Mitarbeiter eine zentrale Voraussetzung, denn nur durch diese können Probleme entdeckt und bearbeitet werden, noch bevor sie einen kritischen Punkt erreichen:

„Das ist die Auseinandersetzung, gerade auch der Kollegen, die in den Ortsteilen arbeiten; natürlich dort auch viel, viel Kenntnis haben, Ortskenntnis haben, und sagen: ‚Also das ist ein Thema, also da müssen wir mal ran.‘“ (Vertreter Planungsamtsleiter)

Die Kenntnis der lokalen Situation ist dabei nicht nur für die Problemfindung zentral, sondern auch essentiell für die Entwicklung geeigneter, passgenauer Lösungen.

Neben der eigenen Beobachtung zählen Stadtplaner und Wohnungsunternehmen auch die vermittelte Beobachtung zu den wichtigen Informationsquellen, die ihre Sicherheitswahrnehmung und Einschätzung des Handlungsbedarfs prägen. Dabei betonen sie die Bedeutung einer möglichst unverfälschten Informationsweitergabe, die nicht über viele Stationen läuft, sondern direkt kommuniziert wird. Ein solcher „authentischer Dialog“ wird zu einem wichtigen Informationsinstrument. Er gelingt leichter im Rahmen lange laufender Projekte wie Städtebaufördergebieten (für die kommunale Planung) oder mit erfahrenen Gebietsbetreuern (für die Wohnungswirtschaft). In solchen langfristigen Prozessen werden die Akteure zu selbstverständlichen Ansprechpartnern für die Bedürfnisse der Bewohner. Auf diesem Wege fließt auch das

subjektive Sicherheitsempfinden aus der Bevölkerung in die Sicherheitswahrnehmung der hier beschriebenen Akteure ein.

Wohnungsunternehmen und kommunale Planung sehen sich auch hier jeweils nur als einer von vielen Akteuren vor Ort: In Sicherheitsfragen werden Ordnungsämter und Polizei, aber auch Jugend- und Sozialämter als mindestens gleichberechtigt in ihren Zugängen zu einem „authentischen Dialog" eingeschätzt. Auch die Kommunalpolitik besitzt in ihren Augen solche direkten Kanäle. Aus diesem Grund reagieren die baulich-gestalterischen Akteure aufmerksam auf Hinweise von diesen Partnern und nutzen diese „Zurufe" oder „Umwegzurufe" (Vertreter Planungsamtsleiter) aktiv bei der Ausgestaltung ihrer eigenen Bilder.

Die subjektiven Komponenten dieser Hinweise erfordern in den Augen der betrachteten Akteure allerdings eine gewisse Gegenprüfung. Zentrale Stellen für objektivierte Daten – als Gegengewicht zur stark subjektiven Informationsbasis – sind für sie das Ordnungsamt und die Polizei als die professionell mit Sicherheit befassten Akteure. Diese beiden Partner dienen in diesem Fall für sie als Beratende, die helfen, die auf informellem Wege gewonnenen Ansätze zu validieren – quasi die Spreu vom Weizen zu trennen.

Medienberichte sind für die Planenden und Umsetzenden eine weitere Informationsquelle. Sie werden nicht nur als Kanal wahrgenommen, der die Meinung der Bevölkerung prägt, sondern der auch andersherum die Stimmung vor Ort aufgreift und somit zu einem Pegelstandsmesser der lokalen Situation wird. Dabei sind neben Vorfällen im öffentlichen Raum auch solche im privaten Bereich von Interesse, da sie als Hinweise auf die Entwicklung der soziale Lage des betroffenen Quartiers gewertet werden. Die Inhalte der Berichte selbst bewerten die Akteure – nicht zuletzt aufgrund einschlägiger Eigenerfahrungen – mit einer kritischen Distanz. Sie stellen für sie nur eine ergänzende Quelle dar. Ungeachtet dessen können Medienberichte über den Umweg über Einzelpersonen in Entscheidungspositionen (z.B. in der Kommunalpoltik oder Geschäftsführung) dennoch großen Einfluss auf ihre Schwerpunkte und Tätigkeiten der operationalen Ebene entwickeln.

6 HANDLUNGEN UND EINFLUSS AUF DIE SICHERHEITSLAGE

Stadtplanung und Wohnungsunternehmen führen im planerisch-baulichen Feld eine Vielzahl unterschiedlicher Maßnahmen durch, die potentiell sicherheitsrelevante Wirkungen für den öffentlich zugänglichen Raum haben: Gesamtstädtische Strategieplanungen, quartiersbezogene Entwicklungskonzepte, Bebauungsplanung, Gestaltungskonzepte und Umgestaltungsmaßnahmen, städtebauliche Planungen und Umsetzungen sowie objektorientierte Gestaltungsmaßnahmen.

Diese Tätigkeiten sind auf verschiedenen räumlichen Maßstabsebene angesiedelt, wobei die Akteure selbst eine Grenze ihres sicherheitsrelevanten Handelns ziehen, wenn sie darüber reflektieren: Die Maßstabsebene des Flächennutzungsplans wird von Stadtplanern nicht mehr als sicherheitsrelevante Maßnahme begriffen, denn über grundsätzliche Aussagen – etwa zur „gemischten Stadt" – hinaus gilt er als zu unscharf in seiner räumlichen Abgrenzung und seiner inhaltlichen Tiefe. Sicherheitsrelevante Arbeit beginnt daher mit einer konkreteren örtlichen Ebene.

Auf dieser Ebene sind die Akteure je nach räumlichem Handlungsschwerpunkt unterschiedlich tätig. Verbindend ist aber ein gemeinsames Grundverständnis: Nur qualitätsvolle Planung und Gestaltung fördert Sicherheit – sei es in Form eines grundsätzlich „guten Entwurfs":

„Ich glaube schon, dass viele Dinge, die mit gutem Entwurf zu tun haben, automatisch auch Sicherheit generieren. Nicht immer und nicht zwangsläufig, aber vieles doch. (…) Das geht von gemischt genutzten Quartieren – was ja im Grunde die nationale Stadtentwicklung auch möchte, dass man also diese unterschiedlichen Ebenen wieder zusammenbringt, das ist ein Faktum – es ist die Anbindung von Wohnquartieren an den ÖPNV, die Erreichbarkeit von Einrichtungen des täglichen Bedarfs…" (Vertreter Architekten)

Sei es als qualitätsvolle Planung bei der Herstellung attraktiver Räume:

„Also bei meinem Aufgabenbereich, den, den ich verantworte, oder für den ich auch ausgebildet bin, Sorge zu tragen, solche Gelegenheiten [Angsträume] erst gar nicht entstehen zu lassen. Also den öffentlichen Raum so auszugestalten, dass er ein Gefühl von Sicherheit erzielt, dass er attraktiv ist in vielfältiger Weise, was eben gleichfalls auch schon ein, eine gewisse Garantie für Sicherheit dann darstellt, weil Attraktivität auch

bedeutet, aus unserer Sicht: Dieser Ort wird dann auch wahrgenommen. Und er wird auch angenommen. Und wenn ich ihn annehme, dann ist eben auch Vielfalt dort. Und wenn Vielfalt da ist, sind auch viele Menschen da. Und viele Menschen sind auch schon wieder ein höheres Maß an Garantie, sich sicher zu fühlen.“ (Vertreter Planungsamtsleiter)

Oder sei es als qualitätsvolle Realisierung in Form einer hochwertigen Gestaltung der Objekte:

„…und die interessante Erfahrung: Je hochwertiger das gestaltet wird, umso höher ist die Hemmschwelle da zu randalieren oder es zu beschmieren. Also das sind – glaube ich – wichtige, schon elementare Sachen gewesen.“ (Vertreter Wohnungsunternehmen)

Auch hier werden mit dem Thema Sicherheit noch weitere Werte – namentlich diejenigen „guter Planung“ und „guter Gestaltung“ – transportiert. „Gute Planung“ oder „gute Gestaltung“ sind dabei Globalansprüche – ein besonderer Fokus auf Sicherheit besteht nicht. Vielmehr wird Sicherheit– neben allen anderen wichtigen Themen – auch durch gute Planung und Gestaltung hergestellt und verweist wiederum auf die Rolle von Sicherheit als lediglich einem Thema unter vielen. Die genauere Betrachtung zeigt, dass sich „gute Planung“ und „gute Gestaltung“ für diese Akteure unter dem besonderen Blickwinkel von Sicherheit wiederholt auf drei Einzelelemente konzentrieren: Die Belebung öffentlicher Räume – über Maßnahmen zur Nutzungsmischung, zur Schaffung einer Vielfalt von Angeboten und einer Attraktivität des Raumes; die erfassbare Gestaltung von Orten – über visuelle Einsehbarkeit, Blickbeziehungen, Beleuchtung und die klare Definition von Funktions- und Verantwortungsbereichen; sowie die qualitätsvolle Ausgestaltung im Objektbereich – mittels gezielter Materialauswahl, technischer Sicherungen und durchdachten Detaillösungen.

Da den Akteuren die Grenzen eines rein baulich-gestalterischen Umgangs mit Sicherheitsproblemen in der Regel bewusst sind, thematisieren sie häufig die Notwendigkeit ergänzender sozialer Maßnahmen: Zum Teil setzen die betrachteten Akteure begleitende soziale Maßnahmen und Prozesse selbst um – die Planungsämter etwa im Rahmen von Beteiligungsverfahren, Wohnungsunternehmen etwa im Rahmen eines eigenen Sozialmanagements und beide z.B. durch ihre aktive Mitarbeit im Rahmen von Programmen zur Stadtteilentwicklung wie der „Sozialen Stadt“. Den Handlungsmöglichkeiten beider Akteure im sozialen Bereich sind jedoch Grenzen gesetzt (v.a. Mittel, Kompetenzen), sodass für eine umfassende Bearbeitung der Problemlage häufig weitere Akteure erforderlich sind.

Für die somit notwendigen Abstimmungen plädieren die hier beschriebenen Akteure für informelle Prozesse. So stellen Wohnungsunternehmen häufig Akteuren aus dem sozialen Bereich Geschäftsräume zum Selbstkostenpreis zur Verfügung. Damit erweitern sie die Handlungsfähigkeit dieser Akteure (geringe Kosten, Präsenz unmittelbar vor Ort) und erleichtern gleichzeitig eine laufende niedrigschwellige Abstimmung. Formalisierungen führen in den Augen der hier behandelten Akteure dagegen zu komplizierteren und langwierigen Verfahren. Als „Betroffene“ wird insbesondere durch Stadtplaner ein weiteres abstraktes Prüfverfahren – diesmal zu Sicherheit in der räumlichen Planung – nicht gerade begrüßt:

„Aber die Kommunen wehren sich auch mit Händen und Füßen dagegen, dass sie eine weitere Prüfnorm irgendwie auferlegt bekommen. Also man muss schon gucken, ist das verträglich mit Kröten und mit Igeln und keine Ahnung. Und dann müsste man noch gucken, ist es verträglich mit Sicherheit. (…) Habe ich auch das Gefühl, da stehen Planer nicht so drauf.“ (Vertreter Kriminalpräventive Gremien)

Dementsprechend sind in Deutschland gegenwärtig auch keine Bestrebungen feststellbar, Sicherheitsfragen in der kommunalen räumlichen Planung über formellem Wege verpflichtend zu verankern. Aktuelle Initiativen bieten stattdessen Weiterbildungsveranstaltungen, Handreichungen oder Unterstützung bei freiwilligen Kooperationen an und setzen explizit auf diese informellen Aspekte.

7 FAZIT

Das originäre Tätigkeitsfeld von Stadtplanern und Wohnungsunternehmen ist vielfältig und von Wechselwirkungen gekennzeichnet. Sicherheit ist ein Thema von erheblicher Breite und weitreichenden Folgeeffekten. Sicherheit in die räumliche Planung und bauliche Gestaltung zu integrieren heißt daher, ein komplexes Thema mit einem komplexen Feld zu verknüpfen – ohne Zweifel eine wenig triviale Verschränkung.

Im Umgang mit dieser anspruchsvollen Ausgangssituation finden sich in der Praxis zwei Varianten: Zum einen diejenige, die der Komplexität des Themas das eigene universale Handlungsverständnis („Sicherheit machen wir immer mit“ bzw. „Synergien“) entgegenstellt, zum anderen diejenige, die bei den entstehenden konkreten Problemen („Angsträume“) auch konkret eingreift. Beide werden dem Gegenstand nicht gerecht, denn Sicherheitsgesichtspunkte sind nur in den wenigsten Fällen angemessen weitreichend in diese planerisch-baulichen Handlungen integriert: Die erste Variante neigt dazu, das Thema Sicherheit zu vernachlässigen und kein eigenes Bewusstsein für sicherheitsrelevante Wirkungen der eigenen Handlungen zu entwickeln. Die zweite Variante behandelt häufig nur Einzelaspekte als Folgen und Symptome ebendieser Vernachlässigung.

Statt dessen muss Ziel für planende und bauende Akteure sein, von Beginn an die Sicherheitswirkungen eigener Tätigkeiten mitzubedenken und eine Sicherheits-Reflexion zu etablieren. Das heißt auch, dass es für die Praxis des Planens und Bauens weniger darum geht, etwas „Neues“ zu tun, als darum, ein Bewusstsein für die Reichweite und (unintendierten) Konsequenzen der eigenen Handlungen zu schaffen.

Die Handlungsoptionen der betrachteten Akteure müssen nicht erweitert werden. Ändern muss sich jedoch das Verständnis dahingehend, dass Sicherheit nicht (nur) als Spezialthema von Kriminologie und Polizei begriffen wird, sondern als fachübergreifendes Handlungsfeld eines lokalen Raums für dessen Handhabung die Zusammenarbeit mit anderen Akteuren notwendig ist. Gerade der intensive und gleichberechtigte Austausch mit anderen Akteuren wie Polizei oder Ordnungsamt, aber auch sozialen und zivilgesellschaftlichen Gruppen kann eine verstetigte Reflexion von Stadtplanern und Wohnungsunternehmen über die Sicherheitswirkung ihrer eigenen Handlungen fördern.

Raumpioniership in sozial benachteiligten Großstadtquartieren: Akteurstypen aus Berlin-Moabit und Hamburg-Wilhelmsburg

Petra Jähnke

(Dr. Petra Jähnke, Leibniz-Institut für Regionalentwicklung und Strukturplanung (IRS), Erkner bei Berlin, jaehnkep@irs-net.de)

1 ABSTRACT

Kennzeichnend für die Stadtentwicklung in Deutschland ist heute, dass Schrumpfungs- und Wachstumsprozesse gleichzeitig stattfinden – allerdings räumlich disparat und regional differenziert. Vor allem in sozial benachteiligten und/oder peripherisierten Stadtteilen werden bisherige Entwicklungsleitbilder und Raumvorstellungen in Frage gestellt. In zunehmendem Maße zeigt sich, dass Politik unter einem wachsenden Handlungsdruck steht. Gleichzeitig ist sie mit ihren wohlfahrtsstaatlichen Ansätzen als alleiniger Akteur überfordert, Problemlagen zu entschärfen und nachhaltige Entwicklungsprozesse anzuregen. An diesem Punkt kommen Raumpioniere und Raumpioniership ins Spiel. Solche Akteure bzw. Akteursnetzwerke werden oft als diejenigen identifiziert, die Neues umsetzen, sozialräumliche Transformationsprozesse aktiv voranbringen und dies mit eigenen Lebensentwürfen verbinden.

Das Leibniz-Institut für Regionalentwicklung und Strukturplanung (IRS) widmete sich diesen Problemstellungen mit einem Forschungsprojekt, das empirisch in Großstadtquartieren im Umbruch in Berlin-Moabit und Hamburg-Wilhelmsburg angesiedelt war. Ausgangspunkt bildete ein Verständnis von Raumpioniership in der Ambivalenz zwischen Kreativität und ‚schöpferischer Zerstörung', welches nicht nur zivilgesellschaftliche Akteure, sondern auch Akteure mit beruflichem Engagement vor Ort einschloss. Untersucht wurde, wer diese Engagierten sind, welche raumbezogenen Entwicklungsvorstellungen sie verfolgen und wie diese in lokalen Gruppen bzw. Netzwerken verhandelt werden. Außerdem war Gegenstand der Analyse, in welche öffentlichen Diskurse deren Visionen bzw. Ideen eingebettet sind und wie diese in lokale Macht- und Wissensordnungen eingeschrieben werden.

Ausgangspunkt bildete die Annahme, dass es die ‚in den Köpfen' verankerten (abwertenden) Deutungsmuster – bezogen auf Stadträume und (bestimmte) dort verortete Bürger bzw. Akteursgruppen – sind, die als wichtige Ansatzpunkte für Quartiersentwicklungen betrachtet werden müssen. Solche Deutungsmuster, die in dem hier zugrunde gelegten Forschungsverständnis auch als soziale Konstruktionen bezeichnet werden, entstehen in kommunikativen Aushandlungsprozessen und können auch nur in Kommunikationen transformiert oder modifiziert werden. Dieser Ansatz, d. h. die Herstellung eines raumbezogenen Zusammenhangs zwischen Wissen, Handeln und Kommunikation, gilt in Verbindung mit Fragen der Raumentwicklung als neu und wird im IRS weiter ausgearbeitet. Dazu erfolgt eine Verbindung des neueren Sozialkonstruktivismus mit dem wissenssoziologischen Diskurskonzept sowie mit ausgewählten anschlussfähigen raumtheoretischen Bausteinen – wie etwa relationalen Raumkonzepten – die einen sozial konstruierten bzw. einen Handlungsraum in den Mittelpunkt stellen.

Ausgehend von den genannten Problemstellungen und theoretischen Zugängen stehen empirisch in den untersuchten Fallregionen identifizierte Raumpioniertypen im Mittelpunkt des Beitrags. Diese sind in einem mehrdimensional bestimmten Akteursfeld verortet, welches sowohl potenzielle, eigentliche und etablierte Raumpioniere umfasst als auch pionierhafte bzw. engagierte Akteure. An ausgewählten Typen wird zudem darauf eingegangen, welche Möglichkeiten und Handlungsspielräume Raumpioniere und deren Netzwerke in Berlin-Moabit und Hamburg-Wilhelmsburg haben bzw. entwickeln, um soziale Spannungen einzudämmen, Lebensqualität zu sichern bzw. Quartiere zu „Wohlfühl-Orten" zu machen.

2 EINFÜHRUNG

Charakteristisch für die Stadtentwicklung in Deutschland seit Anfang der 2000er Jahre ist, dass Schrumpfungs- und Wachstumsprozesse gleichzeitig stattfinden – allerdings räumlich disparat und regional differenziert (vgl. Müller/Schmidt/Selle 2003). Vor allem in sozial benachteiligten und/oder peripherisierten Stadtteilen werden daher bisherige Entwicklungsleitbilder und -strategien in Frage gestellt. Da (Stadt-)Politik in diesen Räumen unter einem wachsenden Handlungsdruck steht und gleichzeitig mit traditionellen wohlfahrtsstaatlichen Mitteln an Grenzen stößt, gilt die Aufmerksamkeit in Wissenschaft und Praxis neuen Ansätzen und Akteuren, die Lösungen für lokale Problemlagen suchen und so nachhaltige Entwicklungsprozesse anregen. An diesem Punkt kommen Raumpioniere bzw. Raumpioniership ins Spiel. In

der Stadtforschung werden diese oft als zivilgesellschaftliche Akteure identifiziert, die in ökonomisch (zeitweise) entwerteten Räumen Entfaltungs- bzw. Freiräume für eigene Lebensentwürfe sehen und dort Neues umsetzen (vgl. z. B. Lange/Matthiesen 2005, Matthiesen 2005).

Dieses Begriffsverständnis wurde im Rahmen eines Forschungsprojekts[1] am Leibniz-Institut für Regionalentwicklung und Strukturplanung (IRS) als Oberbegriff – der empirisch zu fundieren war – für alle lokal engagierten Akteure verwendet, die im Quartier bzw. Stadtteil mit neuartigen Ansätzen etwas bewegen oder verändern wollen. Damit bezog er sich auch auf Unternehmer und Selbständige sowie Vertreter aus Politik, Verwaltung bzw. von Organisationen, die sozial-räumliche Transformationsprozesse vor Ort voranbringen. Ziel der Untersuchungen war es, Antwort auf die Fragen zu geben, wer diese engagierten Akteure sind, vor welchem sozio-kulturellen Hintergrund sie handeln und welche Raumbindungen sie haben, welche raumbezogenen Entwicklungsvorstellungen sie verfolgen und wie diese in lokalen Gruppen bzw. Netzwerken verhandelt werden. Außerdem war Gegenstand der Analysen, in welche öffentlichen Diskurse deren Visionen bzw. Ideen eingebettet sind und wie diese in lokale Macht- und Wissensordnungen eingeschrieben werden.

Ergebnisse dieses Projekts bieten Anknüpfpunkte an Fragen der internationalen Stadtplanerkonferenz 2012 in Schwechat/Österrreich „Re-Mixing the City/ Wiederdurchmischung der Stadt“. Der nachfolgende Beitrag beleuchtet daher, bezogen auf sozial benachteiligte Großstadtquartiere in Berlin-Moabit und Hamburg-Wilhelmsburg, das raumbezogene Wissen und Handeln lokal engagierter Akteure, einschließlich deren Kommunikationsstrategien. Ausgehend von projektbezogenen Forschungskontexten, theoretischen Zugängen und dem methodischen Vorgehen erfolgt zunächst eine Darstellung der damit im Zusammenhang stehenden sozial-räumlichen bzw. stadtentwicklungspolitischen Rahmenbedingungen. Danach stehen empirisch identifizierte Raumpioniertypen, verortet in einem mehrdimensionalen Akteursfeld, im Mittelpunkt. Abschließend wird darauf eingegangen, welche Möglichkeiten und Handlungsspielräume Raumpioniere haben bzw. entwickeln, um soziale Spannungen einzudämmen, Lebensqualität zu sichern bzw. Quartiere zu „Wohlfühl-Orten“ zu machen.

3 FORSCHUNGKONTEXTE, THEORETISCHE ZUGÄNGE UND METHODISCHES VORGEHEN[2]

Für die Untersuchung von Prozessen kommunikativer Raumkonstruktionen in Stadtteilen mit sozialen Problemlagen lag die Annahme zu Grunde, dass es die ‚in den Köpfen’ verankerten (abwertenden) Deutungsmuster – bezogen auf Stadträume und (bestimmte) dort verortete Bürger bzw. Akteursgruppen – sind, die als wichtige Ansatzpunkte für Quartiersentwicklungen betrachtet werden müssen. Solche Deutungsmuster, die in diesem Forschungsverständnis auch als soziale Konstruktionen bezeichnet werden, entstehen in kommunikativen Aushandlungsprozessen und können auch nur in Kommunikationen transformiert oder modifiziert werden. Forschungsleitend war zudem, dass Akteure, die sozial-räumliche Visionen entwickeln bzw. Neues denken und Bestehendes verändern, darüber kommunizieren bzw. andere zur Kommunikation darüber anregen und so auch deren Raumvorstellungen beeinflussen. Kommunikation wird dabei als soziales Handeln verstanden, das sich „Zeichen“ unterschiedlicher Art (wie Sprache) bedient. Außerdem findet diese sowohl in ‚face-to-face’ Kontexten als auch in öffentlichen Diskursen statt und ist mit Machtfragen verbunden. Dieser Ansatz, d. h. die Herstellung eines raumbezogenen Zusammenhangs zwischen Wissen, Handeln und Kommunikation, gilt in Verbindung mit Fragen der Raumentwicklung als neu und wird im IRS weiter ausgearbeitet. Dazu erfolgt eine Verbindung des neueren Sozialkonstruktivismus (vgl. Berger/Luckmann 1987, Luckmann 2002, Knoblauch 1995) mit wissenssoziologischen Diskurskonzepten (vgl. Keller 2008) sowie mit ausgewählten anschlussfähigen raumtheoretischen Bausteinen – wie etwa relationalen Raumkonzepten (vgl. Läpple 1991, Sturm 2000, Löw 2001). Ziel ist die Entwicklung einer Theorie der kommunikativen Raumkonstruktion.

Das Pionierhafte wird in diesem Forschungsansatz also nicht primär an den Aktivitäten für neue oder alternative (Wieder-)Inwertsetzungen von gebauten Räumen oder Freiräumen – bezogen auf den Stadtteil

[1] Das Forschungsprojekt „Raumpioniere im Stadtquartier – zur kommunikativen (Re-) Konstruktion von Räumen im Strukturwandel“, zu dessen Team die Autorin gehörte, wurde zwischen 2009 und 2011 am IRS in Erkner (bei Berlin) in der Forschungsabteilung „Kommunikations- und Wissensdynamiken im Raum“ bearbeitet (vgl. dazu auch Christmann/Büttner 2012, Christmann/Jähnke 2011, Christmann/Mahnken 2012, Neumann/Schmidt 2012).

[2] Nachfolgend werden wesentliche Prämissen des o.g. IRS-Forschungsprojekts dargestellt.

oder das Quartier – festgemacht, wie dies beispielsweise in Ansätzen zur Zwischennutzung geschieht (vgl. zu Urban Pioneers z. B. SenStadt 2007). Vielmehr steht das Neue im sozialen Handeln der lokal engagierten Akteure, einschließlich der Wirkungen auf bzw. Wechselwirkungen mit anderen „Raumdimensionen" im Mittelpunkt. Anders ausgedrückt, Raumpioniere agieren in einem „Matrixraum", d. h. ihr Handeln bezieht sich sowohl auf den Raum als materiell-physisches Substrat als auch auf die gesellschaftlichen Interaktions- und Handlungsstrukturen bzw. die gesellschaftliche Praxis, die institutionellen und normativen Regulationssysteme sowie das räumliche Zeichen-, Symbol- und Repräsentantensystem (Läpple 1991: 196f.).

Da in diesem Forschungsverständnis ein Raumpionier weder allein noch im Verborgenen agieren kann, wenn er mit neuartigen Ansätzen etwas bewegen oder verändern will, waren als Forschungsperspektive nicht nur Einzelakteure, sondern auch Gruppen bzw. Netzwerke sowie öffentliche Diskurse von konzeptioneller und analytischer Bedeutung. Aus der Forschungsperspektive der Einzelakteure bestand das Untersuchungsziel in der empirischen Differenzierung eines Akteursfeldes sowie in der Identifizierung von Raumpioniertypen (zur empirisch begründeten Typenbildung vgl. Kluge 1999, Kelle/Kluge 2010 sowie Rosenthal 2005). Auf ausgewählte Befunde dieser Analysen wird nachfolgend vor dem Hintergrund spezifischer stadtteilbezogener Rahmenbedingungen eingegangen.

4 RAUMPIONIERE UND IHRE TYPIK IN BERLIN-MOABIT UND HAMBURG-WILHELMSBURG

4.1 Sozial-räumliche bzw. stadtentwicklungspolitische Rahmenbedingungen des Akteursengagements

Hamburg-Wilhelmsburg und Berlin-Moabit sind Stadtteile mit sozialen Problemlagen und partiellen Aufwertungstendenzen. Sie kennzeichnen sowohl stete Negativ-Images und soziale Heterogenität[3] als auch Bürgerengagement bzw. Raumpionieraktivitäten vor dem Hintergrund einer zumeist starken Ortsbindung der Bewohner. Hinzu kommt, dass die Zentrumsnähe dieser Räume innerhalb der Gesamtstadt für Akteure aus Politik bzw. Wirtschaft Anfang der 2000er Jahre Anlass war, in diesen bisher wenig beachteten Stadtteilen ungenutzte Entwicklungspotenziale zu identifizieren – wenn auch regionsspezifisch mit unterschiedlichen Intentionen und in verschiedenem Maße.

In diesem Kontext waren für Wilhelmsburg im Untersuchungszeitraum konkurrierende Images identifizierbar. Dem in der Öffentlichkeit negativ besetzten Bild (verbunden mit Begriffen wie Flut, Industrie, Verkehr und Gewalt; vgl. Weißbuch 2002) wird im Rahmen der offiziellen Stadtentwicklungspolitik seit Anfang des 21. Jahrhunderts mit dem „Sprung über die Elbe" eine neue Vision entgegengestellt und öffentlich kommuniziert. Diese zielt im Kontext des Leitbildes „Metropole Hamburg – Wachsende Stadt" auf die vielfältigen Qualitäten Wilhelmsburgs als Wohn- und Arbeitsort in Verbindung mit den verfügbaren Entwicklungsflächen und -potenzialen ab (vgl. Hamburg 2002). Zudem wurden im Ergebnis bürgerschaftlichen Engagements für die Sicherung der Lebensqualität auf dieser Insel – die durch Industrie- und Hafenansiedlungen oder städtische Infrastrukturanlagen wiederholt als bedroht angesehen wurde – im Ergebnis einer Zukunftskonferenz und unter Beteiligung eines breiten Akteurskreises wesentliche Grundlagen für stadtentwicklungspolitische Ansätze auf der Elbinsel erarbeitet (vgl. Weißbuch 2002). Davon ausgehend erfolgt Stadtentwicklung in Wilhelmsburg seit 2006 vor allem unter dem Dach einer Internationalen Bauausstellung[4] (IBA 2013) in Verbindung mit einer Internationalen Gartenschau (igs 2013). Unter dem Motto „Entwürfe für die Zukunft der Metropole" stehen drei Leitthemen im Mittelpunkt der IBA (vgl. www.iba-hamburg.org): Kosmopolis (Suche nach neuen Wegen des Zusammenlebens),

[3] In Moabit waren 2008 ca. 45 % der Bewohner nichtdeutscher Herkunft (Aktionsraum plus Wedding/Moabit 2010) und knapp 30 % waren abhängig von Transferleistungen des Staates, d.h. erhielten Hartz IV oder vergleichbare Leistungen (www.berlin.de). In Wilhelmsburg lag dieser Anteil im gleichen Zeitraum ebenso bei rund 30 %, der höchsten Quote in ganz Hamburg (www.statistik-nord.de). Der Anteil der Bewohner mit Migrationshintergrund wurde in diesem Stadtteil 2009 mit mehr als 50 % beziffert (ebd.).

[4] Als Instrument der Planungs- und Baukulturpolitik folgen Internationale Bauausstellungen (IBAs), die in Deutschland eine über hundertjährige Geschichte haben, i.d.R. drei Prämissen: Antworten auf städtische bzw. regionale Problemlagen werden auf Architektur und Stadtplanung zentriert. Modellhafte Lösungen, die zur Diskussion gestellt werden, orientieren sich an internationalen Maßstäben, setzen aber auch für die planende Verwaltung neue Maßstäbe. Intellektuelle, künstlerische und finanzielle Kräfte werden auf einen überschaubaren Zeitraum konzentriert, in dem auch Experimente und Mut zum Risiko ermöglicht werden (Durth 2008: 8).

Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

Metrozonen (interessante städtebauliche Lösungen für die „inneren Stadtränder“), Stadt im Klimawandel (Stadtwachstum im Einklang mit der Umwelt). Für die Realisierung baulicher, kultureller und sozialer Projekte erfolgt die Bündelung beachtlicher öffentlicher und privater Mittel. Als eine „durch das Standortmarketing induzierte IBA“ ist diese Bauausstellung aber auch mit dem Vorwurf konfrontiert, einer Festivalisierung von Stadtentwicklungspolitik Vorschub zu leisten und so die Beliebigkeit des Instruments zu befördern, auch wenn der realisierte Projektmix mittlerweile spektakuläre Einzelprojekte mit (erfolgreichen) Stadterneuerungsstrategien verbindet (Petrin 2008: 28).[5] Große Aufmerksamkeit gilt im Rahmen dieser IBA/igs auch der Öffentlichkeit und der Bürgerbeteiligung (z. B. Einrichtung eines IBA/igs-Beteiligungsgremiums). Sowohl die mit der IBA induzierten Aufwertungsprozesse als auch die verfolgten bzw. realisierten Beteiligungsstrategien werden von den engagierten Akteuren vor Ort teils sehr kritisch beurteilt. Ihr Handeln ist vor diesem Hintergrund breit aufgestellt.

Die Einbettung Berlin-Moabits in gesamtstädtische Entwicklungsstrategien stellt sich im Vergleich zu Wilhelmsburg anders dar. Das mit dem Konzept „Aktionsraum plus Wedding/Moabit“ entwickelte Leitbild bescheinigt diesem Stadtteil zwar das Potenzial, sich zu einem urbanen Lebensbereich mit attraktiven Wohn , Arbeits , Einkaufs , Freizeit und Erholungsmöglichkeiten entwickeln zu können, setzt aber letztlich nur an der Überwindung gegenwärtiger Defizite und Probleme an (vgl. Aktionsraum plus Wedding/Moabit 2010). Die Standortgunst dieses Stadtteils ist vor dem Hintergrund zahlreich verfügbarer, zentrumsnaher Entwicklungsflächen stadtentwicklungspolitisch und investorenbezogen bisher vor allem für ausgewählte Nutzungen interessant. Diese stehen zumeist mit dem neuen Berliner Hauptbahnhof in Verbindung – wie Hostels und Hotels, aber auch höherwertiges Wohnen. In wenigen Wohnquartieren sind bisher Aufwertungstendenzen erkennbar. Einen vergleichbaren visionären Entwicklungsansatz, wie dies mit der IBA/igs für Hamburg-Wilhelmsburg der Fall ist, gibt es für Moabit nicht. Dies wird auch in der Medienresonanz deutlich, die weiterhin ein zumeist negatives Bild des Stadtteils zeichnet (verbunden mit Begriffen wie Gewalt, Kriminalität, Gefängnis und Gericht). Vor diesem Hintergrund findet Stadtentwicklung in diesem Stadtteil vor allem auf der Basis informeller Planungsinstrumente (wie städtebauliche Wettbewerbe und Masterpläne) und formeller Planungen (wie vorhabenbezogene Bebauungspläne) sowie über Programme der Städtebauförderung (wie „Soziale Stadt“, „Stadtumbau West“ sowie „Aktive Stadt und Ortsteilzentren/Innenentwicklung“) – in unterschiedlichen Zeiträumen und Förderkulissen mit den entsprechenden Beteiligungsverfahren – statt. Bürgerengagement in Moabit wurzelt bereits in der alternativen Stadtentwicklungsszene bzw. in Beteiligungsgremien von Stadterneuerungsansätzen Ende der 1980er Jahre. Es konzentrierte sich im Untersuchungszeitraum sowohl auf die Bewahrung und Sicherung der Lebensqualität in diesem Stadtteil, beispielsweise in Konflikten mit Investorenansiedlungen bzw. interessen, als auch auf die Entwicklung und Umsetzung neuer Ansätze für eine sozial-räumlich verträgliche Aufwertung.

Insgesamt bildet die Gesamtheit dieser Rahmenbedingungen den Kontext des Engagements von Raumpionieren in den beiden Referenzräumen, welches nachfolgend spezifiziert wird.

5 ZUR BESCHREIBUNG EINES AKTEURSFELDES „PIONIERHAFTES ENGAGEMENT“[6]

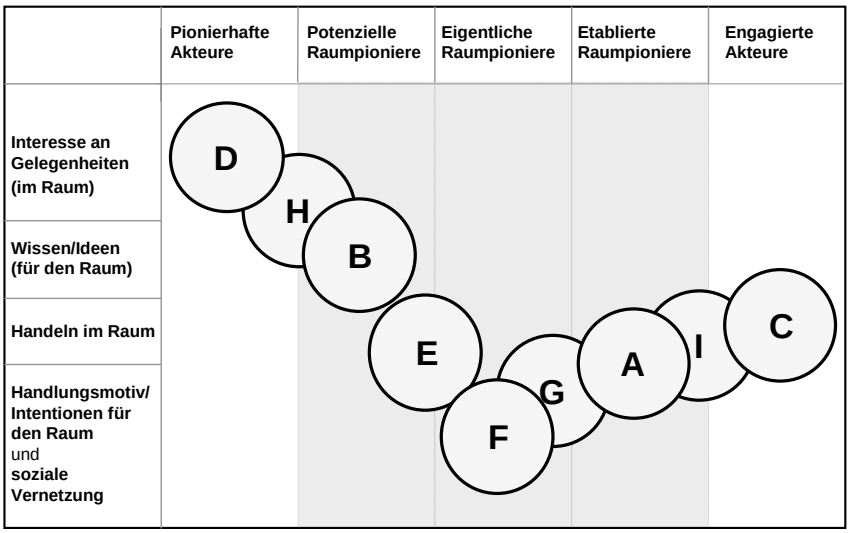
Die Differenzierung des identifizierten Akteursfeldes beruht auf einer Heuristik, die anknüpfend an forschungsleitende Annahmen und erste empirische Auswertungen entwickelt wurde. Danach charakterisieren fünf unterschiedliche Ausprägungen das „pionierhafte“ Engagement neuer Akteure in einem Stadtteil bzw. in einem Quartier (vgl. Abb. 1).

Pionierhafte Akteure haben vor allem Interesse an den Gelegenheitsstrukturen vor Ort (wie Gebäude oder Freiflächen), d. h. sie suchen beispielsweise günstigen Wohn bzw. Gewerberaum oder beides. Ihr raumbezogenes Wissen über den Stadtteil ist gering. Ihr Handeln ist nicht mit der Intention verbunden, sozial-räumliche Ideen für Veränderungen im Quartier zu entwickeln bzw. umzusetzen. Außerdem sind sie auch nicht mit engagierten Akteuren oder Akteursgruppen vor Ort sozial vernetzt.

[5] Mit dem ins Leben gerufenen Netzwerk „IBA meets IBA“, das unter anderem ein Memorandum mit zehn Empfehlungen – als freiwillige Selbstverpflichtung – erarbeitet hat, wird diesem Vorwurf begegnet (faz 2009).

[6] Datengrundlage bildeten die mit Akteuren in den beiden Referenzräumen im Rahmen des o. g. Projekts durchgeführten problemzentrierten Interviews, die für qualitative Auswertungen transkribiert und anonymisiert wurden.

Potenzielle Raumpioniere entwickeln dagegen als Akteure innovative bzw. visionäre Vorstellungen von Aktivitäten in ihrem Quartier für das sie sich bewusst entschieden haben. Sie greifen dabei bereits auf spezielles Raumwissen zurück, haben aber keine sozial-räumlichen Visionen, die sie explizit bzw. intendiert mit dem Stadtteil verknüpfen. Neue Ideen, die sie entwickeln oder aufgreifen und lokal verankern, sind untrennbar mit den eigenen und teils neuen Lebensentwürfen verbunden. Sie münden zumeist in einem projektbezogenen Engagement, wie beispielsweise in Form „experimenteller oder alternativer Kunst im öffentlichen Raum". Ihr Handeln wird öffentlich wahrgenommen und ist (sozial-)raumwirksam, allerdings nicht intendiert. Daher grenzen sie sich davon ggf. sogar ab. Zu anderen Engagierten im Stadtteil haben sie kaum soziale Beziehungen. In ihrer überregional ausgerichteten Community sind sie dagegen sehr gut vernetzt.



Quelle: Christmann 2011, modifiziert.

Abb. 1: Heuristik – Akteursfeld „pionierhaftes" Engagement[7]

Eigentliche Raumpioniere verfügen über umfangreiches Raumwissen und richten ihr pro-aktives Handeln – vor dem Hintergrund ihrer ebenso teils neuen, aber bereits stärker lokal verankerten Lebensentwürfe (im Hinblick auf Wohnen, Arbeiten oder beides) – gezielt auf sozial-räumliche Veränderungen. Sie haben nicht nur darauf bezogene Visionen und Ideen, sondern daraus auch Projekte entwickelt. Diese setzen sie erfolgreich um und verankern sie ggf. weiter institutionell – wie beispielsweise im Rahmen von Social Entrepreneurship[8] oder Corporate Social Responsibility.[9] Mit anderen engagierten Akteuren im Stadtteil sind diese strategisch vernetzt und in unterschiedlichem Maße öffentlich „sichtbar".

Bei **etablierten Raumpionieren** steht vor dem Hintergrund ihres umfangreichen Raumwissens dagegen nicht mehr die Entwicklung und Verankerung neuer bzw. innovativer sozial-räumlich orientierter Ideen, verbunden mit entsprechenden Aktivitäten, im Mittelpunkt ihres Handelns, sondern die Institutionalisierung bzw. Bewahrung des einstmals Innovativen. Dazu greifen sie auf ihre mittlerweile etablierten strategischen Netzwerke bzw. sozialen Beziehungen zurück und sind „bekannt" im Quartier bzw. Stadtteil. Sie verfolgen durchaus noch sozial-räumliche Visionen, konzentrieren sich auf der Handlungsebene aber auf die Etablierung oder Weiterentwicklung bereits eingeführter neuer bzw. innovativer Projekte. Ihr (langjähriges) Engagement für das Quartier bzw. den Stadtteil (beruflich, bürgerschaftlich oder beides) ist fester Bestandteil ihrer Lebensentwürfe geworden.

[7] Die mit Buchstaben versehenen Kreise verkörpern stellvertretend Einzelfälle, deren genaue Einordnung/Zuordnung Gegenstand der Untersuchungen zur Charakterisierung des Akteursfeldes und der Identifizierung von Typen war.

[8] Unter Social Entrepreneurship wird hier das gemeinsame unternehmerische Handeln von Akteuren verstanden, die sich mit ihren Ansätzen der Lösung sozial-räumlicher Probleme zuwenden und dabei den sozialen Mehrwert in den Vordergrund stellen (vgl. dazu Jähnke et al. 2011).

[9] Corporate Social Responsibitity (CSR) kennzeichnet Unternehmen im Wirtschaftsbereich, die mit ihren Aktivitäten über die bloße Erfüllung von sozialgesetzlichen Vorschriften deutlich hinausgehen. Im Vordergrund steht zwar das wirtschaftliche Handeln, das aber in hohem Maße sozial verantwortungsbewusst und nachhaltig angelegt wird (vgl. Beckmann 2007).

Engagierte Akteure schließlich sind ebenso lokal sozial verankert und vernetzt, sie greifen aber vor allem auf bewährte Engagementansätze zur Gestaltung der Quartierentwicklung, zur Verbesserung von Lebensqualität vor Ort u. ä. zurück und handeln eher reaktiv.

Das empirisch identifizierte Akteursfeld wird daher aufgespannt zwischen den Akteursmerkmalen „Interesse an Gelegenheiten“ (im Raum), „Wissen/Ideen“ (für den Raum)“, „Handeln im Raum“ sowie „Handlungsmotiv/Intention für den Raum“, was die „soziale Vernetzung“ der Akteure einschließt (vgl. Abb. 1). Zudem zeigten weitere empirische Auswertungen, dass raumwirksames Akteursengagement auch als „Prozess“ im Zeitverlauf interpretiert werden kann. Dies bedeutet, dass sich Engagierte von pionierhaften Akteuren im Stadtteil zu potenziellen, eigentlichen und etablierten Raumpionieren entwickeln können, worauf ggf. (nur noch) Aktivitäten als engagierte Akteure folgen („Raumpionierzyklus“). Außerdem wurde deutlich, dass von einer Offenheit dieses Prozesses ausgegangen werden muss, d. h. es ist auch ein Quereinstieg in bzw. ein Ausstieg aus jeder dieser „Phasen“ möglich. Dies wäre beispielsweise der Fall, wenn ein Akteur ohne bisherigen Stadtteilbezug Raumpionier-Projekte voranbringt bzw. wenn er seine Aktivität vor Ort nach dem Abschluss solcher Projekte wieder ‚einstellt’.

Und schließlich konnte festgestellt werden, dass sich o. g. Ausprägungen bei ausgewählten Akteuren überlagern können bzw. dass Einzelfälle den „Phasen“ nicht eindeutig zuordenbar sind. Dies machte eine weitergehende Differenzierung notwendig, auf die nachfolgend am Beispiel ausgewählter Raumpioniertypen[10] eingegangen wird.

6 ZUR TYPIK VON RAUMPIONIEREN: MACHER, GESTALTER, ENTWICKLER UND ANDERE

Für die Identifizierung von Raumpioniertypen wurden vor allem die Akteure herangezogen, die sich im Bereich zwischen potenziellen, eigentlichen und etablierten Raumpionieren einordnen ließen und somit den Kern des Akteursfeldes bilden (vgl. Abb. 1), da nur sie, wenn auch auf unterschiedliche Art und Weise, ihr Wissen und ihr Handeln – einschließich ihrer kommunikativen Strategien – auf eine sozial-räumliche Wirksamkeit im Quartier bzw. Stadtteil ausrichten.

Ausgehend von den für Stadtentwicklung bedeutsamen Fragen – welche Aktivitäten das Handeln von Raumpionieren kennzeichnen, was diese Akteure langfristig an städtische Räume bindet und welche Gründe sich dafür identifizieren lassen – bieten folgende Raumpioniertypen, die in beiden Referenzräumen zu finden waren, interessante Ansatzpunkte.

Die **„Macher von Kunst im Raum“** mit experimentellen Ansätzen (potenzielle Raumpioniere) leben seit Jahren in der jeweiligen Stadt und seit längerem im Stadtteil. Sie schätzen insbesondere die Entfaltungsmöglichkeiten, die sie für ihre Ideen lokal vorfinden. Charakteristisch ist ihre positive Identifikation mit dem Raum und zwar genau so wie er ist. Auch in der räumlichen Nähe von Wohnung und Arbeitsplatz (Atelier, Galerie o. ä.) drückt sich die enge Verbindung des lokalen Engagements mit den persönlichen Lebensentwürfen aus. Das Handeln dieser Akteure ist stark durch einen künstlerischen Habitus bestimmt, der vor allem mit Individualität und Freiheit verbunden wird. Ihre soziale Resonanz, d. h. ihre sozialen Kontakte und Beziehungen sowie ihr sozialer Einfluss im Quartier bzw. Stadtteil ist gering, dafür sind sie in der jeweiligen Kunst bzw. Kultur-Community lokal, national und zumeist auch international gut vernetzt. Sie nutzten den Stadtteil vor allem als „Bühne“ für ihre Kunstprojekte. Diese sind neu/innovativ für den Raum, aber nicht oder nur mittelbar auf dessen soziale Problematiken und die Menschen des jeweiligen Stadtteils bezogen. Da diese Akteure Freiräume und Selbstbestimmung schätzen, stehen sie politisch-planerischen Steuerungsinterventionen kritisch gegenüber. Mit ihren Projekten sind sie in der Öffentlichkeit „sichtbar“ und präsent. Sie tragen somit zur Außen-Imageverbesserung des Stadtteils bei, auch wenn dies unter Umständen gar nicht von ihnen gewollt ist.

Die „Gestalter von lokalen Lebensräumen“ mit experimentellen Ansätzen und unternehmerischen Strategien (eigentliche Raumpioniere) kennzeichnet eine Orientierung auf pro-aktives und sozial-räumlich intendiertes Handeln. Ihren Anspruch zu gestalten verbinden diese Akteure in hohem Maße mit „Selbstverantwortung“, die sie auch von anderen einfordern. Sie kennzeichnet ein ausgeprägter unternehmerischer Habitus.

[10] Trotz gewisser Überschneidungen bei der Gruppierung bzw. Zuordnung der Einzelfälle in das zunächst heuristisch bestimmte Akteursfeld waren für jede der identifizierten Gruppierungen gemeinsame Charakteristika sowie Unterschiede bestimmbar, was die Bildung empirisch begründeter Typen rechtfertigte.

Außerdem wohnen und/oder engagieren sie sich schon lange im Stadtteil, verbinden mit diesem ein großes Identifikationspotenzial und haben ein positives Raumbild. Ihre Aktivitäten fokussieren diese Akteure auf die sozial-räumliche Vision „eines Dorfes in der Stadt", denn sie suchen eine soziale Gemeinschaft, die sowohl von gegenseitiger Unterstützung und Hilfe als auch durch Offenheit und Toleranz charakterisiert wird. Vor dem Hintergrund ihres zu großen Teilen ehrenamtlichen Engagements, bei dem sie in der Regel den „Hut auf haben" (wie als Vereinsvorsitzender), verbinden sie immer wieder eigene Lebensentwürfe mit Aktivitäten bzw. Projekten im Stadtteil. Typisch für diese Akteure sind Offenheit für Neues, die Freude am Experimentieren und der Mut zum Ausprobieren. Ihr besonderes Interesse gilt Aktivitäten bzw. Projekten, die soziale Anliegen mit unternehmerischen Ansätzen verknüpfen (im Sinne von Social Entrepreneurship oder Corporate Social Responsibility). Sie stellen sich selbst als „visionäre Macher" dar, sie handeln pragmatisch und lösungsorientiert. Im Stadtteil sind sie daher strategisch auf mehreren Ebenen vernetzt und haben soziale Resonanz.

Die **„Entwickler von Kultur- und Bildungsorten"** mit kommunikativen und partizipativen Strategien (zwischen eigentlichen und etablierten Raumpionieren angesiedelt) charakterisiert, dass sie sozial-unternehmerisch intendiert im Kontext sozial-räumlicher Transformationen handeln und institutionell verankert sind. In dieser Rolle tragen sie Verantwortung (als Vereinsvorsitzender, Geschäftsführer o. ä.) und sind mit der jeweiligen Einrichtung im Stadtteil etabliert. Das Ziel ihres Engagements, ihre Vision, ist die „gesellschaftliche Teilhabe aller" durch den Zugang zu Bildung und/oder Kultur sowie durch Möglichkeiten der Information und Kommunikation – d. h. auch von Migranten, sozial Benachteiligten oder Menschen in prekären Einkommensverhältnissen. Dafür schaffen sie einerseits „Orte" bzw. setzen sich in ihrer institutionellen Rolle und mit persönlichem Engagement für die Sicherung bzw. den Erhalt dieser ein. Andererseits ist für sie Partizipation im Stadtteil von zentraler Bedeutung. Die Entwicklung von sozialem Kapital (wie Vertrauen) halten diese Akteure für besonders wichtig, um Zugang zu den heterogenen Zielgruppen ihres Engagements zu finden. Viele der entwickelten Aktivitäten/Projekte sind für den Stadtteil neu bzw. innovativ, sie arbeiten aber auch mit bereits eingeführten Ansätzen. Akteure dieses Typs wohnen in der Regel schon lange vor Ort, was sie für soziale Problematiken sensibilisiert hat und können zumeist auf eine bürgerschaftliche „Engagementkarriere" im Stadtteil zurückblicken. Sie entwickeln ein positives, auf die lokalen sozial-räumlichen Potenziale fokussiertes Raumbild. In ihrer (heutigen) institutionellen Rolle ‚verfügen' sie über entsprechende organisatorische, personelle und finanzielle Ressourcen (d. h. Mittel der öffentlichen Hand, wie Zuwendungen und zeitlich befristete Fördermittel, sowie eigene Einnahmen und Spenden). Zudem werden die verfolgten Ansätze durch ein breites bürgerschaftliches Engagement vor Ort begleitet. Vor diesem Hintergrund sind diese Akteure strategisch lokal vernetzt und haben soziale und öffentliche (d. h. ihr Engagement wird öffentlich wahrgenommen und reflektiert) Resonanz sowie zum Teil auch eine politische Resonanz (im Sinne einer ‚Beachtung' durch Vertreter der städtischen Politik und Verwaltung).

Neben den o. g. Raumpioniertypen erweisen sich weitere Typen durch regionale Spezifika als interessant, die sowohl Zusammenhänge mit der Entwicklungsgeschichte der Stadtteile bzw. der Historie des Bürgerengagements als auch mit den verfolgten stadtentwicklungspolitischen Strategien nahelegen. So sind beispielsweise **„Hüter der lokalen sozialen Gemeinschaft"** mit partizipativen Strategien (als etablierte Raumpioniere)[11] vor allem in dem Referenzraum zu finden, für den im Untersuchungszeitraum keine stadtentwicklungspolitische Gesamtvision – verbunden mit entsprechenden Gesamtentwicklungskonzepten – vorlag, und aufseiten der Bürger keine permanent wahrgenommene ‚Bedrohung' der Lebens- und Freiräume existierte (Berlin-Moabit). Dies könnten Gründe dafür sein, dass sich dieser Typus weniger politisch-strategisch für oder gegen sozial-räumliche Transformationsprozesse positioniert und engagiert sowie hauptsächlich auf der Informationsebene verbleibt.

[11] Für die „Hüter der lokalen sozialen Gemeinschaft" stellt diese Verbundenheit einen zentralen Wert ihres Lebensentwurfes dar. Kennzeichnend für sie sind ein altruistischer Habitus und der Anspruch, ihren Stadtteil bzw. ihr Quartier als Sozialraum im Ergebnis vergangener sozial-räumlicher Transformationen zu schützen. Ihr Handlungsschwerpunkt liegt bei der Umsetzung partizipativer Strategien für die Sicherung neuer Formen des Bürgerengagements. Ihr Engagement ist zumeist reaktiv, welches sie aber auch mit kreativen Aktionen und Aktivitäten verbinden.

Andererseits waren „Veränderer von Stadträumen“ mit baulichen, kulturellen und sozialen Projekten sowie kommunikativen Strategien (eigentliche Raumpioniere)[12] nur in Hamburg-Wilhelmsburg zu finden, d. h. in dem Referenzraum, wo sozial-räumliche Transformationen mit einer gezielten stadtentwicklungspolitischen (Aufwertungs-)Strategie verbunden werden. Um die gebaute Umwelt bzw. städtische Freiräume tatsächlich zu gestalten bzw. zu verändern, bedürfen Akteure solcher finanzieller, institutioneller bzw. personeller „Kapazitäten“. Auch der politisch-strategisch „Aktive (Bürger) für lokale Lebensräume“ mit konzertierten Aktionen für eine sozialverträgliche Entwicklung (zwischen eigentlichen und etablierten Raumpionieren verortet) ist (nur) in diesem Referenzraum lokalisiert. Er verkörpert Raumpioniere (bzw. Ansätze von Raumpioniership), die mit einem breiten „Bürgerengagement“ auf eine lange und erfolgreiche „Entwicklungsgeschichte“ zurückblicken können und – geübt in der Auseinandersetzung mit Stadtentwicklungskonzepten – nicht nur sozial vernetzt und mit ihren Aktivitäten öffentlich ‚sichtbar’ sind, sondern auch auf der politischen Ebene agieren.

7 FAZIT UND AUSBLICK – MÖGLICHKEITEN UND HANDLUNGSSPIELRÄUME VON RAUMPIONIERSHIP IN DER QUARTIERSENTWICKLUNG

Im Rahmen dieses Beitrags wurde – vor dem Hintergrund eines Forschungsansatzes, der einen raumbezogenen Zusammenhang zwischen Wissen, Kommunikation und Handeln herstellt – ein empirisch differenziertes Akteursfeld beschrieben und auf ausgewählte Raumpioniertypen eingegangen. Dieses Akteursfeld umfasst sowohl potenzielle, eigentliche und etablierte Raumpioniere als auch pionierhafte bzw. engagierte Akteure. Es konnte verdeutlicht werden, dass deren „Absichten für den Raum“, das damit verbundene Handeln sowie die zugrundeliegenden Wissensbestände durchaus verschieden sind. Betrachtet man das identifizierte Akteursfeld im Zeitverlauf, haben Akteure unterschiedliche Entwicklungsoptionen als Raumpioniere, die im Hinblick auf die Entwicklung benachteiligter Stadträume Beachtung finden sollten.

Mit der Nutzung von Gelegenheitsstrukturen vor Ort setzen pionierhafte Akteure brachliegende Potenziale im Stadtteil wieder „in Wert“. Ihr Lebensstil und ihre Wertvorstellungen haben – in der Regel nicht intendiert – Einfluss auf die lokalen sozio-kulturellen Bedingungen. Optionen dieser Akteure für raumrelevantes Handeln bestehen in zwei Richtungen: Wenn sich ihre Bindungen an den Stadtteil verstärken, sie diese mit sozial-räumlichen Visionen verknüpfen, Projektideen dazu entfalten und dafür Umsetzungschancen sehen, können sie sich zu Raumpionieren entwickeln. Ebenso besteht die Option, dass diese Akteure den Stadtteil nach einer bestimmten Zeit ohne weiteres Engagement vor Ort wieder verlassen.

Raumpioniere im engeren Sinne, d. h. potenzielle, eigentliche oder etablierte Raumpioniere, haben eine große Identifikation mit dem Stadtteil oder Quartier, weil sie hier nicht nur Gelegenheitsstrukturen vorfinden, sondern auch Entfaltungs- und Freiräume für ihre eigenen Lebensentwürfe und/oder ihre berufliche Entwicklung sehen. Diese „Raumqualitäten“ verbunden mit sozio-kulturellen, baulich-räumlichen bzw. sozial-räumlichen Visionen bzw. Projekten sind ausschlaggebend für ihr lokales bürgerschaftliches und/oder professionelles Engagement. Da sie dies nur gemeinsam mit anderen Akteuren bewältigen können, entwickeln sie je nach Typus spezifische soziale Netzwerke und entsprechende kommunikative Strategien (Raumpioniership). Entwicklungsoptionen haben diese Akteure vor allem im Bereich zwischen eigentlichen bzw. etablierten Raumpionieren. Gegebenenfalls bestehen diese aber auch in Richtung engagierter Akteure, wenn (nur noch) bereits bewährte Engagementformen im Mittelpunkt des Handelns stehen oder in Richtung „Ausstieg“, wenn die Akteure das Quartier bzw. den Stadtteil verlassen, weil sie ihre Lebensentwürfe nicht mehr mit lokalen sozial-räumlichen Transformationsprozessen in Übereinstimmung sehen.

Eine weitere Akteursdifferenzierung durch die Bildung von Typen war nicht nur für die beiden Referenzräume aufschlussreich, sondern bietet auch im Hinblick auf Lösungen für lokale sozial-räumliche Probleme und die Anregung nachhaltiger Quartiers- bzw. Stadtteilentwicklungen Anknüpfungspunkte.

Aus einer „Bottom up“-Perspektive sind insbesondere die **„Gestalter von lokalen Lebensräumen“,** die **„Entwickler von Kultur- und Bildungsorten“** und der **„Aktive (Bürger) für lokale Lebensräume“** von

[12] Die „Veränderer von Stadträumen“ kennzeichnet, dass sie die visionäre „Veränderung von Orten“ in den Mittelpunkt ihres Handelns zur sozial-räumlichen Transformation stellen. Mit ihrer „auf Zeit“ angelegten und mit einer entsprechenden Ressourcenausstattung und institutionellen Verankerung verbundenen öffentlichkeitswirksamen Handlungs- und Projektorientierung nutzen sie den Stadtteilvor allem als „Bühne“. Lokalem sozialem Kapital messen sie dabei weniger Bedeutung zu als andere eigentliche Raumpioniere.

Bedeutung, da sie ihre sozial-räumlichen Visionen mit gezielten Aktivitäten bzw. einem kontinuierlichen Projektengagement im Stadtteil verbinden. Erstere können mit ihren experimentellen Ansätzen vor allem eine Vorreiterrolle bei der Initiierung von „Neuem" im Zuge sozial-räumlicher Transformationen einnehmen. Dies schließt sowohl die Mobilisierung von Ressourcen, die Motivation und das „Mitnehmen" weiterer Akteure im Stadtteil in ein „positives Umfeld" als auch die Abgrenzungen von Akteuren mit anderen Wertstrukturen ein. „Entwickler von Kultur- und Bildungsorten" sind dafür prädestiniert, in diesen Entwicklungsprozessen – über das eigene Projektengagement hinaus – auch als „lokaler Wissensspeicher", Kommunikator und Vermittler zu fungieren.

Aus einer „Top down"-Perspektive stellen sich die **„Veränderer von Stadträumen"** als besonderer Typus dar. Dieser hat durch eine entsprechende Ressourcenausstattung (wie die einer IBA) Entwicklungskapazitäten, die über Einzelprojekte und spezifische Themenausrichtungen hinausgehen, zur Verfügung und kann so nicht nur einzelne „Orte" im Kontext eines Projekts entwickeln, sondern auch nachhaltige Impulse für die bauliche, kulturelle und soziale Entwicklung eines ganzen Stadtteils im Zuge sozial-räumlicher Transformation setzen.

Für beide Perspektiven gilt, dass das mit Raumpioniership verbundene soziale Kapital – wie Gruppensolidarität, Vertrauen, (sozialer) Einfluss und Informationsaustausch (vgl. Jansen 2000) – als eine wichtige Ressource für Quartiersentwicklungen angesehen werden muss. Stadtentwicklungspolitische Ansätze, die darauf abzielen, soziale Benachteiligungen auszugleichen, Spannungen einzudämmen und Lebensqualität zu sichern, dürfen diesen lokalen Fundus nicht vernachlässigen, negieren oder unterschätzen. Dies impliziert, dass die Vorstellung davon, wie Lebensqualität gesichert werden soll bzw. was ein „Wohlfühlort" ist, sozial-raumspezifisch von den Engagierten und Betroffenen vor Ort sowie den Vertretern von Politk/Verwaltung bzw. Planung ‚ausgehandelt' werden muss. Weil Raumpioniere in einem Stadtteil davon unterschiedliche Auffassungen haben können, ist dies kein leichtes Unterfangen, wie beispielsweise in Wilhelmsburg heute deutlich wird: Trotz sozialer Vernetzung, kommunikativer Strategien und großen Engagements sahen „Entwickler von Kultur- und Bildungsorten" Ende 2011 im Bereich Kultur keine Möglichkeit mehr, mit der IBA weiter zum gegenseitigen Vorteil zusammenzuarbeiten (WIR 2011).

Für die Entwicklung neuer Ansätze in sozial benachteiligten und/oder peripherisierten Stadtteilen ist daher nicht nur eine detaillierte Kenntnis der Akteure bzw. Akteurskonstellationen (die solche Prozesse tragen können) und deren Kommunikations- bzw. Handlungsmuster (wie im Rahmen von Raumpioniership) wichtig, sondern auch ein genauerer Blick auf die dabei auftretenden Konflikte. In einem Folgeprojekt der Forschungsabteilung „Kommunikations- und Wissensdynamiken im Raum" mit zwei weiteren Referenzräumen werden im IRS bis 2014 „Städtische Raumpioniere im Spannungsfeld von ‚bottom-up' und ‚top-down' untersucht. Ziel ist es, durch die qualitative Analyse konflikthafter Governance-Prozesse, an denen Raumpioniere als zivilgesellschaftliche Akteure beteiligt sind, weitere Erkenntnisse zur kommunikativen Raumkonstruktion im Rahmen von Quartiersentwicklungen zu gewinnen.

Re-Mixing and Re-Using: the Urban Integration of the Specialized Filamentary Morphologies in Metropolitan Lisbon

Inês de Castro Luís Lopes Moreira

(MsC Inês Lopes Moreira, FAUTL and DUOT-ETSAB, Rua Sá Nogueira | Pólo Universitário | Alto da Ajuda |1349-055 Lisboa-Portugal, ineslmoreira@gmail.com)

1 ABSTRACT

Twenty years after the consolidation of the administrative Lisbon's Metropolitan Area, its outcomes in terms of a trans-scalar approach to the region are still under development. In this sense, the planning of metropolitan Lisbon is confronted with a multitude of municipal, regional and national plans, acting at different scales, resulting in fractures and leftover spaces on its confrontation points, becoming potential interest areas for speculation and spontaneous urban developments. The consequences of this lack of territorial communication have an increasing presence in the landscape, resulting in the emergence of functionally specialized areas, in strategic points in terms of infrastructural connectivity but unrelated to the neighbor urban fabrics or city structure. At this redefining moment, the urban changes also take the form of obsolete urban areas and empty structures and in this sense, the re-colonization and the re-mixing of uses and urban elements is a key-element in the discussion of the metropolitan areas.

The increasing mobility, the consolidation of the infrastructural network and the resulting changes in the way of inhabiting the city have contributed to a growing urban polarization in metropolitan Lisbon. This network, consisting initially of a combination of harbor, railway and national roads has gradually been replaced by an articulated system of highways, that connect and structure the territory local and nationally. This change has created conditions for the emergence of functionally specialized urban formations, supported by the blurring of traveling distances and the high degree of connectivity. Hence, the network acts as catalyst for the polarization, characterized by the occupation of peripheral areas in strategic locations, creating filamentary morphologies along the highways – metropolitan filaments – with functions mostly related to the tertiary and quaternary sectors (logistics, retail, offices or R&D).

These changes reveal the diverse nature of the new specialized morphologies, spontaneously generated and unrelated to the formally recognized designs, through self-organizing processes invariably developed in parallel to the existing planning tools. Distant from the usual functional and formal logics present in the planning activity, it results of the interaction between the market laws and the layout of the mobility infrastructure (designed independently of the surroundings, aiming to establish the most efficient connection between its points). As the backbone for the new urban formations, the design of this mobility network, its access and connections influence the process of urban development, different from the traditional juxtaposition growth, with morphologies directly related to the infrastructure. According to their nature and location, these urban formations have its genesis related to production and distribution activities, in association with the railway and harbor development. Later, as a reply to new economic and social demands, some of these areas have become obsolete, as others have showed resilience in adapting and incorporating new activities in relation to the highway network. Nowadays, with a fast changing society and the different ways of living in the city, how can the metropolitan filaments re-adapt and re-mix the urban functions?

The morphological changes in Lisbon's territory reveal local features associated with specific geographic, historic, social and economic conditions, which require a multi-layer analysis to the recent urban formations and to their relationship with the supporting infrastructure. The research methodology is based on the identification and classification of specialized urban formations, based on field work analysis of metropolitan Lisbon; and morphogenetic analysis of the metropolitan filaments and their correlation with the overall metropolitan shape and the infrastructural network, based on the layering of cartography of different time periods: a) Until 1970: the harbor and the railway as the support of the industrialization and formation of the metropolis; b) From 1970 to 1990: the setting up of a high-speed road network and the terciarization of the territory; c) From 1990 to 2010: the consolidation of the highway network, the raise of the quaternary sector and the functional specialization of the metropolitan filaments.

2 METROPOLITAN FILAMENTS

The contemporary world is a set of constant and immediate changes that take place at a speed that makes its analysis and conceptualization difficult. These transformations are driven by aspects related to demographics, economics, mobility and connectivity [1], challenging the urban life and its classical paradigms by placing new questions to the cities. Lisbon is not oblivious to this international phenomenon that leads to interpretations of the current structure of the metropolitan territory as an expression of the contemporary culture. The modifications in the way of living and inhabiting the city have caused a fragmentation and a growing urban polarization [2], in which mobility shaped the morphology, with special importance since the introduction of car use in urban daily life, coupled with the increasing number of inhabitants and the need to respond to rapid changes of scale and uses. As result, have emerged new ways of living and socializing, new market logics and new urbanization, driven by the increasing movements in an urban extension that already does not follow the logics of continuity but of the connectivity promoted by the infrastructure network and the availability of building areas, new processes for distribution of goods and information, new forms of work and the changes of social structures (Portas, et al., 2011).

The mobility network of metropolitan Lisbon consisted initially on a combination of railroad, harbor and national roads and was gradually complemented by an articulated system of highways and freeways. This situation has created the conditions for the emergence of functionally specialized urban morphologies, supported by the blurring of traveling distances and the high degree of connectivity. Hence, the network acts as the main catalyst for the emergence of these urban formations characterized by the occupation of peripheral areas in strategic locations in relation to the network, creating filamentary morphologies along the highways, with a high degree of functional specialization [3] (metropolitan filaments). This increase of mobility within the metropolitan region has allowed for the displacement of programs that require large building areas to the outskirts, creating new monoprogramatic poles (Ascher, 2008), dependent on the center for population, supplies and equipment. These specialized areas are defined at the administrative level as clusters (business Area, Science Park, Business Park, etc.) and are deployed in still unoccupied spaces, whether rural or obsolete industrial areas, operating transformations supported by an urban marketing which promotes the proximity and access to the center, or the effective capacity of connection to national/transnational roads and railways or to the airport. With different origins, these urban morphologies tend to be subsidiary of the center, contributing to a growing spatial and social segregation.

The metropolitan filaments formalize a private response to market demands and are usually spontaneously generated and unrelated to the formally recognized designs, through self-organizing processes developed in parallel to the existing planning tools. Distant from the usual functional and formal logics which are present in the planning activity, they result of the interaction between the market laws and the layout of the infrastructure elements, leading to their disorganized image, revealing a lack of integration between its parts – the roads, the new built elements and the physical environment (natural and built). The thickness of the road [4] is, then, dependent on the willingness of the market, distanced from the urban planning and not resulting as an integrated project of these three elements, but as a lack of the understanding of the implantation logics of the recent urbanization and an inability to recognize the spatial structure that supports the landscape.

The territorial changes in metropolitan Lisbon over the past decades allow for an identification of the areas that showed the capacity for regeneration and adaptation, as well as others that have been abandoned

[1] The ability that a point has to be integrated into a network of roads and canals, using multimodality situations that allow mobility, both in terms of transport, telecommunications, water supply, gas or electricity. On the one hand it brings individuals and spaces together, but at the same time allows for the dispersal of urban occupation.In GRAHAM, S.; MARVIN, S. Splintering urbanism: networked infrastructures, technological mobilities and the urban condition. London, 2001.

[2] Set of urban formations that appear impelled by the metropolitan mobility infrastructures, supported by the accessibility or visual display and by activity enclaves based on synergies and location economies. In FONT, A.; LLOP, C.; VILANOVA, J. La Construcció del Territori Metropolità. Morfogènesi de la regió urbana de Barcelona. Barcelona, 1999.

[3] With programs related to secondary and tertiary sectors (manufacturing and distribution) and the tertiary and quaternary sectors (trade, services and research & development).

[4] Formed by the relationship between the road, the growth and physical context. In SECCHI, B. Lo spessore della strada. Casabella, 553/554, pp. 38-41. Milan, 1989.

revealing an inability of reply to different demands. The metropolitan filaments were defined over time in order to meet the needs of the urban structure, taking advantage of the physical and infrastructural conditions without an overall vision. The result is present in metropolitan Lisbon where the segregation of functionally specialized areas led to isolated and abandoned areas where their main industrial function ceased. There is a great range of causes that have driven to this phenomenon in the Lisbon's metropolitan territory, but the paper focuses on three main axes related to the analysis of the undertaken changes at the level of the urban systems, economic activity and urban life.

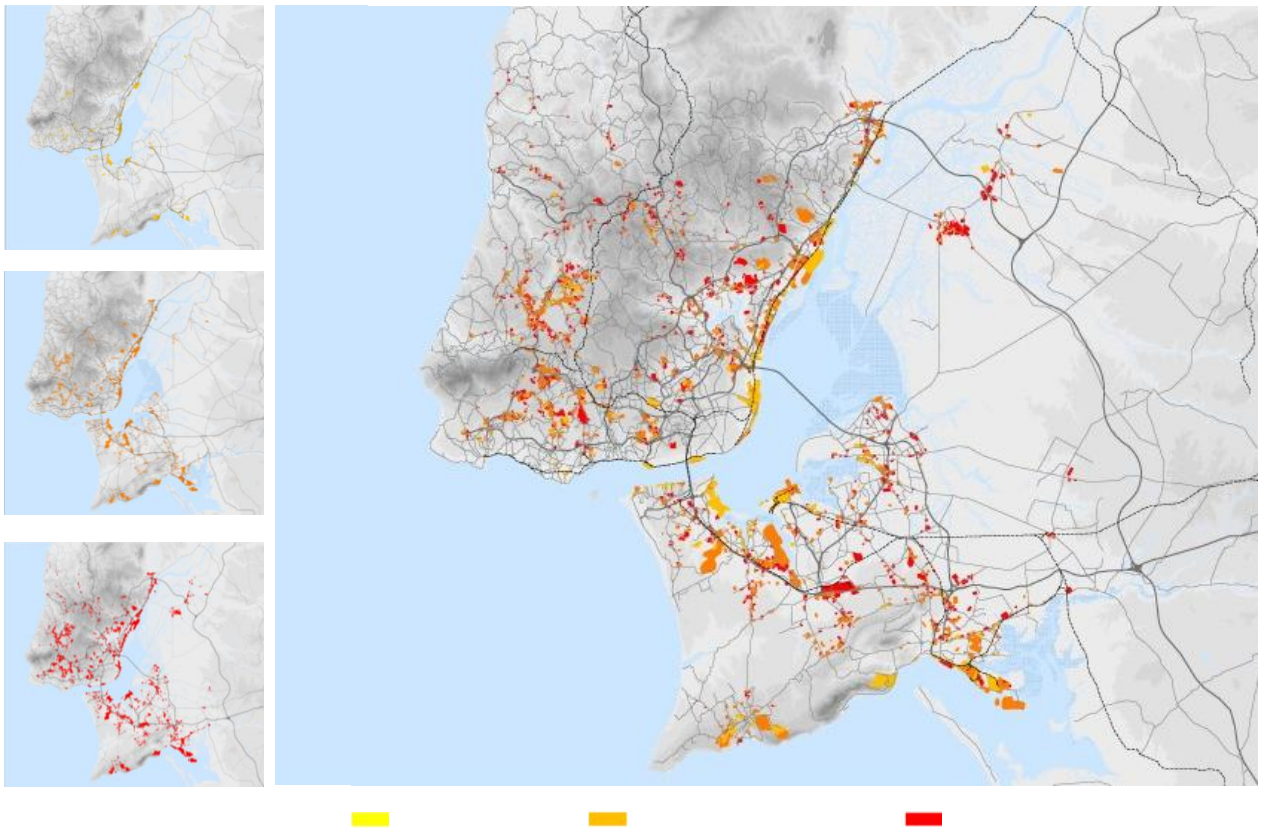

Fig. 1: Space occupied by economic activities connected to the secondary, tertiary and quaternary sector) in Lisbon's metropolitan territory, until 2010. Own elaboration, 2012.

In a fast-changing world, when vast industrial areas are being abandoned and high technological clusters are emerging, the main question driving this analysis lays on how the metropolitan territory can regenerate, adapting and replacing its obsolete areas and creating a different layer of occupation and use. In order to understand the process that led to the contemporary specialization of metropolitan Lisbon, its recent changes and their territorial impact regarding the formation and consolidation of the metropolitan filaments, is presented divided into three time periods: until 1970, from 1970 to 1990 and from 1990 to 2010.

3 THE TRANSFORMATIONS IN LISBON'S METROPOLITAN TERRITORY

3.1 Until 1970: the harbor and the railway as the support for the industrialization and the formation of the metropolis

The configuration of Lisbon as a metropolis was formalized from the 60's onwards, vertebrated by the mobility infrastructure, which contributed to a distended occupation of the territory that extended its physical limits and contributed to a suburban growth concentrated in industrial and residential areas, related to the railways, existing since the nineteenth century and the new highways [5].

[5] In 1944 was opened the section of A5 between Lisbon and the National Stadium, in 1961 was opened the section A1 between Lisbon and Vila Franca de Xira, and in 1966 was inaugurated the 25 de Abril bridge and the section of A2 between Pragal and Fogueteiro.

Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

Despite its neutral position in the World War II, Portugal had an active role in the supply of goods to the involved parties. During this period, the growing importance of the industry was formalized in the implantation of various factories in the region of Lisbon, driven by the increase of exportations and the investment in the production for domestic consumption. Although Portugal was fighting the colonial war, during the 60's there was a growth supported by the expansion of the secondary sector associated with the transformation of raw materials from the colonies, as well as the war industry (Conceição ; Heitor, 2002).Thus, in a region with an incipient presence of the tertiary sector, the industry was the main economic engine, establishing itself as a set of urban development centers, creating jobs, attracting people, other industries and associated services, with a logic of dynamic urban growth.

One of the main characteristics in the genesis of today's identifiable metropolitan filaments is the presence of this industrial structure as the engine for the location of urban settlements, which allowed for the establishment of subsequent activities. Although many of these factories are currently inactive, abandoned or converted, their location logics are present in the territory, in the dialogue with the urban fabrics and with the surrounding infrastructure. Their strategic location with regard to the physical support (topography, water courses, solar orientation, wind, etc.) and the availability of land for construction and connection to the infrastructure (in order to transport raw materials and goods) laid the foundations for the creation of industrial axes. This close relationship between harbor, railroad and the industrial location is present in metropolitan Lisbon: until the consolidation of the high-speed road network, the industrial freight was materialized by the rail and harbor infrastructure, which articulation is evident in the strategic location for a regional and international distribution of goods, by land or sea/river. The Tagus estuary offered exceptional conditions in physical terms as in relation to Lisbon, which catalyzed a development and investment in harbor infrastructure, both in general cargo – as in Alcântara or Xabregas – or as private terminals connected to large industrial units – as is the case of the Sacor refinery in Cabo Ruivo, Lisnave in Margueira, arsenal in Alfeite, Siderurgia Nacional in Seixal or CUF in Lavradio. On the other hand, the Sado estuary was the other main offloading point for the goods produced in the factories of the Setubal peninsula. The development of the harbor had a similar organization to Lisbon, with the transport of general cargo through the terminal of Fontainhas, or via private terminals associated to industries such as Movauto (automobile) or Inapa (cellulose). The metropolitan rail network consisted of five lines, with three serving directly the city of Lisbon, in use since the late nineteenth century – the Cascais line, the Sintra line and the North Line – which allowed for commuting and the expansion of the residential area of Lisbon. The lines of the North, West and South were part of the national mobility network for the transport of passengers and goods, and played an important role in the location and development of activities that would formalize the metropolitan filaments.

These industrial sites had a strong territorial impact as they occupied vast areas, generally located outside the city limits, in a close dialogue with the infrastructure. These industrial areas generated a great attraction of inhabitants and urban growth induced by the job opportunity, as well as the facilities created by the factories for their employees (housing, schools and recreation areas). Later, when these industries became inactive, they were already integrated in dense urban fabrics that developed in their surroundings and present an interesting opportunity for re-mixing the programs and re-using their obsolete space.

3.2 1970-1990: the establishment of a high-speed road network and the tertiarization of the territory

During the 70's, Portugal has undergone profound changes, with particular emphasis in Lisbon, as the capital of the country and stage of various population migrations. The end of the regime and the establishment of democracy the in 1975 were surrounded by a climate of growing political, social and economic instability, associated with fast population growth, the global oil crisis and a raising inflation that led to various social upheavals and strikes (George ; Morgado, 2007). The industrial sector suffered with these changes, as well as with the loss of raw materials from Africa with the end of the colonial war in 1974, resulting in a fall of manufacturing employment. On the other hand, a flow of more than half a million Portuguese rushed to Lisbon escaping the war in the former colonies (Salgueiro, 2001). This set of conditions shaped the phenomenon of the explosion of Lisbon's outskirts, explained by the need for housing a large number of families, stressing the territorial dispersion along the axes defined by the railways and highways, resulting in a high-density urbanization and rapid urban growth. Joining the European Economic Community in 1986 was the turning point for the process of stabilization and democratic consolidation of the country. The opening to the international market and the access to the European funds helped to bridge the structural

delays and boost the economy. This was the moment of transition to the following urban cycle, through the construction of the road infrastructure planned in the Master plan of the region in 1964, sanitation, equipment and the regeneration of degraded neighborhoods.

The metropolitan growth up to 1990 witnessed an expansion of the metropolis on the north bank and the industrial conquest of the south bank of the Tagus, through the establishment of industrial units with high technological component requiring large areas of deployment, accompanied by an accelerated residential development. During the 70's and 80's significant territorial transformations occurred, in which the functionally specialized occupation of strategic areas, allowing for the definition of axes which began the formalization of today's metropolitan filaments. The importance of the harbor and railway in the transport of goods and its consequences in the territorial hierarchy were gradually replaced by the high-speed road network. From the 80's on the territory was structured by a metropolitan system of highways which overlapped and absorbed the prior national road system, consigned to the accessibility at local level – the existing national roads became second-degree distribution elements, that vertebrated an urban growth induced by the higher-order network, with a growing importance in the articulation with the exits of the highways, railway stations and harbors. The process of expansion of the network was based on three main existing axes that have undergone extensions and enlargements. This restructuration, coupled with a growing motorization, introduced different urban experiences that diluted the limits and the central importance of Lisbon. The result was a distended occupation of the territory, as the metropolitan structure was transformed from an organization based on the accessibility to a single center, to an infrastructure network that promotes mobility between various points of great connectivity, creating the foundation for a polynuclear structure.

The pace of the industrial growth had slowed down after 1973, with increased expression in the 80's. This situation is explained by the international economic downturn in the demand for the exportation products, along with the economic restructuring connected to the introduction of new technologies in the 60's leading industries (siderurgy, heavy metalworking, shipbuilding and ship repair). Along with political changes and following the international trends driven by the market opening, the region suffered profound economic changes related to technological and transport improvements. The main result is present in the shift from an economy centered on the manufacturing sector to a service economy. The industrial production model of concentration in large areas with high territorial presence was gradually altered to a post-Fordist model, characterized by the segmentation of the production cycle and its consequent relocation to distant places, inducing the growth of processing and distribution activities. On the other hand, while the industrial activity slowed down, the service sector showed an increasing dynamism, associated with support services to economic activities, storage, distribution and retail. There was, then, a relocation and distribution of services that underscored a trend towards the functional grouping of activities, with the development of industrial and storage areas outside the city in connection with the main roads, in a centrifugal movement away from the harbor (Salgueiro, 2001). Therefore, it had been initiated a new process of hierarchy of the territory – a topological organization of the metropolis – defined by the degree of connectivity of each location in relation to the mobility network. This resulted in a set of opportunity spaces based on the ability and the speed of connection between the points of the network, at a metropolitan and national level, in which the urban growth was connected almost exclusively to the impact of the infrastructure (Morgado, 2005).

The main territorial consequences of these changes are present in the abandonment and gradual reconversion of large industrial areas and the shift to concentrated areas of small and medium-sized logistic units (assembly, processing and distribution of products). In contrast to the previous period characterized by high impact territorial interventions, these decades were marked by the atomization of smaller scale activities through spontaneous processes guided by location logics related to the ability of movement within the region/country. The agglomeration of these activities and its resulting urban morphologies led to the definition of functionally specialized axes in the territory that would be consolidated during the next period. The analysis of these morphologies allows for the identification of two types of relationship with the former industrial layer formed up to 70's: on the one hand, the emergence of urban clusters in previously unoccupied locations, taking advantage of its newly created connections to the infrastructure network and, on the other hand, the intensification and consolidation of the urban morphology from the existing industrial structure.

3.3 1990-2010: the consolidation of the highway network and the functional specialization of the metropolitan filaments

This last period has its origins with the accession of Portugal to the EU, in 1986, which consequences are felt during the 90's with the solidification of democracy and political normalization, allowing for the consolidation of the metropolis and its consequent modifications. The most visible territorial impact occurred in the boost of infrastructure combined with a functional complexity, which allowed for alternative centers to Lisbon. The occupation process that had started in the 80's continued, with urban morphologies directly related to the metropolitan mobility network, creating a topology that has steadily grown in importance in the structuring of the territory. The capital injection combined with the modifications in international relations and the globalization, has originated the changes that have occurred in the industrial and distribution sector. The tertiary and quaternary [6] sectors grew, gradually replacing the secondary sector, determining the obsolescence of the industrial and harbor areas and originating new opportunity areas integrated in the metropolitan system.

During the 90's, by imposition of the European Community were defined the legal conditions for the realization of land management plans, such as the municipal master plans, urbanization plans and detailed plans, which corresponded to a decisive stage for the understanding of the region as a whole, formalized with the establishment of the Lisbon Metropolitan Area in 1991. However, the planning activity couldn't always keep pace with the speed of the social, economic and territorial transformations that took place during this period. The carrying out of these municipal plans to the fullest extent of the metropolitan area showed a great political, technical and financial effort, but has seen its effectiveness compromised by the lack of coordination between the municipal and regional level, giving rise to a set of fragmented views of the region with territorial fractures that reveal a lack of integrative policies and of spatial planning strategies (Bruno Soares, 2003). Taking advantage of this lack of dialogue between the plans, arose the spontaneous urban developments, of private initiative and driven by the market laws, which seek peripheral locations with efficient road connections, forming anonymous agglomerations that can be found spread throughout Lisbon's metropolitan territory.

Great advances were achieved at the infrastructure level, at the mobility network, with the set up of a system of highways along with improvements in existing railway lines, which created a more homogeneous distribution of accessibility and enhanced the emergence of new polarizations. The impact of this metropolitan network, with national and international connections – through the construction of road and rail connections with Spain, harbor and airport improvements – was felt in the definition of various forms of centrality in the territory, which originated a change of location logics, with a more comprehensive mapping process, overcoming the administrative boundaries and establishing international connections for the distribution and commercial purposes. On the other hand, the technological developments, the access and the widespread use of new telecommunication technologies have reduced the importance of the physical presence in activities related to intellectual services. This situation enabled a freedom that was formalized in the relocation of corporate headquarters and high technological industries to business and technology clusters, physically distant from the center where they were traditionally located. Many alternatives to the congested center of Lisbon arose, in locations that offered a set of buildings designed for the specific use associated with the quaternary sector.

The development of functionally specialized urban morphologies created spaces targeted for efficiency, leading to the abandonment of the programmatic and scale mixture that is characteristic of the canonical in the city. Hence, the territorial hierarchy originated by the connectivity boosted the growth and specialization of the metropolitan filaments. This is transversal phenomenon to various metropolises, based on the synergies created between the constituent parts through functional complementarily between research, development and production as well as production, distribution and trade (Vecslir, 2007). It is possible to group them in programmatic typologies: the technological and production specialization, leisure, retail and distribution specialization and the specialization associated with the production, processing and distribution.

[6] The quaternary sector (or superior tertiary sector) of the economy is an expansion of the three traditional sectors, which classifies the activities related to intellectual services, specifically, with the generation and diffusion of knowledge: culture, education, information technology, research and development.

Fig. 2-4: Programmatic specialization areas: Porto Salvo (technological and production); Alfragide (leisure, retail and distribution) and Feijó (production, processing and distribution). Own elaboration, 2012.

The technological and production specialization consists in a set of business incubators, technology parks, business centers and logistics centers that associate corporate headquarters, financial activities, research and development and technology-based industries. The most paradigmatic example of this specialization is in the area between Lisbon, Cascais and Sintra (conditioned by the highways A5 and IC19), which concentrates a large number of business parks induced by the success of Tagus Park – an urbanization plan with an area of 360 hectares, from 1995, resulting of a public investment that combines a municipal and national strategy in to order to invest in the modernization and technological innovation as a means of increasing the international competitiveness of the economy, linking teaching to research. These clusters are supported by the connectivity of the road and rail network for the transport of their co-workers and clients, as well as the consolidated urban settlements and proximity to Lisbon.

The concentration of leisure, retail and distribution spaces consists in an agglomeration of retail, shopping centers, supermarkets and leisure, sports and hotel activities that arises in peripheral locations close to the center. Often these areas are associated with service activities, and use the same logics that reveal a dialogue between the degree of coverage of a specific location in terms of population (the radius of influence in terms of distance) and site conditions (availability and price of land, municipal plans, customers, etc). In this sense, the areas of Alfragide, or the shopping areas of Alcochete and Almada are examples of commercial areas combined with logistic units and services. Their strategy reveals a metropolitan approach by taking advantage of still unoccupied areas that were formerly rural or located in industrial parks, but recently integrated into the mobility network, which allows for the attraction of clients at large distances.

The concentration of production, processing and distribution, through a combination of industrial buildings with commercial, exhibition, storage and logistics activities, is the result of the adaptation to the industrial progress and modernization of the productive sector. The consequences of this change have been felt after the 80's with vast abandoned and obsolete industrial areas, and the shift towards a concentration of small and medium enterprises in industrial parks or logistics centers, also supported by the network connectivity, with special focus on the transport of goods. Based on its favorable conditions, the axis between Xabregas and Vila Franca de Xira, has suffered a gradual replacement of the industrial concentration for a combination with storage, display and trade. A similar process led to the intensification of areas that have emerged in the previous period, associated with industrial activities and storage along the A2 highway between Almada and Palmela, combining exhibition, storage, trade and distribution (mainly automobile or building materials).

4 RE-MIXING AND RE-USING: FROM AN INDUSTRIAL SITE TO PARQUE DAS NAÇÕES

As a result of the technological changes and keeping pace with the general process of obsolescence of heavy manufactory, several examples of abandon of former industrial sites may be found in metropolitan Lisbon. These spaces became of great interest in terms of centrality and touristic potential along the river front and become impulsionators of urban regeneration – the former industrial sites of Lisnave (Margueira), Siderurgia Nacional (Seixal) or CUF (Lavradio). Although several of these sites have been object of studies and proposals, the processes are dependent on the administrative approvals as well on the funding and investment priorities. The most paradigmatic contemporary process of re-mixing and re-using the territory is the process that originated the Parque das Nações, a major urban regeneration scheme developed for the site that hosted the international exhibition Expo '98.

Previously an industrial area with great dynamism, the site was part of the axis that extended along the river from Xabregas to Vila Franca de Xira. This axis aggregated the first industries of Lisbon in articulation with the estuary, the railway and the highway. The urban plan was based on the deactivation of the industrial area

of Cabo Ruivo, formed by the Sacor oil refinery operating since 1947, the city slaughterhouse, the general war material deposit and the major waste and water treatment of the city. The site at the east end of the city, located between the municipalities of Lisbon and Loures, was chosen as it offered the opportunity to regenerate a part of the city giving shape to urban policies which reflected a more critical and interventive approach to the urban structure.

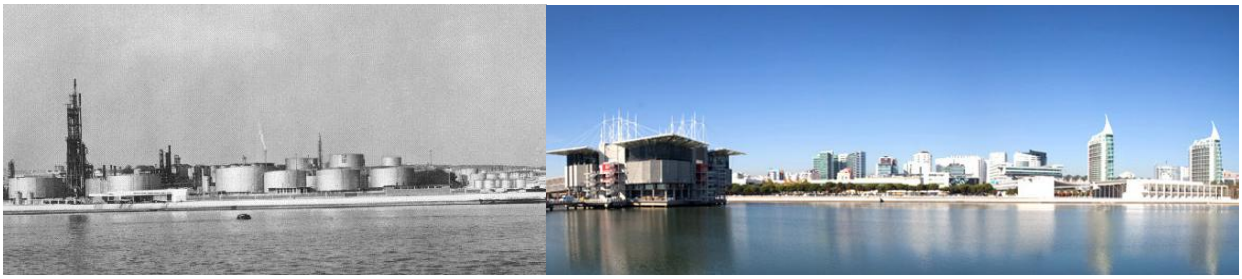

Fig. 5-6: Sacor refinery in Cabo Ruivo (1961) and Parque das Nações (2011). Sources: Serôdio, A. in arquivomunicipal.cm-lisboa.pt (consulted 23.01.2012) and portaldasnacoes.pt (consulted 20.03.2012).

The process started in 1993 with the creation of a private company with public funding (Parque Expo) that would be responsible for all the development and implementation of the plan, and in 1994 a master plan was approved, establishing the master plan of the area as well as six detailed urban plans. The urban design presented as goals the creation of a metropolitan centrality and of an area with environmental quality, revealing the strategy to reinforce the image and competitiveness of the city. The requalification brought improvements in the infrastructures (the construction of the bridge Vasco da Gama, the extension of the metro line, etc.) that allowed for the creation of a new centrality in the metropolitan area, with 340 hectares (from which the exhibition occupied 60 hectares). After the exhibition some of the key buildings remained, creating the multifunctional centrality aimed by the plan, as well as hotels, offices, housing and public spaces in the form of urban park, squares and a river promenade. The program of the operation proposed 638.000 m2 of housing, 240.000 m2 of multi-uses (offices, shopping and others), 85.000 m2 of industry and 467,000 m2 of equipments. Housing and multi-uses/equipments are the dominant urban uses, corresponding to 45% and to 50% (respectively 17% + 33%) of the total 1.430.000 m2 of construction. The urban design technique for functional organization defined areas for equipments (corresponding to the area of the exhibition, including small restaurants and bars); the mixed area (corresponding to the interior zone between the equipments area and the railway including offices, hotels, shopping and residential buildings) and the housing areas in the north and in the south (Costa, 2006). Divided in two phases, the master plan is nowadays fully implemented and the area presents 20.000 inhabitants and 20 million visitors/year, as it constitutes one of the touristic spots for foreigners but also Lisbon's inhabitants (mostly at the weekend).

Fig. 7: Urbanization Plan of Parque das Nações, 1991. Source: GEORGE, P.; MORGADO, S. "Área Metropolitana de Lisboa 1975-2001. De la monopolaridad a la matricialidad emergente = Metropolitan Area of Lisbon 1970-2001. From monopolarity to an emerging matrix pattern" In FONT, A. (ed.) L'explosió de la ciutat : morfologies, mirades i mocions sobre les transformacions territorials recents en les regions urbanes de l'Europa Meridional, pp. 62-85. Madrid, 2007 (reviewed edition).

As part of one of the oldest metropolitan filaments of Lisbon, located in an area in close articulation between the river and the railway and highway, the area of Parque das Nações presents a radical intervention in a segment of an area with great potential for urban regeneration (the axis Xabregas- Vila Franca de Xira). The importance of this urban project doesn't rest only on the created spaces, but also on the opportunity to regenerate obsolete sites of the city by proposing new infrastructure, programmatic mixture and allowing for the integration and dialogue with the surroundings and with the river. Catalyzed by the international event of Expo '98, that acted as the engine for the requalification of the oriental part of Lisbon, the adopted strategy was based on re-mixing programs and creating an articulation between the city and the former industrial

harbor area, by the use of planning instruments (master and detail plans). The example of Parque das Nações allowed for opening the debate about urban regeneration of brown fields in Lisbon and the metropolitan integration of former industrial peripheral areas.

5 CONCLUSION

The current organization of Lisbon's metropolitan territory is the result of a widening and intensification of the structure outlined in the 60's, followed by an urban explosion in the following decades that has led to the present redefining moment, when the future of the metropolis should be questioned and discussed.

The establishment and consolidation of the metropolitan filaments consists in a dynamic process of layering of the territory that has been pointing towards an increasing functional specialization by the concentration of complementary programs, without a programmatic mixing. The mobility network played a decisive role in the establishment of the activities and the occupation of the territory, along with the natural conditions of support, the urbanization and, later, the palnning activity. Thus, urban morphologies emerged, related to activities logically located in a close relationship to the degree of connectivity offered by the mobility network. In this way, the territorial hierarchy is defined by its connectivity were the airport, harbors, railways and the highway system form the high-speed mobility structure (at regional, national and international level), and the national roads systems ensure the local level of distribution and accessibility. It is the dialogue between these two systems that allows for the development of the metropolitan filaments along the transversal axes (national roads), that communicate with the high-speed network.

The origins of the metropolitan filaments reveal a response to the metropolitan demands, structured prior to the planning, related to the settlement of the industrial fabric until the 70's. Since the mid-twentieth century, the close relationship between the railroad and industry was present as an urbanization and economic engine for metropolitan Lisbon. After the 70's, this reality was replaced by the territorial relationship established between the high-speed road network and logistics, exploring different locations that coexisted and complemented the previous industrial layer. The 90's transformations, the deindustrialization process, the current functional specialization and the growth of the quaternary sector originated new (physical and virtual) spaces and created territorial scars related to the abandon of industrial areas, encouraging the discourse of urban regeneration and occupation by new uses.

At a metropolitan scale, the intensification of the specialization of the territory has created axes where the absence of planning originated the segregation and the lack of communication with the surrounding urban fabrics. The recent metropolitan changes have created vast unoccupied areas as the result of the abandon of industries, creating empty spaces and that can be seen as an opportunity to regenerate and adapt to the contemporary demands. The presented example of the regeneration of the area of Parque das Nações was an exceptional process that drew the guidelines for preceding urban regeneration processes. Although there have been punctual actions of re-mixing and re-using obsolete industrial areas, there is still a great challenge in creating overall strategies for integration and re-use of the metropolitan filaments in the urban structure of Lisbon's metropolitan territory. This is one of the biggest urban challenges for metropolitan Lisbon in the near future.

Real Estate Taxation in Poland and its Influence on Spatial Development

Adam Radzimski

(dr Adam Radzimski, Adam Mickiewicz University, Faculty of Geographical and Geological Sciences, Institute of Socio-Economic Geography and Spatial Management, ul. Dzięgielowa 27, 61-680 Poznań, adrad@amu.edu.pl)

1 ABSTRACT

Taxes are the price we pay for public goods, and property taxes in particular are the price for local infrastructure. Theory says that in order to compensate for the „unearned" income, tax contributions should be proportional to the gains from public investments. However, in practice this issue turns out to be very complex, and different countries have very differentiated property taxation systems. For example, either the whole property (land with improvements) or only land may be subject to taxation. Also, the tax rate may be based on property value, on its size or on both of them. In some countries, for example in Poland, apart from regular real estate tax, other taxes or fees may be occasionally imposed, what makes the issue even more complicated.

Depending on specific regulations, real estate taxation may cause various social and spatial redistributive effects. Generally speaking, the lower is the tax in relation to the value of public investments, the higher the attractiveness for private investments will be. The aim of this paper is to look at the relationship between real estate taxation and spatial development processes in Poland. In the first part of the paper the question will be addressed, how just and effective is the current system of taxation, or, in other words, what redistributive effects are likely to occur? In the following part possible alternative solutions will be considered, which can be drawn both from the experience of other countries and from theory. Finally, in the conclusion some remarks will be made on the role of real estate taxation in urban development and urban policy.

2 REAL ESTATE TAXATION IN POLAND

2.1 Historical context

Taxes on property are probably the oldest form of taxation. It was a common rule in the Middle Ages that only the landowners should bear the cost of national defence. Obviously, most taxes in that time were paid by the gentry, but as the rulers realized how much income does urban land generate, also the merchants and artisans were asked to pay their contribution to the crown. Not to mention that the privilege to own land in a city (i.e. to gain "citizen" rights) was related to the obligation to defend it. In Poland a medieval property tax was called "szos" (the name is derived from a similar German tax "schoss").

In more recent times (after WWII), real estate taxation in Poland has been influenced by the socialist ideology. The aim was to achieve a communist society, where there would be no private property, and consequently no market, values nor prices. Yet, socialism – the official ideology of Polish People's Republic – was only "the way towards" communism, so the actual socio-economic system was somewhat mixed. In contrast to the other countries of the Soviet Block, the expropriation of private landowners was only to some extent successful (the capital city of Warsaw is a notable exception). However, the government often failed to recognize differences in land value, which obviously brought many negative consequences. "Planning disasters", like the location of a heavy-polluting steel plant close to the historical city of Cracow, are only the most spectacular of them.

However, in spite of the doctrinal neglect of property values, a decree was passed in 1946 by the responsible minister (a decree was a typical for that period form of legislation, a substitute for a bill), which stated that real estate should be taxed according to the rental value. The rates of property tax were set on a high level: from 20% up to 30%, but only private property was subject to taxation, while the state-supported cooperative ownership was tax exempt. Having in mind the general political climate of that time, such form of taxation might be seen as a means of repression against the private sector. The same decree also allowed local authorities to introduce a number of additional property taxes: a dwelling tax paid by tenants, an "urban tax" for the purpose of covering the costs of road construction, and also a curious "tax on excess housing space".

The system of real estate taxation under socialism was quite complicated, and especially in the early years it was frequently modified. For the purpose of this paper it is interesting to ask when and how taxation based on value has been substituted by taxation based on size. This change did not take place at once, but rather in

several steps. Notably, a decree from 1955 stated that vacant land should be taxed on the base of size, not value, and a 1975 bill applied this rule also to non-rented buildings. There were also several other more or less significant modifications, but until 1990 the system remained mixed. Then the political conditions changed, and in 1991 the new non-socialist government passed a bill on local taxes [1], stating that the tax should be based on property size, not on value. Having in mind the official aim of creating a free-market economy, such regulations might seem a little odd, but at that time the property market has not been well developed yet, so the bill might have been seen as a temporary solution. However, this system of taxation remained largely unchanged in force until today.

2.2 Property tax today

Real estate tax in Poland is imposed on most property, except from rural land and forests, which are subject to special taxes. These taxes are not covered by this paper, and neither are taxes on transfer of property, since it is assumed that they have no or only marginal impact on spatial development. Property tax rates are set by municipal councils, but they must not exceed maximal rates which are published by the Ministry of Finances. These rates are updated yearly on the base of consumer price index. For the year 2012 the maximal rates are as follows (table 1):

Maximal property tax rates (PLN per sqm):	Land	Buildings
Commercial use	0.84	21.94
Housing	0.43	0.70
Other (including facilities of public purpose)	0.43	4.45-10.24

Table 1. Maximal property tax rates for various uses in the year 2012. Source: Ministry of Finances. 1 EUR = ca. 4 PLN

It is worth noting the large difference between the rates for commercial and housing buildings. However, these data tell us only a little if they are not related to income and property price data. According to the Central Statistical Office (Główny Urząd Statytstyczny, GUS), the average salary in Poland amounted to 3435 PLN in 2010. Yet, one must have in mind the income gap between urban and rural areas, which is up to about 50%. A similar gap can be observed in the case of property prices. Substantial price increases have occurred following the EU accession, especially in the largest cities. Prices of land for construction vary depending on region from 30 to 280 PLN/sqm in the case of housing and from 40 to 250 PLN/sqm in the case of services. Obviously, in the capital and other important centres the prices are much above the average: land for housing costs 1200 PLN/sqm in Warsaw and 650 PLN/sqm in Poznań. [2] Housing prices have nearly reached Western-European levels: in a regional centre like Poznań it is difficult to find a dwelling below 4000 PLN/sqm, and in Warsaw prices as high as 6000 PLN/sqm are considered a bargain (certainly, such dwellings can be found only at the outskirts). Prices in medium-sized cities are up to 50% of the capital level, and in rural areas it is a common practice to cut the costs by own work input.[3]

On the base of the available data we can roughly estimate that in the case of housing use, the property tax may reach about 0.1% of value in small cities and rural areas. In large urban agglomerations, however, the tax burden will be much below that level, even if tax rate was set to maximum, which is typically the case. In either case, the property tax burden makes up only a marginal share of the average household budget. Yet, assuming that the local governments aim to maximize their profits, urban and suburban households will be generally better off than the rural ones. The case with commercial buildings is a little different, since the tax rate is over 30 times higher than the respective rate on housing. In small cities and rural areas the tax burden may even exceed 1% of property value, but in the largest cities, and especially in the CBDs, it will be typically below that threshold.

[1] Ustawa z dnia 12 stycznia 1991 o podatkach i opłatach lokalnych (Act on Local Taxes and Fees). All legal acts and other sources of law in Poland can be found at: www.isap.sejm.gov.pl.

[2] Data on land prices were estimated by consulting company "Promocja", www.sekocenbud.pl.

[3] A reliable source of housing price data is The Polish Bank Association (Związek Banków Polskich, www.zbp.pl). However, these data cover only the largest cities. Moreover, the averages tend to be elevated by the prices of expensive apartments, which in fact make up a rather small share of the market. For the purpose of this paper, these data have been confronted with offers available on the internet.

Municipalities may differentiate tax rates according to location, age, technical standard of the building, and the kind of commercial/social activity. However, it is very unlikely that the municipalities ever use this option, since it would require them to run a rather costly quasi-valuation procedure at own cost, and even then they would not be allowed to raise the rates above the maximum. Finally, it is worth noting that the bill contains a very long catalogue of tax exemptions. Among others, all universities and colleges are exempt from the tax, and probably the most curious exemption has been granted to the Polish Association of Allotment Holders, which appears to be a surprisingly strong lobby institution (many allotments are located on valuable urban land). Other tax exemptions may be granted by the municipal council.

2.3 Property tax in the fiscal system

As shown above, the actual burden of the property tax in Poland is very low in the case of housing, and moderate in the case of commercial use. Altogether, the property tax makes up a rather small share of all public revenue in Poland. Other taxes, in particular value added tax (VAT), excise duties, personal income tax (PIT), and corporate income tax (CIT) bring much more revenue. However, most of this revenue is collected by the state budget, while the property tax is especially important for the municipalities (table 2):

Tax/recipient:	Municipalities (gminy)*	Counties (powiaty)	Regions (województwa)	State	Total
VAT	-	-	-	107.9	107.9
Excise duties**	-	-	-	55.7	55.7
PIT	23.2	2.8	0.9	35.6	62.5
CIT	2.0	0.1	3.9	21.8	27.8
Property tax	15.1	-	-	-	15.1

Table 2: Revenue from selected taxes (billions PLN) in Poland by recipients (2010). Source: Ministry of Finances and Central Statistical Office. * Including large cities with county status. ** Total excise duties on energy sources, alcohol and tobacco.

The fiscal system in Poland is a centralized one. The most important taxes are collected directly by the government. Local self-governments (municipalities) charge several taxes, among them a vehicle tax, an inheritance tax, and even a dog tax, but the property tax is by far the most important of them. Municipalities also receive a proportional share of PIT and a much smaller share of CIT. Sub-regional and regional self-governments (counties and regions) may not impose taxes on their own, but only receive a small share of income taxes. All levels of self-government are also supported by subsidies from the state. In 2010 the municipalities received about 34.5 billions PLN of the general subsidy (subwencja ogólna), which is mainly intended to finance the system of primary education. Also, since the EU accession the self-governments, mainly the municipalities, have received structural funds for investment purposes. In the period from 2006 to 2009, total transfers to municipalities exceeded 12 billions PLN.

A remarkable observation can be drawn from the comparison of the tax burden of different production factors. Traditionally three factors of production are differentiated: land, capital and work (recently, there has been a tendency to add technology as a fourth factor). From these three, work is by far the most heavily taxed one: apart from personal income tax, there are also health care and social security contributions, which in fact yield even more revenue for the public finances. On the other hand, land is taxed on a very small rate, even compared to buildings, which are classified as capital assets. Large differences in the tax burden may lead to a tendency to reduce the usage of the most taxed factor (in this case, employment) on the one hand, and use excess amounts of the less taxed factors on the other. A study on the impact of taxation structure on economic growth in OECD countries has shown that countries with higher income taxes tend to perform worse than average. On the other hand, taxes on immovable property turned out to be the most "growth-friendly" (Arnold 2008).

3 REAL ESTATE TAXATION AND SPATIAL DEVELOPMENT

3.1 Spatial development in Poland

Property sector in Poland has developed very rapidly in the last years. This is a catching-up development following many years of stagnation. Large scale state-subsidized housing construction programs of the 1970s ended up in the financial and economic crisis of the 1980s, from which the property sector was slowly recovering over the next decade. State financing ceased, and private financing was not available in sufficient amounts. This situation started to change when foreign capital flowed into Poland as the country moved on the path of European integration. With increasing purchase power, and especially due to better financing conditions (low cost mortgages), the property sector got a new impulse. The accession of Poland to the European Union (2004) symbolically marked the transition towards consumption society. Translated into the spatial language: new residential complexes, office "parks" and shopping facilities, all equipped with large amounts of parking space, and sometimes – but rather exceptionally – accompanied by other functions, for example parks or cultural facilities, have spawned in and around the largest cities. For Polish cities, which under socialism remained rather compact, land consumption has now become an issue.

The system of spatial planning in Poland has been criticised many times for its inability to manage urban growth. Municipalities have been charged with the main responsibility for spatial policy, which they under the given circumstances can hardly fulfil. Local authorities have a very imperfect set of planning instruments at their disposal, and they are not very keen to use them, for economic reasons, as will be explained in the following part of the paper, and sometimes also for political ones. Planners and professionals are, at least at the basic level, familiar with contemporary trends in planning. Applying for European funds has popularized the usage of "western" planning vocabulary, so the documents and strategies are filled with terms like "sustainability", "revitalisation" etc. However, the actual developments are rather quite far from that (Radzimski, Beim, Modrzewski 2010).

Most of research on spatial development in Poland has been concentrated on the weaknesses of the planning system itself. On the other hand, very little attention has been paid to the role of fiscal system. It seems like the relationship between taxation and spatial development is underestimated, or even not considered at all. However, without disregarding the role of development plans, I will argue that if we want to understand the nature of urban development processes, we should understand the role of property taxes in the first line.

3.2 Spatial effects of property tax

Before investigating the particular case of contemporary Poland, let us introduce some broader context. It has become an established practice in the developed countries to make the local authorities responsible for the basic infrastructure, like roads, public transit, water-supply, sewage system etc. However, some decades ago we could still find not so few examples of privately financed infrastructure. In the well-known U.S. "streetcar suburbs" it was quite common to have the tram line constructed by the developer. The estate was delivered as a full product, consisting of both housing and transit. Today the rules are somewhat different, although we can still find examples of private financing of infrastructure, and more and more examples of public-private partnerships.

Public financing of infrastructure (either at local, regional or national level) is usually explained with reference to the theory of public goods. It is a specific kind of goods, which, as the theory says, are consumed collectively, i.e. they can be consumed at the same time by a large number of people, and nobody can be excluded from the consumption of these goods, or it is very difficult to do so. These features, the theory follows, make public goods less attractive for market providers, and therefore justify (in some cases) the intervention of government, in order to maximize the overall welfare. Public goods are sometimes referred to as an example of a "market failure" (Klosterman 2003).

And here the problem begins. To say that "the public should pay" actually means that some kind of a tax is necessary. But what tax would be the proper one? In simple terms, we can take one of two approaches here. The first one is to charge tax rates independent on the quantity of individual benefits from public investments. This solution is quite an easy one, because we do not need to ask how much each individual gained. Yet, easy solutions are not always the best ones. The other option is to make the charges proportional to the gains. Such way of taxation aims to make taxes more similar to user fees. Because of the spatial nature

of local public investments, which are mostly punctual or linear (so not evenly distributed), it is hard to assume that anyone gets the same or almost the same. Therefore, the latter approach seems to be more just.

What form of tax would be then practically the most appropriate to pay for the local infrastructure? A reasonable solution seems to be a tax on property value (ad valorem). It is quite obvious that public investments, for example in light rail transit, are capitalized in property value, and research has shown that depending on the project such gains may reach from 5% up to 30% (Hass-Klau, Crampton 2004, Doherty n.d.). So, if the respective property owner pays an increased tax rate, he simply returns the subsidy he received. If he still pays the same rate, he de facto receives a net subsidy.

In this light we can see that the system of real estate taxation in Poland has got a built-in mechanism of property owners subsidisation. To be sure, municipalities could differentiate real estate tax rates (remarkably, only according to features such as the age of buildings or technical condition, but not the market value), but this is rather a purely hypothetical option. Municipalities, which have very short budgets at their disposal anyway, would have to pay for a quasi-appraisal procedure by themselves, and even in this case they would not be allowed to raise tax rates above the maximums set by law, which, as we have seen, are very low compared to market values. So the local governments have to look for other sources of investment funds, but hardly any are available. It is possible to apply for government grants for special purposes, and in the last years also for EU funds. Altogether, the system of money transfers becomes very complicated.

This system is ineffective and, as I will argue, has got negative impact on spatial development. By enacting a local development plan (miejscowy plan zagospodarowania przestrzennego), local authorities take the legal obligation to supply the necessary infrastructure. In order to do this, they need to pay for the acquisition of land for public purposes (unless they already own it, which is a rare case), and then for the construction work. Even the first step may turn out to be too expensive, and the authorities are well aware, that the investment (unless it is a large shopping centre – see below) will bring only a small increase in direct tax revenue. There might be also some indirect gains from personal income tax or corporate income tax, if new inhabitants or companies are attracted, but these will typically appear after some time, and they will likely be not large enough to cover all the public expenditures. Therefore, it is not easy to predict that in the absence of economic stimulus the authorities are generally not very keen to invest in infrastructure. In particular cases investment decisions may rely more on political factors, than on the economic ones. Local authorities avoid enacting local development plans, using some kind of "incremental planning" instead, which does not cause financial obligations for them (Beim, Modrzewski 2011). The most evident result of such policy are infrastructure shortages in suburban areas (fig. 1), especially in the field of public transit, which lead to automobile dependency and congestion.

Fig. 1. Typical infrastructure shortages in suburban districts of Poznań. Photo: A. Radzimski.

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

Shopping centres are a special case, since the tax rate for commercially used buildings is much higher than the respective rate for housing. Poland has experienced a huge increase in retail space in the course of last years. This process started already in the 1990s with supermarkets and discounters, but recently growth can be observed especially in the sector of large multifunctional facilities (shopping malls). They first appeared in the largest cities, and now are also growing in the mid-size ones. Total sales area usually varies between 20,000 and 50,000 sqm, but larger objects can also be found. Shopping malls make up a significant share of the property tax revenue, which is a strong argument for the local councils, who decide upon the approval of such facilities (fig. 2). Another potentially important source of tax revenue are office centres, but the office market in Poland is mostly developed in Warsaw, and to a much smaller extent in the regional cities (Cracow, Wrocław, Poznań, Gdańsk).

An important disadvantage of the current property tax is that it allows landowners to keep their land idle for long periods of time. Persons or companies who dispose over free capital may buy land, either in the expectation of price increases, or just because it is perceived as a low-risk investment. Such "frozen" properties cannot be used in the productive sectors of economy, so apart from the spatial effects, such "investment strategy" may become an impediment to economic growth. Moreover, not only land market seems to be affected by the taxation system, but also the housing market. Although there are no exact data, it is estimated that several thousands of dwellings built in last years have never been inhabited so far. It is very probable that speculative buying by private persons and investment funds played a role in the unprecedented increase of housing prices in the years 2006-2009.

Fig. 2. Shopping mall: not the prettiest part of the cityscape, but a good source of the property tax revenue. Photo: A. Radzimski.

3.3 Instruments of property value capture

As already mentioned, the current form of the property tax in Poland does not allow to capture an increase of property value caused by public investments. There are, however, special quasi-taxes that have been invented for this purpose. These are the charges on property value increase due to 1) zoning regulations, and 2) division, or subsequent merging and division of property, or the construction of new infrastructure. The first one is charged by the municipality if a more profitable land use has been allowed in the local development plan (for example, housing instead of agriculture). In this case a part of property value increase might be repaid to the municipality in the form of a planning charge, or planning rent (renta planistyczna), as it is usually called. However, there are two limitations that greatly reduce the applicability of this instrument. Firstly, the municipality may decide how high the charge will be, but it must not exceed 30% of the value increase. It is worth noting that in the opposite case – when the property value has decreased due to zoning regulations – the owner may claim from the municipality full compensation, purchase or exchange of the property. Secondly, the charge may be levied only if the owner has sold (or donated) the property within the

period of five years after the plan has been enacted. [4] As we can see, both these regulations put the municipality in an underprivileged position.

The other charge, which is called "adiacent fee" (opłata adiacencka, the name is probably derived from the English/French adjective "adjacent"), is an example of what is known in the literature as "betterment fee". It may be claimed by the municipality in several situations. Firstly, if the property value has increased due to division or subsequent merging and division of properties. Such actions are usually undertaken in order to make land more suitable for construction. In this case the charge must not exceed 30% of property value increase, and may be imposed over three years after the changes took place. In contrast to the planning rent, the charge may be levied even if the owner has not sold the property. Secondly, the charge applies when new infrastructure has been built with the means of the government, self-government or the European Union. Also in this case the deadline is three years, but the limit is higher, namely up to 50% of property value increase. Yet, the definition of infrastructure for fiscal purposes is rather narrow. It generally includes only technical infrastructure, so that schools, kindergartens or parks, which may greatly contribute to property value, are excluded. Moreover, only some kinds of technical infrastructure are included: roads, water supply, sewage system, electricity, heat, gas and telecommunication lines. Also, as the name suggests, only "adjacent" properties are charged, while indirect effects, for example resulting from the construction of a major road, are not included.

Both charges described above are rather problematic tools for the municipalities. It is quite obvious that to apply such "extraordinary" fiscal instruments is politically very unpopular. Also, this form of taxation bears a high transaction cost, since each charge must be based on valuation. An analysis has shown that the cost of property appraisal may take up to one third of the revenue from the fees (Czochański, Dziubińska 2008). Therefore, we should not be surprised that the municipalities show some restraint in imposing the charges. For example, in the city of Poznań the revenue from both charges in 2010 amounted to 1.7 mln PLN, i.e. less that 0.01% of total revenue. For comparison, total revenue from the property tax amounted to 296 mln PLN (13%), and total spending on public roads exceeded 400 mln PLN. Also, the city spent 6.8 mln PLN on the spatial planning office, a special administration unit which elaborates local development plans and other planning documents. [5] So the revenue from planning rent has actually not even covered the costs of elaborating plans. In another large Polish city – Łódź – the charge on gains from infrastructure has been set to null. Such decisions can hardly be justified from the point of view of public finances, but they should be rather judged according to the above mentioned criterion of "political popularity".

3.4 Private financing of infrastructure

The overall efficiency of real estate taxation in Poland is low. Since the municipalities do not get enough return on their investments, they are in result short on money, and also short on infrastructure. So, if the public sector turns out to be unable to fill the task, perhaps the private sector should come into play? Indeed, such process is really taking place, but on a rather small scale. In middle-class suburban districts more and more privately or partly privately financed streets and pavements can be found, not to mention private kindergartens (fig. 3). Such solutions based on consensus typically work on the scale of a small (and rather rich) neighborhood. However, problems occur as we move up to the scale of a large district, or to the city and agglomeration scale.

In these scales several solutions are considered which would facilitate private financing of infrastructure. These are in particular: 1) contracts with developers, 2) public-private partnerships. Although there are no specific regulations of city-developer contracts in the planning law, it is possible to apply general rules of the civil law. Yet, neither the public side nor the private side have shown much interest until now. The few examples have demonstrated that the position of municipalities in such a contract is weak. Once the developer has already finished his project without respecting the contract, it is very hard to get him to fill his obligations. In the case of public-private partnerships, some municipalities have shown initial interest. A wide range of facilities has been considered for public-private partnerships, including underground car parks, tram lines, and even social housing. Yet, the response of investors has not been very enthusiastic so far.

4 WHAT ARE THE ALTERNATIVES?

Everything said before leads to the conclusion that it would be reasonable to replace the current system of taxation, with constant "base" tax and "extra" taxes on value gains, with one ad valorem tax. But this point is only the beginning of discussion, not the end. Both in theory and in practice we can find many forms of real estate taxation, and the choice of the proper one is not so obvious. Let us have just a short overview.

The German "grundsteuer" is based on property value set by the financial administration (einheitswert), which is then multiplied by the usage-specific rate (grundsteuermesszahl) and a location-specific factor set by the municipality (hebesatz). With over 10 bln EUR total revenue, this tax is the third most important source of revenue for municipalities, after "gewerbesteuer" – a special local tax on businesses, and the local share of personal income tax (15%). In the United Kingdom there was a long-established system of property taxation called „rates". In 1989 in Scotland, and in 1990 in England and Wales rates on housing were substituted by a „community charge" (also known as „poll tax"), whereas commercial properties continued to be taxed according to the rates. In Northern Ireland rates on housing still remain in force. In 1993 the unpopular community charge has been substituted with „council tax", a modified version of the rates. Local authorities are allowed to set the rates (not to be confused with the old tax system) of council tax, but the calculation of the tax burden is quite complicated. In the strongly centralized British administration system, the council tax is the only revenue that the municipalities work out on their own. Business rates are collected by the government and then redistributed according to the size of population, and most of the municipal revenue comes from government subsidies. For comparison, municipalities in the United States are to a larger extent self-financing, although the share of property tax in local revenues declined from over 80% in 1932 to less then 50% nowadays. [6] American households typically spend more on property tax than the European ones (median property tax on housing paid in 2010 amounted to 1236 USD, according to the data of the Tax Foundation), but instead they enjoy lower taxation in other fields, particularly on the goods and services.

Fig. 3. Inscription under the sign: „Private area. Entrance only for the residents of Italia estate". Photo: A. Radzimski.

Despite all the differences, a common feature of all the systems mentioned above (and many others too) is that the tax is levied on the value of the whole property (land with improvements). This is probably the most widespread option, but not the only one. In some countries, like Denmark, Estonia or Australia, the property tax is a land value tax. It means that for fiscal purposes only the value of land is considered, without

[6] Data drawn from: History of Property Taxes in the United States, http://eh.net/encyclopedia/article/fisher.property.tax.history.us (30.04.2012).

buildings or any other improvements that the owner had undertaken. This form of taxation has got also a group of proponents among urban economists. One of them puts forward some arguments for the land value tax (LVT): "Current tax policies tend to discourage the development of urban land, because the fruits of those developments are directly taxed. To the extent that those policies are replaced by policies that tap geo-rent, the landowner is incented to develop his land. Recall, an underused site pays the same geo-rent tax as a developed site. The untaxing of production combined with the tapping of geo-rent will induce infilling of the city center, making for a more compact city, agreeable to mixed use and pedestrian activity. Hence, the demand-side push for sprawl is diminished" (Foldvary 2005, p. 124).

The proponents of LVT claim that such tax would have a better influence on urban development that the most common form of taxation. They argue that the landowners would be less likely to hold sites idle, and so the pressure on suburban development would be reduced. They also propose to compensate the increased burden of taxation by lowering other taxes, in particular personal income tax. Foldvary follows: "Today, government works are financed in large part by taxes on labor, profits, sales, and non-land real estate. The owners of land receive an implicit subsidy. This implicit subsidy is of great empirical importance, yet is not discussed in microeconomics textbooks, and is usually ignored in the tax analysis in public finance" (Foldvary 2005, p. 116).

More skeptical towards the idea of a pure land value tax are the authors of a study published by the World Bank (Maurer and Paugam 2000). In their opinion, there are several problems related to the implementation of this tax, for example the acceptability of rates, which would be higher than in the case of whole property taxation. However, they agree that high taxation of buildings is a factor that supports suburban growth instead of infill development. Therefore, they suggest that the transition economies in Central-Eastern Europe should not follow the path of the West, but rather use a double rate system instead. In this system the tax rate imposed on land is higher than the rate imposed on improvements. It is worth noting in this context that one of the transition economies (Estonia) has already adopted a land value tax.

There have also been attempts to reform the system of real estate taxation in Western Europe, and in particular in Germany. This country has got one of the oldest traditions of institutionalized urban planning, and the German planning system is believed to be one of the best in the world. Yet, even in such a well-planned country urban sprawl remains an unsolved issue. Several years ago a research project commissioned by the federal state of North Rhine-Westphalia ended with a conclusion that in order to develop more compact urban structures and reduce unnecessary mobility it is essential to substitute the grundsteuer with a combined tax, imposed on land value and plot size (Apel et al. 1995). Yet, although some time has passed, the rules of taxation in Germany have not changed. There seems to be no strong political will to bring the subject on the agenda.

In Poland the discussion about a possible ad valorem tax, which is usually called "cadastral tax" (podatek katastralny, from cadastre – property register), returns from time to time. This subject appears occasionally in the media, and the articles usually reflect some fears related to this form of taxation. One of the most often raised concerns is the situation of households with low income living in valuable dwellings in good locations. Indeed, if the burden of the property tax was increased without simultaneously lowering other taxes, then the less affluent groups of society would possibly fall in a serious financial trouble. However, it is quite obvious that media coverage is usually superficial and does not go so far to consider complex changes in the fiscal system. Yet, the media have an impact on the public opinion. To make things clear, if ever any alternative real estate tax is considered, it is the tax on whole property value (land with improvements), with single rate. The proponents argue that it is the most widespread form of real estate taxation in Western Europe, and so a good example to follow. Yet, as we have seen, apart from the single common feature the forms of taxation vary significantly, and also alternative solutions are considered.

From the legal point of view, Poland is partly ready for the introduction of an ad valorem tax. According to the Real Estate Management Act (1997) a nationwide property register (kataster) ought to be created, including property values for fiscal purposes. There are certified real estate appraisers, who would conduct the valuation (they already appraise properties for a variety of purposes, for example in the case of expropriation). Yet the crucial issue has not been solved – who and how should pay for the valuation procedure. The 1997 Act states that this should be determined in another act – which has not been passed up to now. Another option would be self-appraisal, but to allow this would require legal changes, and such

solution would certainly meet resistance from the professional lobby. Politically the subject of cadastral tax has been out of agenda for a couple of years.

5 CONCLUSION

Much has been written in the last years about that how the system of spatial planning could be improved. Even the European Union became interested in the subject, although the Community is officially not allowed to intervene into the spatial policies of the member states. Research projects are running, conferences are being organized, and documents like Leipzig Charter are being published. Not disregarding all these efforts, one must admit that we are still away from the desirable goal of urban sustainability. Perhaps some element is missing in the puzzle, and there is a good chance that it is a fiscal solution. The costs of public investments are only to a small extent covered by property owners, who are the largest beneficiaries of them. Poland is probably an extreme case, but other countries do likely suffer under the same disease. Local authorities are dependent on subsidies, and a huge bureaucracy is needed to manage the system of money transfers. This causes a confusion among taxpayers and a growing disbelief in the ability of public authorities to fill their tasks.

The system of taxation needs to be simplified, and more money should be managed locally. If people see the "fruits" of their taxes, they can more easily check the efficiency of public spending. If they see that infrastructure costs in low-density suburban locations are too high, they may choose to move closer to the city centre instead. Fiscal changes alone would probably not make cities compact, because a set of factors on both the public and private side are significant. Yet, an important economic stimulus for urban sprawl would be reduced. Certainly, much depends on the particular solutions, and this question is open at this point. Transition countries like Poland should draw lessons from the experience the West, but also consider alternatives. Perhaps also countries with long established systems of property taxation should consider a reform, in order to give the local governments more autonomy. Finally, I would like to stress that I do not believe that taxes would do the planners' work. Planners are creative, and taxes are not. Good urban design has always been and will be welcome, and fiscal solutions would just allow planners to sail with the wind, not against it.

1 ABSTRACT

City planners and urban designers often argue that downtown development/re-development plans can be best understood when providing two different categories of products; the regulating plan consisting of general controls and diagrams, and the master plan consisting of specific interventions and perspectives. In the case of developing and/or redeveloping old downtowns, this paper argues that these plans are best understood when considering the change in the socio-cultural, behavioral, environmental, and economical conditions of the place.

Doha city, one of oldest cities in the gulf, has witnessed a rapid change in its demographics over the past decade. The city has been thoroughly modernized, a massive change in its inhabitants culture and behavior has occurred and the need to re-develop its old downtown has arose.

Rebuilding the old Doha downtown aims at improving the quality of life and ensuring that heritage and culture carry-on as the country grows and evolves. It is anticipated that rebuilding the old downtown will restore a sense of community, improve the environment, create innovative and inspiring living spaces and enable both locals and expatriates to communicate and integrate.

"The Heart of Doha," a mixed-use urban development project is selected as a study case. The project is being constructed where the old downtown is being demolished. It aims to develop a modern downtown that takes cues from Qatari vernacular and urbanism, yet has a highly contemporary and sustainable approach to bridge the gap between the past and the present history of Doha.

This paper studied the development of Doha city, the reasons that enforced rebuilding the city's downtown and how the change in its socio–cultural, behavioral, economical, and environmental conditions affects its redevelopment plans.

2 INTRODUCTION

Qatar has witnessed an unprecedented growth that affected the country's physical, economical, cultural, and demographical status through the past few decades; its economy has changed from a fishing and pearling based economy to a diverse economy after the discovery of the oil in 1939. Doha, the capital, has expanded dramatically along its major routes leaving the downtown, sprawled, deteriorated, congested, and overcrowded. As a result, an immediate need to regenerate the downtown of Doha. Revitalizing the old Musheireb was proposed as a national project that aimed at to integrating the past and the present of the country. The country's historical heritage, economy, culture, environment, and social enrichments were considered. Three old houses, Alkoot fort in the heritage quarter, and some sikkats and lanes from the old setting were revitalized, other than that the whole area was demolished to be replaced with modern Islamic architectural concepts. The projects aims at energizing Doha's downtown while encouraging local citizens to relocate back at the heart of the city after years of migration to its suburbs. It has been argued that the project is not respecting the local heritage and culture of the place, however, the poor condition that the downtown experienced had called for this demolition act; existing houses are already decaying, streets are no longer accommodating the huge traffic flow, existing infrastructure and utilities are not capable of serving the area anymore, in addition to the overcrowding problem and the distribution of low-income workers in the area.

3 THE TRANSFORMATION OF DOHA, QATAR

Qatar covers an area of 11,437 square kilometers, with a coastline of 563 kilometers. The country is a mostly low-lying, flat, and between terrain stretching into the Gulf from the lands of Saudi Arabia. The Country's central location in geographical terms is politically supported by its position with the states of the Gulf Cooperation Council (GCC); Saudi Arabia, Kuwait, Bahrain, The United Arab Emirates, and Oman.

Qatar's total population has reached 1.7 million people, compared to 1.5 million in 2008, and is expected to reach 2.0 million in 2015 with a constant annual growth rate of 3.97 % and about 3.2 million people, more than double, by 2030. The rapid increase in population over the last few years is attributed to the strong

performance of the economy, which has resulted with a large number of projects, thereby leading to the influx of professionals, service and contracting sector staff and others. (QNB, 2009). However, the composition of the overall population of the country in 2010 was 76 % males and 24 % females. The total population has increased by 128 % since 2004, GDP grew 210 % at current prices from 2004 to 2009, and total government expenditures increased from 2004 to 2009 by 316 %. (Qatar census, 2010).

The State's urbanism movement has gone through three significant phases; the traditional phase, the transition phase, and the modern-oil-related phase. Each one, along with factors of political nature and trade has played major roles in the rise and fall of early towns of Qatar as shown in Fig.1

Doha, the state's capital, is the largest city, with over 80 % of the nation's population. It is also the administrative and economic center of the country , with over 80 % of the nation's population residing in Doha City and its surrounding suburbs. The capital is located on the Eastern Coast of the State of Qatar midway between the country's Northern Coast and its southern border that stretches around 190 kilometers, 98 kilometers north of Doha and 92 kilometers to the south of the city (Al-Kuwari, 1992). According to Qatar Census (2010), Doha (Ad-Dawhah) is a house for 744,029 people comparative to a 340,000 people in 2004 on a total area of 11,427 km². "Doha City" or "Ad-Doha" refers to the city's circular shape that reflects the bay that lies to the east of the city.

However, factors of change behind urban growth were determined to be five according to (Buainain, 1999). First, Doha's geographical location at the center of the settlements provides easy access by population. In addition, Doha's flat topography lacking natural physical barriers aided the expansion. Second, Doha's variety of transportation facilities such as motorways, airways -international airport-, water way-sea port-was another aspect that enhanced urban growth. Third, municipal's national wide scale development plans have been highly invested and implemented such as construction of housing projects, and providing good infrastructure, and others. Forth, Doha's remarkable population growth promoted urban development and creation of new neighborhoods. Finally, the rapid economic activity that is centered in the capital city provided various employment opportunities which attracted local citizens and international residents. However, these stated factors contributed in changing the image of the city and the Doha's skyline by the sea.

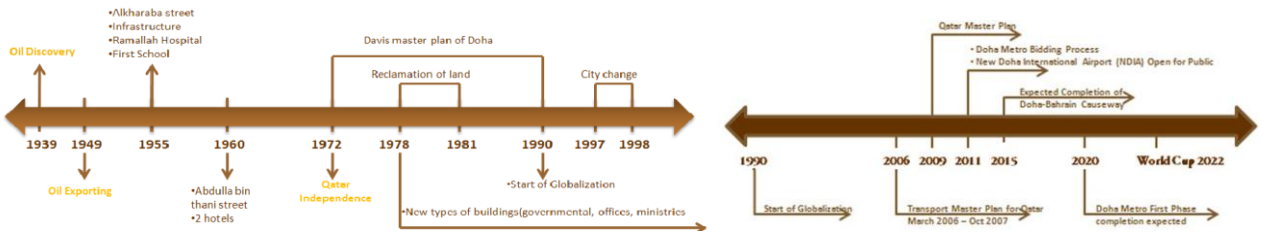

Fig. 1: Qatar's Development Time Line 1999 – 2022

3.1 Doha's Early Traditional Phase; Pre-Oil Era to 1950's

Qatar's ancient inhabitants were referred to as skilled seafarers and merchants. They were settled in the North-western area of Qatar, Al Zobara, the oldest sea port in Qatar. In early 1800's, Al Bida'a, the original site of Doha and other cities in Qatar were developed at a distant from the tribal conflicts that took place at Al Zubara territory in the north of the peninsula. Moreover, it was considered as partially secured from the conflicts among Abu Dhabi Emirate and Bahrain. In addition to the stated reasons, Doha's deep sea water and its circular shape were of the major attracting factors to fishermen and other inhabitants at that time. (Buainain, 1999) During the early twentieth century, people migrated to Doha and continued their pearl-diving, fishing, and nomadic herding activities. In fact, pearling was the major source of living in addition to some other trading activities like importing commodities from Iran, India, and other adjacent countries. Limited water sources, and poor soil conditions affected the early distribution of population in Qatar, however, and as the pearling industry developed, sea ports were established which later made the city as a main trade center. Politically. Doha has emerged as a headquarter of the ruling tribes which hosted the new governmental foundation and therefore became the main capital of the state. See Fig. 2 for the city's development 1937 through 1959.

Fig. 2: Doha City Development through Its Early Traditional Phase (Boussaa et al., 2011)

3.2 Doha's Transitional Phase; Post-Oil Era (1960's)

However, oil was discovered in 1939, its exploitation was halted between 1942 and 1947 because of World War II and the Bahrain embargo. Accordingly, the oil wealth acted as a catalyst for the urban development and the true sense of development in the country began at 1955 where the need to accommodate expatriates emerged. The period between 1949 and 1969 witnessed an increasing in the population by 600 and new administrative centers sprang up to manage the vast revenues.

3.3 Doha's Rapid Modernization Phase; (1970's till today)

Following the withdrawal of the British, the State of Qatar declared its independence on September 3, 1971. Doha as the capital of the new state attracted thousands of foreign experts and workers, employed in the construction and engineering industries. During early seventies Qatar has witnessed an extreme increase in the construction of its governmental buildings; offices, ministries, governmental authorities, so the built environment has emerged. Between 1978 until 1981, the reclamation of land from the sea started to empty out the down town. The reclamation project formed a symbolic and functional tool for the future of Doha where the Corniche has become a symbol for the new city, implementing the governmental and commercial buildings. Since then, Doha has seen the most extraordinary expansion in international banking, sports and tourism activities, as evidenced by the many modern towers, malls, hotels and seats of power scattered throughout the city, and through huge housing developments like the Pearl, a whole commercial, residential, tourist and leisure complex beyond the West Bay area.

Fig. 3 Doha City Development through Rapid Modernization Phase (2000-2008)

This unprecedented rapid urban growth experienced by the State of Qatar for the last few decades (see Fig.3) made effective and coordinated planning difficult which in turn resulted in several problems such as urban sprawl, traffic congestion, and improper spatial allocation and distribution of public facilities and infrastructure.

4 PLANNING OF DOHA AND THE DEVELOPMENT OF THE OLD CENTER

Planning in Qatar was essentially seen as a practical process that mainly aimed at the distribution of electricity, water and sewerage systems around Doha and the smaller towns within the peninsula, based on a

hierarchical road system. To accommodate the population growth and the vast change in Doha's urban life, the government of Qatar appointed several foreign planning consultants to plan for the future of the city; among which Llewellyn Davis was hired between 1972 and 1999. Along this period Davis planning consultant produced a new master plan for Doha and several planning progressive changes took place. Fig. 4. The government was advised to buy back the traditional residential quarters in central Doha and clear them for higher density commercial and governmental land-uses. This single act approach, was the reason behind the migration of large numbers of local Qatari residents from the heart of the city to its suburbs; the death of the old Doha center. The city center was then occupied by Asian workers that accepted the overcrowded conditions of the city center transferring the old memorial Doha downtown into a native deserted city center.

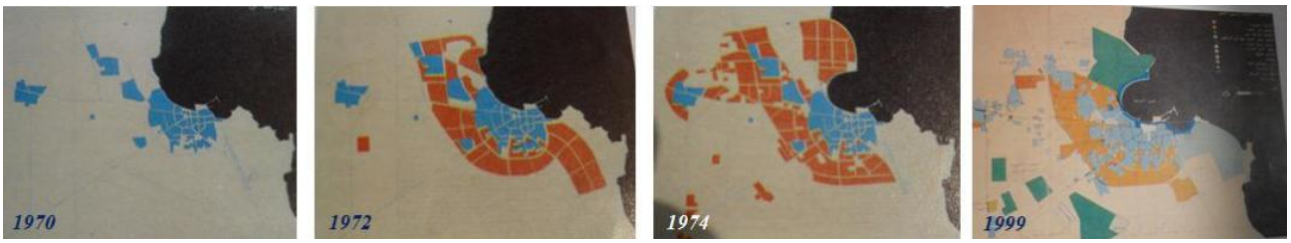

Fig.4 Llewellyn Davis Master Plan. (Hassan, A., 1994)

Davis master plan focused on the heart of Doha as the main goal of development, it mainly focused on preserving the Souk area as the traditional trade area, providing a mixed use residential apartments above the retail shops to accommodate the increased number of expatriates, providing the needed educational facilities for this population, while locating the governmental entities at the northern side opposing the Cornish. Fig. 5

Fig 5 "The Heart of Doha" Initial land use plan by Llewis Davis, (Hassan, A., 1994)

Within the New National master Plan for Qatar, a new district to the north of the old heart of Doha was conceived to be reclaimed and developed as a modern globalized development. William Pereira , an American based architectural and planning consultancy firm was appointed by the local government on 1977 to develop the new district. Land reclamation work was done through this period, shaping the semi circular Cornish of Doha and announcing the west bay or "Dafnah" area with its national projects including, the regional park, the central business district, the Diplomatic area, Qatar University and several 5 star hotels.

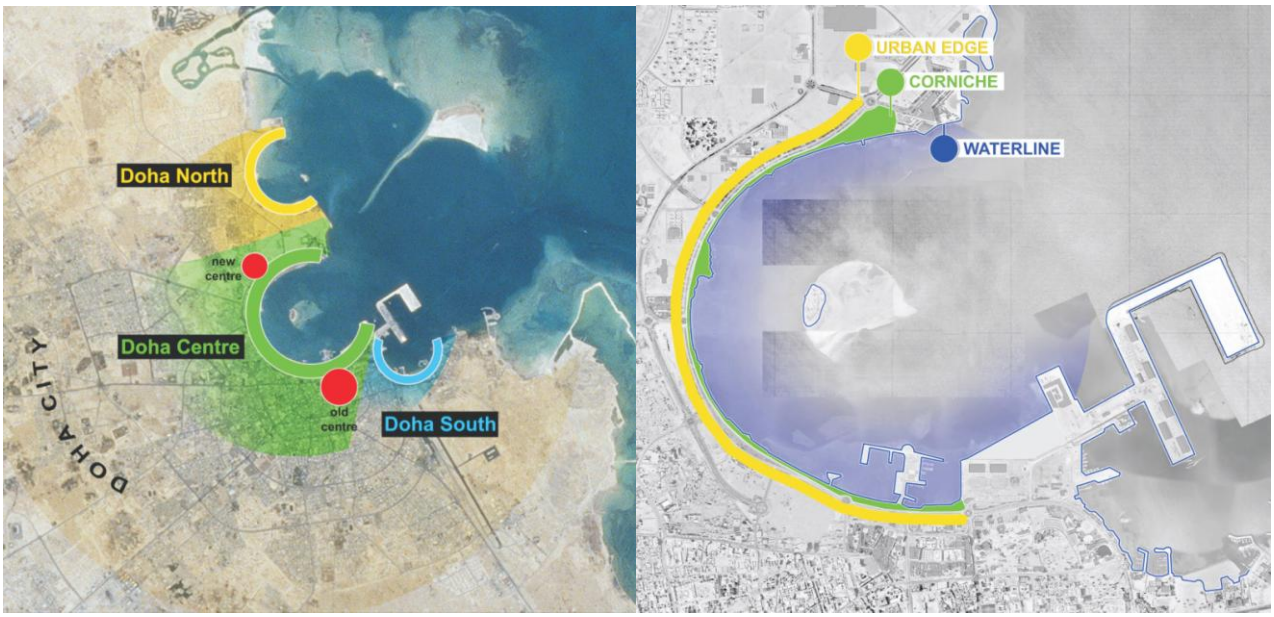

Fig 6 (a) Doha City Development Zones; (b) Elements of Doha Cornice Area

The new Cornish represented a great tool for functional and symbolic development, as it opened the space for new areas to grow and reflect the symbol of the new city of Doha. Within the process of transforming the Doha cornice into an international culture and arts center for the gulf, the government of Qatar announced the project as a competition where the Agha Khan Trust for Culture (AKTC) has instigated a process to gather the innovative ideas and projects. In their report, the AKTC divided Doha into three parts; Doha North, Doha South, and Doha Cornice, Fig. 6. The report stated that the integration of Doha North with the central city by means of other than private car transportation must be considered. Provision of pedestrian and bicycle routes as well as marine connections would enhance the value of the North cornice, which extends from the Sheraton to the Ritz Hotel. Doha South was defined as the area located from the port to the Qatar National Museum and its lagoon, while Doha cornice was defined as the coastal strip from the Sheraton Hotel to Doha Port and its interface with the area of Doha Bay containing Palm Tree Island. The cornice is built on the reclaimed land and is the result of the recent planning strategies that have transformed the dense urban fabric and intricate circulation system of old Doha on the south of the bay.

Today, Doha's traditional and cultural assets are still concentrated in the old center. There is a little left of the traditional city, and the redevelopment policies in the 1960s have totally transformed the area, but the downtown still survives. The old souk area still exists supported by the new souk buildings. Although the buildings have been renewed, the contiguous urban fabric and low rise, high density arrangement of the buildings creates a lively and dynamic environment. The Diwan (the seat of government) serves as a hub between the old center and new developments and provides an opportunity for the old center to regenerate itself while preserving surviving cultural assets.

5 MUSHERIB DEVELOPMENT PROJECT; THE HEART OF DOHA

The absence of the unique identification qualities of the city of Doha, in addition of the social and environmental problems of the globalized modern entities, were the main reasons behind the new cultural initiatives and the new projects imposed by the planning governmental sector in Doha; a number of regional city projects were initiated by the local authorities focusing on creating a cultural unique Qatari architectural language. Among these projects, Mushieb came to shed the light on the social and the economical re-birth of the old downtown of Doha.

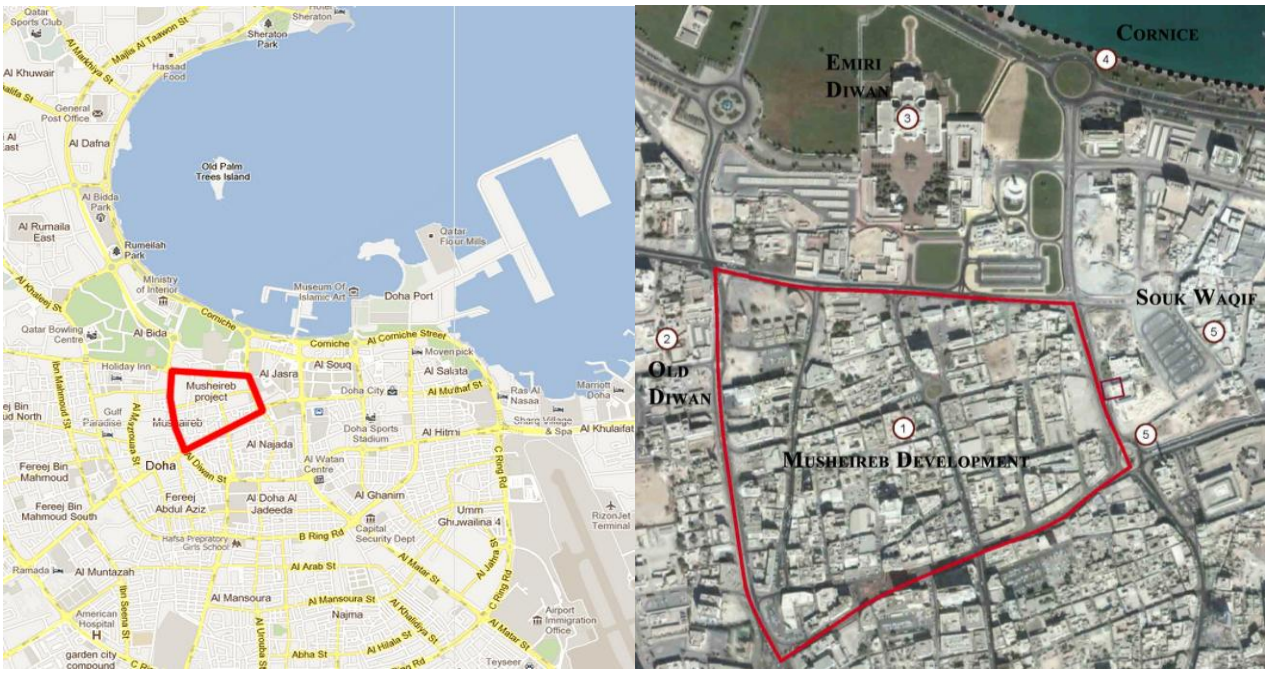

Fig 7 Location of Musheireb Development, Also Known as "the Heat of Doha"

Fig 8 The Fabric of the current downtown with the Dafna area located on the opposite side of the bay

5.1 Project objectives

Rebuilding the center of Doha City Project, also known as " Msheireb project" is developed by "Musheireb Properties". The project started in early April 2006, when EDAW/AECOM was commissioned by Qatar Foundation to plan and design a conceptual master plan for Inner Doha. Through the project, The developer's researched and re-evaluated the role played by the inner city site as the rest of Doha expanded and evolved in keeping with the contemporary trend to a global building vernacular. The decision to revitalize and regenerate The center of Doha City, also called, "Musheireb Development", or "the heart of Doha" came about with the realization that the Kahraba area, once the very hub of community living, an area from where the small Doha expanded to be the modern city today, had completely lost its historic importance.

The 35 hectare (0.35 square kilometers) development is located in Inner Doha, close to the historic origins of Qatar's capital city, see Fig.7 and 8. The project is located at Mohamed Bin Jassim District – central Doha, bordered by Al Rayyan Road to the North- Jassim Bin Mohamed Street to the East- Musheireb Street to the South- and Al Diwan Street (part of A Ring Road) to the West. The site is also adjacent to the redeveloped Souk Waqif, a successful mixed-use scheme based on a traditional Qatari souk and the historical Al Koot Fort. The site is located within a desert climate with relatively high temperature and humidity throughout the year with a close proximity to Doha Bay. The natural slope of the land towards the historic wadi on the site's southern parameter provides inspiration for the induction of water features into the site. The conceptual

urban plan aims to achieve a consistent blend of the Twelve Perspectives formulated as the guiding light for the project including: revitalizing history, heritage, and culture of the place, developing challenging architecture concepts and ideas to connect the past to the present, and achieving high levels of environmental sustainability targets that suits the community. "Musheireb Properties" partnered with international leaders for the project; "ARUP" was contracted as a principal consultant for project management, engineering, transportation, environmental and sustainability services, EDAW/ AECOM was appointed for urban design, planning and landscape architecture services, and Allies and Morrison Architects were appointed for Architecture services. The successful formation of the project could be attributed to the integrated cross-discipline approach and skills of the technical team and guidance from the hired peer review that included eminent professors in urban planning and the history of the Gulf Region from Harvard, MIT and Princeton, specialists from DTZ and Davis Langdon were engaged to provide advice on commercial aspects of the development

The project aimed at rebuilding the center of Qatar's capital city in a way that reinvigorates, modernizes and revives the site, while being true to the traditional culture and heritage that was the foundation of the first communities of Doha. The objectives of developing the" Heart of Doha" project were seen by the local authorities as follows:

- To create a cohesive urban quarter offering a balanced and flexible mix of land use, public realm and social and cultural infrastructure to provide a catalyst for renewal beyond both the period of development and site boundary and where traditional architectural values should be observed within a modern design. Other objectives of the project could be summarized as follows:
- To reduce the urban heat effect and thereby increase the proportion of the year when it is comfortable to use the outdoor spaces; designs should be developed to support and develop that theme;
- To- reduce car use and congestion within the site, whilst improving connectivity across the wider city area;
- To minimize the demand for water and ensure its efficiency; performance targets above the requirements of LEED credits are to be achieved;
- To maximize energy efficiency and reduce carbon emissions across the site; the overall form of the buildings should help reduce the need for cooling;
- To deliver new areas of high quality public realm;
- To facilitate community interaction and social exchange;
- To achieve a dynamic local economy focused on business/industries to maximize the advantages of the site's location and develop key economic sectors while nurturing entrepreneurship;
- To provide schooling within the development to meet the demands of local residents and to promote reduced private car use;
- To promote social inclusion through the provision of housing for different social groups and classes and a mixture of single and family accommodation;
- To promote sustainable waste management through the implementation of a waste and resources strategy; and
- To ensure the use of sustainable and low embodied energy materials through the use of sustainable procurement policy at both the construction and operational stages of the development.

5.2 Musheireb Development; the New Urban Form

The Musheireb Master plan (Fig. 9) creates a new piece of city that engages with the memory, processes an urban morphology of the existing Doha city center. The master plan draws references from old urban form of Qatar and the traditional "fareej" concept; a common space where several families share to interact in the traditional community to create a modern city rooted in tradition. New morphology to accommodate modern forms of transport, infrastructure and lifestyle as well as creating a comfortable walking environment were also considered. The planned new urban form was set to respect the traditional fareej typology and to create a

tight urban grain where low to medium rise buildings are positioned sufficiently close to create natural shade. A combinations of Sikkas (walkways) and Barahas (plazas) are also integrally planned to the new urban form where local residents and visitors are encouraged to walk within the sociable mixed use neighborhood. It is expected that the resulted environment will be pedestrian oriented where the dominance of car is reduced. Vernacular roads are introduced to capture prevailing wind and thus reduce the built up of heat and pollutants. An integrated basement infrastructure for service s is also considered in the master plan allowing narrower streets at ground level to be created.

The conceptual master plan started early 2004 with 5 phases of construction over a period of 8 years where the first phase is expected to be finalized mid 2012 according to the announced timeline. The first phase, referred to as the 'Diwan Amiri Quarter', currently under construction, features a combination of three major governmental buildings including the National Archive, along with heritage sites, a museum and an Eid Prayer Ground. Subsequent phases include a sum of 226 buildings that constitutes a 5-star oriental hotel along with three additional hotels, premier commercial office space, a multitude of residential types and a wide variety of retail shops and restaurants with heights limited between 3 and 30 stories. There is also a significant community and arts focus, featuring a cultural forum, school, nurseries and mosques and a two levels basement for services and private parking space. . See Table 1.

Typology	GFA (SqM)	GFA (SqFt)	Percentage
Commercial & Governmental Offices	280,000	3,014,000	36.9 %
Retail	94,000	1,012,000	12.3 %
Hotel	117,000	1,259,000	15.4 %
Residential	222,000	2,390,000	29.2 %
Community, Cultural, School, Mosques, Museum	47,000	506,000	6.3 %
TOTAL	760,000	8,181,000	100 %

Table 1. Distribution of facilities by area and percentage (Doha land, 2011)

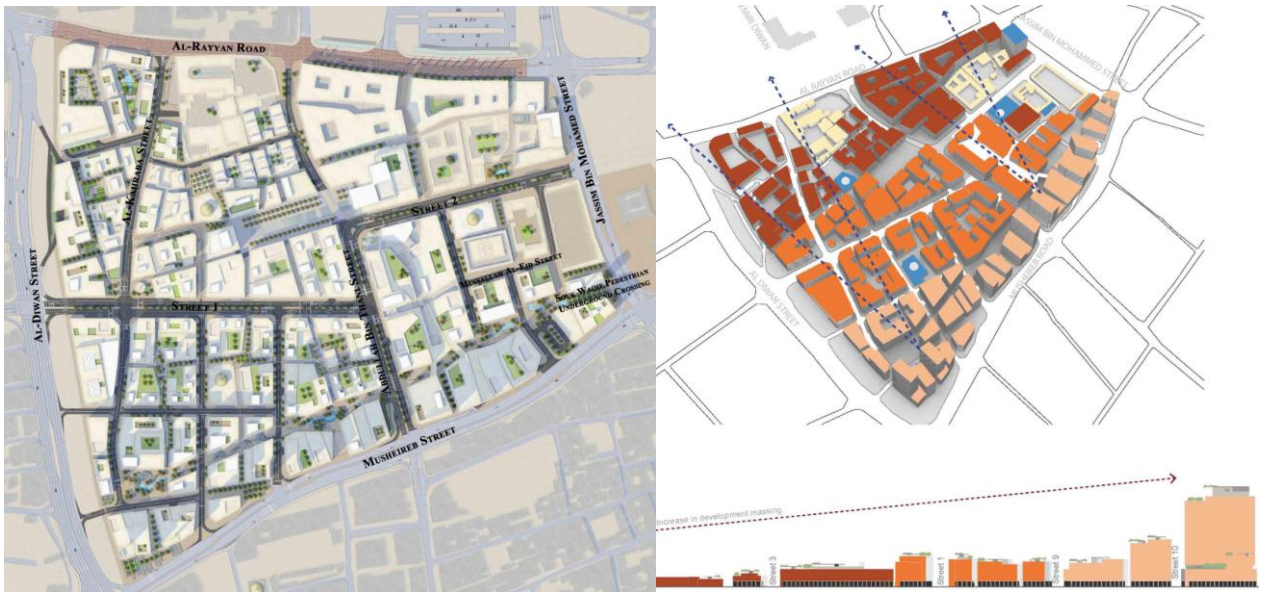

Fig 9 (a) Musheireb Development Sustainable Master Plan; (b) Massing Study (Doha Land, 2010)

The master plan has been broken down into 22 superblocks to provide a manageable structure for identifying development parcels and to structure land uses across the site. All blocks are identified by primary and secondary roads, have hierarchy of open spaces, and maintain permeability for pedestrians. Some other principles were also considered. To ensure citywide legibility and connectivity between blocks, a network of pedestrian routes are woven through each block to link one to the other. The project could also be divided into four main quarters; the Diwan quarter that includes all the new governmental buildings facing the Cornice and Souk Waqif, the heritage quarter that links the site to Souk Waqif and the old historic center, the

retail quarter that extends westwards along Sikkat Wadi Musheireb connected with the old historic retail area of the city along Al-Kahraba street, and the Kahrab quarter, the exclusive residential quarter that contains the high profile office buildings, the school, and the elegant townhouses distributed on fareej clusters on the Northern end of Al-Kahraba street.

6 MUSHEIREB DEVELOPMENT AND THE NEW IMAGE OF THE CITY

The images of the past influenced the image of the future development in the area, see Fig. 10; consequently, the standards that govern the form of the buildings within Musheireb aim to build a harmonious roof space that is diverse, animated and picturesque. These standards encourage the use of the old life systems within modern technological elements such as wind catchers, majlis rooms, loggias and bent houses. This approach aims to soften and enrich the skyline of the site whilst encouraging the day-to-day use of the buildings by creating pleasant habitable environments.

To better identify the new image created for the new Heart of Doha city, the researchers referred to Kevin Lynch's theory on the image of the city and to Hayden's theory on place making. Lynch identifies five elements that provide city image; paths, edges, districts, nodes, and landmarks (Larice, M. & Macdonald, E., 2007), while Hayden believed in the physical meaning of the built environment.

6.1 Kevin Lynch and The Image of the Heart of Doha

In this section, Lynch's five elements will be applied to the Musheireb Development to better understand the image of the new downtown comparative to the old one. Fig 10

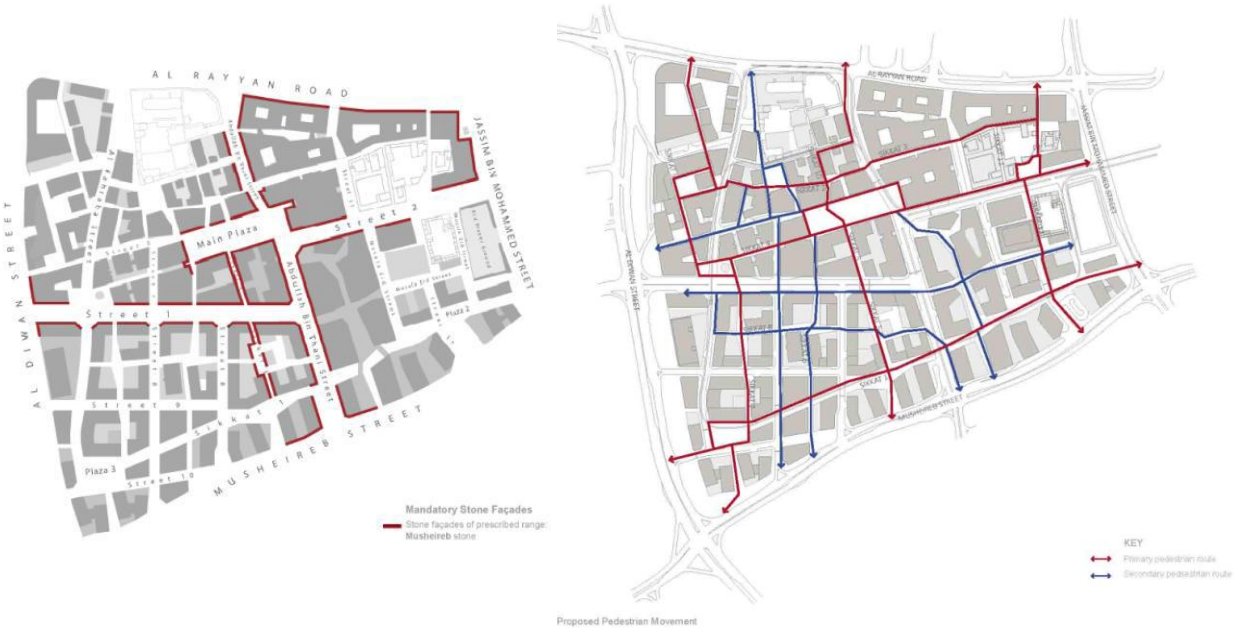

Fig 11 (a) Musheireb Development Major Paths; (b) Pedestrian Paths (Doha Land, 2010)

6.1.1 Paths

As lynch described paths as channels for potential movement along which the observer customarily, occasionally, or potentially moves and as channels that link the city's visual experience with the movement, Street 1, Street 3, and Abdulla Bin Thani Street, Fig 11, could be recognized as three of the most successful paths within the project for their distinct visual character that allows the passengers to capture the structural sense of the old downtown and help the mover to recognize the direction through their recognized facades elements and contents, projections, structure, finishing materials, lighting and signage systems intended to be used. In addition to sidewalks and pavement, a network of shaded Sikkas is being developed to increase pedestrian permeability throughout the Musheireb area. The width of these lanes carry from four to seven meters, creating serial vision and a pleasant urban environment away from the intense heart and population generated by cars.

6.1.2 Nodes

According to Lynch's definition, nodes could be seen as primary junctions, places of a break in transportation, crossings or convergence of paths, moments of shift from one structure to another or might be simply defined as concentrations, which gain their importance from being the condensation of some use or physical characters, as street-corner hangouts or enclosed squares. Two types of nodes could be easily identified in the project, those at major intersections such as Barahat (Plazas) and other social nodes, and those that are characterized by concentration with a thematic activity such as the "Eid Ground". See Fig. 12(a)

6.1.3 Districts

Districts at the "Musheireb Development" (Fig. 12(b)) are recognized with their perceived internal homogeneity and their identifying character with comparable high life standards. It could be seen that the developed master plan has divided the area into eight smaller quarters; Al Karhraba North, Al Kahraba South, Al Diwan, Plaza 1 Quarter, Plaza 3 Quarter, Heritage Quarter, Musheireb Palace, and Al Diwan Al Amiri Quarter.

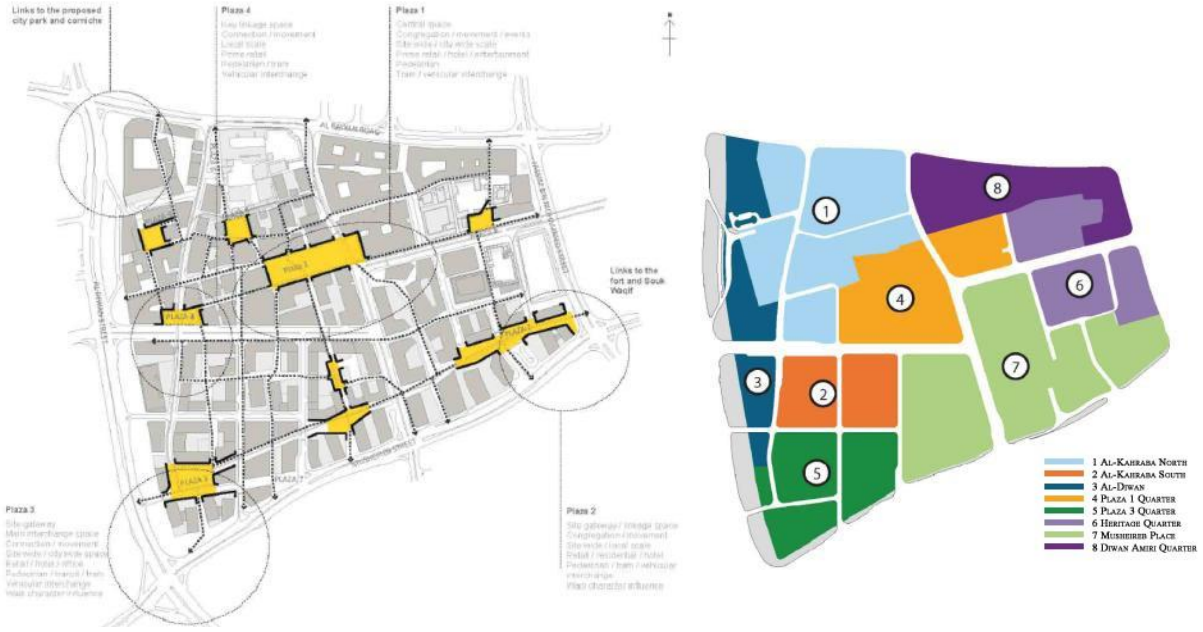

Fig 12 (a) Musheireb Development Nodes (Doha Land, 2010); (b) Musheireb Development Districts

6.1.4 Edges

As pointed out by Lynch, edges are visually prominent, continuous in form and impenetrable to cross movement. They could be defined as paths or boundaries of districts and might often act as edges. Accordingly, the proposed arrangement of buildings and the building heights within the project could be seen acting as solid physical edges specially at the southern part of the project where tall buildings are intended to be located along districts 5 and 7, as shown on Fig. 12 (b) and Fig. 9 (b).

6.1.5 Landmarks

The comprehensive regeneration of the inner Doha area presents an exciting opportunity to create a new distinctive "sky line" for the area, to complement West Bay (Dafna area) on the opposite side of the Bay , Fig. 12. The gradual increase in massing of buildings from the north of the site, peaking in the south along the alignment of Musheireb street creates an interesting skyline for the site. Looking towards the Bay, the roofs will provide an attractive foreground for the developments located further back; In other words, the new image for the new downtown developed area.

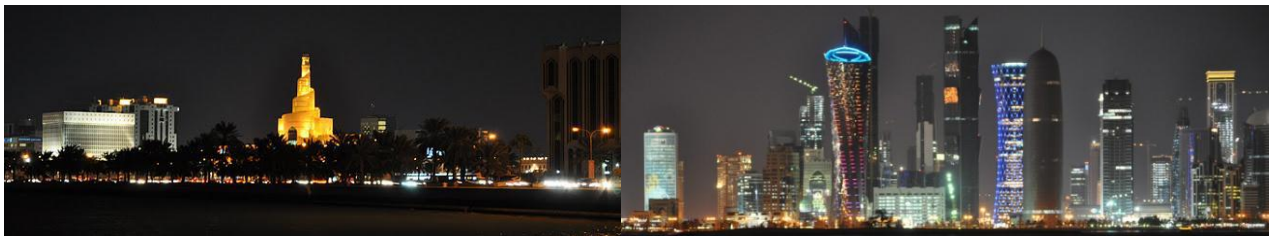

Fig 13 (a) Skyline of Musheireb Development and the surrounding area with Al-Fanar, Souk Waqif as a landmark; (b) West Bay (Dafna Area) Skyline 2010 as seen from Musheireb Development location

6.1 6.2 Dolores Hayden and the "Heart of Doha" Memory

According to Dolores Hyden (Hayden D., 1997), "place making is as much about meaningfulness to local people as it is about unique and memorable form." . In that context, Place memory is the key to help citizens to define their past and to connect the physical built environment with their culture. Within the "Musheireb Development" project, storytelling plays an important role in creating the social memory ,the sense of belonging was found to link people to the place for its historical importance. Places with memories were re-used such as. "Musala Al Eid", the concept of "Wadi Musheireb", "Barahas", and "Sikkas" were used to revitalize the old heritage and to connect different generations.

The quality of these four key spaces were examined against the "Project for Public Space" idea introduced by Dolores Hayden. Key attributes used to evaluate these spaces included, access and linkages, comfort and image, sociability and the uses and activities intended to be held at.

6.2.1 Access and Linkage:

After analyzing the master plan in terms of connectivity, safety, and pedestrian access, thee project was found to be:

- Well connected with the surrounding context by means of different public transportation options;
- Visual connections are well achieved where building heights varied from high-rise in the southern part to low/mid-rise along the north side;
- Public transit stops are conveniently located next to most of the hyper nodes areas identified in the master plan;
- Retail frontage were added to the ground level of the project, enhancing the connectivity of the project and fulfilling some safety considerations;
- Pedestrian routes and bicyclist routs are well connected;
- Car use is limited in the inner heart of the project; and
- Underground parking is planned for.

6.2.2 Comfort and Image:

Criteria used to evaluate comfort and image included pedestrian first impressions on the project, location of convenient facilities, safety, cleanness, and environmental quality. The following conclusion was drawn:

- The architectural language used to draw the memory of the place plays an important role in embracing the identity of the place;
- Safety was considered through the intimate designed pedestrian lanes and the retail frontage designed on the ground floor.
- Environmental management systems will be used to control the project. LEED criteria and measurement guidelines will be used to evaluate the project in terms of sustainability, in addition, environmental traditional systems were very well addressed in the architectural drawings of the project.
- In terms of cleanness, no evaluation could be determined at this stage of the project.
- In terms of location of convenience facilities; no evaluation could be determined at this stage either

6.2.3 Uses and Activities:

Criteria used included types if activities, targeted user profile, usage of space throughout the day, and management. The evaluation of this attribute could be summarized as follows:

- The project offers mixed use facilities where different activities take place;
- Since the project aims at serving a fully integrated community, different user categories are begin served;
- No clear ideas on the daily uses of the different project spaces has been identified so far except for the residential, schooling, and retail uses; and
- The management procedures are not clear yet.

6.2.4 Sociability:

When people see friends, meet and greet their neighbors, and feel comfortable interacting with strangers, they tend to feel a stronger sense of place or attachment to their community – and to the place they are in. Criteria used to evaluate the sociability attribute included; sense of belonging, group ageing, and facilities.

- The mix-used nature of the project offers services to wide range of different ages;
- The uses of Barahat were not clear in the master plan, and hence it was not clearly evaluated; and

- It is still not clear whether or not the projected social spaces will create a sense of belonging and engagement, Nevertheless, it is expected that a social memory of the place will be created.

In conclusion, the benefits of the place could be seen as follows:

- The project has a high real estate values;
- Higher demand on the projected services;
- It helps in re-vitalizing the Heart of Doha;
- Provides basic facilities for residents;
- Offers enhanced environmental qualities;
- Improves walkability and reduces car dependency

7 CONCLUSION

Qatar has grew dramatically through the last 40 years from a fishing and pearling based economy to a diverse economy after the discovery of the oil specially in the past three decades. The capital, Doha, has changed physically, economically, culturally, and demographically. The city has grown from one single core and expanded from it outwardly along major routes leaving Doha's downtown heavily congested due to the remarkable increase in Qatar's population from 750,000 in 2004 to 1,700,000 in 2010. It was very essential to redevelop the downtown of Doha to accommodate the urban expansion in the heart of the city. Many projects had been proposed and completed to improve the conditions in Doha's downtown. One of the main projects currently under construction is Rebuilding the center of Doha City project known as the Musheireb project. The Musheireb project was proposed to be a fresh and integrated approach where heritage, economic, sustainability, environment, and social enrichment are considered holistically. The project aimed at rebuilding the center Doha in a way that reinvigorates, modernizes and revives the site, while being true to the traditional culture and heritage that was the foundation of the first communities of Doha.

In this paper, two concepts including the Kevin Lynch's five elements concept and the Dolores Hayden place making concept were applied to better understand the image of the new downtown compared to the old one. According to the analysis, the project fulfilled many of the criterions listed in both concepts, however, the response of locals to this development is still unpredictable. There are some concerns that local people will not leave their houses located in the suburbs to live in apartments or villas even in a luxurious and well-designed project like Musheireb. In conclusion, Musheireb is a vibrant project for a city downtown according to its components and to the guidelines it addresses, however, it is not clear if it will address the social, heritage, and cultural needs of the local people. A post occupancy assessment will be needed in the future to evaluate if the project met the public interest and needs or not.

1 ABSTRACT

Delhi, a capital city of India is new extension of older settlements. This historic power centre has seen the rise and fall of many empires, which have left behind a plethora of monuments along with crunched settlements. Walled City (Shahjahanabad) is the seventh city of Delhi. It's rich heritage is dying. "King is no longer the rich King he used to be, the city looks as if pains were taken to keep up the buildings worth preserving" (Lady Fanny Eden, 1838).

Mughal monarch Shahjahan moved his capital from Agra to Shahjahanabad circa in 1638 AD with organic street pattern. That time the city was designed for 60,000 population which is spread over 569 hectares enclosing a wall punctured with seven major gates from which radiated highways to all parts of his empire. As per Indian 'Vastu Shastra' (Architecture) is perceived to have influenced its settlement geometry as a bow and arrow shaped semielliptical city. City was planned on man macrocosm analogies (Datmann, 1969); Spine as Chandni Chowk, Ribs as streets, Head as fort, Heart as Jama Masjid, Organs as Sarai (Rest House) and Wall as skin.

It was planned with a concept to have different identified areas earmarked with specific uses and trades such as jewellery, clothing and accessories under moonlight square 'Chandni Chowk'. The streets/lanes and bye lanes were of varying width designed primarily for pedestrian movements and animal driven vehicles. The original layout of the city was changed with the advent of British regime. Subsequently, the introduction of railway line along with growth of industries and commerce was largely responsible for increase in population thereby making the area most densely populated in Delhi. Presently more than 1500 persons reside in a hectare in part of this area. As found typical of central core of the metropolitan cities, the residential population of the walled city has been steadily declining from 0.042 millions in 1961 to 0.035 millions in 1981 and 0.0235 million in 2001 (MPD-2001) due to movement of people away from the central core.

The image varies from the ancient forts and settlements of Mughal Emperor's to the distinctive retail and wholesale markets of the modern days. Immensely rich in cultural heritage, Shahjahanabad with its palaces, mosques, bazaars (markets), gilded domes, havelis (mansions), katras (locality) and maze of lanes and bye lanes had been one of the most beautiful cities of the Orient. In public memory Shahjahanabad is a mess of chocked traffic movement, intense commerce (not only wholesale but also crowdpulling actvity), a maze of dark narrow alleyways, and a great tangle of billboards and electric cables. The walled city is plagued with problems of traffic congestion, infrastructure deterioration, unauthorized construction, dilapidated housing condition and makes traders of the area to convert their residential premises for non-residential uses. Urban renewal is often part of the gentrification process in Walled City. But this 'Special Area' is lacking to meet the demand of present need to typecast planning policy.

The consecutive three perspective plans do not follow its original pathway and always deviating from old. 1st Master plan (1961-81) 'Urban Renewal' policy was framed for redensification with maximum 100-150 pph with facilitate with essential community facilities deviating from existing density of 1500 pph of area did not help out to reshape the city. 2nd master plan for 2001 emphasized it as 'Special Area' with new planning code for making residential hub from deviating retails trade area. And now 3rd Master Plan 2021 imposes the fairy tale renewal and redevelopment policy in sake of revival of lost glory. One of the most challenging developments in cities revolve around the world are renewal, regeneration, reframe, remixing and redevelopment. This paper aims to highlight the malpractice of ever changing policy for reshaping city without considering its natural gamut and frameout the sustainable pathway for revival of its glory.

2 INTRODUCTION

Shahjahanabad or the walled city is the seventh city of Delhi. Prior to it, six other cities were built on different sites namely Lalkot, Siri, Tughlakabad, Jehanpanah, Ferozabad and Purana Qilla. Barring Shahjahanabad all other six cities perished. However, the Shahjahanabad city by and large retained its

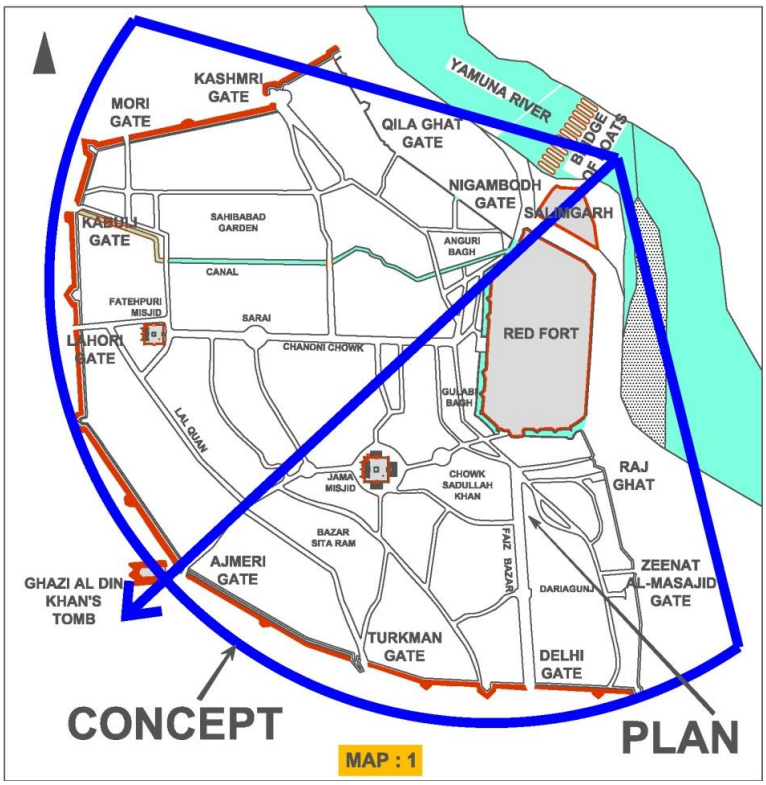
tradition and original character over the period by accommodating the growing and changing population as well as various kinds of economic activities.

Shahajahanabad was built in 17th century for a population of 60,000 covering an area of about 569 hectare. The city was developed in typical Mughal style, densely built with organic street pattern. It was planned with a concept to have different identified areas earmarked with specific uses such as different activities and trades in different lanes. The streets/lanes and bye lanes were of varying width designed primarily for pedestrian movements and animal driven vehicles. The original layout of the city was changed with British regime and further alignment of railway line along with growth of industries and commerce was largely responsible to increase in population.

Now, it is characterized by intense wholesale and retail commercial activity. It is also the cultural, administrative and economic heart of the old Delhi. Further the city is also renowned for its rich heritage and secular architecture. As per the Master Plan of Delhi (MPD) – 2001 and Zonal Development Plan the walled city has been designated as Special Area (Zone-A) for which conservation and environmental upgradation are the utmost need. The city suffers from inadequate infrastructure, traffic congestion, unauthorized constructions and misuse of residential premises for non residential activities. Hence the city has a presence of mixed land use with commercial activities in the ground floor and residential use in the second floor. There is an urgent need for redevelopment of these areas by decongestion so as to provide better living environment which should be backed by shifting of non-conforming industries, noxious and hazardous trade, upgradation of physical and social infrastructure, revival of old glory.

3 DELAYERING

Three distinct layers have marked this city; the Mughal City (1638-1819), the Colonial Shahjahanabad (1819-1947) and the post Colonial Shahjahanabad (1947 onwards). The tenacity of traditions and the porosity of space over a time span of nearly four centuries make this city miserable. These periods have been briefly summarized below.

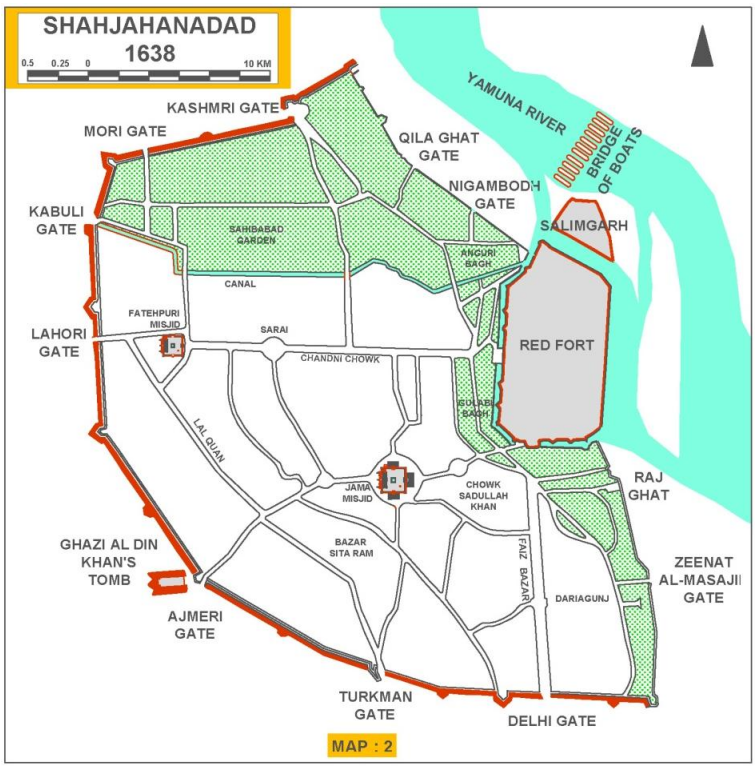


Mughal City: Mughal monarch Shahjahan established Shahjahanabad circa 1638 as a capital city from Agra, city of seven wonder Taj Mahal when the monarchy was at its peak and he its greatest builder. The city for 60,000 people, spread across 569 hectares enclosing a wall punctured with seven major gates (Kashmiri Gate, Kabuli Gate, Lahori Gate, Turkman Gate, Delhi Gate and Zennal Al Masjid Gate) from which radiated highways to all parts of his empire, was planned on principles prevailing for cities in that era. The city's urban design was an amalgamated model of Persian, Islamic and Vedic principles. Its architects Ustad

Hamid and Ustad Ahmed made this with Islamic cosmology, man macrocosm analogies; Spine – Chandni Chowk, Ribs streets, Head fort, Heart Jama Masjid, Organs Sarai, Wall skin. One of the most common descriptive models of the Islamic city in German Geography is that Dettmann (1969) described it as formal geometric pattern. The Vedic texts of 16th century Vastu Shastra and the Mansara on architecture and city planning respectively are perceived to have influenced its settlement geometry as a bow shaped semielliptical (Karmukha) (Map 1) city located on a river, its axes interpreted as the bow and the archer's arm, and, its circumferential streets the bow shaft. The junction of the two axes, an auspicious center, is the Emperors Palace. Scholars have further explored the dimensional relationships of the city's main elements, and chroniclers have recounted boulevard streets with water channels, grand mosques, havelis and gardens of the courtiers, arcaded bazaar (market) streets, prominent localities, baolis (stepwells), sarais (rest houses), kotwalis (Police stations), exclusive garden retreats, baradaris (community halls), chhattas (arcade) kuchas gallis (net weaving), madrasas (islamic school), maktabs (elementary school), khanqahs (place for spiritual retreat), khirkis (window) – a host of other elements of the material culture, some still surviving.

The hot and dry climate of Delhi made it necessary to develop an elaborate hydraulic system in order to ensure a constant, year round supply of water. It entered the city by the Kabuli gate in the North West and then split into two branches – one down the middle of Chandni Chowk and other into fort. There were 678 wells in city as per Roberts report in 1847 (Gupta 1981 p 19). Mughal garden had splitted in Chhar bagh (four gardens) concept. Tis hazari bagh just outside Kabuli gate, Raushanara begum garden near Lahori gate, nawab sirhindi and one near kashmiri gate. City was subdivided into 12 thanas (Police Post). According to Robert's report on the Census of Delhi in 1845-46 the city had population with 137,977 in 576 mohallas.

The main axes of the city were the two major boulevards connecting the fort to the city gates, larger and more important one was Chandni Chowk running from the Lahori Gate of the fort to the Fatehpuri Masjid (mosque) (Map 2). From there the road sidestepped to the north before continuing to the Lahori Gate of the city masjid. The road was laid out between two local points of the city creating an imperial axis. Chandni Chowk was forty yards wide and contained 1500 shops of a uniform design. Each shop occupied on room under one section of long arcade two squares divided chandni chowk into three sections. First square in rectangular square and second one is octagonal square. Second one is faiz bazaar running north-south from the Akabarbadi gate of the fort to Delhi gate. Other than these two the third bazaar was between fort and Friday mosque. Others several existed in city. Fort place was self contained unit with diwan-e-aam (Hall of Public Audience), diwan-e khas (Hall of Private audience) and etc. another important mosque is Jama Masjid.



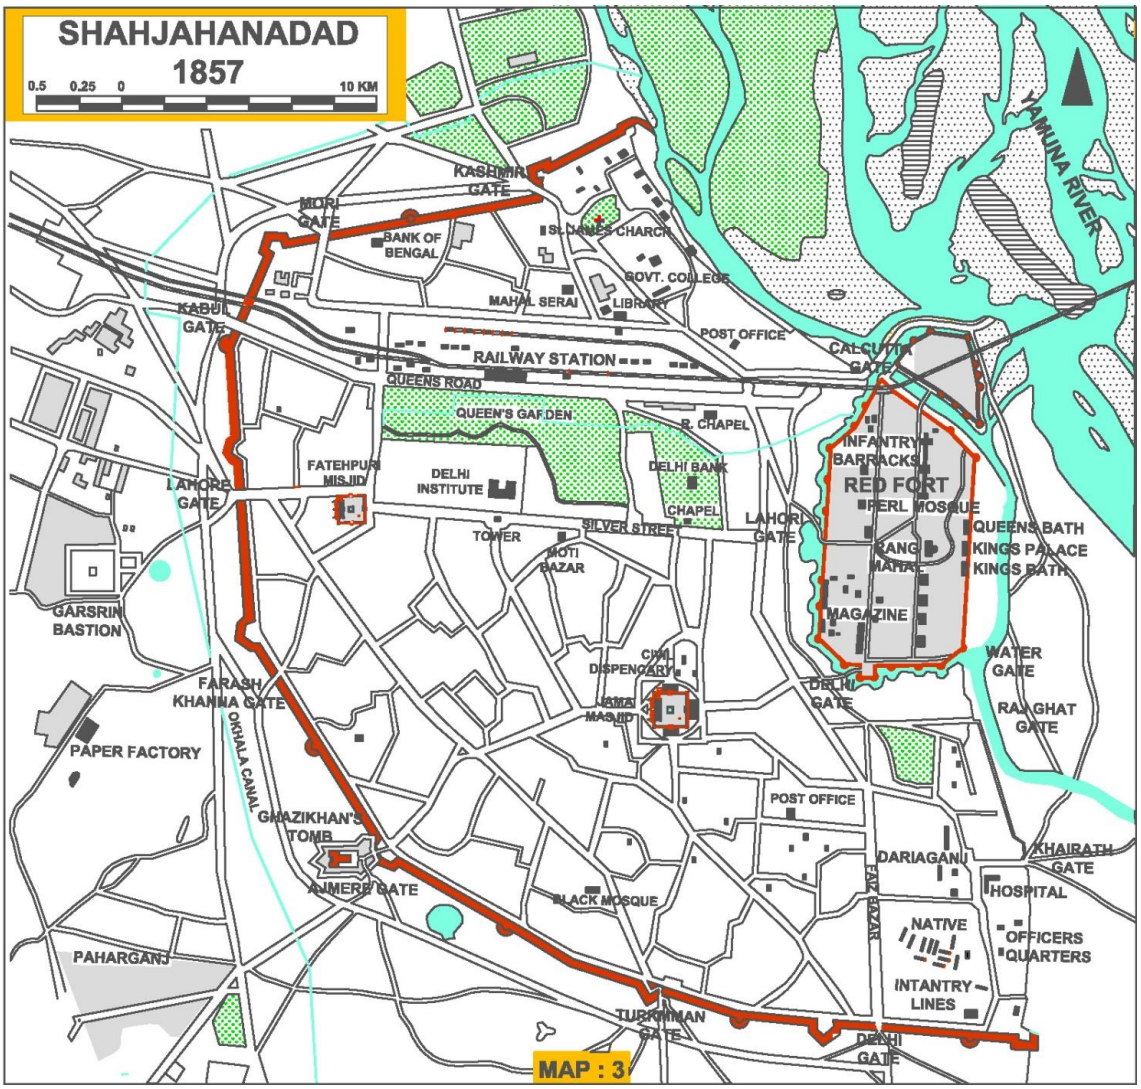
ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

Courtyard houses of various scales, complexity and ornamentation signified the owner's status and social ranking; the larger Havelis reproduced a scaled down version of the Palace complex and were self contained. These Havelis with their spillover dependants building around them formed the nucleus of the 'morally system. Several locality names (Teliwara, Malliwara, Katra Nil, Farash khana, Ballimaran, Khari Baoli…) survive in the original, imprinting the associations, images of work settings, caste or social grouping, or the peculiarities of that area (Khari Baoli saline water stepwell, Chahlpura locality of 40 houses, Chandni Chowk silver square etc). Faiz bazaar and Chandni Chowk the two main axes had well stocked shops of even imported goods. The city had a healthy trade presence.

Colonial Shahjahanabad

Two phases mark this period, a begin 1803 onwards and an aggressive 1857 to 1947 one. Early British rule was marked by mild activities, as, proposing sanitary guidelines, restoring the indigenous Shahjahani water system, establishing satellite settlements outside the city walls (Civil Lines, Mubarakbagh, Kishanganj, Cantonment) and the Residency for Ochterlony and, later, Metcalf. After the 1857 revolt, large parts of the city were restructured making British power more visible. The notable changes were ejecting the city's population and destroying one third traditional neighbourhoods.

Introducing Edgerton Street (Nai Sarak) (Map 3) into the fabric and other new streets towards the centre and north of the city had formed. Replacing the Royal Sarai with the Town Hall had introduced the railway system 1867 by removing gardens and katras in that area, clearing the surroundings of the Palace complex 500 yds around as a defence measure, holding three Darbars, (1877, 1903, 1911); established a temporary capital as Civil Lines (200 acres) and planned a new capital. The reconfigured roads for isolating the Red Fort and changed water channel to roads divided red fort and Chandni Chowk and ultimately fragmented the city; introduced trams , the chowks was functioned for commerce rather than for community.



Post Colonial Shahjahanabad

The new establishment was seized with housing people of a divided country and Shahjahanabad offered an opportunity from its vacated properties by muslim families after partition of India in 1947. The new Master Plan detailed out strategies (through zonal plans) (1961) of population densities, land uses, exiting of obnoxious industries, and as well as special programmes for greening, improving, rehabilitating, conserving or redeveloping degraded areas. Schemes which got implemented were an implant of an outside world (Turkman Gate cluster housing in four storey apartments) which destroyed about 3 hectare area of old gate (Phatak Talyan), one largest courtyard and two mosques from Shahjahan's time i.e Dujana house, an earlier Palace of Mughal nobility was demolished to rehouse displaced persons but was only partly executed. Bazars around Jama Masjid were cleared and a garden introduced with shops relocated in a low profile Meena Bazar. Besides these planned changes, the city was on a commercial overdrive. Wholesale trade (60% of the entire city's) aligned along most bazaar streets in Chandni Chowk, Chawri Bazaar and introduced into traditional neighbourhoods. There was a tenfold increase in three decades. In the process, the katras and havelis are reshaping for commerce in an uninterrupted process. Whilst there is population loss in the city, those who cannot afford are getting more cramped in their living space. Three perspective plans for last 50 years put earmarked policy framework to revitalize the city glory. But in reality policy never comes into action in forefront and lack behind to substantiate the demand of present urge.

4 CHARACTERISTICS OF SHAHJAHANABAD

Table 1: Population Growth in Walled city (1951-2001)

YEAR	POPULATION (000)	% GROWTH
1951	381	-
1961	420	10.25
1971	409	-2.62
1981	400	-2.20
1991	350	-12.50
2001	235	-32.86
2011	158 (estimated)	

Source: Zonal Development Plan, Zone-A

Demographic Characteristics: As found typical of central core of the metropolitan cities, the residential population of the walled city has been steadily declining from 0.042 milllion in 1961 to 0.025 million in 2001 (MPD-2001). This has been mainly due to movement of people away from the central core. This was, however, accompanied by a reverse process of increase in the other activities and working population, which had further aggravated. The population figures indicate saturation by 1961 and afterwards it has been declining continuously as evident in table 1. It is mostly a high-density area. The density varies from 1596 to 17 persons per hectare (pph). The highest density is found in Chitli Kabar where as many as 1596 persons reside in a hectare. The lower densities are found in the areas of Red Fort, Railway Station, Daryaganj and Kashmere Gate, which are relatively built at later date in early forties. These areas contain some open spaces. In other areas like Churi Walan, Kucha Pati Ram, Farash Khana and Tilak Bazaar are also very high-density areas comprising of 1354 to 1501 persons per hectare.

Landuse Characteristics: Out of 569 Hectares, the area under residential measures 181 Hectares, this is 31.8% of the total area. The area under commercial use is 11.7% of the total area. The public and semi public facilities, (dispensaries, police and fire stations, dharamshalas/religious shelters, night shelters and public toilets) occupy an area of 41.80 hectares, which is 7.5% of the total area. Parks and playgrounds including Gandhi Grounds (in front of Delhi Railway Station) and open space in front of Jama Masjid occupy an area of 96.87 Hectares or 17.0 % of the Walled city area. Roads and streets occupy 131.70 hectares constituting 23.1% of the total area. There are 10 main roads with the right of way of 80 feet to 120 feet, where the commercial activities are recommended on the ground floor and also commercial activity on upper floors to continue.

Economic Characteristics: As per the available secondary data out of the total enterprises located in urban Delhi, about 7% are located in the Walled city. Out of total employment 35.80% people are engaged in retail trade followed by manufacturing and repair (18.42%). Beside these the other important avenue of employment includes wholesale trade (11.90%), financial services (9.05%) and Hotel & Restaurants (3.77%). Total revenue of this area is Rs 14.6 Crore compare to main business hub in Delhi Connaught Place

is only Rs. 4.6 Crores. Chandni Chowk-Khari Baoli –Shradhanand Marg Commercial Complex not only caters for the needs of Delhi, but also serves as the major commercial center both wholesale and retail for the entire Northern India. Food grain market at Naya Bazaar and Khari Baoli, hardware and paper trade at Chawri Bazaar, iron and cement at Ajmeri Gate, cloth markets in 'Katras' of Chandni Chowk, electrical appliances at Bhagirath Palace area, motor parts in Kashmere Gate and cycle traders near Jama Masjid constitute the vast wholesale trade for which Delhi is the major center.

Housing Characteristics: The extreme congestion within the Walled City and incursion of a myriad variety of activities and trade has deteriorated the living conditions. Majority of city houses are in advanced stage of decay and several areas have been overtaken by blight. During rainy season the houses are in danger of collapse. Even otherwise a large number of dwellings have undergone radical transformation including additions and alterations, which paradoxically made them more unlivable. As per surveyed by Housing and Urban Development Corporation (HUDCO) and Municipal Corporation of Delhi (1998) observed that out of total number of the properties surveyed at the selected stretches of the walled city only 4.6% are with ground floor construction while 23.8% have G+1 construction and remaining properties i.e, 71.5% have more than first floor construction which signifies the intensification of the building activities in the walled city.Shahjahanabad has within it 42 of the 170 protected monuments controlled by the national Archeological Survey of India (ASI). The Indian National Trust for Architectural and Cultural Heritage (INTACH) have documented and furnished list of 800 listed heritage building within Walled City.

Traffic & Transportation Characteristics: Metro Rail has given relief from traffic suffocation to users of old city. Total traffic is about 50,000 in a day on main corridor i.e. Red fort to fathpuri Masjid. Presently bus service has been provided to cater local traffic from main Chandni Chowk corridor. But due to presence of slow traffic like Rikswa (Cycle Driven tri-cycle), Hand driven cart, animal driven cart, auto, it becomes chaos.

5 MASTER PLANS APPROACH FOR WALLED CITY REGENERATION AND ITS SHORTFALL

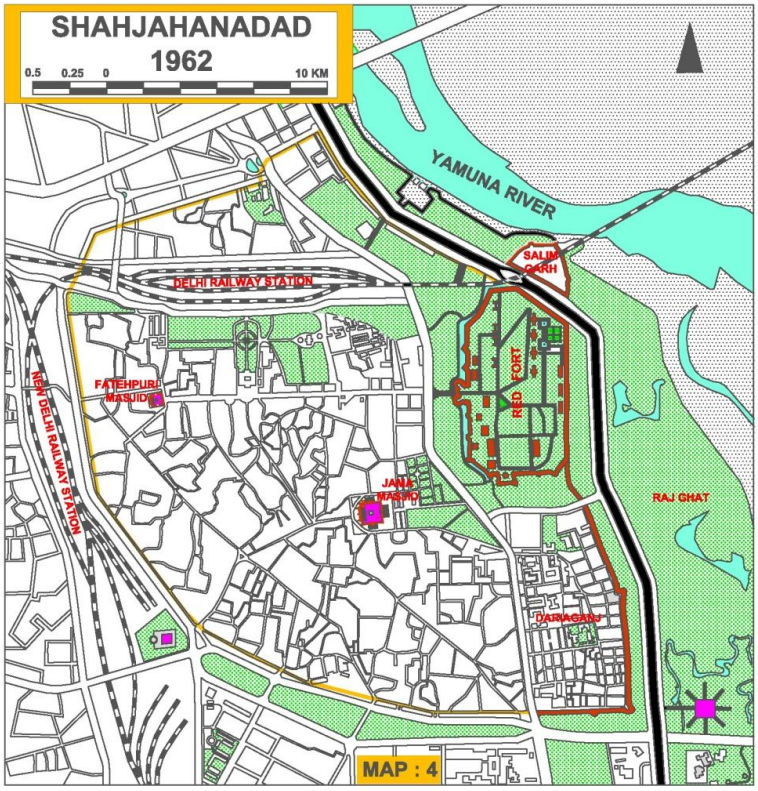
The Master Plan for Delhi provides policy frame work guiding for walled city's development. The consecutive three perspective plans do not follow its original pathway and always impose new deviating from old. The ever changing policy does not help out for reshaping the city from uninterrupted process of cramped development.

Delhi Master Plan 1962 Approach: The first master plan of Delhi (MPD) 1962 (Map 4) projected the concept of 'Urban Renewal' comprising of redevelopment, rehabilitation and conservation strategy. The 'first stage' of development considered redevelopment operations. It was framed for redensification with maximum 100-150 pph with facilitate with essential community facilities deviating from existing density of 1500 pph of area.In recognition of the approach described above, the preparation of Zonal Development Plan (Zone-A) aimed at:

(i) Provision of a circulation pattern with minimum widening of roads and demolition of structures in order to avoid major dislocation of the people and work. Standards for roads out skirting the zone vary from 24 to 36 feet. Suitable parking lots of sizeable areas were to be provided at convenient points where existing road width was 10-15 feet.

(ii) Provision of minimum community facilities in accordance with the prescribed standards; substantially lower planning standards were prescribed in MPD-1962 for the Walled city due to paucity of land. The land for the provision of community facilities would be made available by:

- Utilizing the space under Evacuee and Government properties;
- Clearing the non-conforming land uses;
- Acquiring and demolishing dangerous and the dilapidated structures.



Turkman Gate cluster housing in four storey apartments imposed with destroying about 3 hectare area of old gate i.e Phatak Talyan under the above part (a), one largest courtyard and two mosques from Shahjahan's time i.e Dujana house, an earlier Palace of Mughal nobility was demolished to rehouse displaced persons but was only partly executed. Bazaars around Jama Masjid were cleared and a garden introduced with shops relocated in a low profile Meena Bazar. Besides these planned changes, the city was on a commercial overdrive.

The entire Walled city was identified into three major components of urban renewal on the basis of the degree of deterioration and obsolescence. These were:

(i) Conservation Areas: The residential areas that needed protection from the spread of slums. Katra Neel, Ballimaran, Dariba Kalan and New Darya Ganj were grouped in this category.

(ii) Rehabilitation Areas: The areas partially blighted where buildings deteriorated due to neglect. Phatak Habash Khan, Chadni Chowk, Naya Bans, Farash Khana, Churiwalan and Kutcha Pati Ram were classified as rehabilitation areas.

(iii) Redevelopment Areas: The areas in very dilapidated conditions. Jamuna Basti, Lal Darwaza , parts of Matia Mahal and Suiwalan were classified as areas ripe for radical development

However, not much headway was made in improving the conditions.

Delhi Master Plan 2001 Approach: As per second master plan, MPD –2001 (Map 5) Walled city has been earmarked as 'Special Area' for the purpose of development. This area cannot be developed on the basis of normal regulations. Special regulations have been worked out for this area and incorporated in the Development Code.

The main objective for the development of Walled city is to clean the area from noxious and hazardous industries and trades to check further commercialization and industrialization of the area and to revitalize the same to its glory of the past.

The population in the walled city increased to saturation upto the year 1961, but since then, there is large-scale infill by commercial use replacing residential use. The trade and commerce activities have intruded much more in all the residential areas in the Walled city.

The special regulations as per MPD-2001 specifically emphasized:

(i) The predominant land of this area is to be made for residential.

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

(ii) The noxious industries and hazardous trades should be shifted from the walled city immediately within a maximum period of five years to be replaced by other compatible uses.

(iii) The public and semi public uses and services like hospital, dispensaries, colleges, school, police stations, fire stations, post offices, local government offices, parking,etc sholud be retained in their present locations and also additional sites could be indicated in the Urban Renewal and Zonal Plans. Any changes or additions thereof shall be in accordance within the overall policy frame prescribed in the plan.

(iv) Control for building /buildings within the use premises:

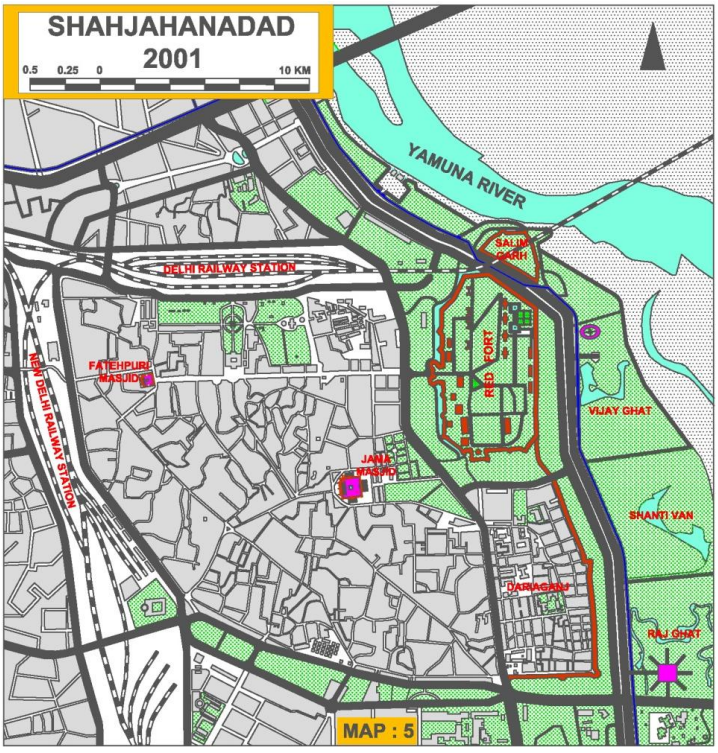
- Maximum ground coverage and FAR should be same as for the residential plot in plotted development.
- The street width in front of the plot should be left on the basis of Urban renewal scheme of the area.
- The building shall be permitted to be constructed practically in the same form and style as existing as far as possible.

(v) Within Walled city the building control regulations for special area should had been as under:

- Lajpat Rai Market: The single storied market on either side of Chandni Chowk to be retained.
- The isolated use premises like school adjoining Jama Masjid, presentation Convent School and the church at Kashmere Gate, Municipal Offices at Old Hindu College Building Complex should be retained with existing building volume.

Second MPD emphasized to rebuild walled city as a residential hub from exiting commercial trade house of Delhi that was impractical in nature. Deviating from first master plan with controlled density new code had introduced for this special area planning. It was envisaged that as far as possible Urban Renewal Project shall be self-financing. But in actual practice, no headway could be made in preparation of urban renewal schemes.

Delhi Master Plan 2021 Approach: According to the third MPD for 2021guidelines, a major theme is redevelopment of old and degraded areas while taking care those buildings of 'heritage value are protected and conserved' with special emphasis on:



Chandni Chowk recreating the lost glory: The Red Fort, Jama Masjid and Chandni Chowk have been put forward for protection and conservation of heritage buildings. Chandni Chowk as it is the centerpiece and dominant axis of the Walled City without going for large scale demolition and disturbing the present

activities, identified for revitalize the area for optimum transformation in the ambience of the Chandni Chowk can be achieved. It includes:

(i) Boulevard Development: Capturing full road right-of-way, re-paving of road by granite stones, transplanting grown up trees, development of tourist/information booths, music stands, kiosks, telephone booths, public toilets, etc., controlling signboards, hoardings and putting up new signages, shifting of overhead cables and wires in the underground space.

(ii) Improving street lighting, light masts and lighting of building facades.

(iii) Running of free coaches/trolley buses between Red Fort and Fatehpuri Mosque.

(iv) The informal unorganised shops and vendors to be restricted in the lanes perpendicular to it.

(v) Create a tourist/people friendly environment Chandni Chowk with complete pedestrianisation and trees.

The large scale encroachments on public lands, particularly road right of ways continue unabated.

Metro Corridor Development: Lack of zonal plan for this area for 2021 the Master Plan guidelines state that an opportunity for redevelopment in Delhi is offered on the two sides of the metro rail routes. The main priority is to decongest the old city and to shift traffic generating activities from the old City. About 50 per cent of the Inner City is within 8 to 10 minutes of walking distance from Metro Stations in Chandni Chowk. This has released congestion from already choked roads and reduced the parking demand. This has provided opportunity to pedestrian some of the roads in the Walled City and other area. It has improved accessibility and encourages decentralisation of wholesale trade from old Delhi. Already flower whole sale market had shifted from Chandni Chowk to Noida phase I in NCR

Shifting of wholesale trade, noxious industries and hazardous business from the old City: it is proposed to develop counter centres in the form of Integrated Freight Complexes at the peripheral location to shift from the Special Area in a time frame by a set of incentives

- New industrial area,
- Development of Truck Terminals, Vehicle Repair Workshop, Old Car Markets, Motor Parts Markets at periphery of Urban Delhi and
- Railway Freight Terminals.

The dreams of shifting of wholesale trade, noxious industries and hazardous trades have by and large remained on the papers.

Building Bye Laws improvement: Highly optimistic policy in Special Area planning has proposed front and setback of building. The incentive of additional FAR, alongwith other measures like liberalisation of land use time bound approvals, etc are also found in policy. But this special area needs special focus from general condition of Delhi. There is no space between building, 100% covered area. Without breakthrough of building practically front and set back cannot be framed. On other round policy never appreciates major demolition of structure. The self contradictory policy needs to work out feasible, applicable zonal plan for landuse control with main emphasis on conservation practice. Action plan along with sector plan is more appropriate than only strategy planning in this case. The main problem of land control in this area is ownership and original permissible limit identification. So, Conversion charges, development charges, betterment levy and other charges are impractical. The fairy tale renewal and redevelopment policy does not make justice to community.

Practitioners suggested several attractive areas/streets (like Chandni Chowk & Dariba) can be taken up for urban renewal and pedestrianisation. Not only the Inner City, but also 30-40 years old housing complexes continue to suffer degradation and unauthorised additions and alterations. These are ripe for urban renewal, for which local bodies should encourage the residents/cooperatives and Resident Welfare Associations to take up urban renewal. But due to without incorporating local people perception planning are formulated and remain on paper itself.

6 OTHER PLANS

Steering Committee Recommendations: According to the Streering Committee constituted by the MOUD (1996) recommended decentralise the wholesale trade particularly those which are hazardous. The Steering Committee pointed out that the residential area having unique character especially within the walled city

should be conserved with care and sensitivity as well as entry of vehicular traffic needs to be restrained to maintain the desired level of circulation and parking.

Delhi Urban Heritage Foundation: In 1997, Delhi Urban Heritage Foundation was set up under Delhi Development Act. It had emphasisesd to frame out rules and regulation and institutional framework for conservation of heritage and urban renewal. It also referred to create partnerships and commitments among stakeholders, to mobilize government/private investments, monitoring of the implementation projects.

Chandni Chowk Redevelopment Plan (2009): Municipal Corporation of Delhi (MCD) has formulated Shajahanabad Redevelopment Corporation (SRDC) division for revitalization of Walled city. It has come up with several redevelopment plans firstly: Redevelope Chandni Chowk i.e. Red Fort to Fatehpuri Masjid square, secondly Conservation of Heritage Building, thirdly Conservation & Heriage walk fourthly multi level car parking near railway station . The main emphasis of this plan is as follow:

- create unique urban space for ultimate tourist destination by using environment friendly technology, pedestrianization,
- eco friendly battery operated transport system within city premise,
- restricted vehicular path with underground cable system,
- tree avenue street furniture for leisure, information centers,

The goal of this action plan is to make walled city as ultimate tourist destination without considering its heartbeat activity. The Steering Committee recommended almost 15 years back to decentralise the wholesale trade from this urban fabric. But recent action plan only restrict vehicular movement on particular stretch without palnning of decentralise the traders. Commercial encroachment from the informal sector neither of which were planned for by the original city planners of Shahjahanabad. To remove the encroacher without wholesale shifting is not possible at all. It can say that ‘a chain is only as strong as its weakest link’. Imposing growth never sustain from deviating its original footway. Imposing regeneration has proved leading to its condemnation as a whole of Walled City.

7 CONCLUSION

The walled city is plagued with suffocating condition with traffic congestion, infrastructure deterioration, unauthorized construction, dilapidated housing and overall low quality of life. The transformation of residential premises for non-residential uses acts as a barrier in the conservation of heritage, urban renewal, land assembly, legitimate property tenure, titles and transfers, infrastructure upgradation, financial mobilisation, development rights, etc. Unattending application of plans leads it as a staus of slum under the Slum Area Act, 1956. Neither the legal framework, nor the present organisational structure have been able to control unauthorised reconstruction of historical havelis/buildings or in taking up any meaningful redevelopment. On the other hand indiscriminate application of the several plans has proved counter-productive in economic and physical regeneration of the Special Area. In order to address Special Area effectively to the emerging issues there is the need for conservation and decentralisation of activity to make amendments. The utmost strategy for revitalizing the glory of Walled city are:

(i) Conservation approach to retain the overall traditional character of the Walled City. Those building are heritage importance should be conserve. Shahjahanabad has within it 42 of the 170 protected monuments controlled by the national Archeological Survey of India (ASI). The Indian National Trust for Architectural and Cultural Heritage (INTACH) have documented a list of 411 Listed Buildings within Shahjahanabad. The Delhi chapter of INTACH has proposed 8 Conservation Zones. There are 10 heritage walks (SRDC)

(ii) Decentralisation of trade, commerce and industry from core area of Shahjahanabad. The main street, now termed Chandni Chowk, runs from the Red Fort to Fatehpuri Masjid is fully congested with garments whole trader. North of the street, there is the mansion of Begum Samru, now called Bhagirath Palace is known for electronics goods. South is the street is Dariba, a famous street from Mughal period for jwellery shops, beyond which is Jama Masjid. Daryaganj is a section that used to border the river at Rajghat and Zeenat-ul-Masajid. Its main arteries are Netaji Subhash Marg/Bahadur Shah Zafar Marg leading to India Gate (north and south) and ends upto railway station. And other Khari Baoli roads aligns on east west from chandni chowk road was carrying flower wholesale market now it has shifted. Lala Lajpat Rai for electronics goods, The Ajmeri Gate to Chawri Bazar axis wholesale paper trade located towards the Jama Masjid and

ironhardware towards the Ajmeri Gate, Cycle wholesale market towards fatehpuri masjid, Nai sadak for printing press, Grocery roads need to be shifted in designated area. Environmental up-gradation requires reducing degenerative effects of traffic ongestion.

(iii) Visual integration of major landmarks to revitalise the past glory. Enhance the existing visual link between the three major landmarks namely Red Fort, Jama Masjid and Fatehpuri Mosque as per original concept of Walled City of Shahjahanabad. This could have been possible to restrict FAR increase. The old building does not carry the loads for further rise. Judicious landuse regulation could have been possible to revive its glory.

(iv) Pedestrianisation of Chandni Chowk to impart grandeur to the monuments will make completely free of vehicular traffic so as to restore the human scale and convenient living. Battery operated vehicle, man driven rickswaw all make chaos and accident.

(v) Introduction of mughal activities such as traditional/craft bazaar, heritage walk/rides, generation of urban culture at neighbourhood level such as festivals/fairs to attract tourists. Encroachment of facets is to be vacated. Ancillary commerce will automatically shift with the shifting of trades and wholes market

Regeneration of heritage urban space of Delhi, Shajahanabad will be possible to manifest its glory through decntralise trades, landuse control and zonation practice monitoring amendments and stop further development and back to in-situ situation.

Remixing New Ideas with Old Countries–the Attempt to Apply Airport City Concept and Special City Quartier Concepts to the Armenian Landscape

Stephanie Betz

(Stephanie Betz, Frankfurt, betzsteffi@web.de)

1 ABSTRACT

The article poses the question, how administrative units and enitities, responsible for a developing country can generate value of modern city quartier reflections even if correlations are not "visible" at first sight. Based on the strategic concept of Airport Cities, introduced by John D. Kasarda of the Kenan-Flagler Business School at the University of North Carolina, model ideas and potential development pathways will be presented and discussed with selected employees of the administrative bodies of planning authorities and airport responsibiles of Erivan airport Zavrots. The existing lessons learned and their impulse generated have lead to valuable insights.

2 CONCEPT AND APPLICATION AREA

2.1 Airport city concept as development engines

In John Kasarda book "Aerotropolis: Airport-Driven Urban Development" (2000), a new phenomen called "Airport city" has been introduced to city planners, airport executives and academic economic thinkers as well as administrative bodies on variuos levels. Based on the dynamics created by the pure traffic ("the buzz") and the directly connected functions of airports, business infrastructure and internal allocation decider should seek proximity to airports. For the establishment of corporate real estates and communities of airport city inhabitants should be placed at vene-alike lanes to and from the aviation functions instead of supposedly preferable movements away from noise, traffic and environmental impacts towards urban areas or movement towards traditional city centers.

Airports which have either been traditionally and small within the city centre or new and allocated in the outer vast suburban area on large scale seemed the two available options. New developments like "densification programmes" at Memphis or consequent Area Development at Amsterdam Airport with dedicated companies for city development and quartier marketing seemed to herald a new area.

Airport executives from around the globe pursued this strategic approach and therefore allocated planning resources, investments and shareholder groups in structured, even clustered ways at the heart of their operations. Their investment did not exclusively focus on the development of direct and traditional non-aviation functions like travel value shops at departure gates, but have spread into entertainment parks, brainwork campuses or media centres. This changed settlement as well as planning approach have changed significantly from its former pure infrastructural setting for landings and takeoffs of planes. The revenue streams which could have been generated from rents, fees, marketing campaigns and real estate development have nearly grown as high as the aviation-related income (ratios differ significantly due to definition, revenue assessment and airport profile).

Based on academic research of the past decades, an internal benchmark study has been undertaken in 2008/2009 to assess existing planning approaches, models, success factors and development paths of selected Asian and European airports. Due to preselection criteria and decided strategic commitment of the respective managements, the group of probands was subjective and certain results might be predetermined as certain characteristics of Airport City concept applications were self-evident. Referring to this preset selection criterias and therefore limited assessment, a more open approach and therefore an attempt to apply the ideas to completely different airports has been taken into consideration.

2.2 "Old country–need for action"

Inspired by engagement with economists and academics for cultural history and economics at the DUA (Deutsche Universität in Armenien) in Armenia, the idea to apply the idea to this emerging country was born. In interviews and discussion rounds, the ideas of Airport City as well as the results of the aforementioned benchmark studies have been presented and selected feedbacks have been tracked for this article.

Armenia, as an interior land, surrounded by Georgia, Aserbaidschan, Iran and Turkey but restricted by effectively two closed borders, has to rely on the aviation and the corresponding infrastructure to engage with the rest of the world in terms of economic traffic, knowledge transfer and social planning tasks (living, studying, travelling, etc.) to manage the challenges at hand–dealing with employment situation, effects of the diaspora, need for development of soft and hard infrastructure, etc. [1]

With roots grown in a culture of trade, Armenia has the general open mindset for infrastructure projects and should be in touch with modern infrastructure concepts and models to align its planning activities, objectives and resources accordingly. Within the last decade, comparably large infrastructure projects have already been launched–communes and cities fight for scarce resource and search for governmental support for development projects, ranging from universities to city routes. The question of adequate allocation of these resources as well as planning attention and intelligence is faced by the administrative bodies as well as associated advisory boards.

Even in hindsight to its historic role as a hub of trade routes, its geography and its position as one of the emerging countries within the Caucasus region with the strongest boom, the objective to become "hub for trade and tourism between Asia and Europe 1[2]" seems too eager and ambitious–however, the value of the vision might be alignment of various stakeholders, the inhabitants and the market forces.

2.3 Presentation of success factors for Airport Cities, resulting from initial benchmark study

Within the initial benchmark study, relevant and determining factors for the success of an airport city have been identified and defined. Each of these factors has been assessed for the Zvartnots, based on secondary research and selective interviews. Deeper assessment has been planned in next phase of cooperation.

- Ownership structures: Factor includes aspects like investors, their profiles and objectives as well as their potentially varying expectations, priorities and planning horizon.
- Location/Connectivity: Factor deals with infrastructural network aspects, intermodality with other infrastructures, levels of competition/cooperation for transport mode
- Airport core functions: Factor assesses the positioning in terms of hub, capital airport, percentage rate of logistics, effectiveness of aviation functions (mid-/long-term)
- Area and space situation: Factor includes evaluation of current and short-term situation as well as potential for extension for intended cluster settlement
- Framework parameters: Factor includes institutional and legal framework, responsibilities and competences within administrative units, etc.
- Planning and development culture: Factor includes prognosis and trend assessment, milestones and schedules of responsibilities and takes a closer look at planning and resource allocation procedures
- Leadership: This "soft" factor deals with the positioning of the airport, or more precisely the airport management team. It provides insight into the role, either as the "engine" of the process, supported by resources, competences and corresponding staff profiles, corporate culture and structure elements.
- Shareholder and stakeholder engagement: Factors deals with potential vision and mission for the concept, the handling of joint platforms for engagement and interaction, the level of trust and comfort for joint activities as well as formalized processes like mediation procedures or installed task forces

2.4 Application of success factors and lessons learned

Regarding the aforementioned factors, the following initial assessments have been undertaken for Zvartnots International Airport in 2011 with focus on the hard factors. The results represent only excerpts of the overall report.

[1] Various interviews with representatives from DUA (Deutsche Universität in Armenien), 2010/2011
[2] http://www.armien.am/forum/index.php, Artikel: Der neue Flughafen Zvartnots verbindet Deutschland mit Armenien 6x wöchentlich, accessed on the 17th of November 2010

2.4.1 Ownership structures

Early in the process, the need for investment into the existing facilities as well as management know-how transfer was perceived. Alike other countries in comparable situations, e.g. former satellite countries and their capital airports, the decision for cooperation and concession models like PPP or management contracts have been made. This resulted in 2001in a 30-year contract concerning the operation and building of new facilities by the Armenia International Airports CJSC with an Argentine company, which belongs to business man Eduardo Eurnekian [3]. By involving the financial resources, the aviation-related infrastructure investments for rising passenger flows, e.g. terminals, new tower, arrival have been secured. The question still remains, if the resulting aviation-related fees cover the revenue expectations of the consortium or which other steps for the close-by areas might be necessary, to strengthen the location, the city and the country as a whole for internal/national and external/international markets.

2.4.2 Location/Connectivity

One key element of airport profile is their connectedness to city, region and country. Due to the current state of development, the main transport to and from the airport is via one main road and via taxi. As the rest of the country is on comparably lower development, the existing state might be sufficient for the medium term (1.44 mio. passengers in 2009; 1.6 mio. passengers in 2010). The capital Eriwan is approximately 10 km away and the next airport also lies close by. A more detailed assessment of infrastructure plans for the area is planned in the next step.

However, assessing the factor "location" on a meta level, e.g. Armenia´s position as an interior country, with relatively limited infrastructure connections to its neighbours, it might result in a negative result, and therefore "blocking" factor for Armenian development. But on the other hand, it might lead to the overall conviction and push towards leveraging even more of the attractiveness of the airport and, with this, its importance as infrastructure supplier and node for all kinds of traffic.

2.4.3 Airport core functions

Bearing the latest passenger numbers in mind and the underlying growth path, the provided facilities, as seem more than sufficient for the upcoming decades. The outlined and mostly finished activities like arrival halls, tower and logistic facilities had been necessary to cover the demands after the change in the political situation with the former UDSSR and the declaration of independence. The factor can be assessed as generally positive, taking into consideration the general size of the airport.

2.4.4 Area and space situation

The airport is located in medium proximity to the city, defined by the main road and forestral areas on one side. The overall situation is therefore positive, as potentially limiting factors like close-by residential areas, water or environmentally protected areas or historically protected buildings are not existent.

In discussions on this aspect of whether the allocation of clusters, buildings and business should take place here, the general impression was reinforced that there might be areas which are more pressing for investment. Nevertheless, the question of long-term development and conservation of future potential should be kept in mind, as John Kasarda mentions repeatedly [4].

In addition to the questions, if respective settlement and allocation should be pursued, the question needs to be answered which clusters should be selected and attracted. The traditional clusters are logistics (which has already been included in the planning process), aviation-related services like aircraft maintenance and catering but also hotels and conference operations as well as connected social/entertainment and leisure services. The overall size of the airport and situation of the airport leads to a limited provision of these services and proposes the allocation of tertiary services within city limits.

2.4.5 Framework parameters

As mentioned before, the political situation in Armenia and the resulting framework parameters have been undergoing significant changes within the last decades, including the Berg-Karabach conflict, the situation and borders and the aftermaths of diasporas. However, the position and profile is continuously improving

[3] www.wikipedia.com on Zvartnots airport, assessed on the 17th of November 2010
[4] Kasarda, J., Lindsay, G., Aerotropolis – the way we´ll live next, 1st edition, 2011

and therefore the institutional and legal frameworks are still under development and design–this might have repressive as well as beneficial for planning procedures and projects.

Within the evaluation, that also covers the level of economic attractiveness of countries and locations, the level of stability of the law and more precisely the legal bindingness of contracts and negotiations have been assessed as "positive", especially referring to international organizations, such as the German society for investment and development (Deutsche Investitions- und Entwicklungsgesellschaft (DEG) [5].

2.4.6 Planning and development culture

These factors have been assessed in close relation with the framework parameters. The ongoing geopolitical and social changes also impact on the respective culture, style and approaches–however universities, independent consultancies, administrative bodies are engaging in this field. In the special case of Armenia, the effects of the diaspora need to be taken into account which might lead to a faster, better and more efficient solution. Besides financial aspects and the attraction of foreign investments, other factors come into play and have been stressed by the World Bank, especially for countries in transition [6]. These include quality of investment culture, speed of change in management culture, proximity to established markets, speed of transfer of new managerial skills, simplicity of access to existing access due to cultural links, potential position for advices to governments of home countries with respect to improvement of investment climate and deregulation. This factor therefore bears immense potential.

2.4.7 Leadership

This factor is assessed in a next step of the research project with organizational structures and processes to be analyzed for approaches of knowledge transfer, vision alignment and general positioning towards "beyond the fence" developments. The potential of engagement between transmigrants which return to their home country as well as new entrants need to be leveraged especially for this important factor of the country´s development [7].

2.4.8 Shareholder and stakeholder engagement

Within the initial benchmark study, this soft factor of cooperation and communication has been given special attention as negative experiences like demonstrations, court cases with solid blocks against further development or cost intensive mediation procedures have been collected sufficiently at other airports as well as infrastructure projects. These lessons learned should be taken into account early in the process as engagement with concerned groups like inhabitants, local business communities, environmental groups and planning units are of importance for the overall success of this kind of projects. As the development stage of the country and the airport are still on a developing path (approximately 3.5 mio. overall Armenian inhabitants and approx. 2 mio. passengers in the near future), the active consideration of platform installation, forming of task forces or marketing units is still too early.

The general public has (hopefully) realized the importance of tourism and air traffic for their country and its development–this might result in limited resistance against airport-centered developments. However, continuous monitoring of the atmosphere and support of this process is recommendable.

3 SUMMARY AND OUTLOOK

In conclusion, the main lessons learned of the idea exchange and analysis process are captured as follows:

- The success factors which have been identified during the initial benchmark studies can be taken as feasible starting points for other airports and provide in their entity a framework for thought-provoking impulses and analysis.
- Airports can be seen as nucleus for sociopolitical and resource allocating considerations of countries and also serve as interesting research areas for city planners, economists and business people.

[7] Dreusse, Mareike in „Zwischen Deutschland und Armenien: Die transnationale Diaspora als Akteur des sozialen Wandels", Universität Wien, 2008

- Nor the pure direct application nor forceful imposing of a concept according to the principle of "one size fits all" is to be aspired and to be understood as a guarantee for success, but the initiation of dialogues, reflection and assessment of ideas and models.
- The individual and collective examination of transferability and the deduction of knowledge for the individual work and ideas, independent of type of position as either planner or responsible at an institutional unit with conceptual tasks for guidelines or resource allocation has been the intended purpose of the research project.
- The task of remixing new ideas with old country has been completed by the attempt to apply and connect these two apparently non-connected aspects.
- As an outlook, the research team intends to assess the soft factors in more detail and monitor the ongoing process between the actors involved mid-term.

Resilience, Resistance, Reinvention of the Right to the City

Judith Ryser

(jryser@dircon.co.uk, www.urbanthinker.com)

1 ABSTRACT

This paper looks at 're-mixing the city' as a path to sustainability from the other end of the telescope. It argues that 'the good city' - regardless of its definition[1] - requires equitable 'mixing' of both urban populations and urban fabric, to sustain diverse urban spaces with wide access. Key to social and spatial justice in the city is 'the right to the city'[2] for all, as deliberated over the last half century by Henri Lefebvre,[3] Manuel Castells[4] and David Harvey,[5] seminal among many other scholars. The paper examines urban protest movements agaist the divisive effects of the economic crisis and whether such resistance is the requisite context of an inclusive urban constallation[6] fostering the right to the city and a more sustainable and resilient re-mixing of cities.

2 CLARIFYING 'REMIXING', 'SUSTAINABILITY' AND 'RESILIENCE'

The CORP12 conference is asking whether re-mixing the city is contributing to its sustainability and resilience. It states that cities are changing constantly with a quote from Heraclitus: *"there is nothing permanent except change"*. Urban change takes place all the time, driven by complex forces and taking different forms. Some unpredicted changes are inflicted from the outside, by natural or man-made disasters, wars or terrorist attacks. Some are slow and continuous, such as the deterioration of the physical fabric, redundancy of infrastructure, inadequacy of the building stock for new uses. Some recur spontaneously brought about by those who are coming and going and those who use the city every day, "urban dwellers", an urban phenomenon Lefebvre named "habiting".[7].

Re-mixing through large scale spatial interventions in cities tends to be led from the top, predominantly by capital investment into real estate. Traditionally, planning assumed this role in many mature economies, and on occasion politicians or professional visionaries made their mark.[8]

When changes imposed from above by the few on the many become intolerable for the dispossessed they bring revolt into the streets. Using the example of present day London this paper concentrates on people's manifestations for the right to the city, and in particular for their right to use as well as to shape the city.[9] It inquires what civic resistance, demonstrations, riots and occupations may contribute to a more democratic and equitable re-mixing of the city.

---

[1] The notion of "the good city" has been explored by many scholars: Kevin Lynch wrote about good city form in 1984, and David Donnison about the good city in Britain with Paul Soto, Heineman1980. In 2006 Ash Amin (University of Durham) argues in favour of the good city as a formative arena in Urban Studies; and John Friedman, pleads for The Good City, in defence of utopian thinking, International Journal of Urban and Regional Research Vol 24, Issue 2, pp 460-472,June 2000.

2.1 Re-mixing

City structures and functions vary enormously throughout the world due to, inter alia, historic development, cultural context, morphological conditions, urban economy and city competitiveness. Before thinking about remixing the city, it is useful to explore to what extent cities are already mixed. Many cities are getting increasingly diverse, in terms of population, socio-economic status, activities, etc. Often, the renewal of their fabric tends to follow yesteryear's convergent solutions. They are driven by the development industry and their star architects, supported by relaxed planning legislation and urban design postulates, such as high density around transportation interchanges. Such urban change is designed to yield the highest land and property values through considerable increase of density. This is achieved by resorting to skyscrapers[10] and groundscrapers;[11] capturing air rights above public buildings and absorbing rights of way on the ground; producing securitised buildings with segregated uses for ease of trading on the stock market,[12] and in monotonous sprawling suburbia[13] delivered and sold by volume builders.

Of course the urban fabric encompasses a much greater variety of buildings, spaces and places. Quantitatively though these prototypes dominate urban change. While they contribute diversity to the city fabric overall they tend to produce segregated fragments within the city, as they are increasingly gated and inaccessible and even their open spaces are privately owned and controlled.[14] The legacy of zoning planning based on modernist separation of functions is also contributing to spatial segregation. There is thus a need for re-mixing cities with greater social and spatial justice in mind,[15] to provide wider access to more places for a larger number of people living, working and playing in the city.

2.2 Sustainability and resilience

Sustainability[16] has entered the vocabulary of urban change, following environmental and later ecological concerns. This all embracing notion is rarely specified in operational terms and tends to serve political dogma as much as the need for mitigation and/or adaptation to climate change. Here sustainability is interpreted as a feature of inclusion, making sure that re-mixing the cities provides spaces for all city users.

Resilience is the latest newcomer to the virtues required for successful urban change. On the material side, it implies durability, a high quality urban fabric, built to last with proper know-how. On the human side, it means stamina and staying power, also of those who are not well served by mainstream urban regeneration and change. It may infer balance, equity between urban supply and demand, between city uses and city users.

3 FINANCIAL CRISIS AND URBAN AUSTERITY

Referring to Castells,[17] the tripartite power base of neo-liberal capitalism consisting of the financial system, corporate media and the political class has led repeatedly to economic crises. As a palliative, those in power are resorting for citizens' taxes, usually without their consent. The political managers of the economy are imposing austerity with its corollaries of inflation or stagflation and rising unemployment at the cost of citizens' living standards and material security. Economic crises are perceived by many as failure of the market based economy.[18] Far from re-mixing cities towards greater sustainability, understood as a better

[10] For arguments in favour of skyscrapers see: London Report, Skyscrapers, Clustering 'Improve Sustainability" <http://siteselection.com/ssinsider/snapshot/sf020429.htm> about Tall Buildings and Sustainability, Corporation of London. balance between economic, social and environmental wellbeing, the current financial crisis, is socially and spatially divisive.

As physical spatial entities, cities are a construct of social relations, not a given determining social behaviour by reactions to a particular physical environment. Nevertheless, cities are affecting social practices in turn.[19] Cities appear to take the brunt of the current economic crisis. Many austerity measures imposed by nation states have direct repercussions on urban services. Rising unemployment particularly among the young, high fee paying university education, lower social support systems all contribute to youth unrest. Cuts of public sector jobs and expenditure, wage freezes, shrinking pensions and higher, often progressive taxes reduce propensity to consume and threaten economic recovery.

The need of debt repayment and scarce credit availability is affecting the development industry, except for a limited amount of urban infrastructure projects which exercise a Keynesian effect on urban development. They are not offsetting the sub-prime mortgage collapse and its dramatic effects on the housing market, forcing people out of their homes and putting increased pressure on housing, especially low cost dwellings in cities. Slum landlords are already renting out sheds with beds[20] and squatters are occupying whole rows of houses.[21] The expectation that the financial and corporate sectors will return to 'business-as-usual', together with breathtaking salary inflation of the richest is a graphic expression of rampant polarisation between the 1% and the 99% as Occupy[22] is putting it. Not surprisingly cities are becoming the privileged place of urban contestation and unrest. The economic crisis has mobilised protest among those who believe in a more equitable social order, in inclusive, participatory democracy, in economic and spatial justice as discussed by Soja.[23] Conversely, those in power resorted to top down interventions by repressing such movements.

4 LONDON PROTESTS AND THEIR EFFECTS

In London, four main types of protests have taken place recently, expressing grievances about economic hardship and violations in the protesters' view against the right to the city. They include long term pacific peace camps, student protests against fee rises, spontaneous riots triggered by a police shooting, and Occupy lsx, a global resistance movement taken up in London. Other 'direct actions' in cities include those driven by necessity (use of intermediary and abandoned spaces, sleeping rough and squatting) and whatever the establishment understands under the notion of 'improper behaviour in public places'.[24]

4.1 Long term pacific protests in peace camps

Peace camps are not new in London. Their aim is to stay until they have obtained change. A memorable long term protest against apartheid was held in front of the South African embassy. The peace camp against various wars entered by the UK unjustly in the perception of the protesters was started by Brian Haw[25] in 2001. He and followers have settled in front of the parliament until February 2012, when the government has finally managed to change the law to evict the protesters, [26] a move very much contested by those who defend freedom of speech and human rights.

Peace camps are deliberately non aggressive. Exposed to seven million tourists per year, the camp on Parliament Square was disturbing for the establishment which sometimes clamped down on protesters disproportionately.[27] Haw claimed that "the question is not what is wrong but when are we all going to stop what we know is wrong". He called for evolution, not revolution. Yet, the war in Iraq went ahead, UK

[19] This reversal of the environmental determinist paradigm has been developed by Manuel Castells. (1972) 1977 (translation by Alan Sheridan). The Urban Question, a Marxist approach. Edward Arnold.

[25] Brian Haw was an astute protester who managed to contest the various attempts of government to evict him. He died of cancer in 2011 at 62. He said that 'The marchers should not just have one day out in the sunshine, they should stay".
[26] The central government and now the mayor of London are prohibiting even taking photographs, something which may not be enforceable on millions of yearly tourists.
[27] Two young women, Maya Eans and Milan Rai who read out names of civilian victims of the Iraq war in front of 10 Downing Street, the seat of the Prime Minister were arrested.

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

soldiers stay on in Afghanistan and political positions regarding Iran and other countries 'of national interest' remain open.

What have peace camps achieved? Concerning South Africa it could be argued that peace camps in front of embassies were creating political consciousness and embarrassment, thus contributed to the end of Apartheid. In the case of the anti-war protests, they have irritated politicians, the London mayoralty and the local authority, but whether and to what extent they contributed to the change of mind of some politicians on military interventions is doubtful. Nevertheless, peace camps prolong the debate on the right to protest in the public realm against the right to space of others.

4.2 Student protests

The London student protests were triggered by a single interest, the massive increase of university fees. This differed from the far wider claims made by the 1968 student revolt in France which aimed at social change perceived as a common cause with workers.

Forcing students into high debts at a time when political austerity measures were seeking to curb state and personal debts was considered an indefensible contradiction. The students staged sit-ins at universities and took to the streets in organised marches sanctioned by the establishment. The tactics used during the marches differed. The police ignored the initial march until opportunistic infractions into buildings and street fights got out of hands. During the second march police presence was overwhelming and interventionist, but during the third march nimble IT assisted protesters in dispersing into several smaller demonstrations and disbanding them before the police could respond.

The protesters were not a homogeneous group, nor were their perceived opponents, university administrations and the police on behalf of the state. Represented only in part by their trade union, students did not agree on a unified approach to their protests, as became apparent during the marches. While the majority was in favour of peaceful demonstrations, some factions resorted to scuffles, and anarchists, agents provocateurs and other trouble makers infiltrated the marches to use them as an opportunity for violent behaviour. Police kettling was denounced as unjustified institutional violence and draconian punishments were considered disproportionate.

What had student protests achieved? The fee increases were implemented, many universities even used the maximum £ 9,000 fees per annum as a norm. Grants and other support systems were cut and the only concession was that fees did not have to be paid up-front and that repayment was conditional to future income, no guarantee to attract more students from modest backgrounds.

4.3 Summer riots

In August 2011 an initially peaceful local protest march was organised in London against police killing a local inhabitant Mark Duggan to demand justice for the family. This was soon followed by rioting, looting, arson, physical attacks and civil disorder. Aided by BlackBerry Messenger services news and rumours sparked off violent riots in several other London districts, destroying homes, businesses and vehicles and looting shops for four days leading to millions of pounds of damages, injuries, two deaths and spreading to England albeit not to Scotland. A greatly increased police presence made hundreds of arrests, the courts issued harsh punishments and the riots eventually died down.

Although these riots reminded the 1980s confrontations with the black population in Brixton, the current events were not seen to being racially motivated. The riots were unanimously condemned and many were taken aback by their intensity, motivation and mixed participation. Not everyone agreed with the instant judgement of the government that the cause was "a broken society in moral collapse"[28] and many contested the notion of a 'feral underclass'. Academic debates identified contributing factors as socio-economic causes, unemployment and spending cuts, social media and gang culture, as well as criminal opportunism, but also chronic worklessness, illiteracy, truancy, drug abuse and youth alienation, multiple deprivation, poverty and increasing gap between rich and poor. Poor policing and political indecisiveness were also seen as contributors, but fewer references were made to racial tensions, family breakdown and lack of male role

[28] the words used by the Prime Minister David Cameron.

model, and David Lammy, the MP for Tottenham where the riots originated saw a connection with fatherless families which lack male role models.[29]

The popular press was quick to single out black male youth with criminal records but evidence proved that rioters with previous convictions were overestimated.[30] Feedback showed a very complex participation in the riots, including youngsters from wealthy backgrounds and adults, as well as parents who looted with their children, opportunistically joined by bystanders. While there was vigilantism and the popular press demanded punitive intervention, a large number of volunteers undertook clean-up operations in their local areas, some sign of social cohesion when in need.

How do these events equate with localism[31] and the Big Society, the twin prongs of the current coalition government? No public inquiry is planned to understand the complexity of these riots and how they could erupt so unexpectedly and violently. Nevertheless, the London School of Economics and Political Science has launched an investigation with the Guardian newspaper with a grant from a charitable trust.[32] Meanwhile the metropolitan police is engaging in a campaign against gang culture. Both the peace camps and the student protesters distanced themselves from the riots while some social interest groups and individuals attempted to understand their causes.

Many made a link between the behaviour of the establishment, the ruthlessness of the financial sector which brought about the economic crisis and the impunity with which the rich and powerful were able to return to privileges and unearned rewards. Many were outraged by the light touch members of parliament received for fiddling their expenses, the callousness with which phone hacking was trivialised, the cosy relation which prevailed between power bases, politicians, the police and the media, the ostentatious exposure of wealth and ease of writing off a lost generation, all factors which are cumulatively eroding authority among the silent majority.

For a number of critics this amounts to resentment of the establishment. For Alan Woods[33] riots are an expression of impotent rage which wears off as the state apparatus recovers its poise, although in his view none of the political parties are on the right track to tackle the causes of these riots. For Dick Pountain[34] the fact that the establishment was helping itself to public goods led the excluded to justify their disrespect for property of others. In his view, the digital economy is contributing to this as it erodes the concept of property "as a relationship between persons about things", thereby blurring the vision of the young between digital and material reality. Competitive consumerism and brand fetishism reinforces public perception of a two track justice system, unfair sharing of the austerity burden, and breeds a feeling of individual powerlessness.

What was the outcome of these riots? Vox populi was demanding repression to counter the erosion of the established order. The establishment was clamping down harder on the 'undeserving' poor and the idle, increasing deregulation and curbing health and safety measures. Ironically, both sides accuse each other of greed and criminality.[35] Both sides also call for more self-governance, albeit with different meanings: on the government side to shrink the state and reduce redistribution, on the revolt side to achieve greater personal empowerment.

4.4 Occupy lsx London

Occupy lsx (London Stock Exchange) forms part of a global protest movement which started on 15 October 2011 in many cities throughout the world,[36] the most visible being OWSm Occupy Wall Street in Zuccoti Park in New York. In London Occupy wanted to establish itself in front of the stock exchange, but the square

which has been privatised during urban regeneration was cordoned off as indicated by the poster "Paternoster Square remains closed indefinitely".[37] Occupy settled opposite the neighbouring St Paul's Cathedral instead. They also created a tent site in Finsbury Square and set up the 'Bank of Ideas'[38] nearby in an empty building owned by UBS, a Swiss bank. Except in New York and London most Occupy groups managed to stay only for a short period. Many continue online though and are networked globally.

The goal of the Occupy movement was to deal with inequality between the rich and powerful, the 1% and the other 99%. Occupy contests concentration of power in the banks, organisation of society around the accumulation of wealth, consumerism, violence, conformity and lack of real democracy in political decision making. Paul Mason wrote for the BBC that "what Occupy wants to do is much bigger than any single-issue campaign or cause. Its followers mean to limit the power of finance capital and build a more equal society, while rejecting the hierarchical methods of the political parties that once claimed to do so. In this sense the movement is a kind of replacement social democracy".[39] What others understood from the protestors is "that Occupy lsx is about creating a space for people to articulate arguments about the government's economic policy and its consequences: unemployment, increasingly expensive education, and the privatisation of the NHS. The vague sense of unease many of us feel is here, amplified and expressed".[40] Politicians and bankers remained conspicuously absent while many known figures agreed to speak in front of St Paul's[41] and many more participated in debates and self-management sessions in the Tent City University set up by Occupy lsx.

Deliberately bottom-up without identifiable leaders,[42] Occupy disoriented the Press which was expecting spokes persons, press releases and sound bites.[43] The politicians and the media accused them of having no demands, no proposals and no urgency, although they had reached consensus on ten principles early on.[44] Police branded Occupy lsx and UKuncut as terrorists.[45] When Occupy got media exposure politicians tried to fob them off by saying that they had made their point. Their persistence disturbed both the church which was ambiguous about its position and led three senior clerics to resign and the City Corporation which claimed that Occupy was obstructing the highway which was patently untrue. Although some officials showed up in

[37] When I stood by the security barrier peering in, armed only with an iPhone, a security guard approaches menacingly. Curiously, the press release from Mitsubishi Estate – Paternoster Square's owners – is describing the square as a "public space." http://occupylsx.org/

[42] For writings about such alternative governance structure see Carne Ross. 2011. The Leaderless Revolution. How ordinary people will take power and change politics in the 21st century. Simon & Schuster

[43] http://www.totalpolitics.com/blog/268367/what-occupy-lsx-are-getting-wrong.thtml

[44] This initial statement was collectively agreed by over 500 people on the steps of St Paul's on 26 October 2011. Like all forms of direct democracy, the statement will always be a work in progress and is used as a basis for further discussion and debate. http://occupylsx.org/?page_id=575

1. The current system is unsustainable. It is undemocratic and unjust. We need alternatives; this is where we work towards them.
2. We are of all ethnicities, backgrounds, genders, generations, sexualities dis/abilities and faiths. We stand together with occupations all over the world.
3. We refuse to pay for the banks' crisis.
4. We do not accept the cuts as either necessary or inevitable. We demand an end to global tax injustice and our democracy representing corporations instead of the people.
5. We want regulators to be genuinely independent of the industries they regulate.
6. We support the strike on the 30th November and the student action on the 9th November, and actions to defend our health services, welfare, education and employment, and to stop wars and arms dealing.
7. We want structural change towards authentic global equality. The world's resources must go towards caring for people and the planet, not the military, corporate profits or the rich.
8. The present economic system pollutes land, sea and air, is causing massive loss of natural species and environments, and is accelerating humanity towards irreversible climate change. We call for a positive, sustainable economic system that benefits present and future generations. [1].
9. We stand in solidarity with the global oppressed and we call for an end to the actions of our government and others in causing this oppression.
10. This is what democracy looks like. Come and join us!

[45] http://www.independent.co.uk/news/uk

the camp[46] the City finally managed to obtain an eviction order. Besides very visible personalities speaking up for Occupy in public, others participated in teach-outs, including the odd banker. Occupy also encouraged fun by accommodating music bands and welcomed other protest movements. They went out of their way to keep the camp orderly with chemical toilets, recycling bins, a kitchen,[47] a first aid facility, maintaining through passages, cleaning the space and trying to keep drugs and alcohol abuse at bay but accommodating the homeless.

Occupy refuted violence, remained courteous, obtained material help from sympathisers and were accepted by some surrounding businesses. Occupy see themselves as a group of likeminded people who join out of their free will, respect public common goals and leave the movement if they disagree with them. Occupy's wide ranging supporters were continuously discussing their purpose. This was seen by some observers as an act of performance, important in itself and actualising them in their own eyes. Thus the longer they managed to camp out the more successful they felt,[48] an important reason for the establishment to eject them.

"..the saga continues. But the clock also ticks. This week could see the end of Occupy lsx, or it could see the path cleared indefinitely. The external pressure on the movement has synced up neatly with internal conflict over its future, as Occupy tries to decide what its priorities are and which of its myriad aims it's going to have to drop for now".[49] Some say "Occupy has said all it can, done all it could ever hope to achieve and is coming to its natural end."[50]

Occupy lsx was evicted on 27 February 2012 from St Paul's and reduced to the site on the fringe of the financial Square Mile. Like many Occupy movements elsewhere, they plan to increase their online activities. Their objective is "Occupy 2.0", which includes pop-up camps, teach-outs and citizens programmes.[51] The test will be whether they will managed to achieve consensus about the use of their website and their future in general.[52]

From the very diverse comments it is clear that Occupy lsx has managed to stimulate debate on the inequitable effects of the economic crisis, but political action seems unlikely as the cohesion between financial capital, politics and the media shows no sign of waning.

5 EFFECTS OF URBAN PROTESTS ON CITY RE-MIXING AND FUTURE PROSPECTS

Before dealing with effects of urban protests on remixing the city, it is necessary to establish what the four London protest movements have in common and what distinguishes them, also from past events in the 1960s and 1980s.

5.1 Outcome of current and past resistance manifestations

Where do the London protests stand now and where will they go? The anti-war peace camps are almost rooted out after ten years. No greater parliamentary controls have materialised over engaging in wars, and what the peace camps perceive as 'unjust wars' show no sign of waning. The student protests have died down without noticeable changes to student recruitment from more modest backgrounds and little easing of new financial conditions imposed by law. There may even be signs of increasing stratification between universities and less equal opportunity despite government utterances. Many summer rioters have ended in goal while many more are vilified. Police accountability remains questionable and material damages were

[46] http://www.vice.com/en_uk/read/occupy-london-judge-tour-december This visitors included Cooper (for lsx) vs Wilkinson (for the city) Justice Keith Lindblom.

[47] Italian chef Alesandro Petruzzi, organizing a kitchen that provided 1,500 meals a day, insisted: 'I'm not political. I'm a trained chef. I know about health and safety. I decided to volunteer because this is something moral for me. I just want to be a good citizen.'

[52] This comment of an occupier shows Occupy's will to persevere: "No matter the differences between me and other occupiers - we each wake up on a cold hard ground in London because we believe there are solutions to be found. I don't think we can tell you what we want, but we can draw your attention to what is wrong, we can encourage a conversation about subjects previously kept quiet and we can work together with each other (as we are, in remarkable ways) to establish a real democracy within the group. This fledgling democracy has been a hard one to hatch but is evolving in surprisingly beautiful and simple ways. We are indeed BEING the change we wish to see. "

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

inflicted mostly on poor areas with insufficient government compensation for victims, worsening living conditions mainly among the deprived classes.[53] On 22 February 2012 the courts have sanctioned the order to evict Occupy lxs from the area in front of St Paul's. Globally the occupy movement seems to have slimmed down with no permanent camps remaining, and a retreat to digital networking. Occupy have raised some debate among the political class and were given some exposure in the media but they did not become a permanent discussion partner of the establishment.

Turning to the past, during the protests in Paris in May 1968 like now students, workers, minorities, sometimes dissidents among the establishment were claiming the right to the city. Then many countries were on a unique trajectory of growing wealth and prosperity while now long term economic stagnation is likely to affect large parts of an interdependent world, critically analysed by Harvey.[54] Then head-on confrontation led to bloody battles, while now awareness of violence triggers instant reactions of the establishment which in turn were opposed by networks of communication capable of mobilising solidarity and nimble action against perceived injustice, as pointed out by Marcuse.[55] The May 68' protests created resonances throughout the world, without the help of current ICT infrastructure and took many different forms. However, they died down, often with contrary effects to what the protesters had been fighting for. Later, the '68 movements gave rise to many retrospectives and evaluations.[56] Just like the protests of '68 and the race riots in the 1980s the London manifestations were short lived and fizzled out.

5.2 Common ground between protest movements past and present

Regardless of the apparent lack of effectiveness of these resistant movements it is worth investigating their common features and whether they have managed to provoke any urban change. What these movements had in common in the past as well as at present is to reach out for inspiration from activists, radical academics and political polemists. Some of them continue to contribute to resistance movements.[57] Others who had inspired previous movements were rediscovered[58] and new thinkers with political interests are addressing current reasons for resistance.[59]

From a substantive point of view, the demands of all these movements do not differ widely in their essence and they share many similarities with earlier social movements. They request greater equality, social and spatial justice, and in particular the right to the city. They want an inclusively public realm where all can exercise freedom of speech. Their broad grievances are with financial capitalism, reckless and greedy behaviour of the wealthy, lack of respect for the environment. Their claims include single pursuits like abolition of nuclear power or protection of the rain forests, as well as broad welfare objectives such as more jobs, eradication of poverty and better wealth distribution.

The protest movements took a range of forms and provoked mixed feelings among the participants as well as in society at large against which they protested. Although mainly peaceful, some of these protests degenerated into anger, aggression and rage by those who subscribe to violence, but they were also an

expression of frustration and envy of those who felt disenfranchised. Far from obtaining concessions these movements provoked backlashes, sometimes ending up in reactionary politics.

From the point of view of tactics used by these movements, many commentators saw modern communications technologies available to both sides of these protests[60] as the main difference between contemporary public manifestations and 20th century resistance movements, such as the protests of the nineteen-sixties and the race related riots of the nineteen-eighties. Alex Krotoski[61] refers to Manuel Castells, as one of the first sociologists of the internet, who considers that the more autonomous and rebellious a person's attitudes are, the more they use the internet; the more they use the internet, the more autonomous their lifestyle becomes. The Sukey communications network[62] is representative of technological support systems on the internet for such popular uses.

Virtual revolutions around the globe leave a rich trail of publicly available information which provides useful insight into the struggle of these unrests, including their internal inequality, incomprehension and inefficacy. 2.6 million tweets provided the background for an academic analysis of the London riots and their dynamic.[63] Krotoski studied the impact of global digital media and concluded that the ethical issues of resorting to information generated on the internet remain a moving target for both the establishment and grass root users, and sees the need for some consensus on ground rules for the use of this information glut.

In terms of human relations, what distinguishes past from present protest movements is that the absence of hierarchic leadership is more prominent now. It has become an irritation for the establishment which is ill equipped to negotiate with fragmented, loose, horizontal and constantly shifting networks of opponents.[64] Bottom-up direct democracy forms part of the objectives of alternative movements which contest autocratic authority, dominance of the strong over less aggressive groups, and of majority over minority rights. Their experimenting with alternative more decentralised governance has repercussions on the shape of urban living and the fabric which would best accommodate such self-management and self-reliance. It is surprising therefore, that in the UK it is the state should promote localism and it is doubtful that such 'state localism' is in agreement with local self-management of social movements.

5.3 Relation between resistance movements and urban change

The London movements may be too recent and many intriguing questions remain outstanding about their effects on the fabric and the use of the city. Why do such protest movements never seem to succeed in changing society towards their values and objectives? And why - despite their apparent failures - do such movements recur time and again?

The object of the paper is not a study of urban protests as such but their relation with urban remixing. What do these and past protests share and how do they differ in the way they may influence urban change? Referring to the 'urban question' and 'right to the city' debates, it could be argued that resistance movements are transforming the physical shape of the public realm and its meaning by their very presence in the public realm and their claim to equal rights of occupying urban spaces.

One approach to analyse such possible interactions is to relate the spatial dimension of riots to the spatial characteristics of the urban fabric where they take place. An example is The Space Syntax Network which has undertaken a 'crisis mapping analysis' of the London riots in 2011.[65] Their thesis is that overly complex spatial layouts of large post war housing estates with their underused spaces have an effect on social patterns. In their view, this urban fabric leads to social malaise and antisocial behaviour, reinforced by the presence of unsupervised children which creates a segregation of user groups. The study shows that the places where riots have occurred in London (84% in the north and 96% in the south) are within 400 m of established town centres and large post-war housing estates. Conversely, town centres without large post-war estates remained unaffected. They found that the majority of convicted rioters live on such estates. Critics query the socio-

economic assumptions underlying this analysis and the direct links between physical space configuration and social behaviour and attach greater importance to studying the relationship between rioting and socio-economic deprivation.[66]

Often social resistance is disturbing the physical comfort zone of the establishment. When manifestations take to the streets they are accused of being eyesores and, more importantly, an impediment to the 'right to the city' of the majority. The response of the establishment, often confounded with anti-terrorism measures, is eviction and a paraphernalia of physical measures, such as bollards, fences, barriers, CCTV, anti-social urban furniture, sloping public benches with divisions, etc. Most alarmingly though, the planning process is assisting land and real estate owners in gating the public realm. Far from enriching spatial mix, or remixing the city in favour of greater diversity of the urban fabric as well as its use, these responses are creating more spatial segregation through privatising public realm and increasing the scale of excluded private spaces. Contested by writers like Anna Minton[67] such 'ground controls' are contradicting the intentions and meanings of movements which claim social and spatial justice.

Some are considering protest movements from the point of view of urban change when exploring alternative urbanisms. For example the UGRG concentrated on Alternative urbanisms.[68] Many contributions focused on alternative praxis, such as urban resilience strategy, enhancing community ownership in the Big Society and advocated voluntarism, philanthropy and social action with focus on localism. Papers analysed adaptive and self-reliant communities and place-led responses and concluded that reliance on self help and collective ownership requires a robust organisational infrastructure.[69] Some refer back to the demands of the situationists, which would create an unitary urbanism. They look at the spatial dimension of self organising architecture and how it redefines the notion of the commons, understood by Guattari[70] as conflating environment, social relations and individual and collective subjectivities. For them self-managed spaces enable alternative production of space, as a cultural social action and a challenge of homogeneous and hegemonic structures.[71] Others imagine the city as a refuge for political justice in the urban.[72] Squatting in Berlin in the late seventies and early eighties[73] is seen as a form of critical urbanism based on 'separation'[74] and is explored as an instrument for wider urban change. Mutualism practiced by the Transition Towns was also explored as an engine of change of the urban fabric.[75]

If urbanism incorporates a dialectic of crisis and reform, it could become a programme of reform[76] in which protest movements would have an inherent place in the city. Looking at all these alternatives the question remains whether they amount to urban resilience which could have a comprehensive impact on the man-made environment and its uses, as opposed to purely biological resilience such as resistance to physical hazards in urban planning?[77]

6 CONCLUSION

Optimistic views of urban change enacted in urban visions and movements are countered by feelings of powerlessness and disillusionment. The latter contribute to the waning of protest movements owing to police clamp downs and new legislation which supports physical exclusion from public spaces. Coming back to the initial theme of whether remixing the city can lead to more sustainability and resilience, and whether such resilience includes the right to the city for all, it appears from the evidence of resistance movements presented here that such social resilience and resistance seems to have only tenuous impact on the urban

fabric. Conversely, mainstream urban regeneration and gentrification are progressing steadily.[78] If anything, the efforts and aspirations of global movements seem to provoke greater restrictions on the use of the city expressed in fragmentation, gating and surveillance of the public realm, the very place where urban change towards more open cities should occur.

[78] Such mainstream progress of urban development is confirmed in Greg Clark's forthcoming reassessment of the London World City report of 1991, HMSO 'London World City, 20 Years on'; and by Eric Sorensen, ex civil servant, ex-CEO of London Docklands Development Corporation and Thames Gateway, now director of Central London Forward who dismissed the current resistance movements as irrelevant at an LSE seminar on London urban policies 12/02/2012.

1 ABSTRACT

Continuous growth and expected shortage of inner city building sites are some of the crucial challenges in Vienna, likewise affecting future social housing policy, organisation of public and individual transport and urban renewal strategies. Currently, each of these problems is addressed through disconnected planning strategies and measures.

This paper will present the concept and future research programme on the issue of Resizing. Resizing will address the dynamic interaction between public space, mobility, user participation and building structures in different city quarters regarding boundary conditions. The objective is to develop integral, long term and multi-optional scenarios which enable holistic redesign for dynamical systems such as neighbourhoods, city districts and urban areas. The notion of the habitat as a dynamical system in constant change, rather than the completed static objects, as traditionally viewed, is crucial to our hypothesis. The role of transport infrastructure and their interdependency with the building structures as well as with their utilizations plays a crucial role in achievement of sustainability aims within urban or periurban context.

Resizing addresses the challenge of growth under the conditions of sufficiency and long term resilience and within a holistic, systemic approach on the level of a neighbourhood, city or region. Re-seizing aims to activate the potentials of existing structures. The real prospective for achieving the aims of low or even zero emission lie in integral, long term scenario approaches for existing build environment. Resizing scenario strategies simultaneously take into account building stock and its inhabitants as well as the material, technical and social infrastructures of the habitat.

The goal of research is to objectify and deepen the knowledge base on the urban communities and further to develop applicable tools and strategic measures for their sustainable redesign based on the scenario/options approach. The investigation will extend beyond the building into habitat and community as well as integration of past use as knowledge base future development.

2 PROBLEM STATEMENT

According to Häußermann, Läpple and Siebel (Häußermann, Läpple, Siebel, 2008) the term city merges completely different realities: expensively growing megacities in Africa, Asia and South America, but also shrinking cities in former DDR and in rural parts of Austria which are contrasted by growth in cities with attractive job markets such as München and Vienna. There are changing former industrial cities like Linz, university cities such as Göttingen and Graz next to newly founded cities for example Brasilia and Chandigarh but also Karlsruhe and St. Pölten. Because the cities in the global perspective develop under vastly unequal conditions of size, economic conditions and prospective development, it is not possible to define one universal theory of urban development. However, European cities under the condition of industialisation in Europe have developed similarly. For 150 years in Europe, as observed by Häußermann, Läpple and Siebel, urban development and growth were interconnected, yet in future, there will be growing and prospering cities next to shrinking and stagnating ones. Within cities, there prosperity and decline will take place simutaneously. (Häußermann, Läpple, Siebel, 2008).

Therefore, the future strategies for achievement of sustainabily aims should move forward from the singular optimisation of thermal- and energetic performance towards more holistic, systemic approach which includes optimisation of infrastructures, connectivity and accessibility.

2.1 The Effects of the transport system

The growth of cities has to be considered in interdependency with the speed of the transport system (Knoflacher, 1996). While public transport due to its efficiency and focus on lines (with clearly defined

access points) was still able to integrate into the urban fabric, the car began to disperse the dense functions and structures, which were mainly divided into small sections. The effects of constant travel time budgets combined with the excellent accessibility of the private car and its high travel speed brought an enormous increase in travel distances (Knoflacher, 1997). Urban sprawl and concentration effects occurred simultaneously and were enhanced by the predominant post-War planning strategy of functionalism. Both factors contributed to a spatial separation of functions.

Urban settlements, as well as natural systems, are more stable the greater the diversity of their functions is (Amt der NÖ Landesregierung, 1988). The vitality of cities or towns (considered as organisms) is depended on reconcilable infrastructure. The speed of individual motorized transport demonstrably leads to the loss of function of many villages (Knoflacher, 1996; Knoflacher, 1997).

The Consequences for the quality of public space

The speed of the car changed public space and its perception by the residents. In addition to the direct transport-related purpose of public (living-)space it is primarily a space for social exchange.

It was further a common-, communication, recreation and adventure space, which provided social closeness and experience of neighbourhood and allowed a complex set of different uses.

These changes of public space have led to a temporary or permanent exodus from the cities, made possible by the infrastructure built for the car. Living environments that are not excessively endangered by motorized traffic have not only positive effects on social relations but also on the physical development of children (Sauter & Hüttenmoser, 2006; Hüttenmoser, 1996).

The excessive use of individual transport (private cars) corresponds with the individualisation tendencies of the society in general, as shown by the percentage of single households in dense urban areas. In Vienna, the percentage of single households has reached 47 %.

The car enabled a new city dimension

While the urban development (until about the year 1920) in the European cities resulted in structures that required a specific settlement and transport area[1] usage about 50m² per capita and below, the car-oriented urban structures have a specific area demand of about 300-400m² per capita and much further. The traffic area in the city districts of Vienna varies between 14 ("Gründerzeitviertel") to 50m² (outskirts) per capita.

This enormous land consumption is the result of the large specific area requirements of car traffic compared to other means of transportation promoted by a car-oriented urban development in the last decades characterized by structures with a low-density.

3 SUBJECTS OF INQUIRY

In the course of further research, we will analyse current sectoral planning processes and the factors, which shape them. There is a gap between detailed and short term refurbishment of single buildings and construction of smaller urban developments on one hand, and long term urban development strategies on the other. While Scenario-based planning a well as integrated strategies are widely deployed in a large scale urban planning, these methods can also be transferred to smaller urban areas such as city districts and neighbourhoods and thus enable both highly specific, as well as integral, transsektoral and mid- to long term planning processess. One specific urban district which meets the criteria of transferability and in which different elements of the built environment are present (material and social infrastructures, education, transport, housing and production sites of all age classes) will be chosen for evaluation and subsequent scenario definition. The objective is to find specific limits of growth within the existing and potential new structures under the premise of social sustainability, most notably the notion of intragenerational equity and intergenerational justice concering access to urban resources such as housing, transport, education production and recreation/leisure. It is also crucial to identify all factors shaping the transformation of the city districts such as norms, subsidies and procedures etc. next to relevant actors and stakeholders in order to incorporate these parameters into scenario transfer phases. Research aims for a better understanding of structures and agencies in existing sturctures and processesses and at the same time transfer and development of planning methodology.

[1] Including business, green and water areas

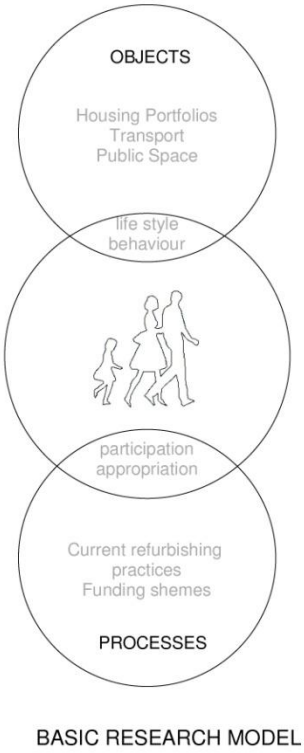

Fig. 1: Basic research model. Basic research is necessary in order to develop both redesign scenarios, as well as to determine the planning approach. The triangular research areas include: objects, users and processes.

4 SYSTEMATIC APPROACH FOR INTEGRATED DEVELOPMENT

In the context of the proposed research, the term social sustainability implies a combination of a view on density in urban quarters with more traditional aspects of sustainability, e.g. energy efficiency of buildings and infrastructures. This has the capacity to bring to light new ways of reaching regeneration and reorganisation of urban quarters.In urban planning, integrated or strategic perspectives are highly valued, and yet specialisation gains increasing importance (Hamedinger et al., 2008). The application of concepts of sustainability in urban planning has, however, led to a widely criticized fragmentation of approaches and measures. Therefore it is necessary to reclaim the importance of an integrated approach under the paradigm of social and cultural sustainability, a paradigm which has, the potential to integrate other aspects of sustainability into one perspective It will emphasise solutions which are not solely based on specialised measures, such as thermal insulation of building surfaces or improvement of public transport, but which combine many measures and thus reduce rebound-effects and achieve higher reductions of CO_2 emission.The notion of the habitat as a dynamical system in constant change, rather than the completed static objects, as traditionally viewed, is crucial to our hypothesis.

4.1 Boundary conditions

The impacts of urban growth

Till the 19th century cities could only grow within the border of the carrying capacity of their accessible environment. If the so-called “ecological footprint” of the city was exceeded by overexploitation of natural and/or human resources, the urban development came to a collapse (Knoflacher, 2010). With the availability of cheap and abundantly available external energy from coal, oil and gas for steamships, railways, car traffic and airplanes, cities grew much further than in their past. (Source) In year 2008 the share of urban population has passed 50 % of the global population (UNO, 2008). This is only possible as long as the whole globe can be used as the life supporting system for cities and cheap fossil fuel for the transport system is available. (Source) The analysis of available resources, the bearing capacity of fertile ground, atmosphere and the ecosystem was exceeded already many years ago as the report to the Club of Rome 1972 and 30 years after have proved (Meadows, 1972; Meadows, 2004).

As far as these scenarios are concerned, also strategies like "De-urbanization of cities" are imaginable where cultivation and issues like self-growing of food products could be part of a resizing process and today's sealed areas of traffic lanes have to be converted into fertile ground.

The metabolism of cities

The so called antropogenic metabolism of cities includes all material stocks owned or stored in private households or needed for its functioning. The antropogenic storage, being approximated to 350-400 Mg/capita consists to the largest amount of building residues and infrastructures (Rechberger, 2009). With the constantly increasing consumption of goods, growing cites and infrastructures, the related extraction of raw materials is also increasing and we will presumably soon be facing the limits of natural deposits. Seen in this light, the cities with its building stock and infrastructure will represent valuable resource of materials in the future (Rechberger, 2011).

The material flow balance for the city of Vienna shows slight accumulation of materials in the city (input slightliy larger than output) which implies on growth of material storage (Brunner, Rechberger, 2002).With the increased refurbishment activities in the future years even more materials will be entering the stock. The current refurbishment scenarios do not take into account the increase of material storage in the antrophosphere, nor the upcoming of the waste these materials will produce in the end – for those materials do not disapperar but remain in the cities to leave them as building waste . With the decreasing economic life duration of the buildings, the upcoming of the building waste is consequently increasing. Current refurbishment practices based on non-renewable resources have therefore double effect – the large rucksack on grey energy for the production of the insulation material (polystyrol) and upcomminig of hardly degradable or reusable materials on the other hand, at not very long life duration rates (40 years). For new incoming material flows, the construction methods need to be developed in order to enable easy and economic assesiblty, dismantling, extractability and reusability; as well the end of life in "final sink".

Buildings and CO_2 emissions

Austria is a forerunner in "green building" through largest density of passive hauses worldwide (Paula, Zillner, 2009). 70 % - 90 % of new housing construction receives a form of housing subsity. The housing subsidy has much sharper requironments on thermal building performance than the building code, the subsidy sum depends on the aimed building performance quality, which again is based on the EU categorisation-guideline (Energy Building Perfomance Directive). In the year 2000 the Thewosan (Thermal-Energetic Housing Refurbishment) subsidy was introduced, with aim to reduce the CO_2 emissions, use of non-renewable energy sources, and finally heatig costs. The introduction of this subsidy resulted in increased refurbishment activity in the following years.

The city of Vienna has own climate protection programme (KliP), in framework of which the Thewosan was launched, with following spheres of activities: Energy seizure, energy use (special focus on buildings), mobility and city structure, agriculture, public relations. The evaluation of the first KliP programme (1999 - 2010) shows that the main CO_2 emission originator in Vienna is traffic (Jamek, Mader, 2011). Also on national level in the period form 1990 till 2010 the traffic sector shows the largest increase in energy consumption by 76 %. The end-energy consumption by sector is allotted with 33 % to traffic, 28 % to industry and 26 % to private households; further 11 % to services and 2 % to agriculture (Umweltbundesamt, 2012). Traffic, next to industry plays not only crucial role in the energy consumption, but also as major originator of the CO_2 emissions.

4.2 Structural changes of buildings, infrastructure & life style

The rate of new construction for housing in Austria is approximately 1 % per year (2,200 housing units/year) (Lechner, 2010). Within this context, the existing stock offers the main medium for implemetation of measurements for achievement of sustainability.

The existing buildings have traditionally been connected to very long life duration (50 to 200 years) and as such to stability and persisency. The actual death rate of buildings in Vienna is almost neglectable, differenty from other European cities. Eventhough longlasting, the building stock has been undergoing multiple structural and functional changes throughout the lifecycle. The changes in historical housing stock ranges from the smaller but numerous retrofits of sanitary infrastructure (Basenawohnung), functional retrofit

(merging of housing units), attic conversions and since the end of 90ies the increased activity in thermal refurbishment. While the retrofit of buildings was a peripheral area of the construction industry in the 70ies, more than 50 % of the construction works are nowadays related to existing structures. Therefore measures as maintenance, repairs, modernization and/or reconstruction play a more and more important role in the construction industry (Däuber, 2007).

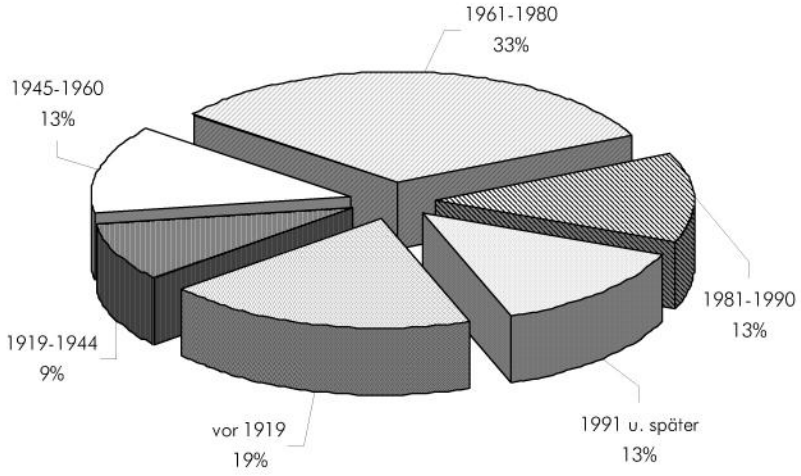

Fig. 2: Housing stock in Austria according to building period in 2002. (Statistik Austria Wohnungen 2000 in: Czerny et al, 2002)

Through public policy and number of subsidies (e.g. Thewosan) the thermal refurbishment played crucial role in the general retrofit of existing buildings. The main re-construction measurement was the refurbishment of building envelope through application of ETICS (External Thermal Insulation Composite Systems); due to the costs based largely on polystyrene insulating core. We argue that current building technologies of the thermal refurbishment of building envelope have low potential for further reduction of emission.

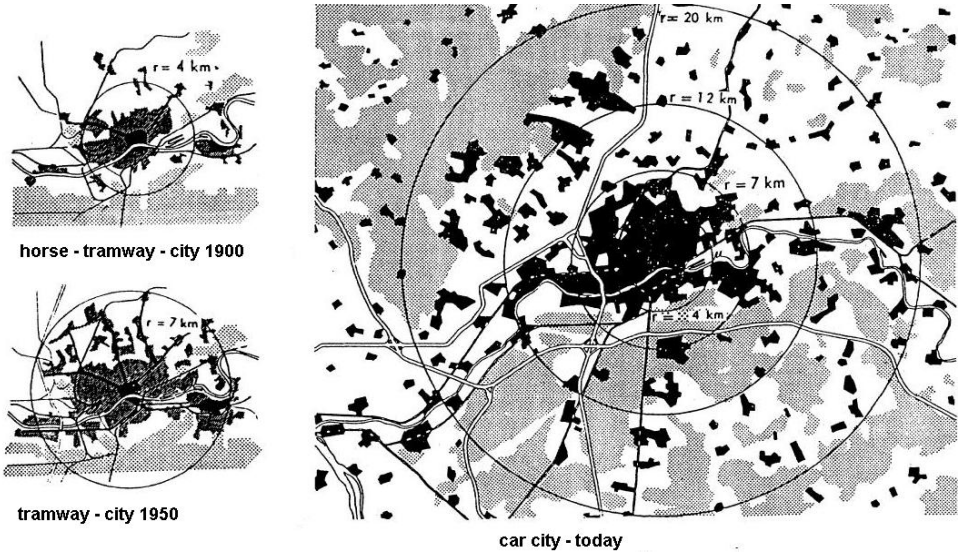

Fig. 3: The city at 1900, 1950 and today ("car city"). The settlement structures were expanded by the first means of public transport, enlarging the zone of influence into the hinterland. Ultimately high speed public and private transport pushed the city borders even further and enabled urban sprawl. This extensive construction of infrastructure coincided with separation of functions and the triumph of the car (Wortmann, 1985; Macoun et.al., 2010).

The studies of refurbished homes have shown, that through the refurbishment the lifestyle of the homeowners also changes and shifted from the energy conserving attitude (e.g. through lack of central heating only the living-room is heated) towards energy consuming attitude (heating of entire apartment) (Korjenic, Bednar, 2010) which leads to discrepancy in prediction of actual end-energy consumption and in some cases even to increased energy consumption.

Further on, the sizes of housing floor space has constantly been increasing; as well as the number of single households. Average floor space of dwellings has increased from the 88.8 m² in year 1997 to 98.2m², in year 2007; with considerable rize in the size of house owner dwellings from 116.5m² in year 1997 to 132.8 m² (2007). In 2007 in 35 % of the Austrian dwellings lived only one person (of these 43 % men and 57 % women), the rise compared with 1997 (30 %) was considerable. In Vienna the part of single-dwellings was 46 % (of these 39 % persons in the age of 60 or more years) (Statistik Austria, 2007).

In terms of measueremnts for climate protection, this leads to conclusion that eventhough the efficiency of HVAC techonologies and building performance is increasing, so is the general consumption of the floor area; which again leads to intensified resources-consumtion (energy, materials and land).

4.3 Scenario development

In Vienna, we can also observe a gap between strategic planning at the scale of the city and the actual processes of implementation. For instance, one of the goals of the Viennese strategic plan for city development is the principle "city of short distances". This strategic document however is not obligatory, in fact, it has no legal consequences. The following planning processes are divided by disciplinary and sectoral boundaries. Scenarios at the scale of built environment in neighbourhoods, to include the stage of scenario transfer, both into visions, such as strategic planning but also into instruments as well as actors, who shape the field. As this method requieres several (for instance 2-6) scenarios, different aspects of sustainability can be evaluated. As our focus lies in social and cultural sustainability , the principle of diversity and inclusion is therefore relevant for all elements of the built environment (Housing, pducation, social and material infrastuctures, transport and production) at the scale of local neighbourhood.

Diversity, inclusion, intergenerational justice and intragenerational equity

Hopfner and Zakrzewski point out that first global declarations on sustainable development (Report of the World Commission on Environment and development in year 1987 and Rio declaration in year 1992) clearly link sustainability to intergenerational justice and equity (Hopfner, Zakrzewski, 2012). This moral dimention of sustainability thus at a level of the city district addresses the question of access to urban ressources such as housing, amenities and transport. In terms of intragenerational equity social mobility and equality of opportunity must also be addressed. Social housing policy can prevent segregation or enhance it, school organisation can provide equal opportunity or deepen it, transport strategies can take into account users with different abilities or it can privilege only certain types of mobility.

Aspects of resilience

Resilience can be understood as the ability of a system to return to a stable state following a strong perturbation caused by failure, disaster or attack (IP, 2011; Patterson et.al., 2007; Hawes & Reed, 2006). The Community and Regional Resilience Institute defines resilience as “The capability to anticipate risk, limit impact, and bounce back rapidly through survival, adaptability, evolution, and growth in the face of turbulent change” (Plodinec, 2009; Amdal, 2010). According to Murray-Tuite (Murray-Tuite, 2006) a resilient transportation system has ten properties: redundancy, diversity, efficiency, autonomous components, strength, adaptability, collaboration, (Godschalk, 2002), mobility (Victoria Transport Policy Institute, 2005), safety, and the ability to recover quickly (Murray-Tuite, 2006).

With the rapid growth of cities according to area expansion and population and the increasing global interdependencies in the financial and energy sector the concept of resilience is becoming more and more important. In transport and city planning resilience is often reduced to short-term natural disasters, although the different types of structures and the interaction between built structures and users under consideration of changing boundary conditions should be taken into account.

The resilience of a city is directly connected to the type of transport infrastructure. A dense and attractive network for walking and cycling affects the flexibility in case of disturbance and thus the degree of resilience. Non motorized traffic requires no external energy for their movement and the cost of maintaining these infrastructures is relatively low.

The organization of parking cars – the key factor in the resizing process

The linking of parking space and housing (or other uses) is codified in the building regulations of the federal states. With the commitment to provide one parking space per residential unit people are not only forced to own a car, but also - depending on the distance from the apartment to the parking space – forced to use it. Other forms of urban-mobility thus remain without a chance. Although the obligation for the provision of a parking place can be fulfilled up to a 500m distance to the assigned object, by default, it is built as close as possible. Parking the car in collective garages allows the opportunity to reuse public space for many purposes. 70 % of today's lanes in side-roads would be superfluous (Knoflacher, 1996).

Re-seizing the City – Recapturing of public space – the necessary beginning

The changing boundary conditions of the last 10 years (demographic change, fuel prices, etc.) as well as the effects of transport policy over the past 40 years led to a population growth in the city of Vienna. Measures to improve the quality of public space were done at the same time (Stadt Wien, 2012).

Although a consistent, effective, area-wide conceptual extension of gentrification of public space is missing to date, a decline in the degree of motorization between 2002 and 2008 by around 4 %, based on the improvement of public transport and cycling infrastructure and the implementation of a consistent parking management was achieved. This initiates a potential for the usage of public space in its original diversity and is a necessary starting point for the resizing process in the city.

5 CONCLUSIONS

The notion of reaching sustainability of built environment through increasing of efficiency needs to be questioned, since basically it is founded in the neoclassical economical theory based on constant growth. Through rapidly growing consumption, ownership of ever more goods, increasing area of living space per capita, anthrophogenic material storage is growing and consequently the natural reserves are decreasing.

In the future more material will be provided in the cities, than in the natural environment. The refurbishment strategies have also largeliy relied on the extraction of materials form nature and its depositing in the material storage of the city. On the one hand the resources for this type of refurbishment will soon be limited, on the other will cause the upcoming of the waste as outcome in the long term scenario.

The strategies that solemnly rely on the increasing of efficiency have been shown as not successful: despite the ever more efficient HVAC technologies and building hull performance the energy demand of household has constantly been increasing. Similarliy in the efficiency improvement of the car transport, at the fuel intensity improvement of 100 %; there is the rebound effect of 44 % km more driven (Ajanovic, 2011).

The crucial question in achievement of sustainability is the question of lifestyle – the better the building performance the higher (in terms of consumption) the lifestyle. Therefore a concept of "progressive efficiency" (Harris et al, 2008) – increase of the efficiency along with the intensity of energy use together with active actions towards energy conserving is porposed as a way towards more sufficient instead of efficient life style. However to achieve this level of awareness, intensive participative processes involving users (occupants), planners, industry and political decision makers are necessary. "The question is how much sacrifice is avoidable, how much is necessary, and how much we are willing to accept" (Harris et al, 2008).

Further research is needed in order to objectify and deepen the knowledge on the existing city disticts on the principle of integrated urban development for existing city districts, with the emphasis on social and cultural sustainability. The principle of intragenerational equity und intragenerational justice are therefore crucial when defining future use and development of local neighbourhood resources which include housing, social infrastructure, education, production and transport.

1 ABSTRACT

Facing the complexity of urban and regional systems, as they are characterized by several elements continuously interacting each other and making complex governance in ordinary and extra-ordinary conditions, tools for manage strategic choices could be suitable. Therefore, due to the systems complexity, often it is needed, before to identify strategies, to clarify what the problem is, and clearly consider all relevant aspects.

In this paper, we present a Strategic Option Development Analysis (SODA), applied to the problem of seismic risk reduction, with involvement of different kinds of stakeholders, acting on territory with several roles. The problem structuring has highlighted which are the components, in terms of available tools, elements on the territorial systems, stakeholders, etc. contributing to enhance resilience, as we recognize that this is the main characteristic that a system must have in order to answer to a seismic event.

The paper is organized as follows: in the second paragraph, a framework concerning the seismic risk problem and the relationship between seismic risk and resilience. The third paragraph contains a deepening concerning resilience, and in the fourth is finally presented the approach applied to the problem of seismic risk reduction, the SODA. Results of adopted approach are presented in the fifth paragraph.

2 SEISMIC RISK AND RESILIENCE

Natural disasters, nevertheless continuous scientific and technological development, cannot be avoided, and, as history too often teaches, when a calamitous event occurs, it produces high damages. The learned lesson seems to be that prevention strategies are not adopted in order to mitigate possible damages, but generally interventions follow a catastrophic event, trying to mitigate its effects.

Therefore, as mentioned, scientific and technological development continuously gives some contributes to handle natural disasters, and produce results in terms of strategies to adopt before a risk crisis; considering the possibility of such disasters, with a defined risk assessment, we must work in order to face them, and to react, with at least as possible loss, in terms of lives, injured people, damages on buildings and infrastructures and indirect effects. First of all, we need to know what to do to face emergency conditions; then, how to manage crisis in order to limit damages caused by natural and other disasters and finally to go over crisis and to guarantee the re-establishment of ordinary conditions.

Risk assessment takes into account several components: generally, it is defined as a function of hazard, exposure and vulnerability (UNDRO,1980). Hazard concerns natural characteristics of a natural phenomenon; for instance, if we consider seismic risk, hazard depends on historical seismic characteristics, ground geological characteristics, geotectonic and seismic-genetic structure characteristics, which do not depend on human intervention, so that we are not able to control them.

Exposure, instead, concerns the human presence in a certain area. So, if hazard conditions are worrying (i.e. hazard is high), then human settlements must not be established there. Anyway, generally knowledge about hazard is subsequent to settlements, stratified during the centuries, so that displacement represents a strong decision with several impacts on inhabitants. Concerning the not yet urbanized areas, instead, hazard knowledge is strategic in order to allow a rational and safe planning.

The third component is vulnerability, that is defined as the tendency of a certain element to be subjected to damages or corruptions, depending on its own physical and functional characteristics (Fera, 1997). Generally, vulnerability is referred to the elements composing a settlement; in the case of seismic risk, for instance, vulnerability mainly refers to seismic vulnerability of buildings, and other structures, as roads, bridges and so on, and its evaluation depends on structural characteristics, determining building behavior in

case of seismic actions. Technical codes supply building criteria taking into account the relation between the structure and the hazard on its location.

In the last decades, anyway, the concept of vulnerability has been presented also with a wider meaning, considering it at urban scale. Considering for instance Manyena (2006), it has been recognized that global activity in a town can be compared to activity of a network system, where each edge, working at local level, contributes at global level. From this point of view, it becomes evident that physical damages are not unique components of global damage. Moreover, it has been observed that earthquake effects are not limited to physical damages, but they have some ripples on economic, social and political activities, and they have a strong role onto city capacity to react.

This framework, taking into account the wider concept of vulnerability, leads to a new approach in risk prevention, going over building structural adjustments, and highlighting that single components work as a whole system, in which it is possible to recognize not only physical elements, such as buildings and streets, but also social, economic and political functions.

New approaches must define tools able to mitigate such urban seismic vulnerability; therefore, it should forecast, before a seismic event, what kind of response the single components might show. Such an approach aiming at mitigating urban seismic vulnerability, must maximize system resilience, as the capacity of a certain system to adapt to new, generally negative conditions, to re-establish normality (Comfort, 1999).

3 RESILIENCE: GENERAL FRAMEWORK

The International Strategy for Disaster Reduction, Hyogo Framework for Action 2005-2015, defines resilience as the capacity of a system, community or society potentially exposed to hazards to adapt, by resisting or changing in order to reach and maintain an acceptable level of functioning and structure, and that is determined by the degree to which the social system is capable of organizing itself to increase its capacity of learning from past disasters for better future protection and to improve risk reduction measures. Not accidentally the strategy is exactly called Building the resilience of nations and communities to disasters: resilience concept is placed at the core of strategies.

In origin, the concept has been developed in the field of ecology: following the Holling (1973) definition, it is a property of a system, measuring its ability to absorb changes of state variables, driving variables and parameters and still persist; the concept is strictly related to that of stability, intended as the ability of a system to return to an equilibrium state after temporary disturbance. In the risk management literature, resilience to natural hazards is defined (Pelling 2003) as the ability of an actor to cope with or to adapt to hazard stress. It is a product of the degree of planned preparation undertaken in the light of potential hazard, and spontaneous or premeditated adjustments made in response to felt hazard, including relief and reuse.

In the concept of resilience it is possible to recognize also a social dimension: according to Bruneau et al. (2006), community seismic resilience is defined as the ability of social units to mitigate hazards, to contain the effects of disasters when they occur, and to carry their recovery activities in ways that minimize social disruption and mitigate the effects of future earthquakes. This can be achieved both working on structural aspects and emergency response and strategies, involving institutions and organizations, and in particular those related to essential functions for community well-being, as acute-care hospitals. Communities must be capable of coping a stress situation, where they must manage demands, challenges and changes, with available resources and competences (Paton et al., 2001). In the Godshalk (2003) vision, community networks must be able to survive and function under extreme condition, as condition sine qua non the city system will be vulnerable.

Considering resilience as a property of each system component and of the whole system, anyway, is not helpful in order to identify strategies. How to measure this property? How to put in action strategies working on components and on the global system at the same time? How to recognize the augmented resilience before a disaster? Obviously, this is not a unique aspect to be considered. Considering natural disasters, several strategies could lead to enhance resilience in terms of augmented capacity of absorption and recovering from changes (Barnett, 2001), referring to resilience properties. Bruneau et al. (2006) consider that resilience is characterized by almost four main properties:

- the robustness, as the ability of elements to resist to a certain stress, without suffering degradation or loss of functionality;

- the resourcefulness, as the capacity of identifying problems and finding solutions depending on priorities and available resources;
- the ability, as the capacity to meet priorities and to achieve goals as quickly as possible;
- the redundancy, as the substitutability of elements in order to satisfy some requirements no more satisfied by a degraded element.

Even if such properties seem to be abstract, they can find a concrete application. For instance, decentralization of decision making (i.e. creating several decision making centers in a town) or strategies about mobility, generally refer to redundancy, and so on.

Paton et al. (2001) define a resilient city as a sustainable network of physical systems and human communities, where the first ones include all kind of structures and infrastructures, acting as the body of the city, its bones, arteries, and muscles, and the second ones represent the social and institutional components of the city, including all kind of associations and organizations and acting as the brain of the city, directing its activities, responding to its needs, and learning from its experience. The metaphor makes clear that during and after a stress, both systems are determinant: if body collapses, the entire system collapses; if brain breaks down, the entire system breaks down.

Therefore, the most important aspect concerns how to define and apply strategies. Observing cities, they can be modeled as network systems, with a main trunk, hierarchically more important than some secondary branches. In terms of response to a disaster event, therefore, trunk elements must have a faster response, because they are charged of main activities of city, and moreover they represent place identity.

4 HOW TO IDENTIFY RESILIENCE: THE PROPOSED APPROACH

The last two sections open several issues, but not yet show the way to identify elements to enhance territorial systems resilience: they show exactly the research process, that, at this point, lead us to a precise conviction. We are at now persuaded that the seismic risk mitigation is a particular kind of problem, that we are not able to solve with traditional paradigms of operative research, but, that need a preparative phase of structuring.

Seismic risk mitigation involve several stakeholders, with several different expertise, and a different role in a particular field of city and territorial systems organization. Therefore, the problem needs to be handled at several reference scale, considering differences between the quarter, the city, the region, and in a context of knowledge more and more precise, but not exact, so that we are facing with a problem – the earthquake occurrence – that we don't know exactly when, how and where it will occur.

Moreover, we recognize that a strong component of resilience is related to communities, that must be involved in a something, as a participative process, to be prepared.

In this huge amount of aspects to be considered, and in front of the exigency to involve the stakeholders, the most helpful tool, we thought, could be starting from the problem structuring. So, the proposed approach, Strategic Option Development Analysis, in order to develop a participative process, build a cognitive map representing the problem and highlight, with the stakeholder contribution, which are the elements enhancing resilience.

4.1 trategic Option Development Analysis

SODA (Eden, Ackermann, 2001) is a method aiming at identify general problems with the support of cognitive mapping, in a participative context, where actors are related to the main issue, and need to agree about possible solutions. The method is of the techniques of the family of problem structuring, suitable when it is not possible to adopt classic method of operative research, because problem nature is not well clarified, there are qualitative and quantitative aspects, there are several points of view to take into account, several actors, knowledge is not exact, consequences of potential actions are not certain and so on.

Main idea is to focus on the problem, and, with creativity and spontaneity, identify all elements related to the problem, in terms of sub-problems, causes, effects, other related problems etc. Discussing around the problem helps each participant to clarify its ideas, and to enrich its store of knowledge also with contributes from other participants. Conflicts can be solved, finding evidence for their existence, and identifying small actions toward an overall objective, that everyone shares, and obviously is related to the resolution of problematic situation.

The method is based on the hypothesis, helping in the process development, that a best solution cannot exist, but that it is therefore possible identify partial solution, steps towards a solution, conflicts resolution, and that the participative process produce anyway a positive result.

Kelly (1955)‘ theory of personal construct is adopted in the SODA approach. In brief, the theory affirms that each subject, affected by his own experience and cultural background, looks at the world and builds a representation through a systems of concepts. He defines concepts in natural language, and considering his emotional component. Therefore, in a participative context, several subjects are involved to contribute to a shared vision of the particular problematic situation: the discussion can produce a map, as a merge of the entire concept that each subject can express, and identifying common relations.

Generally, SODA approach is adopted in several steps. First one is characterized by individual interviews, during which the facilitator helps the interviewed subject to express ideas concerning problematic situation, and represents these ideas on a cognitive map. Once all interviews have been carried out, a collective workshop is organized. Facilitator presents a merged map, derived from the single maps, and helps subjects during discussion.

The merging phase is strategic, in order to allow each subject to identify in the merged map its personal contribute, but at the same time, it is important to highlight conflicts, and work, during workshop, on their resolution. This last passage leads to a team map, containing also identification of strategies and actions. As mentioned, not always it is possible to identify a solution, but anyway, the shared vision of the problem is an important result.

4.2 Cognitive mapping

SODA main goal is to clarify the problematic situation and identify possible solutions, through a shared representation, that make possible to take into account qualitative aspects, and at the same time highlights the importance of relations between elements in the situation. For this aspect, cognitive mapping is a suitable technique. Maps are something that everyone builds in its mind every time he searches for the meaning of world. As Kelly (1955) affirms, in the attempt to give meanings to the world, men build a concepts system, where the number of concepts is limited, and each concept is conceived in relation to some personal emotional perceptions. Then, concepts are hierarchically organized, identifying some cause-effect relations. In the SODA context, cognitive maps are representation about a problem. They are composed as a network with edges and nodes. The direction of an edge defines a hierarchy, and usually denotes causality.

Once maps are conceived, it is possible perform some analysis in order to highlight particular aspects; for instance, the shape of the map helps to identify the complexity level of problem. When a map is plate, there is no evidence of a strong hierarchy between concepts, and on contrary, with a pyramidal structure, it becomes evident the presence of a reduced number of heads, and of some predominant concepts, and so on. Another interesting aspect is related to number of edges entering in a particular node: this denotes the relative importance of node compared to other ones.

The possibility to automatically perform analysis is particularly useful when the map reaches a large number of concepts, making difficult reading; analysis, moreover, help to identify contradictions and conflicts, often present in a merge map, obtained starting from individual maps.

In this research, Decision Explorer software has been used in order to build the map and, then, to perform the analysis. Decision Explorer is software developed at Bath and Strathclyde University, as a tool for managing soft issues, as the qualitative information surrounding complex and uncertain situations, and at not developed by Banxia Software.

It is important to clarify that cognitive maps generally are built in order to better understand a specific problematic situation, sharing with other involved stakeholders, and not to build a knowledge model. As declared, also the cognitive map that has been realized does not represent a knowledge model about seismic risk.

5 THE ROAD TO A SHARED MAP ABOUT SEISMIC RISK MITIGATION

In order to reach our research goal, a workshop has been organized, inviting several experts on seismic risk mitigation. In particular, the experts comes from the field of seismic risk, the field of Civil Protection and the field of urban and spatial planning, and they have been chosen in a large variety of different expertise.

During the identification phase of possible involved stakeholders, it emerged that seismic risk mitigation is a very large field, interesting institutions and scientists, each of them with different responsibilities and, usually, working on its own specific subject and not interacting with other actors.

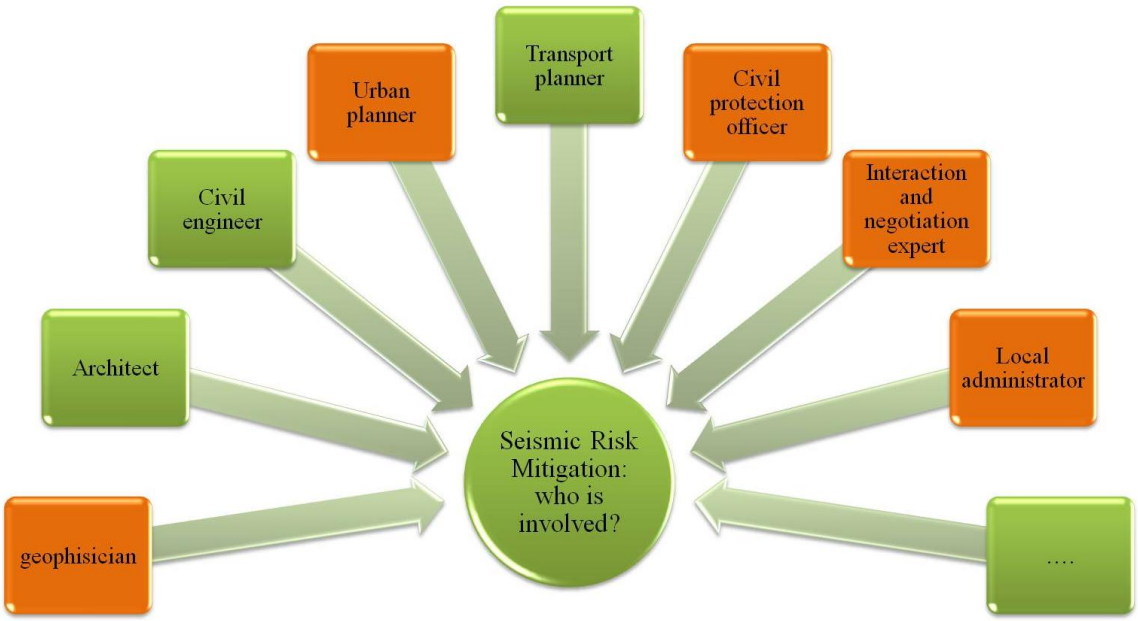

Figure 1: Stakeholders potentially involved. In the orange box, the experts invited to participate during workshop.

The workshop, conceived in a unique session of about four hours, has been organized in three main parts; during the first one, a general framework has been presented to invited experts. In the second one, a discussion about general framework has been carried out: each expert expressed its opinions and gives some interesting issue to develop. The third phase has been individual: each participant was asked to write its own map starting from the general framework above discussed.

The general framework focuses the attention on main elements characterizing seismic risk mitigation problem, as shown in the following map:

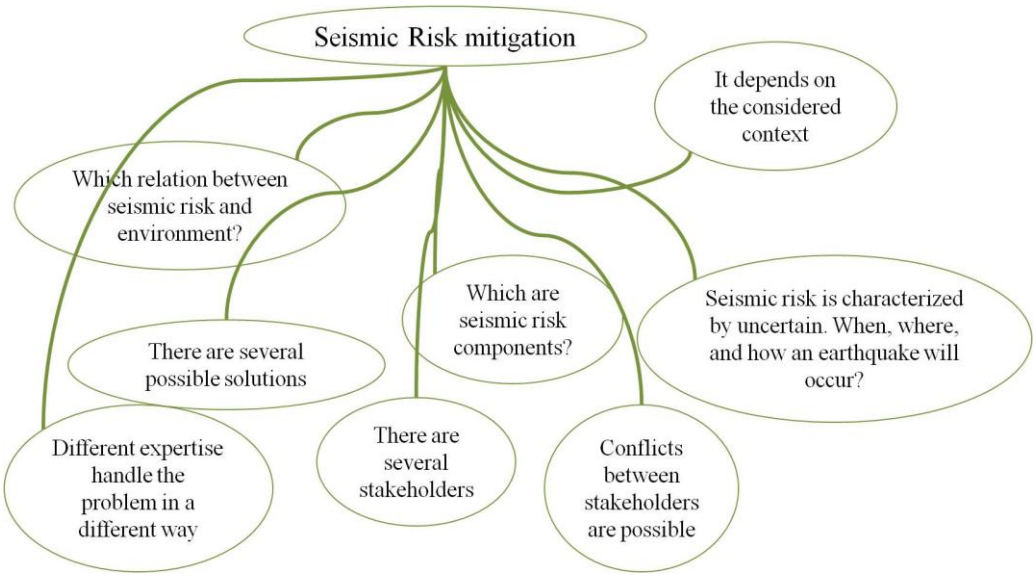

Figure 2: problem positioning

Discussion followed. In this phase, each expert clarified its ideas and discuss with other of their reciprocal position in the context of seismic risk mitigation. In this phase experts interacted in a strong way; each of them asked to speak several times; the feeling, unfortunately, was that they felt the difficulty to compare with different expertise, and finally the asked creativity was not significant: each expert contributed to the discussion, but he continued to stay in its field, without a perspective change.

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

In the third phase, each expert was asked to create its own synthetic map, considering the elements on the general framework and evidence emerged during discussion. Workshop unfortunately stopped at the delivery of experts' maps, but research still is on: the collected maps are the basis for the team map obtained, discussed in the next paragraph. Map is not reported because it is very large and moreover it is in Italian language.

6 EVIDENCE FROM THE MAP

The obtained team map presents a high level of complexity. It is composed by more than 200 concepts, with an intricate network of relations, both of causality, connotativity, means-ends. This means that team map highlights some possible contributes to seismic risk mitigation. Through map reading and analysis, the possible contributes to seismic risk mitigation have been grouped in six strategies, referred to different domains, and including a certain number of actions, as schematically represented in the next figure:

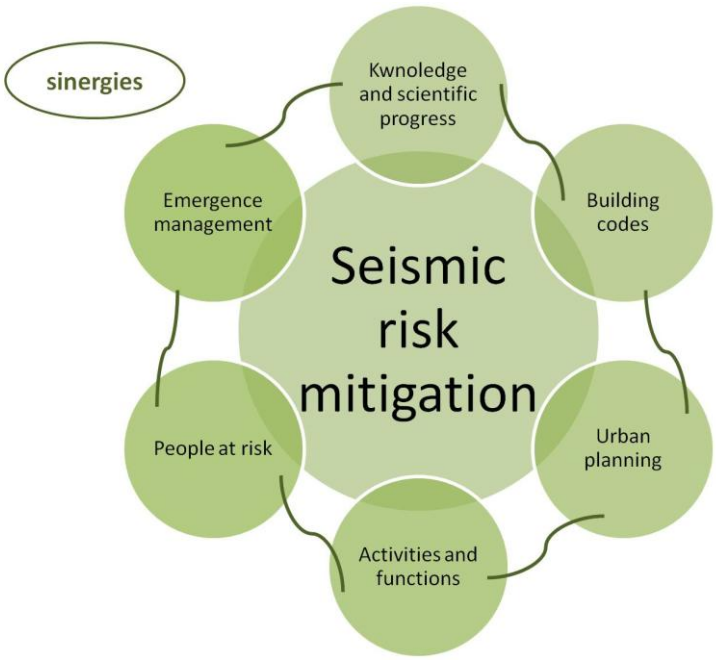

Figure 3: groups of strategies identified in the team map

As the scheme proposes, it emerged that the overall objective, the seismic risk mitigation, depends not by the single strategy, but by the global achievement on the overall strategies. Therefore, the map highlights some interrelations between actions of each strategy, indicating the need of harmonization, as mean to produce synergies. The six strategies are briefly described in the following:

(1) Knowledge about hazard: scientific development is strategic. Each progress in the science can produce effects on avoided damages. The consciousness that natural risks cannot be avoided must not stop the research about, because we are persuaded that as much as possible a phenomenon is known, as better we can defend.

(2) Building codes. Resistance of buildings is not enough to resist to the earthquake, but it is true that main effects of earthquake affect structures. It is important improve buildings characteristics. Moreover, it is interesting the new emerging theme of perceived safety. A possible strategy relies on the contribute that private citizens can give to make safer their buildings. At now, a citizen buying a car asks for car safety characteristics, but not so often a citizen, buying an apartment, asks for structural characteristics, taking for granted that it is.

(3) Relation between buildings (that is, vulnerability) and territory (that is, hazard) urban planning. If an area has a high risk, urban plans must avoid settlements, and prefer safer solution, even if they are expensive, and even if this produce conflicts with landowner.

(4) Territorial system functioning. Not only buildings make a city. In each building a function is carried out. There are squares, schools, hospitals, offices, prisons, public spaces etc., and each day people move from

their homes to other places, contributing to a flux. This flux of people and activities must be regulated, in order to optimize the global functioning and avoiding possible collapses.

(5) People at risk. Strong evidence emerged during workshop: seismic risk is not well known. People do not perceive the importance of prevention, nor are conscious that they are exposed to risk. When an earthquake occur, it is perceived as something impossible to contrast, ignoring that prevention is possible, in several ways.

(6) Emergence management. Finally, with the consciousness that seismic risk can be contrasted but not avoided, strategies to manage emergency phase must be defined. Institutions, experts, decision makers and citizens must be prepared to react, each one with its own contribute.

As mentioned, synergies between the six strategies emerged as necessary to reach the objective. If each strategy is strictly separated from the other ones, the global result will be underdeveloped. A global vision is strongly recommended, in order to make effective each strategy, and avoiding a possible negative resonance, but searching to amplify benefits.

Figure 4: photos from workshop with experts

7 CONCLUSIONS: WHERE IS THE RESILIENCE?

Analysis on team map produces an interesting result: in the node represented by resilience concept, a high number of edges enters, making evident that resilience is considered as the property of a territorial system influencing the behavior after a disastrous event. Therefore, as resilience is defined as a property of the whole system, we argued that it can be enhanced working on the whole system, and adopting coherent strategies.

Here is the resilience, in the synergies between strategies, founded in a global approach to the problem. This evidence is as more important, as the workshop highlights that at now experts are not used to work in team, but considering their field as the unique one. During the workshop, each of them continuously tried to defense its position, and only after discussion the need to harmonize single strategies was finally recognized and accepted.

As workshop represents only a test, in conclusion we want to enhance the need of working with involved stakeholders, as SODA approach allows, in order to make them conscious that seismic risk mitigation depends on system resilience, and system resilience can be achieved working on harmonized strategies.

1 ABSTRACT

Urban green spaces have different benefiting values for urban life. Besides their ecological values, they are important for retreatment and recreation and provide positive contribution for the subjective well-being of the citizens. The EU emphasizes this importance for the urban spaces in various guidelines and directives, like in the Charta of Leipzig with its contents of a vital city. However in terms of a measurable classification, there is just a concentration on the European Union Environmental Noise Directive. Additionally, questionnaires to request personal subjective opinions are used. This research study aims to show if this issue could be reduced to one dominating factor or how the well-being of the citizens could be reflected by more complex correlations. By now, a qualitative and concurrent method to arise the recreation value by the well-being of the citizens is missing. The research approach includes the usage of an ambulatory assessment device (wristband) with psychophysiological measurements. Hence, a wristband ("SMART-Band") has been developed which can measure unobtrusively emotions in real time as product of unswayable body functions. By this method, subjective feelings and emotions could be transferred into quantifiable values. Furthermore, correlations with these values and the noise level from EU directives are in focus of the research. The study took place in four different urban spaces with specific noise loads and recreational characters. The test persons (n=18) were equipped with wristbands ("SMART-Band"), video cameras and noise detection technologies (instruments of the Laboratory of Monitoring and Spatial Sensing of the University of Kaiserslautern). For supplementary validation, information gained from questionnaires and tagging smartphone technologies are used.

2 INTRODUCTION

Through developments in recent years such as ubiquitous computing and pervasive sensing (Martino et al., 2010), the human environment is increasingly enriched by vice versa connected sensors, which generate spatial planning-relevant data. With the help of new mobile technologies, citizens are more and more integrated in this network of applications and could interact with it in the future. First thoughts on this have been considered some years ago with the theory of "Citizens as Sensors" (Goodchild, 2007) or a "People-Centric Urban Sensing" (Lane et al., 2006). This ensures that citizens, who should be the focal point of any planning consideration, may be considered as active sensor for the urban environment. Pervasive Sensing in its current status is marked by the fact, that the primary external influences singularly are measured, but the direct effects and interactions of the citizens will not be considered. So far, it is important that not only the sensor measurements of the citizen were taken into account, but also into which emotions they were resulting. This study will introduce devices and methods, which will consider the human sensor and its emotional perception. One important influencing factor is urban noise on test persons and the correlation with their emotions. Aim is to define methods and new insights for defining the quality of a place. The study "Sensing the City" shows the potentials of psychophysiological monitoring and prospects for their use in urban planning. The study takes place in three urban areas in the city of Kaiserslautern in which the participants are connected with different kinds of psychophysiological monitoring devices and audiovisual measurements.

3 STATE OF RESEARCH

3.1 Monitoring and Spatial Sensing

Monitoring contains an observation of a phenomenon over a specific period of time, with the result of using the gained forecasts for a reactive or constructive control. Regarding the used data, monitoring needs a systematic collection, analysis and documentation of these data in order to do an analysis over time of quantitative and qualitative entities (Streich, 2011). Charateristically for monitoring methods are very detailed and strictly implemented protocols with exact timestamps and a continuous recording of the observed object or event. Only by using this data collection, it is possible to generate time series, which are the basis for forecasts. Especially in the working field of spatial planning, the accompanying time series analysis was emphasized. With the appearance of Web 2.0 and associated technological opportunities as mentioned in both previous points, many new developments will influence the approach of monitoring. Besides, the empowerment of non-experts to create, analyse, visualize and publish geospatial information will contribute data for monitoring.

Due to the mentioned elaborations, it has to be distinguished between deductive monitoring (top-down) and inductive monitoring (bottom-up). Deductive monitoring is mainly composed of data generated by time series analysis: People collect data sets, with or without the awareness that they wear a sensor device to collect data, or unconsciously, like the connection dataset of cell phones. Regardless of the fact how these monitoring technologies deal with personal data and data security, the continuous recording of these kind of data has a large potential, not only for spatial planning. Inductive monitoring approaches, especially in spatial planning have to be considered in a different way and could be described as a concluding approach from the entirety. It could be seen that the following trend is going to be detected: the growing amount of interest in the use of "Sensing the city". Sensing the city in this case means the combination of georeferenced data with the help of ubiquitous mobile computer systems and sensor technology. Furthermore, in this context, the term "Geoweb" from the British magazine "The Economist" (2007) is mentioned as well as it is metaphorically referred to "Web 3.0" or "GeoWeb" (Batty et al., 2010, p.1). In particular, the GeoWeb phenomenon refers to "the development and changing nature of map-based, data mash-ups. It tries to explain the basic concepts behind map mash-ups, how geospatial data gathering and analysis has changed and how new technologies and standards are impacting on this" (Batty et al. 2010). During the last years, a drastic increase in available GIS-data source and especially rapid developments and price reduction in sensing technologies could be observed. To make use of this immense amount of data within monitoring systems, real-time data integration mechanisms and approaches have to be developed (Resch et al., 2009) and would be desirable in this context. Essential parts of a "Sensing the city" system are (smart) sensors, humans (as sensors) and a monitoring system (Exner et al., 2011).

3.1.1 (Smart) Sensors

"Base-sensors" for spatial planning are sensors for detection of location and direction of an object (Streich, 2011): These sensors can be subdivided in sensors for self-location (for example a GPS-Tracker) or position detecting, how it is used for radar equipment or the detection of Cell-ID in mobile phone networks. With the help of GPS and a compass, it is possible to detect the moving direction. Other available technologies are data collecting devices with the assistance of visual sensors (like digital cameras), audio sensors or in addition sensors for the measurement of the degree of air pollution. A general overview and classification in sensor types could be distinguished: sensors for state variables and material properties, sensors for geometrical and mechanical parameters, electromagnetic and optical sensors and other possibilities for image processing (Schanz, 2007) or, like in the present case, the skin conductance and the skin temperature (Zeile et al., 2011). All the sensors produce mostly quantifiable data and could be used in different planning related issues.

Crucial point is to organize these complex and heterogeneous data sets and new technologies. So it is necessary to develop new methods for its use, administration, organization and management. Basic research for the handling of these data sets is essential in this regard. An interesting approach for this is to use "bikers" as sensors as shown in the Copenhagen Wheel project (Outram et al., 2010), in which environmental conditions like CO and NOx concentration, temperature, noise (dB) and humidity were directly measured by sensors during bicycle rider's tours through the city. Focus in these cases were

particularly citywide sensory data, data management, the integrated real time visualization in a top down process with a bottom-up approach. Hence, one of the most important issue in planning processes is "to involve humans into a "sensing process", because they function through their body impressions as a synchronized multi-sensor" (Exner et al., 2011).

3.1.2 Human as sensors

Like above mentioned, it is necessary to integrate people's skills for gathering sensor data. In 2010, "The Economist" stated out to this point: "Everything will become a sensor, and humans may be the best of all". Due to the technological development in smartphone business, the combination of Smartphone - Human Interaction could be a huge potential in planer's everday work if it is possible to use this specific ability of people for monitoring spatial phenomena. Their abilities in terms of sensing will result together through interaction with the user itself in the rise of new planning relevant sensor data. Furthermore, crowdsourcing integrates an entirely new mode of participation in processes of urban discussion for geospatial data gathering" (Exner et al., 2011).

3.2 Noise reduction in spatial planning

Environmental noise may be defined as unwanted sound that is caused by emissions from traffic (roads, air traffic corridors and railways), industrial sites and recreational infrastructures, which may cause both annoyance and damage to health. It is to be considered as one of the main local environmental problems in industrialized countries. Noise in the environment or community seriously affects people, interfering with daily activities at school, work and home and during leisure time. Furthermore environmental noise causes an increasing number of complaints from the public.

Generally, action to reduce environmental noise has had a lower priority than that taken to address other environmental problems such as air and water pollution. However, it has been estimated that around 20 percent of the European Union's population or close on 80 million people suffer from noise levels that are considered to be unacceptable – i.e. that many or most people become annoyed, that sleep is disturbed and that serious long-term health effects like increase of hypertension are to be feared. The European Union calls these 'black areas'. An additional 170 million citizens are living in so-called 'grey areas' – these are areas where the noise levels are such to cause serious annoyance during the daytime – but no serious health damages. Only 150 million Europeans live in 'white areas' that are not seriously affected by environmental noise (EU-WG-AEN, 2003). These are mostly rural areas or privileged places in urban areas.

The reduction of environmental noise is subject to two important restrictions. The first is that spatial systems or infrastructures are to be assessed, not the sources of sound emissions like cars or aircrafts. Therefore, environmental noise assessment and mitigation is not concerned with technical questions, such as constructing cars in a way that makes them quieter, but rather with the question of infrastructure planning and its impact on residential and leisure areas. The second major restriction is that there are some kinds of noise that may not be assessed in the environmental context – the most important one being neighborhood noise, which is a question of architecture, of social behaviour and of legislation, but not of spatial planning – although there are some connections to planning (Rumberg, 2009). A recent goal of noise mitigation according to the European Union Environmental Noise Directive is to protect quiet areas against an increase in noise. Especially in densely populated cities urban parks and green spaces are of great importance. The designation and protection of quiet areas is thus a contribution to maintaining a high quality of life in the cities.

3.3 Emotional Mapping (based on skin conductance and skin temperature)

The human-being has ever been in the focus of any planning consideration. Thus, it is only logical to determine him as sensor and source of individual data concerning its environment. How does a person sense its actual surroundings and how can these impressions and emotions be measured objectively? Recently, a multitude of researchers (psychologists, neuron-scientists, medical scientists, computer scientists, etc.) occupy themselves with these questions. They work in the field of "Affective Sciences" on emotions and their influence on human behaviour and society (NFS Affective Sciences, 2011). The immediate transferability to space is quite obvious. In this context, two main criteria to identify unaffected emotions, which are triggered by the surroundings, have turned out:

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

- Affective emotions have to be recorded in real-time and for every instant to identify particular on-site situations
- The measurement must not hinder or disturb the individual to avoid the collecting of cognitiv influenced emotions

Considerable research in the field of classical emotion research and the Affective Sciences shows consistently that emotional reactions come along with changes in the activity of the autonomic nervous system. These internal reactions are reflected in specific physiological parameters (e.g. skin conductance and skin temperature) (Kreibig, 2010), which are classified as vital data of the individual. Methodical with regards to content, the recording and analysis of this vital data is called psychophysiological monitoring. "Recent technological developments, such as a sensor wristband, now allow the recording of these parameters outside a lab, even without limiting a test person's mobility. A wrist-sensor like that is therefore the ideal instrument to record emotional stress reactions one encounters while moving through urban space [...](Bergner et al., 2011, p.249)." One possible approach, in case of outdoor measurements, is the identifying of mental load (stress) with the help of physiological indicators. Stress can be understood as a product of anger and fear - highly negative emotions. The analysis of stress moments especially helps to identify deficits in the urban environment. All these facts favour the usage of psychophysiological monitoring coupled with ambulatory assessment (wearable computers) for real-time studies in space. The combination with the field "Monitoring and spatial Sensing" offers completely new perspectives for the spatial awareness and performance of encompassing spatial analyses. This approach was already pursued in several project studies. First test series were done in the emomap-project (Zeile, 2010). Furthermore the so-called EmBaGIS (Emotional Barrier-GIS)-studies were conducted in the context of urban spatial barriers for handicapped people (Bergner et al., 2011).

4 REPERTOIRE OF METHODS

To capture spatial relevant data, different kinds of methods are combined into an overall approach. Focal point is the comparison of noise measurements and psychophysiological data, which brings the principle of humans as a sensor in the classical consideration of spatial planning data collection.

4.1 Noise measurements

A key method for the assessment of noise load and its effects is noise mapping. Noise mapping is the representation of acoustic data in a cartographical format and the assessment of noise exposure in the context of public health and quality-of-life in a multi-level modelling process. Its benefits are the visualization of acoustic data and, by combination, of the information with a geographical information system (GIS) enabling the correlation of different datasets. Thus population density can be related to noise exposure to generate information about the number of people exposed to noise levels above a certain criteria level. In general, the purpose of noise mapping is to give an accurate statement of sound levels in a location, to provide noise trend data, to establish exposure levels of a population for risk estimation purposes, to identify pollution hotspots and relatively quiet areas for the definition of priorities, to yield information as to the effectiveness of management schemes and to inform as well the public as decision makers (Rumberg, 2009).

To effectively cope with noise problems in spatial planning a quantitative and informative basis-of-discussion is required. Environmental noise in general is not constant over the time but is normally showing a complex time structure. So the instantaneous sound level is no sufficient description for environmental noise, and long-term-descriptors – such a average sound levels, weighted average sound levels such as LDEN (a 24-h hour average level in which evening and night time is weighted) and peak (or maximum) sound levels and NATs (number above a defined threshold) – are complemented. The effects of noise on humans highly depend on this time structure. Strong noise peaks appearing at low background levels are particularly disturbing while generally higher, but constant levels (e.g. near to highways) are perceived less intensely. In comparison to that, other collected data to measure noise exposure and its effects on human beings is generally poor - and data on noise effects is often difficult to compare due to very different measurement and assessment methods.

Generally noise data may be achieved by measurement or prediction. In the majority of cases prediction models based on complex emission and propagation algorithms (e.g. ISO 9613) are used for noise mapping in larger areas and for long-term-description. For these cases noise prediction software (e.g. CadnaA, Lima

and SoundPlan) is available. For short-term-monitoring in specific locations measuring the instantaneous sound levels using noise level recorders is more suitable.

4.2 Psychophysiological Monitoring

The recording and observation of changing body functions (physiology) are part of the psychophysiological monitoring, which shows individual emotions localized in real-time. This research focuses on negative emotional reactions, which can be classified as "stress"-reactions. A negative experience is given, if the skin conductibility increases and shortly afterwards, the skin temperature drops (Bergner, 2011). The following graphical curves illustrate this process (Fig. 1).

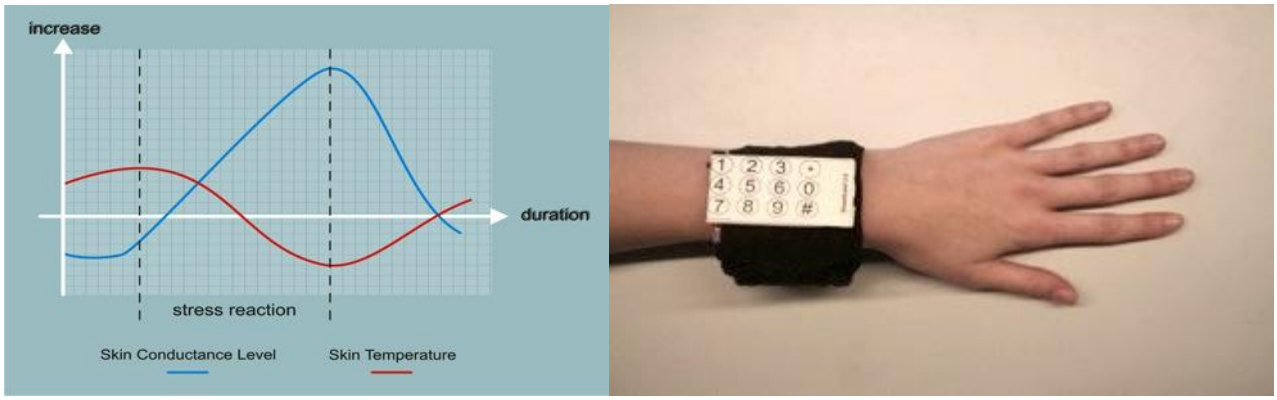

Fig. 1: Stress reaction & SMART-Band (Own source)

It is obvious that the qualitative visual analysis of the physiological data is rather time-consuming. To shorten this procedure, the mathematical function of the mentioned parameters is simplified with the first derivation. Hereby, the slope values of the curves can be used for statistical analysis. The method of using scoring points (increase in skin conductibility = Scoring +1; decrease in skin temperature = -1) was already used in studies before (Bergner et al., 2011). With the help of a sensor wristband (SMART-Band by www.bodymonitor.de) the changing body functions are measured and recorded. This wristband was developed by GESIS, the Leibnitz-Institute for Social Science in Mannheim (Papastefanou, 2009).

5 STUDY "SENSING THE CITY"

The aim of this study was to identify urban retreat and recreational areas against the background of the European Union Environmental Noise Directive with the help of psychophysiological measurements. The idea behind was, that in a city can exist qualitative retreat areas with a high recreational potential, caused by good urban design, although the areas could not be classified as a retreat area by the European Union Environmental Noise Directive. One example for this phenomenon is the fact, that people have the impression that the subjective quality of sojourn is even high on a loud street, if a fountain is located on the street and people can hear the sound of the fountain splashes.

5.1 Study Set-up

During the study, the following parameters were modelled /measured:

- Noise pollution (quantitative modelling with immission control software for location determination)
- Noise pollution (quantitative & qualitative measurement with noise level recorder)
- Subjective perception by using SMART-Bands (and alternative SenseWear devices), recorded through skin conductance level and skin temperature
- Additional geotagging of impressions via RADAR SENSING App via KML
- Traditional 5 level ICBEN-questionnaire (International commission on biological effects of noise), which described the perception of noise pollution.

The test persons (n=18) were a group of students from the local university. Ten were male and eight female with an average age of 25,4 years (m=27; w=23,5). They had the excercise to concentrate on reading a book in the different areas over a time span of 30 minutes.

The test persons were equipped with:

- SMART-Bands for measuring physiological data
- SenseWear upper arm bands for measuring physiological data
- Neck Cameras to identify the individual audio-visual impressions
- Smartphones (with the installed tagging RADAR SENSING App)

Before the setting up the study, first step was the analysis of the city of Kaiserslautern to identify potential areas with high suitability for quiet recreation. The test persons filled in their standardized ICBEN questionnaires on noise pollution, where they wrote down, if they had the impression at this place to be considered a relaxed situation. Following the phase of data collection with Sensewear-Band and SMART-Band in which the subjective physiological responses were measured in fact of rapidly changing situations of noise. Simultaneously, the local sound signals were recorded and measured.

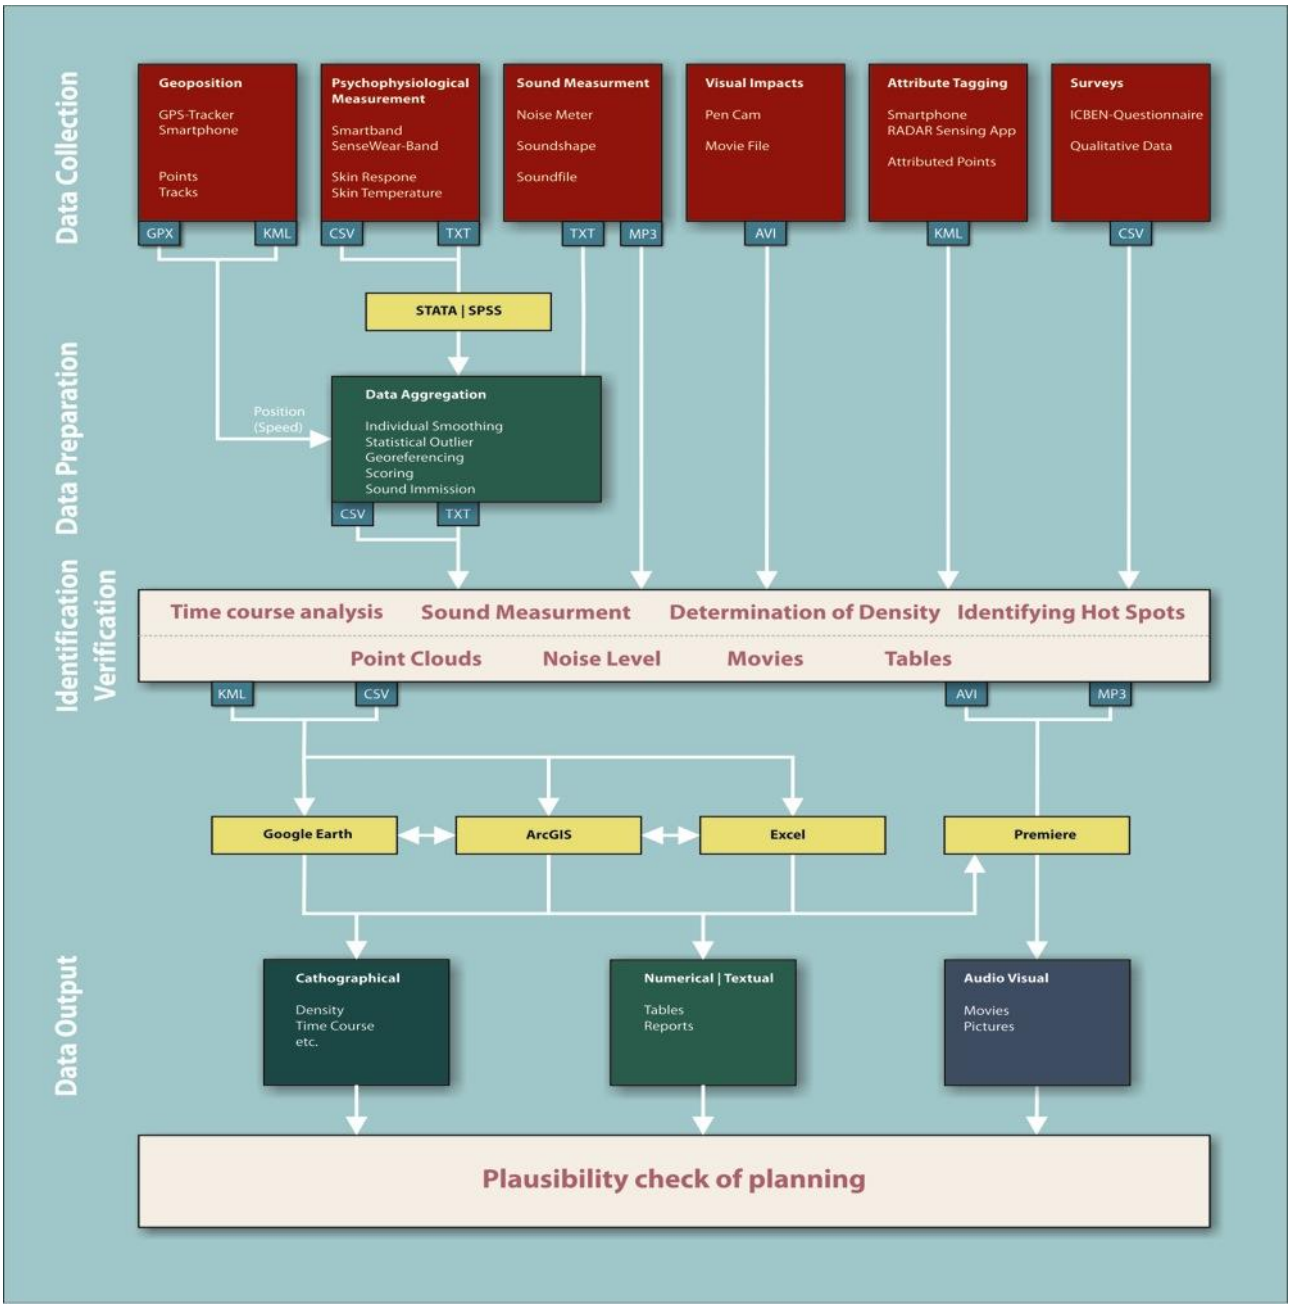

Fig. 2: Study-workflow (Own source)

In order to validate the hypothesis of the connection between different noise levels and the emotions of the test volunteers, four characteristic study locations were identified in the city centre of Kaiserslautern. All four locations have specific characteristics and noise levels:

- Location Volkspark: bigger inner city park, which is mostly calm and has a high potential for recreational purpose – test bed for the visualizations in this paper
- Location Fackelrondell/Stadtplatane: inner city area in an area with an intense surrounding traffic, recreation purpose just for a short-time stay possible
- Location Stadtpark-Straße (street side): inner city area in an area surrounded with medium intense traffic, although the park is mostly calm, the sidelines are strongly influencing by traffic noise.
- Location Stadtpark-Kern (centre): inner city area in an area surrounded with medium intense traffic, the measurement was collected in the calmer centre of the park.

The comparison of the noise levels on an afternoon over the period of a 30 minutes time span reflects the various specifics of all four test beds. It could be seen, that the level on the "Stadtplatane" with an intensive traffic is in average much higher than all other levels. The "Volkspark" for example has a stable level, which was just interrupted by two specific situations, a playing child and a passing lawn mower. Both measurements in the "Stadtpark" also showed differences because of the traffic, though the distance between both measuring sites are less than 100 meters.

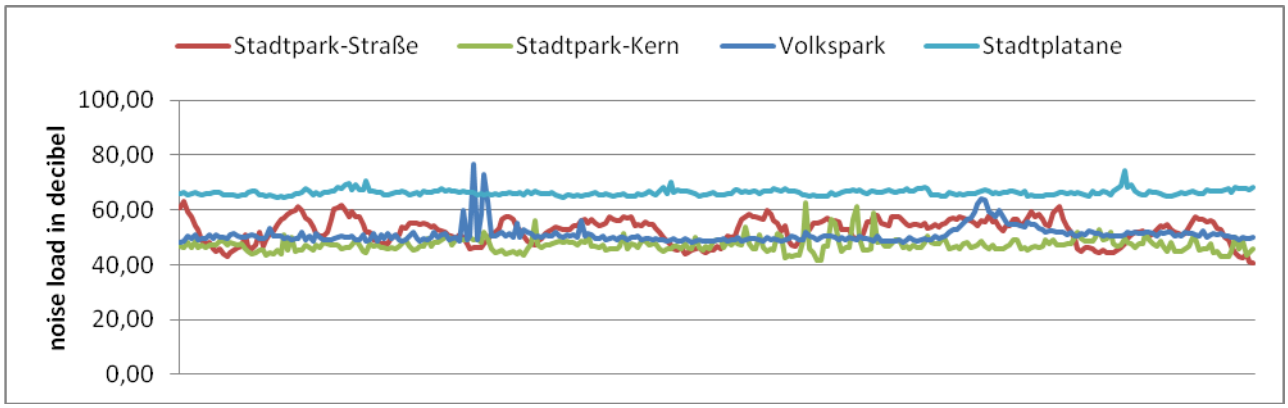

Fig. 3: Comparison of the noise levels from the 4 study locations (Own figure, based on work of Diehl, Michel and Keller for the study project Sensing the City, 2012)

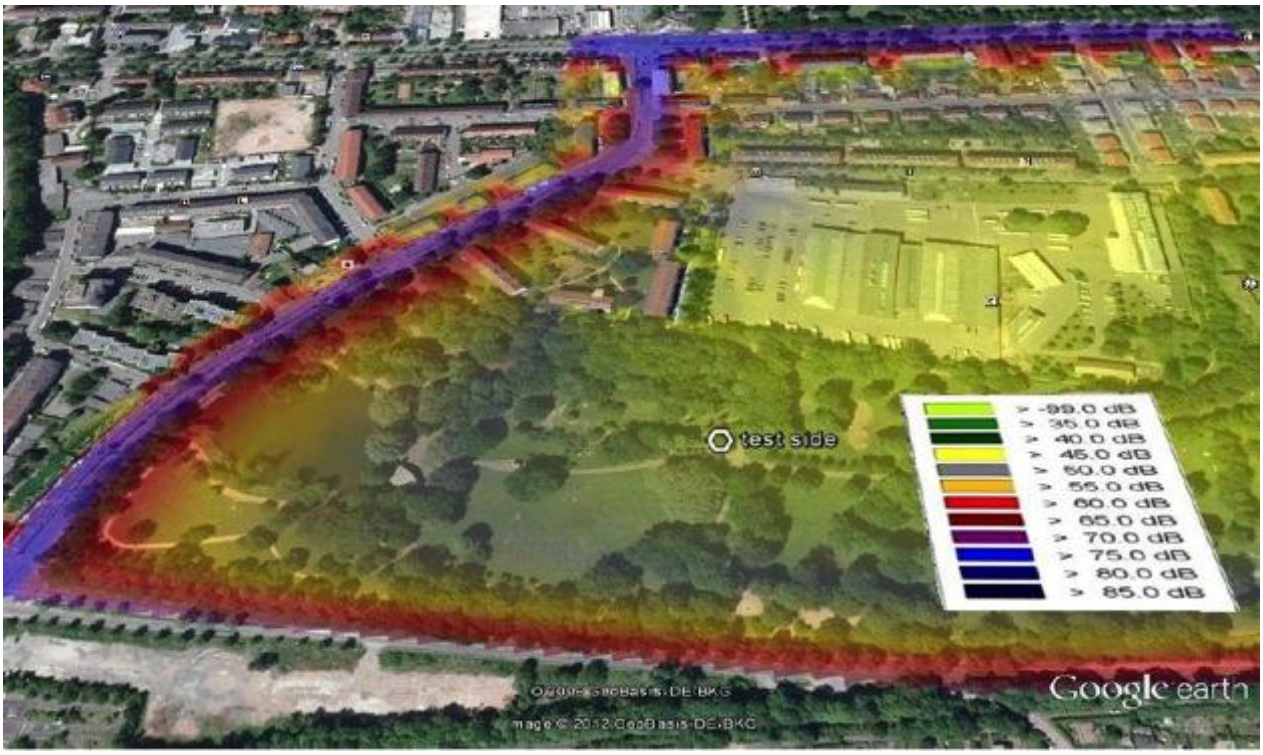

Fig. 5: Test side "Volkspark" (Own source, noise map produced with CadnaA)

Deeper insights of the study in terms of visualisation were given with the results of the test study of the area "Volkspark". The measurement site is directly in the middle of the park and has a comparatively low noise

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

level. The test bed and the noise distribution could be seen in the following figure. Due to the calm environment, this spot brings the best circumstances for analysing the reaction of the test person on specific noise incidents.

5.2 Findings and visualization

Emotional mapping is a new field of study for noise effect research in gerneal as well as for the impact of the research in this topic. With this new set of technologies, it will be easier to prove assumptions about the correlation between noise load and subjective well-being. This approach is shown by a combination of quantitative and qualitative analysis. The results of the test persons show a correlation between both entities. The following picture illustrates the decibel level and the number of stress reactions in a time-series chart. The correlation between two specific events (a passing lawn mower and a playing child) could be seen clearly.

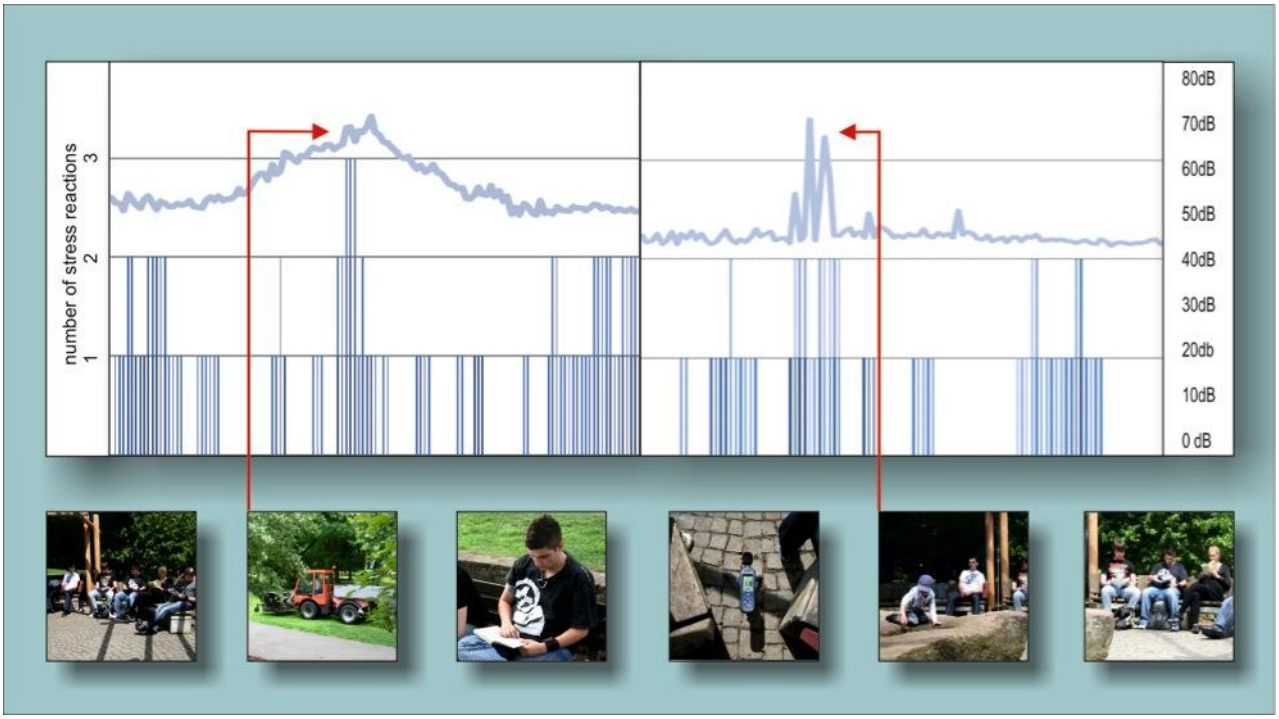

Fig. 4: Qualitative analysis of noise at the location “Volkspark” (Own figure, based on work of Diehl, Michel and Keller for the study project “Sensing the City”, 2012)

The possibility to integrate georeferenced measurement data into Google Earth shows a further potential of this method. The subsequent figure shows an example for a visualisation of emotional data of three test persons during a passing lawn mover. As it can be seen in figure 4 as well, a raising noise level induces a raising stress moment. This raising skin conductibility during stress responses could be visualized with localized vertically moving bullets on a scale as it could be seen in figure 5, which could be considered as a localized “pulse” for the volunteer.

Fig. 5: Different stress emotions of the locations “Volkspark” during a crossing lawn mower (compare figure 3) (Own figure, produced with gpsvisualizer.com, 2012)

6 CONCLUSION

The logical combination of new technical monitoring methods and people centric surveys opens completely new perspectives to capture humans' environment. The knowledge of the perception and feelings of the urban population provides for an improvement of "spatial awareness". In case of recreational benefits of urban green areas, some interesting findings have been outlined. First indications are found that there is correlation between high noise amplitudes and stress of the participants in the study set up. A constant high noise level however is covering people's perceptions of the actual local surroundings and leads to fewer and lower stress reactions. Taken as a whole, in the study is shown that besides the noise level, some other influencing factors on the well-being could be detected (for example awareness of movement around, presence of other people, odors, light, etc.) Hence, the methods to sense urban space have to be extended to determine spatial awareness. The interdependency of the environment and the subjective well-being is obvious and could not be described only with a few selected influencing factors. The approach to combine environmental data with the vital data of people therefore is still a new field of research, which has many advantages in contrast to classical methods of data collection, analysis and their comprehension and could be seen as a scientific enrichment.

One further research task lies in maturing technology and method. The used SMART-Band is presently in the state of prototype. So, there are small deficits in the usability and the data structure. Currently, a next generation of SMART-Bands will be developed, including a new sensor generation for delivering much more reliable data sets. Hence, an automation of the data analysis process is needed. Real-time processing by "the push of a button" is a desirable aim to reduce the dependency on the actually mainly manually analysis.

Furthermore, the consideration of the data at hand was based on static measurement locations and there has to be an enrichment of the emotional data with the use of GPS-data in order to see a pepole's emotions during their movement through urban areas. This topic is going to be considered in our upcoming research project "Sensing in green areas". Another field of research will be the qualitative analysis, in order to find out, which spatial circumstances could lead into which correlating body reactions. In this context, it is necessary to create a comprehensive and synchronized consideration of the various data flows. There will be further insights for classifications of "good" and "bad" stress situations and the different specific personal levels of the physical activity for example. Besides the measured implicit values of the test person, there could be as well an additional examination of own estimations of subjective well-being. That could be measured either in ordinary questionnaires or via special mobile phone questionnaires. More information for this will be provided in the conference paper "A New Urban Sensing and Monitoring Approach: Tagging the City with the RADAR SENSING-App". People are able to use this software to attach locations in the urban environment with either positive, negative or neutral remarks and to tag various values like cleanliness, sojourn quality, urban design/architecture, social environment, accessibility, lighting, seating or for example traffic. As an overall conclusion, these new methods could bring new insights for planners in order to detect time-space-patterns in urban environments and will be a new field of research in the future.

7 ACKNOWLEDGMENT

The authors are grateful to the support of the University of Kaiserslautern, which enabled these research studies by support this department and the faculty of spatial and environmental planning with financing the "Laboratory for Monitoring and Spatial Sensing". Furthermore, thank goes to the German Research Center for Artificial Intelligence (DFKI) for extensive knowledge transfer and for cooperating in informal projects. The authors would like to express their gratitude to German Research Foundation (DFG – Deutsche Forschungsgemeinschaft) for supporting the project "Development of methods for spatial planning with GeoWeb and Mobile Computing (Städtebauliche Methodenentwicklung mit GeoWeb und Mobile Computing)". In addition, this study used data of MSc-course "Digitale Simulationsmodelle" at the University of Kaiserslautern in the faculty of "Raum- und Umweltplanung" in the summer 2011. Due to that, we thank all participants of this course and we acknowledge their working during the seminar.

1 ABOUT THE NATURE OF 'SHARING'

'Sharing' refers to the voluntary act of giving something out that belongs to one self with good intentions. The term sharing belongs to the definition category of separation; such as 'to keep' and to 'to give' belong. In contrast, 'to share out' or 'to steal' belong to a different category, since the subject is a different one: usually, one does not own the items. In turn, if one keeps or gives items, they are usually part of one's assets or fortune and therefore, are self-referring.

'To give' can be further fragmented into two terms: (1) 'to give a gift' and (2) 'to exchange' (Lempart 2008). (1) Known in social sciences as the gift economy, it is the habit of exchanging goods and services without formal agreement about it. Depending on cultural circumstances, giver and receiver are connected through social indebtedness or other forms of social interaction (Mauss 1968). The concept of quid pro quo as well as barter trade and money exchange are not in place (yet) and therefore, is considered the forerunner of (2) exchange. In a perfect economic world, commodity exchange is handled with either money or with other commodities with no space left for personal feelings of feeling indebted. Balanced reciprocity can be characterized by the equivalence of tit-for-that, whereas in a negative reciprocity one exchange partner wants more than he is willing to give (Sahlins 1972).

Following the concept of Belk (2007: 128), "sharing is the third form of distribution", which differs from the commodity exchange as from the gift economy. Belk argues, that a few things can only be shared instead of traded or given. He takes positive sharing experiences such as a sunset, communication, as well as negative ones like "[…] guilt, shame, and proceeds of a crime in which we participate".

Subjects of sharing

When 'sharing', two or more people enjoy the benefits or costs that derive from possessing a thing. They forgo the label of mine and yours and define it as ours instead. Our sharing may be exclusive for just our use or include others in the use. One lends, allocates or pools resources and authorizes its use; usually for a prescribed amount of time. Renting out an apartment, leasing a car as well as theft or illegal trespassing are not considered sharing, since they either belong to an exchange or stealing. And of course, people share a language, cultural habits and heritage, but this happens more on an incidental than on an intended and conscious level (Belk 2007).

Looking at tangible goods, people share apartments, car rides or XXL popcorn at the cinema, whose duration is determined. In contrast, we all share architecture or famous landmarks, which will not become less even if 1000 other individuals look at it. On an intangible level, executive boards share power and responsibility. The open innovation scene is characterized by sharing knowledge, ideas and implementation time.

2 INCENTIVES & BARRIERS TO SHARE

When writing about 'sharing' incentives, it makes sense to distinguish between intangible and tangible goods. Open innovation and in particular, the internet made it possible to retain the good while giving it away (Weiner 1992); resulting in some sort of 'cheap altruism' (Coyne 2005). In this paper, the focus is on an infrastructural environment and therefore, will not be considered further in this paper.

The incentive to share tangibles was originally to offer unconditional hospitality to strangers and those in need. Nowadays, communal sharing can be found primarily in the immediate family with direct allocation of resources (Fiske 1991). Another incentive could be to be able to afford goods one would not have the resources for; in other words: leverage a lifestyle beyond individual possibilities (Belk 2007). This applies for time-share vacation homes, collectively shared cars or boats and other goods that might not appeal to a tight budget. A nice lifestyle example in this context is the online subscription model, where on can rent designer dresses and then return them when not needed anymore. When donating money to a charity or pick up friends' stuff on the way from somewhere, we feed our self-image of being a good person and helpful. Another option might be that one feels he has to give something back to society since he has been lucky in his life. As discussed above, the keeping-while-giving concept can be extended in the sense that one borrows

a driller and is expected to return it when not used anymore (Belk 2007). As Foster (1969) pointed out, the 'unlimited good' makes us believe that there is an unlimited supply of goods. Belk (2007) comes up with the example of a child admiring our collected shells on a beach and we give them to the kid without thinking about it twice. The potential determination of supply seems to indicate a decline to share; unless the good would turn bad. This may be a non-refundable ticket to a concert one is not able to go to or food leftovers that would become non-eatable the next day.

Obstacles to sharing involve many aspects, however, all of them need some sort of possession as a base. As defined above, sharing requires ownership that enables us to share with others. The feeling of possession and attachment toward our things make us less inclined to share (Belk 1992, 2007). "To the extent that we feel a possession is a part of our extended self, we are more likely to wish to retain it" (Belk 2007: 131 and as cited: Belk 1988; Kleine, Kleine and Allen 1995). Belk (2007) defines another impediment to sharing; materialism, defined as the value a person gives its possessions. "Materialists believe that possessions are the key source of happiness or unhappiness in life" (Belk 2007: 131). Despite the fact that materialism is not associated with positive values, study participants sought for a higher salary, a faster car, a bigger house and other materialistic issues (Ger and Belk 1999). Coming back to the shell example mentioned above, limited resources or the belief that resources are fixed are probably a widespread reason not to share. As far as intangibles are concerned, intellectual property rights and their competitive advantage is a major reason not to share. Hence, the coca-cola formula is still well protected as are a lot of pharmaceutical mixtures.

3 URBAN MOBILITY & SHARING

- Short introduction into individual and public transport within the framework of 'sharing'
- Exploration of multimodal transportation within the framework of 'sharing'
- STATUS: data collection

4 EMPIRIC APPROACH & DATA

- 10-15 expert interviews from various sectors (urban mobility, automotive, city planner, human factors…)
- In-situ research across different cultures and "mobility circumstances"
- STATUS: data collection

5 CONCLUSION & OUTLOOK

- The theoretical and field research undertaken so far indicate a potential gap between current user behavior and required future user behavior however, more in-depth analysis needed
- STATUS: following data collection

1 ABSTRACT

Berechnungen zum demographischen Wandel zeigen, dass die Bevölkerung in Deutschland und in den einzelnen Bundesländern mittel- bis langfristig (Zeithorizont 2020/2050) von Alterung und Schrumpfung betroffen sein wird. Oftmals werden in Bezug auf zu erwartende Schrumpfungsprozesse Themenfelder wie Wohnungsmarkt und soziale sowie technische Infrastrukturen betrachtet. Zur infrastrukturellen Grundversorgung zählt jedoch auch die Sicherheit, die sich mit dem Schutz vor Kriminalität [1] und Verkehrsunfallgefahren befasst, und damit auch bedeutsam für die Lebens- und Standortqualität der ansässigen Bevölkerung und von Unternehmen ist.

Als Folge der möglichen Bevölkerungsentwicklung ist auch mit Auswirkungen auf die Sicherheit zu rechnen. Gerade in ländlichen Regionen kann die verringerte Bevölkerungs- und Siedlungsdichte zu einer erhöhten, subjektiv empfundenen Unsicherheit der (verbliebenen) Bevölkerung führen. Beispielsweise können bestimmte Bereiche in den Städten und Dörfern von der Bevölkerung zunehmend als unsicher bzw. als „Angsträume“[2] empfunden und deshalb eher gemieden werden, obwohl diese Räume i.S. der Kriminalitätsbelastung möglicherweise keine besonderen Gefährdungen aufweisen.

In der wissenschaftlichen Diskussion besteht Einigkeit darüber, dass mit der Alterung und der damit in Verbindung stehenden Bevölkerungsschrumpfung die technischen und sozialen Tragfähigkeitsgrenzen von Infrastrukturen in Teilen unterschritten werden (können). Es besteht die Gefahr der Stilllegung von Infrastrukturen aufgrund sinkender Auslastung und Wirtschaftlichkeit. Für bestimmte, dünn besiedelte Gebiete wird dabei eine Rücknahme der Versorgung aus der Fläche prognostiziert („Anpassung durch Reduzierung“). Dabei ist auch davon auszugehen, dass Sicherheitsressourcen der öffentlichen Hand eingespart, mindestens jedoch optimiert werden müssen. Dennoch wird auch bei geringer werdender Bevölkerungs- und Siedlungsdichte ein Anspruch auf Erhalt von Mindestsicherheitsstandards in der Fläche notwendig sein, um zum einen die objektive Sicherheit der Bevölkerung in allen Teilräumen eines Landes/ einer Region zu gewährleisten und das subjektive Sicherheitsgefühl [3] der Bevölkerung zu berücksichtigen. Zum anderen kann die Sicherheitsinfrastruktur auch dazu beitragen, den Verlust von Standortattraktivität und damit die Herausbildung einer negativen „Abwärtsspirale“ in diesen Räumen zu verhindern. Anpassungen, Neuausrichtungen und technologische Systeminnovationen zur öffentlichen Sicherheit sind somit unumgänglich.

Im Rahmen des Beitrages sollen die querschnittsorientierte Problematik der Anpassung der sicherheitsbezogenen Infrastruktur im Zuge der Alterung und Schrumpfung der Bevölkerung aufgezeigt und beispielhaft baulich-räumliche, sicherheits-organisatorische sowie technologische Maßnahmen, die einen Beitrag zur zukünftigen Sicherheit der Bevölkerung leisten können, dargestellt werden.

[1] Als Kriminalität können die Taten, die im physischen sowie im virtuellen (Stichwort „Internet-/ Cyberkriminalität“) Raum stattfinden, zusammengefasst werden. Im Rahmen des Beitrages wird die im physischen Raum vorkommende Kriminalität betrachtet; das Thema „Internet-/ Cybersicherheit“ wird hierbei vorwiegend ausgeklammert.

[2] Als „Angsträume“ können Bereiche gekennzeichnet werden, die aufgrund ihrer Baustruktur, Lage oder Nutzung von der Bevölkerung nach Möglichkeit gemieden werden. Beispiele dafür sind: monofunktional strukturierte Räume, die zu bestimmten Tageszeiten kaum genutzt werden; Grünflächen, die ausschließlich als Abstandsflächen dienen und wenig gepflegt werden; Unterführungen, die nicht oder nur kaum einsehbar sind sowie insgesamt schlecht ausgeleuchtete Bereiche; Haltestellen und Wartebereiche; Parkplätze und Tiefgaragen, die unübersichtlich und zu bestimmten Zeiten wenig genutzt werden; etc.

[3] Der Begriff ‚Subjektives Sicherheitsgefühl’ bezeichnet die Einschätzung des Einzelnen seiner Sicherheit oder – aus umgekehrten Blickwinkel – der Gefahr, dass seine Rechtsgüter beeinträchtigt werden.“ Schewe, Christoph S. (2006): Subjektives Sicherheitsgefühl, Seite 322, in: Lange, Hans-Jürgen (Hrsg.) (2006): Wörterbuch zur Inneren Sicherheit, Wiesbaden, 322 – 325. Somit ist die subjektive klar von der objektiven Sicherheit abgrenzbar, die statistisch (z.B. Polizeiliche Kriminalstatistik) darstellbar ist.

2 EINLEITUNG

Im Rahmen des folgenden Beitrages sollen die Bestimmungsfaktoren des demographischen Wandels (Alterung und Schrumpfung der Bevölkerung) umrissen und mögliche Auswirkungen auf die öffentliche Sicherheit, insbesondere in alternden und schrumpfenden Räumen, dargelegt werden. Um auch zukünftig eine an das subjektive Sicherheitsgefühl der Bevölkerung angepasste Sicherheitsvorsorge [4] durch die Träger von Sicherheit [5] erbringen zu können, erscheint eine ergebnisoffene Überprüfung und Anpassung der bestehenden Standards der Sicherheitsvorsorge unumgänglich.

Der Artikel soll zudem mögliche Anpassungen, Neuausrichtungen und technologische Systeminnovationen zur öffentlichen Sicherheit, die einen wirksamen Beitrag zur Erhöhung des subjektiven Sicherheitsgefühls der Bevölkerung leisten können, in baulich-räumlicher, sicherheits-organisatorischer sowie technologischer Hinsicht an die geänderten Rahmenbedingungen aufzeigen. Damit soll auch ein Denkanstoß für die Akteure der sicherheitsbezogenen Infrastruktur gegeben und für die Thematik des Anpassungsbedarfes der Sicherheitsvorsorge in der (Fach-)Öffentlichkeit sensibiliert werden.

3 SICHERHEIT ALS BESTANDTEIL DER DASEINSVORSORGE UND AUFGABE DER RÄUMLICHEN PLANUNG

3.1 Sicherheit als Bestandteil der Daseinssorge

Die Schaffung und Erhaltung der öffentlichen Sicherheit als Aufgabe des Staates kann neben weiteren wesentlichen Gütern und Leistungen der Daseinsvorsorge (Verkehrswesen, Ver- und Entsorgung, Bildungs- und Kultureinrichtungen, Krankenversorgung, etc.) als Bestandteil der infrastrukturellen Grundversorgung charakterisiert werden, welche die Bevölkerung vor Kriminalität und Verkehrsunfallgefahren schützen soll. Somit ermöglicht die Prävention vor Kriminalität und Verkehrsunfallgefahren erst eine dauerhafte Siedlungstätigkeit und stellt einen bedeutsamen Faktor für die Lebensqualität der Bevölkerung und einen Standortfaktor für Ansiedlung und Standortvorsorge von Unternehmen–gerade vor dem zunehmenden Wettbewerb der Kommunen und Regionen um Einwohner und Steuereinnahmen–dar.

3.2 Sicherheit als Aufgabe der räumlichen Planung

Kriminalprävention, welche „die Gesamtheit aller staatlichen und privaten Bemühungen zur Verhütung von Straftaten (umfasst)“ [6] wird nicht nur von den Polizeibehörden, sondern auch durch die Kommunen u.a. im Rahmen der räumlichen Planung durch Teilbeiträge zur vorbeugenden Bekämpfung bzw. Vermeidung von Kriminalitätsgefahren umgesetzt. Durch geeignete stadtplanerische und städtebauliche Maßnahmen, wie beispielsweise durch die Anwendung der Mischung städtebaulicher Funktionen, sollen Tatgelegenheitsstrukturen im öffentlichen Raum verringert sowie der Entstehung von „Angsträumen“ vorgebeugt werden. Daneben bestehen seit längerem verschiedene Konzepte, die eine stärkere Einbindung von kriminalpräventiven Maßnahmen in die räumliche Planung zum Ziel haben und hauptsächlich auf der Block- bzw. Gebäudemaßstabsebene ansetzen. Dazu zählen die Konzepte „Defensible space“, „Crime prevention through environmental design“ (CPTED) bzw. dessen europäische Variante „Designing out crime“ (DOC) sowie die Europäische Vornorm ENV 14383-2 (Vorbeugende Kriminalitätsbekämpfung–Stadt- und Gebäudeplanung). Obwohl diese Konzepte einen Beitrag zur Erhöhung des subjektiven Sicherheitsgefühls der Bevölkerung leisten können, werden sie bisher nur in wenigen Kommunen umgesetzt.

In der gesetzlich normierten, förmlichen Bauleitplanung werden–zumindest in Ansätzen–auch Aspekte der Sicherheit behandelt: So besagt u.a. § 1 Abs. 6 Nr. 1 BauGB [7], dass die Sicherheit der Wohn- und

[4] Der Begriff Sicherheitsvorsorge kann nicht ausschließlich auf polizeiliche Aufgaben bezogen werden. Im hier verstandenen Sinne wird Sicherheitsvorsorge als Prävention vor Kriminalität und Verkehrsunfallgefahren definiert.

[5] Als Träger von Sicherheit werden vorrangig die Polizeibehörden betrachtet, wenngleich in der Praxis beispielsweise Kommunen, Private oder eine Kombination dieser („Sicherheitskooperationen“) mit dem Aspekt der Sicherheit betraut sind. Aus diesem Grund werden die unter Abschnitt 5 benannten Ideen und deren Umsetzung zur Anpassung der Sicherheitsinfrastruturen an die geänderten Rahmenbedingungen nicht nur als zentrale Aufgabe der Polizeibehörden aufgefasst, sondern auch darüber hinausgehend als Erfordernis der Kommunen und weiterer Partner verstanden.

[6] Krevert, Peter (2006): Kriminalprävention, S. 165, in: Lange, Hans-Jürgen (Hrsg.) (2006): Wörterbuch zur Inneren Sicherheit. Wiesbaden, S. 165 – 169.

[7] Baugesetzbuch (BauGB) in der Fassung der Bekanntmachung vom 23. September 2004 (BGBl. I S. 2414), das zuletzt durch Artikel 1 des Gesetzes vom 22. Juli 2011 (BGBl. I S. 1509) geändert worden ist.

Arbeitsbevölkerung bei der Aufstellung der Bauleitpläne zu berücksichtigen ist. Zwar bezieht sich der genannte Paragraph ausdrücklich auf den Aspekt der Sicherung einer menschenwürdigen Umwelt (insbesondere Beachtung des Immissionsschutzes)–zumal der Begriff der Sicherheit im Baugesetzbuch auch nicht näher definiert wird. Vertreter der Planungspraxis sind jedoch der Auffasssung, dass der „(…) verwendete Begriff der Sicherheit kriminalpräventive Aspekte auch nicht aus(schließt)–genauso wie er zum Beispiel unter objektiven Gefährdungsgesichtspunkten frauenspezifische Belange oder unter dem Aspekt der Barrierefreiheit Belange behinderter Menschen beinhaltet.“ [8] Somit sollte der Aspekt der Kriminalprävention in der Stadtplanung berücksichtigt werden. [9] Als Mangel wird aus der Praxis jedoch immer wieder beklagt, dass die für die Sicherheit zuständigen Polizeibehörden in Rheinland-Pfalz nicht als Träger öffentlicher Belange in der Bauleitplanung als verpflichtend anzuhörende Stellen beteiligt werden. [10]

4 DEMOGRAPHISCHER WANDEL UND MÖGLICHE AUSWIRKUNGEN IN BEZUG AUF DIE SICHERHEIT

4.1 Demographischer Wandel am Beispiel Rheinland-Pfalz

Verschiedene Berechnungen [11] zum demographischen Wandel besagen, dass die (erwerbsfähige) Bevölkerung in Deutschland und in den einzelnen Bundesländern, wenn auch in unterschiedlichem Maße, mittel- bis langfristig (Zeithorizont 2020 bis 2050) altern und schrumpfen wird. Zwar beinhalten Bevölkerungsvorausberechnungen keine verbindlichen Daten und Ziele, sondern verdeutlichen lediglich die generell möglichen Entwicklungstendenzen. Die grundsätzlichen Aussagen sollten aber aufgrund ihrer weitreichenden Folgen von Politik und Verwaltung beachtet werden. Als Beispiel sei an dieser Stelle auf das im Südwesten Deutschlands gelegene und in weiten Teilen ländlich, d.h. durch eine geringe Bevölkerungs- und Siedlungsdichte, geprägte Bundesland Rheinland-Pfalz verwiesen. Die Bevölkerungsvorausberechnung für Rheinland-Pfalz [12] beinhaltet in ihrer „mittleren Variante“ [13] für den Zeitraum von 2006 bis 2020 einen Rückgang der Bevölkerung um ca. 128.000 Personen (-3,2%) auf rund 3,9 Mio. Einwohner. Gleichzeitig wird eine erhebliche Alterung der Einwohner des Landes erwartet: So wird der Anteil der jungen Menschen (Bevölkerung unter 20 Jahren) in diesem Zeitraum um -17,2% abnehmen, währenddessen die Zahl der älteren Menschen (Bevölkerung 65 Jahre und älter) +11,1% sowie die sehr alter Menschen („Hochbetagte“: Bevölkerung über 80 Jahre) um +43,6% zunehmen wird. Bis zum Jahr 2050 wird sich die Entwicklung der Alterung und Schrumpfung der Bevölkerung voraussichtlich noch verstärkt fortsetzen. So wird die Einwohnerzahl um ca. 603.000 Personen auf rund 3,45 Mio. (-14,9%) bei gleichzeitiger weiter

[11] Vgl. u.a.: Statistisches Bundesamt (Hrsg.) (2009): Bevölkerung Deutschlands bis 2060, 12. koordinierte Bevölkerungsvorausberechnung, Begleitmaterial zur Pressekonferenz am 18. November 2009 in Berlin, Wiesbaden und Statistisches Landesamt Rheinland-Pfalz (2007): Rheinland-Pfalz 2050, zweite regionalisierte Bevölkerungsvorausberechnung (Basisjahr 2006), statistische Analysen Nr. 7, 2007, Bad Ems.

[12] Eigene Berechnungen auf Grundlage von: Statistisches Landesamt Rheinland-Pfalz (2007): Rheinland-Pfalz 2050, zweite regionalisierte Bevölkerungsvorausberechnung (Basisjahr 2006), statistische Analysen Nr. 7, 2007, Bad Ems, S. 134.

[13] Der zweiten regionalisierten Bevölkerungsvorausberechnung für das Land Rheinland-Pfalz liegen drei Modellvarianten zugrunde: Die untere, die mittlere und die obere Variante. Für diese drei Varianten werden gemeinsame Annahmen getroffen: Die Geburtenrate steigt von derzeit 1,32 auf 1,4 Kinder je gebärfähiger Frau bis zum Jahr 2010 und bleibt bis zum Jahr 2050 konstant. Die Lebenserwartung nimmt bei Frauen von 81,6 auf 88,2 Jahre und bei Männern von 76,5 auf 83,6 Jahre zu. Die Varianten unterschieden sich nur hinsichtlich der Annahmen zum Wanderungsgeschehen: Bei der mittleren Variante steigt der jährliche Wanderungsüberschuss im Jahr 2007 auf 5.000 Personen und bleibt danach bis zum Jahr 2050 konstant. Vgl. Statistisches Landesamt Rheinland-Pfalz (2007): Rheinland-Pfalz 2050, zweite regionalisierte Bevölkerungsvorausberechnung (Basisjahr 2006), statistische Analysen Nr. 7, 2007, Bad Ems, S. 73ff.

voranschreitender Alterung zurückgehen. Dabei wird ein Rückgang junger Menschen um -34,5%, eine Zunahme älterer Personen um +38,2% sowie sehr alter Menschen um +145,0 % berechnet.

Zudem verlaufen die skizzierten demographischen Entwicklungen in Deutschland und Rheinland-Pfalz bedingt durch Binnen- und Außenwanderungsprozesse regional sehr unterschiedlich und erzeugen dadurch unterschiedliche Wirkungen sowie demographisch bedingte Betroffenheiten. So sind parallele Schrumpfungs- und Wachstumsprozesse sowie Alterungsprozesse, wenn auch in unterschiedlicher Dynamik und Intensität, festzustellen: während die Metropolregionen in Deutschland auch zukünftig noch von einem Bevölkerungszuwachs profitieren können, werden insbesondere periphere ländliche Räume (mit Strukturschwächen) in Ost- aber mittlerweile auch in Westdeutschland [14] (z.B. Teile des Saarlandes und von Rheinland-Pfalz) von dem Bevölkerungsrückgang deutlich geprägt. Neben dem demographischen Wandel sind zudem auch Veränderungen der gesellschaftlichen bzw. sozio-ökonomischen Struktur (soziale Segregation, Vereinsamung, Abnahme der Haushaltsgrößen, Beschäftigungsstrukturen, etc.) zukünftig verstärkt zu erwarten.

In der wissenschaftlichen Diskussion wird davon ausgegangen, dass aufgrund der beschriebenen Entwicklung Tragfähigkeitsgrenzen sozialer und technischer Infrastrukturen in demographischen „Verliererräumen“ unterschritten werden (können). [15] So wird beispielsweise für die Region Westpfalz als eine der fünf Planungsregionen des Landes Rheinland-Pfalz zukünftig für weite Bereiche von überdurchschnittlichen bzw. deutlich überdurchschnittlichen technischen und sozialen Tragfähigkeitsproblemen der Infrastrukturausstattung ausgegangen. [16] Dabei besteht bei Unterschreitung der Funktionsfähigkeitsschwelle die Gefahr eines Systemausfalls bzw. einer Stilllegung der Infrastrukturen aufgrund mangelnder Auslastung und daraus folgender Wirtschaftlichkeit. Dies kann zu einem Rückzug der Infrastrukturversorgung in der Fläche („Anpassung durch Reduzierung“) in dünn besiedelten Gebieten führen. Oftmals werden in Bezug auf Schrumpfungsprozesse jedoch nur ausgewählte Dimensionen, wie die Themenfelder Wohnungsmarkt sowie soziale und technische Infrastrukturen, betrachtet. Es ist jedoch davon auszugehen, dass sich aufgrund des demographischen Wandels auch Auswirkungen auf die Gewährleistung der öffentlichen Sicherheit als Teil der infrastrukturellen Grundversorgung ergeben werden.

4.2 Mögliche Auswirkungen des demographischen Wandel auf die öffentliche Sicherheit

So sind einhergehend mit dem demographischen Wandel veränderte Kriminalitäts- und Verkehrsunfallentwicklungen anzunehmen [17] [18] , die bis zur Entstehung von „kontrollfreien“ Räumen in zunehmend dünnbesiedelten Regionen zur Begehung von Straftaten für bestimmte Tätergruppen reichen können. Denkbar ist beispielsweise auch, dass durch den Bevölkerungsrückgang die polizeilich registrierten Straftaten sowie die Anzahl der Tatverdächtigen abnehmen könnten. Aufgrund der Veränderung der Bevölkerungszusammensetzung ist zusätzlich mit einem veränderten Täterverhalten sowie, je nachdem, ob demographische Faktoren dominierend für die Entwicklung der Fallzahlen sind, leichten Verschiebungen der Deliktarten zu rechnen. Währenddessen Jugend-, Diebstahls- und Aggressions-/ Gewaltdelikte durch den Rückgang der jungen Bevölkerung voraussichtlich eher zurückgehen könnten, wäre eine Ausdehnung von Vermögens-, Fälschungs- und Betrugsdelikten durch die Zunahme der älteren Bevölkerung denkbar. Zudem besteht die Gefahr, dass Straftaten gegenüber alten und pflegebedürftigen Menschen in der institutionalisierten Pflege aber auch im häuslichen Umfeld, beispielsweise aufgrund von Überforderung,

[14] Vgl. Bundesministerium des Innern (2011) (Hrsg.): Demografiebericht, Bericht der Bundesregierung zur demografischen Lage und künftigen Entwicklung des Landes, Kurzfassung, Berlin, S. 3.
[15] Vgl. dazu: Bundesamt für Bauwesen und Raumordnung (BBR) (2005): Raumordnungsbericht 2005, Berichte Band 21, Bonn.
[16] Vgl. a.a.O., S. 110.
[17] Vgl. Spiess, Gerhard (2009): Demografischer Wandel und altersspezifische Kriminalität, Projektion der Entwicklung bis 2050, in: Naderi, Robert (Hrsg.) (2009): Auswirkungen demographischer Entwicklungen auf Sicherheitsfragen, Vorträge aus dem gleichnamigen Workshop vom 19./ 20. November 2007 im Bundesinstitut für Bevölkerungsforschung, Materialien zur Bevölkerungswissenschaft, Heft 128, Wiesbaden, S. 35 – 56.
[18] Vgl. Laubenthal, Klaus (2005): Phänomenologie der Alterskriminalität, in: forum kriminalprävention, Zeitschrift der Stiftung Deutsches Forum für Kriminalprävention, Ausgabe 3/ 2005, S. 5 – 7.

zunehmen könnten. [19] Darüber hinaus ist zu befürchten, dass sich durch die erhebliche Alterung der Bevölkerung Änderungen im Verkehrsunfallgeschehen ergeben könnten. Beispielsweise könnten Verkehrsunfälle mit aktiver und passiver Beteiligung älterer Verkehrsteilnehmer, z.B. in Folge von vermindertem Reaktionsvermögen im Straßenverkehr, zunehmen.

Für diese möglichen Entwicklungen bleibt zu vermuten, dass gerade in peripheren ländlichen Regionen eine verringerte Bevölkerungs- und Siedlungsdichte voraussichtlich zu einem erhöhten subjektiven Unsicherheitsgefühl der (verbliebenen) Bevölkerung führt und dadurch bestimmte Gebiete in den Städten und Dörfern von der Bevölkerung zunehmend als unsicher bzw. als „Angsträume" empfunden und deshalb gemieden werden könnten („Rückzugsverhalten" bis hin zur Verödung öffentlicher Räume), obwohl diese Räume i.S. der Kriminalitätsbelastung möglicherweise keine besonderen Gefährdungen aufweisen. Somit könnten aufgrund der demographischen Entwicklung subjektive Anforderungen an die öffentliche Sicherheit ansteigen.

Neben der demographischen Entwicklung beeinflussen jedoch auch weitere nicht vorhersagbare wirtschaftliche [20], gesellschaftliche [21], politische, rechtliche und technische Entwicklungen, welche Schwankungen im zeitlichen Bezug unterworfen sind, die zukünftige Kriminalitäts- und Verkehrsunfallentwicklung in Bezug auf Tatgelegenheiten, -begehungsweisen und Kriminalitäts- bzw. Verkehrsunfallschwerpunkte, etc. Als Beispiel sei an dieser Stelle die Internet-/ Cyberkriminalität genannt. Erst durch die rasante Ausbreitung und zivile Nutzung des Internets seit Mitte der 1990er Jahre konnte eine bis dato unbekannte Form der Kriminalität entstehen, auf die sich die Akteure der öffentlichen Sicherheit, beispielsweise durch die Erarbeitung angepasster Präventionsangebote, einstellen mussten. Eine weitere Herausforderung für die Gewährleistung der öffentlichen Sicherheit stellt ferner der zunehmend eingeschränkte finanzielle Handlungsspielraum der öffentlichen Haushalte aufgrund steigender Schuldlasten sowie sinkender Steuereinnahmen dar, der zukünftig voraussichtlich auch Auswirkungen auf die Sicherheitsvorsorge, beispielsweise in Form von Strukturreformen der Polizeibehörden, haben wird.

Zwar stellen die getroffenen Aussagen zu den möglichen Veränderungen des Kriminalitäts- und Verkehrsunfallgeschehens lediglich eine Extrapolation der bisherigen Entwicklung unter Berücksichtigung vorausberechneter demographischer Veränderungen dar, woraus sich mögliche Trends ableiten lassen können. Dennoch ist davon auszugehen, dass eine verringerte Bevölkerungs- und Siedlungsdichte auch strukturelle Auswirkungen auf die zukünftige Kriminalitäts- und Verkehrsunfallentwicklung hat und sich dadurch ein hoher Handlungsbedarf dazu ergibt, die Sicherheit im öffentlichen Raum zu gewährleisten. Die Veränderungen der zukünftigen Bevölkerungsentwicklung in Deutschland und Rheinland-Pfalz sind im Grundsatz hinreichend thematisiert, in Modellrechnungen erfasst sowie im Allgemeinen wissenschaftlich und praktisch erörtert. Zudem bestehen zahlreiche Untersuchungen zu möglichen Auswirkungen des demographischen Wandels auf ausgewählte Themenbereiche der öffentlichen Daseinsvorsorge. Beispielsweise wurden im Rahmen des Aktionsprogramms „Modellvorhaben der Raumordnung" (MORO) des Bundesinstitutes für Bau-, Stadt- und Raumforschung (BBSR) innerhalb des Themenschwerpunktes „Infrastruktur und demographischer Wandel" im MORO-Forschungsfeld „Masterplan Daseinsvorsorge– Regionale Anpassungsstrategien" die Auswirkungen des demographischen Wandels auf verschiedene Infrastrukturen anhand von Modellregionen untersucht und dafür angepasste Handlungsstrategien entwickelt.

[19] Vgl. dazu auch: Bundesministerium für Familie, Senioren, Frauen und Jugend (Hrsg.) (2012): Kriminalitäts- und Gewalterfahrungen im Leben älterer Menschen, Zusammenfassung wesentlicher Ergebnisse einer Studie zu Gefährungen älterer und pflegebedürftiger Menschen, Berlin.

[20] So ist ein Zusammenhang zwischen der Kriminalitätsrate und dem wirtschaftlichen Ungleichgewicht in der Bevölkerung feststellbar. Neben einer steigenden Arbeitslosenquote kann gleichfalls, wenn auch zeitverzögert, der steigende materielle Wohlstand einer Gesellschaft zu einem Ansteigen der Kriminalität führen. Vgl dazu: Landeskriminalamt Nordrhein-Westfalen (LKA Nordrhein-Westfalen) (2006): Trends der Kriminalität in NRW, eine Zeitreihenanalyse unter Berücksichtigung demographischer und ökonomischer Entwicklungen, kriminalistisch-kriminologische Forschungsstelle, Forschungsberichte Nr. 3/ 2006, Düsseldorf, S. 26.

[21] So könnte ein zahlenmäßig messbarer Anstieg der Kriminalitätsrate auch auf ein geändertes Anzeigeverhalten der Bevölkerung (z.B. bei Bagatelldelikten) zurückzuführen sein und damit auf eine Verschiebung des sogenannten Dunkelfeldes (den Strafverfolgungsbehörden unbekannte Delikte) zugunsten des Hellfeldes (den Strafverfolgungsbehörden gemeldete Delikte) der Kriminalität hinweisen.

[22] Im Gegensatz dazu fehlen bislang noch Untersuchungen und Konzepte, welche die Varianten in den Bevölkerungsveränderungen und die daraus folgenden Konsequenzen für die Sicherheit hinreichend thematisieren und Handlungsempfehlungen zur zukünftigen Gewährleistung der Sicherheit der Bevölkerung–auch im Hinblick auf die Definition von neuen Sicherheitsstandards–aussprechen.

5 ANPASSUNGSBEDARF DER SICHERHEITSVORSORGE UND HANDLUNGSMÖGLICHKEITEN

5.1 Anpassungsbedarf der Sicherheitsvorsorge

Wie obenstehend dargelegt, besteht ein Anpassungsbedarf der sicherheitsrelevanten Infrastruktur, um auf die möglichen Veränderungen des Kriminalitäts- und Verkehrsunfallgeschehens bedingt durch die demographischen Wandlungsprozesse sowie auf etwaig auftretende Kürzungen der Finanzmittel für die Sicherheitsinfrastrukturen ausreichend reagieren zu können. [23] Trotz der voraussichtlich auftretenden Änderungen bei der Kriminalitäts- und Verkehrsunfallentwicklung wird zukünftig kein wesentlich geringerer Bedarf an sicherheitsbezogenen Leistungen der Daseinsvorsorge als bisher bestehen, denn auch bei einer geringer werdenden Bevölkerungs- und Siedlungsdichte wird ein Anspruch auf Erhalt von Mindestsicherheitsstandards in der Fläche notwendig sein, um die objektive Sicherheit der Bevölkerung in allen Teilräumen eines Landes/ einer Region zu gewährleisten sowie um das subjektive Sicherheitsgefühl der Bevölkerung zu berücksichtigen und damit eine dauerhafte Siedlungstätigkeit in diesen Räumen auch weiterhin zu ermöglichen.

Anpassung der Daseinsvorsorge wird im Allgemeinen charakterisiert als „Verkleinerung, Angebotsumstrukturierung, räumliche und eventuell personelle Flexibilisierung, oder auch die Suche nach neuen Trägerschaften und Allianzen“ [24] und umfasst im hier verstandenen Sinne verschiedene strategisch und operativ wirkende Maßnahmenbündel im Spannungsfeld von Vorsorge, Durchführung und Nachsorge. Dafür werden im Folgenden für die Themenfelder „baulich-räumlich“, „sicherheits-organisatorisch“ sowie „technologisch“ mögliche Ansätze und Ideen skizziert, die eine neuartige Verknüpfung der Ebenen Regional-/ Stadtplanung und Sicherheitsvorsorge in Verbindung mit technologischen Aspekten darstellen.

5.2 Handlungsmöglichkeiten in baulich-räumlicher Hinsicht

Als mögliche baulich-räumliche Maßnahmen zur zukünftigen Gewährleistung der Sicherheit der Bevölkerung, die im Wesentlichen eine strategische, vorsorgende Wirkung entfalten, sollten die bestehenden kriminalpräventiven Konzepte in der planerischen Praxis (vgl. dazu Abschnitt 3.2) auf ihre derzeitige Anwendung und Wirksamkeit hin evaluiert und abgeschätzt werden, ob diese auch zukünftig unter geänderten Rahmenbedingungen zu einer wirksamen Prävention der Bevölkerung beitragen können. Ggf. resultiert aus dieser Überprüfung ein Weiterentwicklungsbedarf, der gemeinsam von den Polizeibehörden und der Planungspraxis in anwendungsnahen Projekten entwickelt werden sollte.

Da eine Abhängigkeit zwischen dem subjektiven Sicherheitsgefühl der Bevölkerung und den räumlichen Gegebenheiten besteht und es, wie schon erwähnt, anzunehmen ist, dass zukünftig eine verringerte Bevölkerungs- und Siedlungsdichte zu einem verstärkten Unsicherheitsgefühl der Bevölkerung führen kann, sollte es verstärkt im Selbstverständnis der Planungswissenschaft und -praxis liegen, die Entstehung möglicher Tatgelegenheitsstrukturen bzw. „Angsträume“ im öffentlichen Raum stärker als bisher vorsorgend zu vermeiden bzw. bestehende durch geeignete planerische Maßnahmen (objektiv) zu beseitigen. Für die

[22] Vgl dazu: Bundesinstitut für Bau-, Stadt- und Raumforschung (BBSR) (2009a): Masterplan Daseinsvorsorge – Regionale Anpassungsstrategien, MORO-Informationen 4/ 1 – 02/ 2009, Bonn und Bundesinstitut für Bau-, Stadt- und Raumforschung (BBSR) (2009b): Masterplan Daseinsvorsorge – Regionale Anpassungsstrategien, MORO-Informationen 4/ 2 – 11/ 2009, Bonn.

[23] Zwar werden sich aus den demographischen Änderungen zukünftig unterschiedliche Herausforderungen in Bezug auf die Prävention vor Kriminalität und Verkehrsunfallgefahren ergeben, die jeweils angepasste Strategien und Maßnahmen der zuständigen Akteure in der Praxis erfordern; dennoch werden im Rahmen des Beitrages beide Themenbereiche zusammen behandelt, um in einem ersten Schritt für die möglicherweise auftretenden Herausforderungen zu sensibilisieren.

[24] Kocks, Martina (2006): Lokale und regionale Infrastrukturplanung, S. 98, in: Bertelsmann Stiftung (Hrsg.) (2006): Wegweiser Demographischer Wandel 2020, Analysen und Handlungskonzepte für Städte und Gemeinden, Gütersloh, S. 97 – 105.

Identifikation solcher Räume ist die Verknüpfung mit empirischen Studien, wie Bevölkerungsbefragungen, sinnvoll und denkbar. Darüber hinaus ist auch zukünftig ein verstärktes Augenmerk auf die Umgestaltung von Verkehrsunfallschwerpunkten, d.h. die effizientere Planung und Ausführung von Verkehrsanlagen als Beitrag zur passiven Verkehrssicherheit und zur Prävention von Unfällen, von Seiten der (Verkehrs-)Planung zu legen.

5.3 Handlungsmöglichkeiten in sicherheits-organisatorischer Hinsicht

Aufgrund der geänderten Rahmenbedingungen (demographischer Wandel und zukünftig veränderte Kriminalitäts- und Verkehrsunfallentwicklung) sollten in erster Linie eine zukünftige Arbeitsteilung staatlicher, kommunaler und privater Sicherheitsorganisationen definiert, analysiert und bewertet werden. Aufgabe der Polizeibehörden wäre es demnach, die bestehenden Organisationsstrukturen kritisch zu überprüfen und die Frage zu beantworten, ob mit den bestehenden Strukturen auch zukünftig eine angemessene Gewährleistung der Sicherheit der Bevölkerung, gerade auch in peripheren ländlichen Räumen, möglich ist. Dazu würde auch gehören, über eine interne Umstrukturierung der polizeilichen Organisationsstrukturen und die Umnutzung bestehender Kapazitäten sowie die Optimierung der räumlichen Verteilung und Erreichbarkeit der jeweiligen Dienststellen, die jedoch ggf. auch eine Vergrößerung der Einzugsbereiche bewirken könnten, i.S. eines vorsorgenden Strategieansatzes nachzudenken. Die Ermittlung ausgewogener Standortentscheidungen und die Definition neuer organisatorischer Zuschnitte unter Berücksichtigung einer veränderten Arbeitsteilung könnte dabei durch Geographische Informationssysteme (GIS) wirksam unterstützt werden.

Es ist auch daran zu denken, die Präventionsarbeit stärker an den demographischen Entwicklungen ausrzurichten und beispielsweise Präventionsstrategien für eine alternde Gesellschaft zu entwickeln. Da die Gefahr der Opferwerdung von Senioren aufgrund der im Alter auftretenden Kompetenzeinbußen bei gleichzeitig oftmals im Verhältnis zur realen Gefahr übersteigertem Unsicherheitsempfinden gegeben ist, bedarf es Präventionsmaßnahmen, die gezielt auf verschiedene mögliche Tatbereiche (sozialer Nahraum, Internet, etc.) sowie auf die aktive und passive Teilnahme am Verkehrsgeschehen abzielen. Aber nicht nur speziell für die ältere Bevölkerung, sondern auch für die verbliebende Bevölkerung in peripheren ländlichen Gebieten, die besonders von Alterung und Schrumpfung betroffen sind, sollten angepasste Präventionsangebote entwickelt und gemeinsam mit Akteuren aus dem sozialen Bereich (Schulen, Beratungsstellen, etc.) vermittelt werden.

Durch die verstärkte Kooperation der Polizeibehörden mit Kommunen und Privaten („Sicherheits-/ Ordnungspartnerschaften“) [25] und eine insgesamt stärkere Institutionalisierung der schon jetzt in einer Vielzahl der Kommunen vorhandenen kriminalpräventiven Räte und Gremien würde auch das Ziel einer strategischen Verstärkung der bürgernahen Polizeiarbeit („Community Policing“ [26]) verfolgt werden können, was letzendlich auch einen Beitrag zur Steigerung des subjektiven Sicherheitsgefühls der Bevölkerung leisten könnte.

5.4 Handlungsmöglichkeiten in technologischer Hinsicht

Bezüglich des zielgerichteten und operativen Einsatzes sowie der Weiterentwicklung von technologischen Maßnahmen sollten die Sicherheitsorganisationen gemeinsam mit Forschungsinstitutionen und Unternehmen aus der IT-Branche zusammenarbeiten. Dazu sollten angepasst an die (Alltags-)Bedarfe der staatlichen, kommunalen und privaten Einrichtungen entsprechende Anwendungen zur Qualitätssicherung sowie

-steigerung derer Arbeit unter geänderten Rahmenbedingungen entwickelt werden. So wäre durchaus denkbar, im Polizeibereich Technologien zur Einsatz- und Fahndungsunterstützung anzuwenden. Neben der Übermittlung von aktuellen Lagedaten (täter-, gebäude- und umfeldbezogen) an die Einsatzkräfte sowie an weitere Institutionen der nicht-polizeilichen Gefahrenabwehr (Feuerwehr, Rettungdienste) bei (Großschadens-)Ereignissen, die eine schnelle Reaktion der Sicherheitsbehörden erfordern (z.B.

[25] Vgl. dazu: Schümchen, Werner (2006): Ordnungspartnerschaften, in: Lange, Hans-Jürgen (Hrsg.) (2006): Wörterbuch zur Inneren Sicherheit, Wiesbaden, S. 207 – 209.

[26] „Community Policing“ ist ein aus den USA stammendes Konzept der Kriminalprävention auf kommunaler Ebene, welches die ganzheitliche Schaffung eines Kooperationsverbundes von Polizei, Kommune und Bürger zum Ziel hat. Vgl. van Ooyen, Robert Christian (2006): Community Policing, in: Lange, Hans-Jürgen (Hrsg.) (2006): Wörterbuch zur Inneren Sicherheit, Wiesbaden, S. 44 – 48.

Banküberfälle, Einbrüche, Amokläufe), durch Augmented Reality-Techniken könnte beispielsweise eine leistungsfähige Hardware-Infrastruktur in den Dienststellen zur optimierten (Fahndungs-)Routenberechnung bei Einsätzen angewandt werden. Zudem könnte die flächenhafte Einführung von interaktiven Navigationsgeräten und Streifenwagen für die Einsatzkräfte geprüft werden.

Aber auch für die (Prozessoptimierung der) Aufklärung von Verkehrsunfällen könnten technologische Maßnahmen zum Einsatz kommen. Neben der Absperrung und Verkehrsunfallaufnahme, welche die Begutachtung und Vermessung des Unfallortes sowie die Vernehmung von Betroffenen und Zeugen beinhaltet, erfolgt die eigentliche Sachbearbeitung in der zuständigen Dienststelle. Der Einsatz von technologischen Maßnahmen im Verkehrsunfallaufnahmeprozess, beispielsweise die 3D-Ausmessung des Unfallortes sowie die direkte Informationsübermittlung an die Dienststelle (z.B. Führerscheindaten, Zeugenaussagen), könnte eine verbesserte Arbeitsteilung mit den Dienststellen sowie eine insgesamt einfachere, schnellere und gerichtsfeste Aufklärung von Verkehrsunfällen ermöglichen.

Darüber hinaus könnten technologische Maßnahmen, die einen wirksamen Beitrag zur Steigerung der subjektiven Sicherheit der Bevölkerung liefern können, in der sozialen Lebenswelt der Bevölkerung angewandt werden. Dazu zählt beispielsweise der Einsatz von Alltagstechnik (z.B. Smartphones) in verschiedenen räumlichen Gegebenheiten (Wohnung, direktes Wohnumfeld, öffentliche Straßen und Plätze, öffentlicher Personennahverkehr), die sich von intelligenten Alarmierungssystemen für den Notruf über die personalisierte Steuerung der Straßenbeleuchtung bis hin zum Einsatz akustischer Signale in (vermeintlichen) „Angsträumen“ zur Abschreckung erstrecken könnten.

Bei all diesen Maßnahmen muss jedoch im Vorfeld der Anwendung die Frage nach Ausgestaltung und Einbindung der Technologien in bestehende Arbeitsabläufe geklärt werden, um diese von den Sicherheitsorganisationen und der Bevölkerung (im Notfall) praktisch handhabbaren zu können und um Akzeptanz–gerade auch im Hinblick auf verschiedene Alters- und Nutzergruppen–für deren Einsatz zu erlangen.

6 FAZIT UND AUSBLICK

Um die in diesem Beitrag sowie die in der Literatur getätigten Aussagen bezüglich der möglichen zukünftigen Kriminalitäts- und Verkehrsunfallentwickung zu verifizieren, ist es erforderlich, in praxisbezogenen Forschungsprojekten und Modellvorhaben in vom demographischen Wandel besonders betroffenen Modellregionen Szenarien zu erstellen, die es ermöglichen, offene wissenschaftliche und praktische Fragen zu beantworten. Zum einen bedarf es näherer Informationen zum Zusammenhang zwischen dem demographischen, ökonomischen und gesellschaftlichen Wandel und den voraussichtlichen Folgen auf die Kriminalitäts- und Verkehrsunfallentwicklung auf verschiedenen räumlichen Ebenen (Bund, Land, Region). Dabei wäre auch zu klären, ob zukünftig mit einer signifikanten Änderung der derzeitigen Kriminalitäts- und Verkehrsunfallbelastung der Bevölkerung zu rechnen ist. Zum anderen wäre zu untersuchen, wie sich dieser Wandel auf das subjektive Sicherheitsgefühl der Bevölkerung, gerade auch in peripheren ländlichen Räumen, konkret auswirken könnte.

Aus den Forschungsergebnissen könnten neben den hier im Beitrag skizzierten ersten Ideen weitere kurz- bis mittelfristig umsetzbare baulich-räumliche, sicherheits-organisatorische sowie technologische Maßnahmen zur strategischen und operativen Anpassung der sicherheitsbezogenen Infrastruktur abgeleitet werden. Dazu gehören auch Aussagen zu Ausstattungsmerkmalen und Erreichbarkeiten der sicherheitsrelevanten Infrastruktur. Die Erkenntnisse könnten zudem Ansatzpunkte für mögliche Strukturreformen der Sicherheitsorganisationen darstellen und sollten in querschnittsorientierten Handlungskonzepten einer zukünftigen Sicherheitsvorsorge (in alternden und schrumpfenden Räumen) münden. Dadurch könnte gleichfalls der Verlust von Standortattraktivität sowie die Herausbildung einer negativen „Abwärtsspirale“ in vom demographischen Wandel besonders betroffenen Räumen verhindert, mindestens jedoch abgemildert werden. Voraussetzung dafür ist jedoch, dass die entwickelten Konzepte Akzeptanz in Politik, Verwaltung und Öffentlichkeit finden. Während der Umsetzung der Maßnahmen und Handlungskonzepte sollte zudem eine kontinuierliche Evaluation stattfinden, um ggf. daraus Schlussfolgerungen für eine weitere strategische und operative Anpassung der Sicherheitsinfrastrukturen an praktische Herausforderungen zu ziehen.

1 ABSTRACT

Many European cities implement shared spaces or other mixed traffic concepts in order to revitalize city centers and provide alternatives to car-centric road designs. The main idea is to treat all modes of traffic equally and encourage social interaction between road users with the prospect of cooperation over egoism. Furthermore a higher attractiveness of a road for people requires a careful traffic behavior, increased safety and lower speeds and a more attractive urban environment overall. Little research has been done how and if the new road design can also help pedestrians and bicyclists to reclaim previously car-dominated spaces.

The analyses of existing implementations can support planners by objectively showing the effect on traffic behavior. In this paper the traffic situation at the Sonnenfelsplatz in Graz (Austria) is compared before and after it has been redesigned from a complex roundabout to a shared space. The traffic flow in the investigated area is about 1.000 motorized vehicles, up to 600 bicyclists and 3.000 pedestrians in the peak hour (before reconstruction). This location has been chosen because of the diversity of traffic modes and the high traffic volume in general. Therefore, the trajectories of pedestrians, bicyclists and cars have been recorded and analyzed. Among the compared characteristics are: The spatial distribution of road users, the consistency in speed and travel times, length of paths as well as safety aspects.

Given this extensive evaluation and the lack of an existing simulation model, we also describe the requirements for developing a simulation model. A trustworthy simulation could help architects and city planners to decide if and in which configuration a shared space zone could improve an urban area. A catalog of requirements from urban planners' perspective is created and discussed.

2 INTRODUCTION

The concept of designing public roads, junctions and spaces as so called Shared Spaces is increasingly popular in recent years and is seen as a chance to reduce the car-dominance in cities throughout Europe. In shared space designs, the segregation between motorized and non-motorized traffic is removed, creating an integrated space without traffic signs or signals, curbs and road markings. Instead, traffic flows are controlled by social interactions and supported by infrastructure measures like colored roadsurfaces and the thoughtful placement of road furniture. Due to this lack of legally binding elements like pedestrian crossings, people are said to be more safety-conscious and to pay more attention to the behavior of other people (Hamilton - Baillie, 2007).

There is ongoing debate about the merits and practicality of shared space: (Hamilton - Baillie, 2007) and (Clarke, 2006), mostly show the positive factors like reduced crash statistics or average speeds. Especially when it comes to opinion-based results, the situation is not as clear anymore. Especially the elderly and disabled people feel less safe in shared spaces (Gerlach et al., 2008). Given this discrepancy between hard facts like crash statistics and public opinion, this paper wants to research the missing link in between: How has people's actual behavior in a shared space changed after a reconstruction.

Therefore, a semi-automated annotation tool was developed (Schönauer et al., 2012a) which allows fast and accurate annotations of bicycles, cars and pedestrians in a highly frequented crossing. Video footage has been recorded at the Sonnenfelsplatz in Graz, Austria before and after a reconstruction using shared space principles from a complex roundabout (see Fig. 1).

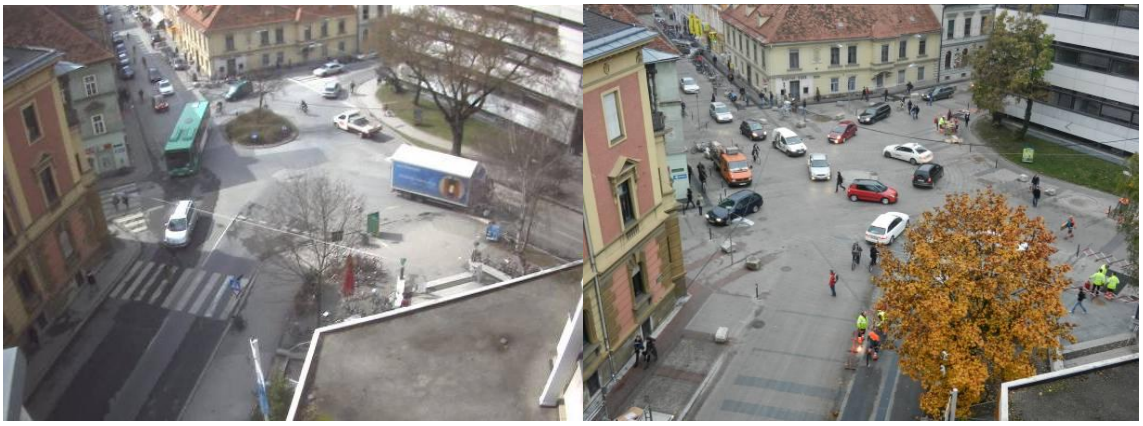

Fig. 1: Sonnenfelsplatz. LEFT: Before the reconstruction. RIGHT: After the reconstruction as a shared space.

The resulting movement trajectories of pedestrians and vehicles form the data base for further traffic flow analysis, spatial distribution of speed and interaction characteristics. The results of this analysis provide two fundamental benefits:

- The before and after comparison identifies potential benefits and drawbacks of the new road design.
- The analysis of the spatial distribution of the after data yields empirical information for civil engineers and is the basis for reliable traffic simulations.

The spatial distribution is especially interesting, as it builds the data base how the new space is actually used. The long-term goal is to link people's behavior directly to the influence of certain design elements like street furniture or trees. Therefore, after the spatial analysis, we conclude our work with discussing the requirements from urban planners' perspectives.

2.1 Related Works

With the growing number of already constructed and planned shared spaces, more research deals with the effects of the various design elements on the behavior of pedestrians and cars. Especially the UK has a wide range of reports on the design of shared spaces (Department for Transport, 2011) which act as guidelines for transportation planers and researchers the safety effects of a handful of converted shared spaces throughout Europe (Reid et al., 2009). The report summarizes the results of an appraisal stage in which available evidence on the performance of Shared Space has been collated and reviewed. It also includes a literature review by examining the most often characteristics of shared spaces. Among those are: Economic activity and property values, flows of users across the street, opinions of users, use of facilities such as seating and proportion of pedestrians moving freely. Especially the last property is a fundamental idea of shared space, but Reid acknowledges there is little data available. We try to fill this gap by analyzing the pedestrian paths using trajectories obtained from annotated video footage.

Many of the other properties are often examined by opinion polls. E.g. (Kaparias et al., 2011) describes a stated-preference study which queries specific elements of a shared space (like pedestrian density, vehicle density, speed of verhicles, …) which affect the willingness of drivers to actually share the space with pedestrians in a shared space.

Actual change in behavior by doing video analysis has been researched by (Bliek, 2010) by comparing the probability of cars stopping at intersections of conventional roads to the probability at redesigned shared spaces in Montreal. Two shared space crossings were compared to two reference crossings with similar properties of size and traffic volume. It was observed that drivers are more likely to give way to pedestrians on the shared spaces than on the conventional crossings.

(Karndacharuk et al., 2011) provides an extensive data aquisition and analysis of behavior in three streets in New Zealand which have been converted to shared spaces. Their performance indicators include: Dwell times, activities (eating, chatting, …), retail ocupancy rates in the area, speed reductions for cars and overall crash history. At the time of this writing, however, only the „before" period has been captured and analyzed, the data of the „after" period will only be fully analyzed in late 2012.

The conclusion of literature research indicates that there is not a well-defined set of optimization attributes which fits for every shared space. Depending on the surrounding and intention of the shared space, sometimes it could be beneficial to increase the dwell times of pedestrians, while in other situations the main objective could be the reduction of the travel times of pedestrians. The only recurring objective is, however, that shared spaces should encourage shared usage of the space instead of retaining the old behavior on a newly designed road. This is also the main research objective of this work.

3 BEHAVIOR ANALYSIS

As we have explained previously, Shared Space is rather a design guideline with multiple different ways of interpretation instead of a ready-to-use design which is implemented the same way in all projects. Thus we must acclaim that our findings are not necessarily transferable to any other Shared Space – it can, however, be used as the basis for verifying and refining existing guidelines.

3.1 Data Collection

Data has been collected at the Sonnenfelsplatz in Graz before and after the reconstruction to a Shared Space. In 2009 a classical traffic survey was conducted (Koop. Sonnenfelsplatz, 2009) counting the vehicular flow and the number of pedestrian crossings. It shows a pedestrians crossing count of about 3.000/h , a total daily traffic volume of up to 1.500 cars/h and a cycle rate of 12% (including a marginal part of motorbikes). Table 1 gives the number of counted traffic participants and the time of survey.

		Traffic survey 2009	Video analysis: Roundabout 2010	Video analysis: Shared Space 2011
DATE	**weekday, date**	Thursday, 15.10.2009	Tuesday, 23.03.2010	Thursday, 27.10.2011 / Friday, 28.10.2011
	time	06:00 - 20:00	12:53 - 12:57	10:38-12:42 (12:40 – 12:42)
COUNT	**pedestrians**	between **510** and **860** P./h at every crossing (12:00-13:00)	55	75(43)

	cars, busses, trucks	**941** between 12:00 - 13:00 **(15162** in 14h)	49	115(43)

Table 1: Road traffic survey and Data Collection Overview.

For this paper the movement trajectories of pedestrians and vehicles have been generated by tracking the objects in video footage and transforming the trajectories to world coordinates. Semi-automated tracking is used to obtain the data (Schönauer et al., 2012a). Fig. 2 shows an screenshot of the data annotation process in the video pictures.

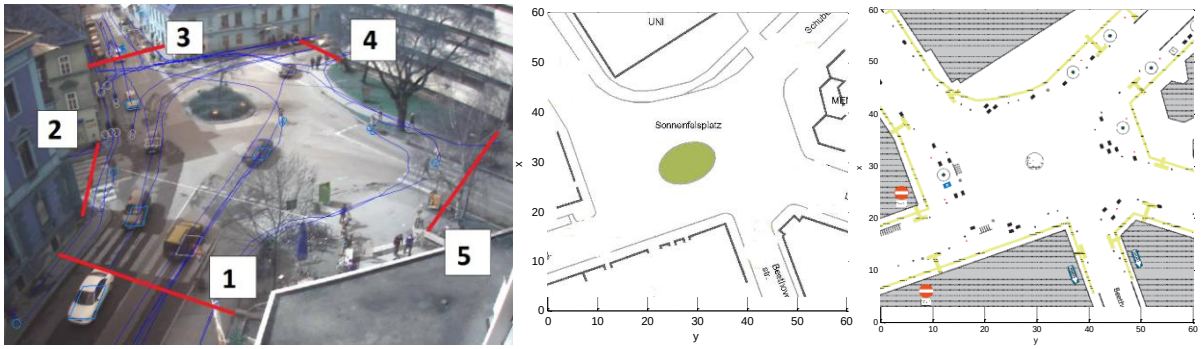

Fig. 2: LEFT: Screenshot of the pedestrian and vehicle tracking at the Sonnenfelsplatz in 2010, showing the measurement lines (red) and its numbers. MIDDLE: Scheme of the original design. RIGHT: Scheme of the new design

Road users are classified into pedestrians, bicycles and cars and tracked during their time inside the origin/destination measurement lines. The analysis focuses on two comparable scenes of a duration of several minutes in both the roundabout in 2010 and the Shared Space in 2011. The intersection of a trajectory with two of the five measurement lines (indicated with red lines in Fig.2) assigns the origin/destination to every track. In the further steps these trajectories are analyzed regarding spatial behavior, speeds and interaction properties.

3.2 Space usage

The willingness to share the available road space between traffic modes is a major aim of the Shared Space concept. This chapter qualitatively shows for each mode the spatial distribution change of the chosen paths. Before the reconstruction, the individual choice was narrowly constrained. On the left side of Fig.3 it is

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

shown that pedestrians (red) cross the road in the area of the crosswalks. Bikes (green) and cars (black) follow the regulations to circle the central traffic island. Overtaking maneuvers of bicycles can be observed within the roundabout.

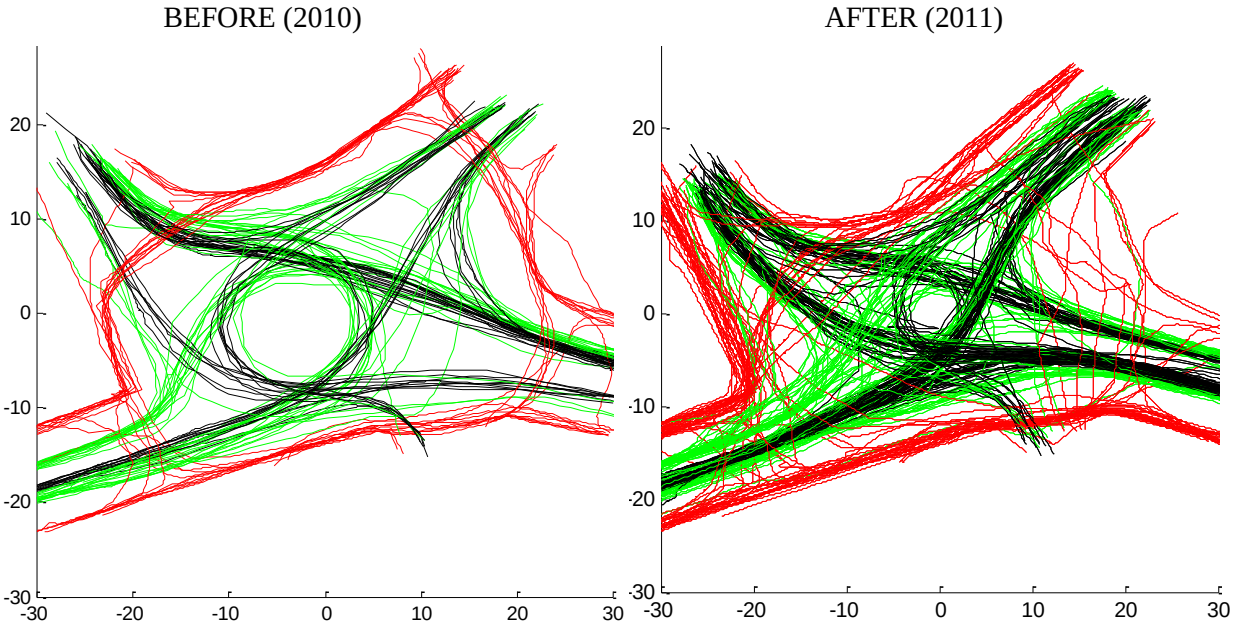

Fig. 3: Trajectories of pedestrians and vehicles. LEFT: Roundabout in 2010 (before). RIGHT: Shared Space in 2011 (after).

After the reconstruction several changes in the walking behavior can be observed. Pedestrians crossing the road are now using shorter paths closer to the squares center (Fig.3, right hand side). A higher variety in individual path choice can be observed, especially in crossing the road.

In the new design a slightly elevated island forms the center of the square, causing a white spot in the trajectories (Fig.3, right hand side). However, the islands' dimensions have been reduced from 8m x 11m to about 3m x 3m. Due to the smaller island the driving radii have also changed: At low turning angles (going "straight") the radii increased - at "U turns" the radii in cars and bikes trajectories decreased.

The trajectories in Fig.3 imply two phenomena in the redesign reducing path length and the travel time:

- A shift of the pedestrian crossings to the square's center.
- Changes in the driving radii of vehicles.

Travel time, average speeds and path length were calculated for each cell in the origin/destination (O/D) matrix. The empirical weight (number of samples in this mode and O/D relation) was considered in cumulating the results for each mode. The classification into O/D releation generates small groups of trajectories for most of the links and the statistical significance shows that the standard deviation error is refusing the tests. Higher sample sizes could provide a better statistical validity. To overcome the lack of data the next approaches do not split the trajectory sample into O/D relations.

3.3 Speed distribution

For the investigation of the speeds additionally to the path in world coordinate’s accurate timestamps for each single point are required. Therefore the camera encodes the timestamps in each single video frame in real time and errors caused by frame drops and deviating frame rates can be identified and taken into account. For a better comparison the whole trajectories were resampled to 0.1 second intervals which corresponds a frame rate of 10 frames per seconds using a linear interpolation algorithm.

The speeds are calculated for each segment in a trajectory using two neighbouring points and timestamps. For the computation of the speed distributions, the speed values are smoothed using moving average over the last two values. This was necessary to reduce jitter resulting from the annotation on discrete pixel positions in the video frames getting transformed to real world coordinates.

In Figure 4 the speed distributions for each mode separately are shown from left to right and for comparison between the roundabout with the Shared Space configuration one upon the other.

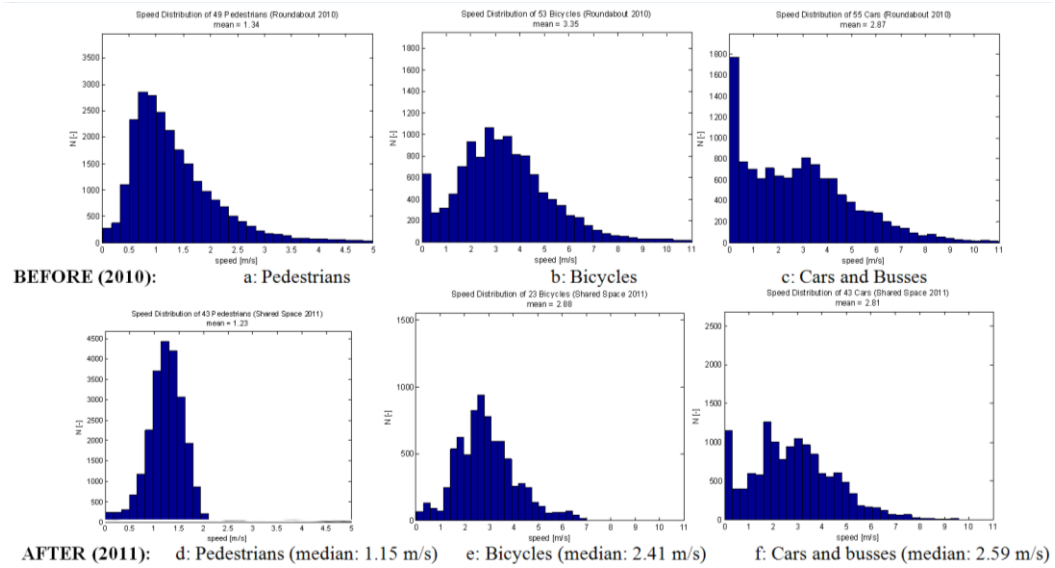

Fig. 4: Histograms of speeds before and after the reconstruction.

Inspecting the shape of the distributions in Shared Space for all modes they are narrower indicating a more constant speed and less stop and go behaviour compared to the roundabout. The mean speeds decrease in Shared Space as well as the speeds maximums. This could be an indication that people in the roundabout make short runs to pass the street before the vehicles arrive. The desired speeds within pedestrian crowds are Gaussian distributed with a mean value of approximately 1.34 m/s and a standard deviation of about 0.26 m/s (Henderson, 1971). The mean speed fits perfectly with the observed pedestrians in 2010, the distributions in the observations show standard deviations of 0.79 (before) and 0.37 (after).

The walking speeds in the Shared Space are lower but due to the shorter routes the total travel times decreases. For the cars the main difference is shown in much lower peaks in the Shared Space at lower speeds indicating less waiting times and a more continuous flow. In the following the spatial distribution of the speeds is investigated.

3.4 Speed maps

Driving and Walking speeds are major traffic performance and safety indicators. To show its spatial distribution the modal speeds are calculated for a cell grid of a grid size of 1m x 1m. Based on the generated grid speeds an estimator algorithm provides continous calculation of speeds in the map. The result is shown in Fig. 5.

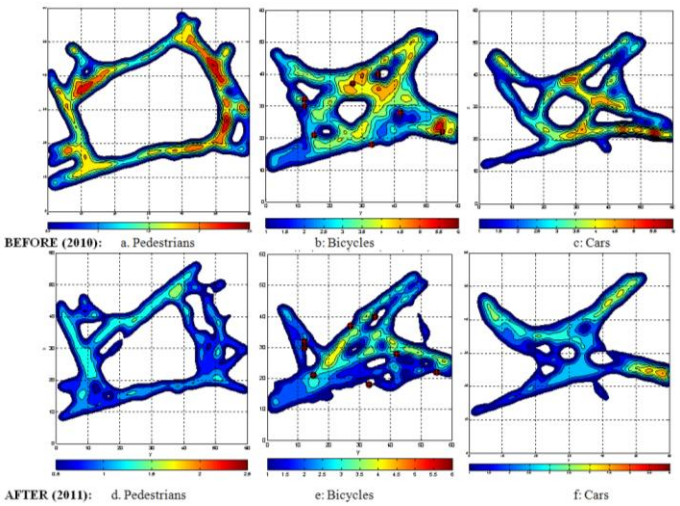

Fig. 5: Modal map of estimated speeds, based on cell grid speeds, all speeds in m/s. TOP: 2010. BOTTOM: 2011.

In the pedestrian class the main change is the shift to a more homogeneous speed level, especially the crossings of the roads are done in steady speed, which correlates with the findings in chapter 3.4. While

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

bicycles' speed levels generally has dropped, their maximum speeds lie close to the center of the square. Reasons could be the higher awareness or the reduced space and a higher number of obstacles for bicyclists.

Car traffic speeds went down, especially in the area of interactions with all other modes the average speed level clearly sunk. In Fig.5b and Fig.5e the registered accidents in which bicyclists were injured between 2006 and 2008 (Koop. Sonnenfelsplatz, 2009) are marked by an red cross in a black filled circle (only in the central column). The comparison to 2011 shows that within all this spots the average speed sunk significantly. No accidents including pedestrian injuries have been recorded. At the time of submission no accidents in the redesigned scheme have been reported.

3.5 Safety aspects

Safety studies focuses often focus on the interaction between and within motorized and non-motorized traffic, as well as the conformity to traffic control regulations. Traffic safety analysis has traditionally relied on historical collision data. However, the shortcomings with this approach are the rare and random occurrence of collisions and its poor availability of data. Traffic conflicts are more frequent than traffic collisions. The first concept of road traffic conflict techniques (TCTs) was proposed by Perkins and Harris (1967) and involve observing and evaluating the frequency and severity of traffic conflicts at an intersection by a team of trained observers. Ismail et al. (2010) use indicators of time as objective and quantitative measure of the severity of conflicts.

This paper wants to outline the impact of speed and distance between traffic participants. We define a new indicator, including relative speed, and distance in time and space of a pair consisting of a non motorized road user and a car. It is calculated as the quotient of the squared relative speed and the distance between the object. Side constrains are the maximum distance of 5m and a time difference of maximum 3 seconds. To offer a spatial analysis we calculate for each 1m x 1m cell in the survey spot the median of the elements:

$$C_{xy} = \frac{1}{n * i * j} \sum_{\alpha=1}^{i} \sum_{\beta=1}^{j} \sum_{n=1}^{length(traj_i)} \frac{\left|(\vec{v}_\alpha - \vec{v}_\beta)\right|^2}{d_{\alpha\beta}}$$

,

where Cxy gives the relative squared speed by distance quotient for the cell at x,y. The vectors vα, vβ are the speed vectors of the bike (respectively pedestrian) α and the car β which are at a distance dα,β. A total number of i x j couples of i bikes (resp. pedestrians) and j cars are considered. The choice of data couples is constrained by distance in space (<1m) and time (<0.5s)

This indicator offers a simplistic approach to identify the spatial distribution of safety relevant variables. Fig. 6. shows the indicator Cxy calculated for 2010 and 2011, for pedestrians/cars and bikes/cars.

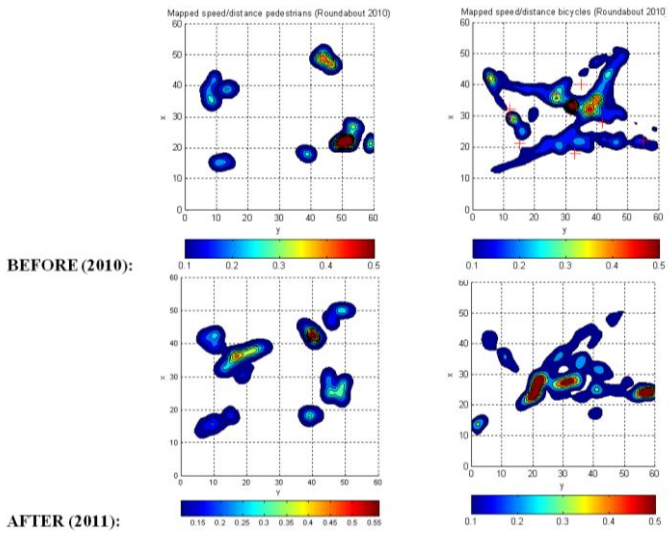

Fig. 5: Indicator Cxy based on cell grid speeds [m/s]. TOP LEFT: Pedestrian/Cars in 2010. TOP RIGTH: Bikes/Cars in 2010 (red markings for accidents during 2006-2008). BOTTOM LEFT: Pedestrian/Cars in 2011. BOTTOM RIGTH: Bikes/Cars in 2011.

The higher values represent spots where pairs of non-motorized road users and cars meet at higher speeds and lower distances. The comparison of BEFORE and AFTER shows that the hot spots moved and for bikes got even concentrated. Considering the lower driving speeds an explanation could be the smaller vehicle driving space and the smaller distances between vehicles. There is no scientific evidence to directly conclude to accident probabilities. Nevertheless hot spot areas are close to the occurred accidents in 2006 to 2008 (indicated in red crosses in the Fig.5, top right). Nevertheless the method has to improved including conflict classifications to generate prediction qualities. One major finding is that the total sum of all cells went down by about 10%.

4 APPLICABILITY IN THE PLANNING PHASE

Shared Space is a so far seldom implemented design concept that makes it difficult to point to existing examples. Furthermore, examples of Shared Space differ from each other because of the big variety of local conditions, design elements and traffic mixes. This makes it extremely difficult to show the effects of a planned Shared Space with the presently available tools. Different topography, complex traffic situations and a wide variety of design elements are a great challenge for planners.

The behavior analysis from Chapter 3 gives the confirmation that the intended goal of remixing the traffic at the Sonnenfelsplatz did happen. However, it is still hard to conclude which specific elements helped to achieve the effects – making it difficult to assess the impact of potential future Shared Space projects. Therefore, we suggest creating a realistic Shared Space simulation which could help in the planning phase for future projects. A simulation model allows the planners to test the effects of different design elements before they are built. It could help during the concept phase by

- addressing capacity concerns,
- determining potential bottlenecks and
- improving safety and comfort

It also would be suitable to illustrate the traffic flow in a planned Shared Space to citizens, politicians and stakeholders. The persons concerned should get a clear view, how the new design would work.

4.1 Planning requirements for the simulation

The difficulty lies in the identification and proper modeling of various design elements. Several design elements and traffic characteristics must be taken into account for an appropriate simulation. Also different road users have various characteristics and differ in traffic behavior and must therefore be simulated separately. The final important requirement is modeling the correct origin-destination relations as the space usage might change completely with additional offers like benches or other places to stay.

4.1.1 Types of road users

The foremost question is to decide which type of road users must be present in any Shared Space simulation to be helpful at all:

- Motorized vehicles, pedestrians and bicyclists are widespread in Shared Space. Private motorized vehicles should be treated separately in three classes: passenger cars, motor-bikes and heavy vehicles.
- Public transport occurs not in every Shared Space area. But if it does, it is very important, that it can be simulated, especially when the stations are located close to the investigated area and congestions caused by i.e. bus stops reach back in the shared space area.
- Persons in wheel-chairs and blind people are not wide spread, but call for a special approach not only in the simulation but in planning generally.
- Other road users were found to be not so important for the simulation. Such as emergency vehicles are so seldom, that their priority for the simulation is lowest.

4.1.2 Design elements

Different design elements affect traffic behavior in different ways. Road users stay away from poles, hedges and trees. Seats are obstacles as well, but also points of interest. Curbs, grassed areas and trees have a

separating and a guiding effect on traffic behavior. Different colors of the sidewalk influence traffic behavior in a softer way. The structure of the surface influences the chosen route through an area or to a destination. Points of interest like shops and seats attract the road users.

Given the vast number of different design elements outlined above, these determining factors call for an accurate analysis of effects of design elements on the traffic behavior and the interaction between the road users.

4.1.3 Origin and destination points

The most common origin and destination points for all road users are at the borders of the planning area where they enter or exit the shared space. Within the area different road users have different points of interest, which attract them. Important points for vehicles in general are parking facilities. Cyclists do not use cycle stands only but also poles for parking. Stations of public transport are origin and destination for vehicles and for passengers as well. Entrances are the primary origins and destination of residents. Shops and restaurants are origin and destination points for pedestrians and cyclists. Some elements as shop windows attract people. They are origin and destination and invite people to stay for a while.

4.1.4 Prioritization

The great number of design elements and the various traffic mixes makes it necessary to identify the most relevant factors, which should be included in the simulation. The criterions for the assortment are occurrence, relevance and the data availability. These criterions are applied to the road users, to the design elements and to the origin-destination relations:

- The occurrence describes the frequency of different road users and design elements in existing Shared Space areas. If a certain type appears often, it is important that it is represented in the simulation. The absence of seldom types is acceptable.
- The relevance takes the effects of a certain element into account. Some different elements influence the traffic flow in a similar way. Such elements can be simulated as one.
- The data availability was treated for a pragmatic reason. Even if an element occurs often and affects the traffic flow it cannot be simulated if there is not enough information about it available.

These criterions are categorized in three classes for every type of road user, for design elements and for different origin-destination relations. The single criterions are aggregated to the criterion priority. The priority stands for the importance of an element to be represented in the simulation model and often depends on cultural peculiarities. For the analyzed area in Austria, following the above criteria the priorities of road users are cars, bicycles and pedestrians. The most important design elements at the Sonnenfelsplatz are obstacles like pollards, benches, greens and side areas where pedestrians feel safe.

4.2 Outlook

Given the extensive behavior analysis and analysis of planning requirements, the first steps towards a generic simulation framework suited for Shared Space planners have been done in (Schönauer & Schrom-Feiertag, 2010), (Schönauer et al., 2012b) and applied to two fundamentally different locations in Austria. Future research work deals with the effects of more design elements like benches or different road surface materials.

5 CONCLUSION

We have shown an approach to validate the effectiveness of a shared space implementation in an environment with highly diverse traffic modes. Especially at times of little traffic, the usage of the available space has changed and not only pedestrians but also cars use more abbreviations, leading to shorter paths and lowered travel time. Against our expectations, the travel times of bicycles did increase slightly though. Possible causal explanations could offer the lower turning radii and the higher conflict potential in the centre of the square. Statistical shortcomings in the analyze can't be excluded completely and further investigation is needed.

The paper shows the spatial distribution of path choice, resulting in a clearly wider variety in walking and driving positions. The distribution of speeds shows a lower mean and a higher homogeneity for all modes. Finally a new approach is applied to show the spatial distribution of quotients of relative speeds and distance

of pairs of non motorized road users and a cars. The result shows shifts in location and intensity of the "hot spots". The comparison with locations of historical accident is done. To conduct valid correlations or even do accident predictions more research is needed.

Furthermore, we have given an overview of the requirements of transport planners in Shared Space projects. This helps towards creating reusable design guidelines and later even a simulation model. However, there is still a missing piece in linking specific design elements to the behavior of people. This paper gives specific guidelines for the analysis of people's behavior in shared spaces. Using these analysis techniques the effects of placing certain design elements can be validated by comparing the trajectories in an before and after study.

6 ACKNOWLEDGEMENTS

The authors thankfully acknowledge Christian Rudloff and Dietmar Bauer for their continuous valuable contribution and support on this research topic. Further, the authors thankfully acknowledge Stefan Schrom and Clemens Vierthaler for video annotation, Christopher Lindmayer for providing a road design scheme and the planning team Kooperation Sonnenfelsplatz for providing traffic survey and accident data.

The work on that paper is part of the project MixME. The authors gratefully acknowledge the support of the Austrian Ministry for traffic, innovation and technology (BMVIT) by funding the project within the national funding framework IV2Splus.

Socio-Technical Assisted Neighborhoods

Annette Spellerberg, Lynn Schelisch

(Prof. Dr. Annette Spellerberg, Department of Spatial Planning, Urban Sociology, University of Kaiserslautern, annette.spellerberg@ru.uni-kl.de)
(Dipl.-Ing. Lynn Schelisch, Department of Spatial Planning, Urban Sociology, University of Kaiserslautern, lynn.schelisch@ru.uni-kl.de)

1 ABSTRACT

In a joint project, engineers and sociologist develop a technical and social assistance system providing functions in the domains of comfort, safety, health and communication to enable older adults to live independently as long as possible in their familiar domicile. In the course of the project, apartments of older tenants in an existing housing stock are equipped with an Ambient Assisted Living (AAL) system. Next to technology, social integration plays an important part in the project. First results show that after a few months already the socio-technical system may encourage the involvement of the elderly into the residential district and help to avoid loneliness. Further research has to show to which extent the system also contributes to the domains of safety and security, as well as health.

2 INTRODUCTION

In aging societies, most elderly people wish to stay in their self-chosen-environment as long as possible, even if they experience a growing loss in quality of life and health problems. At the same time, the traditional system of care for older adults ceases and the costs for professional care constantly grow.

There are various approaches to reach the goal of living an independent daily life in the familiar domicile despite these conditions. Some of these approaches include technical solutions, such as wheel chair lifts, remote controlled shutters, in-house emergency call stations or door cameras. Others embrace alterations to the home, such as enlarging doors or mounting hand rails in the bathroom. Some of the mentioned solutions are already widely spread and may help an elderly person to move more easily within the home or enhance the feeling of safety and security. However, they are often limited to the home and only cover certain aspects of aging, e.g. constrained movement, which does not apply to every elderly person by far. Other aspects such as loneliness or the need of low-threshold assistance for housework or grocery shopping are left aside. As a consequence, new concepts, including social and technical solutions, have to be developed.

The mobilization of social communities in neighborhoods currently receives significant attention from policy and decision makers in the field of social planning and in the housing industry. Vibrant neighborhoods are expected to enhance the quality of life of senior citizen as well as their ability to live an independent daily life. For an active neighborhood it is often necessary for it to be supported and guided–for example by active individuals, community centers of municipalities or nonprofit clubs or by a community facility of the landlord.

Since August 2010, engineers and sociologist at the University of Kaiserslautern, Germany work together with different partners in the field of social service, technicians, and a cooperative building society in a joint project [1] ("Technisch-soziales Assistenzsystem für Komfort, Sicherheit, Gesundheit und Kommunikation im innerstätischen Quartier–TSA)" on the development of an assistance system for independent living for senior citizens living in an urban area.

3 THE TSA PROJECT

The purpose of the TSA-system is to assist senior citizen in daily life by providing functions in the domains of comfort, safety, health and communication and by promoting their social integration with the help of an active neighborhood community and involvement into the residential district. The project comprises a technical and a social part, which intertwine [Schelisch 2011].

[1] The project is funded by the German Federal Ministry of Education and Research (BMBF) as part of the initiative "Altersgerechte Assistenzsysteme für ein gesundes und unabhängiges Leben – AAL" and takes place between August 2010 and July 2013.

3.1 The Technical Concept

One aim of the project is to equip several apartments of elderly tenants in existing housing stocks with an Ambient Assisted Living (AAL) system. In this case, ambient means a technological environment which is intelligent, but not necessarily noticeable, and adapts to the daily lives of users. AAL systems may include networks of various switches, sensors, and actuators, and also special equipment such as video cameras, emergency assistance systems, and central control terminals. AAL is seen as a promising contribution in helping to live independently and safely in the familiar domicile. But until now it is not clear which technological concepts and which single devices are of use for elderly people and are accepted at the same time. Apart from pilot projects AAL-technology is not prevalent in senior households. Therefore, one objective of the practical project is to directly involve the target group into the development process of an Ambient Assisted Living system.

The ambient technology in the TSA project consists of different wireless home automation components, such as motion detectors, door and window reed contacts, remote controlled lights, a door camera, and other home automation devices. The core integration element of the technical system is a touch screen computer based unit named “PAUL” (Personal Assistive Unit for Living), developed by the University of Kaiserslautern and CIBEK technology + trading GmbH [Schelisch/Spellerberg 2009]. PAUL enables the user to control the home automation equipment, use different features in the fields of media and entertainment (e.g. news, radio, internet access to certain webpages, photo album, calendar of events, alarm clock) and communication (e.g. video telephony, virtual bill-board) and also comprises an ambient emergency detection system [Floeck/Litz 2009; Rodner et al. 2011].

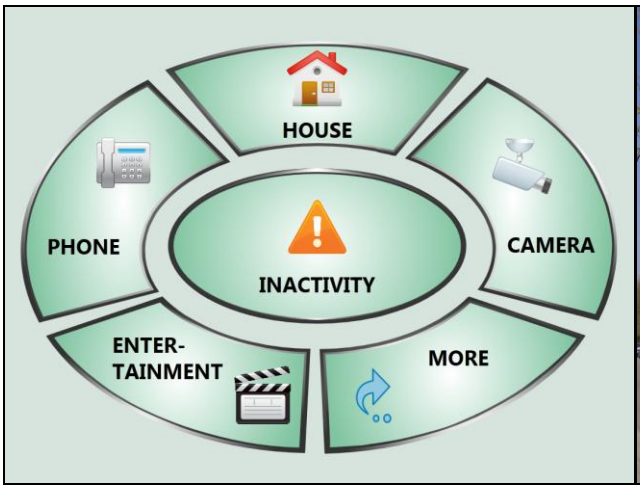

Fig. 1: Entrance Screen of PAUL. Fig. 2: Housing Stock of the GBS in Speyer, Germany.

In a previous project, most technical features and their usability for the elderly were tested over a period of three years in a newly constructed building [Spellerberg 2010]. In contrast, the apartments in the TSA project are equipped with wireless components for the most part, which allow an installation without constructional changes.

Between summer 2011 and spring 2012 ten out of 20 targeted apartments in the German cities of Speyer (Gemeinnützige Baugenossenschaft Speyer, GBS) and Kaiserslautern (Deutsches Rotes Kreuz, Kreisverband Kaiserslautern) were equipped with a PAUL each. All apartments are situated in different buildings, which were built in the 1920s and 1960s for the most part. As the development of the TSA system is an iterative process and the direct involvement of the target group into the development process of the technology is relevant in this project, not all functions were installed right from the start. At first, all home automation devices (besides the door camera) and in the fields of entertainment and media were installed, functions in the field of communication were added about four months later. A first testing phase of the ambient emergency detection system will be started soon. Other functions will follow within the year 2012. Although remote controlled shutters are not part of the initial technical concept, the participating households in Speyer have the possibility to upgrade their apartment with electric shutters for a low monthly fee (six Euros per shutter) and operate them via PAUL. Four out of eight participating households have already made use of this possibility.

3.2 The Social Concept

The social part of the assistance system consists of establishing and maintaining social contacts in the neighborhood and the integration of general and special services from facilities nearby. At this point, the local neighborhood club plays an important connecting role. The neighborhood club was founded in 1999 and is managed by a social worker. The club offers coffee parties, seasonal events, readings, cooking sessions, as well as promotion of neighborly help, assisted grocery shopping, and so on. Especially elderly people make use of consultation. The club also acts as a multiplier for tenants interested in participating in the project.

One aim of the TSA-project is to enable the participants to order domestic support services and other additional services from their district with the help of PAUL. These services may include services of the landlord (repairs), the local neighborhood club (promotion of neighborly help, assisted grocery shopping), a nearby nursing home (warm meals, laundry service, and procurement of other services), the German Red Cross (ambulatory care, social services, housekeeping service), doctors, hairdressers and other facilities nearby. The requests for these services are to be posted by the participants directly via PAUL's touch screen (development by CIBEK) or by a video telephone connection to a concierge. In the TSA project the concierge is situated at the nearby nursing home (Speyer) and the German Red Cross (Kaiserslautern), respectively. The concierge will then forward the request to a service provider, which preferably is located close to the participants dwelling. This service will presumably be launched in summer 2012.

3.3 Sociological Research

In order to evaluate the requirements, experiences and acceptance of the assistance system and determine the perspective of the users, the project is supervised by sociological research. To gather feedback, the participants were interviewed ahead of participation and will be questioned several times during the project duration. At regular meetings in the facilities of the local neighborhood club, organized by the sociologists, the participants of the TSA project exchange experiences and discuss how the concept may be developed further. The information about which functions work and are regularly used and which cause problems or are less used are directly taken into account for the ongoing development of PAUL and the TSA system.

In addition, a written survey of tenants of the GBS aged 60 and older (n = 171) was conducted to find out more about the general acceptance of AAL technology, the willingness to pay for the installation of certain devices in the field of home automation and health technology and to assess the needs of service offers requested via PAUL [Schelisch/Spellerberg 2012].

3.4 The Participants

Suited for participating in the TSA project are all tenants of the two participating landlords aged 60 and up (exceptions are possible). Because PAUL is designed to be self-explanatory, the participants do not need to have any special skills. Tenants with little or no technological competence so far are also welcome. The participation, including the use of all technical devices and a 24-hour home emergency call service, is free of charge.

Currently, ten tenants in Speyer (eight households) and two tenants in Kaiserslautern (two households) participate in the project. The eight female and four male participants are aged between 52 and 86 years. The average age is 72. Only four of them, including the three youngest, have ever used a computer, only two have internet access at home. Three (female) participants can be considered as technophile. The state of health was quantified by their personal rating: except for a younger man, all participants have medical issues, including one woman having multiple sclerosis and two who fell down several times already and are not able to leave their apartments alone. Five of the twelve participants show a confident interest in participating; six others seem to participate mostly because family members (children or partners) wish them to do so. Yet another person shows an interest in participating, but only because of the health functions of PAUL.

3.5 Results so far

The results of the quantitative study show a relatively high level of acceptance to use AAL-technology at home from the perspective of potential users, especially in the fields of safety and health. However, a market potential for the tested techniques may not necessarily derive from the statements on the acceptance of use. Seniors are often very reluctant in the use of technology, even if they have very positive attitudes [Meyer et

al. 2001]. They often mean the need of the devices for “others”, while they would not use them in their own home. This was also attested in the acquisition of new participants. In the beginning, the acquisition of new participating households was very difficult. Often people were generally interested in participating, but rejected for various reasons, e.g. if the partner (mostly husbands) had no interest or if they felt not to be “old enough”, although their age fit well to the project. However, after several months, the project has spread. As many of the participants willingly provide information to family members, neighbors, and friends about the functions PAUL has to offer, current prospects are for the most part acquaintances of persons already participating. Other interested tenants are recruited by the local neighborhood club. Without the local neighborhood club and its support as a local first port of call, the acquisition of new participants would not work.

In spring of 2011 oral interviews were conducted with the first seven participating households [2] of the TSA project in the framework of the sociological research. The participants were asked to comment on 24 different service offers (e.g. delivery of groceries, hairdresser service at home, repair services and home cleaning) and to indicate whether they use these services at present or would like to use one or more of them. Overall, it is found that the interviewees have a positive attitude towards the proposed service offerings, and would make use of professional help, but only in case the support cannot be covered by family members or other acquaintances. Most interviewees emphasized that they would only make use of the services if there is an urgent need. Furthermore, financial reasons also play a crucial role in the actual acceptance of support services. The interviewees want to keep living independently as long as possible, even though it becomes cumbersome for them. Furthermore, they turn down outside help in order to stay "busy" or feel "fit”. The projected possibility to order these services via PAUL was valued positively by a total of six of the eight interviewees.

Although a comprehensive survey about the use of the different functions of PAUL is only scheduled for summer 2012, one can already get an idea about the use of PAUL by the participants. Talks and discussions with the participants show different levels of acquisition. While some use PAUL on a daily basis and try out new functions by themselves, others only look at PAUL from time to time and wait for the ambient emergency detection system to be launched and for the door camera to be installed. For the latter persons, only functions in the field of health and security are important .[3] Participants, who use PAUL very often, also mention more suggestions for improvement. Desired improvements mentioned by the participants in the TSA project include a better navigation of the internet access, a desired possibility to exchange written messages and pictures to other PAUL users, as well as individual changes of saved radio frequencies and websites. All mentioned suggestions for PAUL belong to the fields of entertainment and communication.

Even though PAUL is designed to be used without instruction also by people with no or little computer literacy, earlier results in a similar project in Kaiserslautern indicate that PAUL might not be suitable for people suffering from dementia. Even a previously self-evident use of PAUL can be "unlearned".

It is aspired that the TSA system enables the elderly to become connected to other people in the neighborhood and thus enforce face-to-face contacts. For two months now, the participants can contact other users, a contact person at the local neighborhood club, technical support and relatives via PAUL using video telephony (Skype). However, only few participants use this function on a regular basis so far. They use their common telephones instead. Nevertheless, one can already state that PAUL has a connecting effect, despite the fact, that the practical part of the project has started just recently: The participants enjoy the regular project meetings to which they bring home made cake. They sometimes also meet additionally without the sociologists and developers to exchange their experiences with PAUL and show functions others have not tried yet. Some offer mutual assistance, e.g. accompany to the supermarket, chauffeur to various places, and check if everything is in order. Also, some of the participants became more active in the neighborhood club. Already, new friendships were formed.

[2] The survey was conducted using semi-structured interviews and an additional short standardized questionnaire. Six tenants of the GBS and two tenants of the German Red Cross (DRK Kreisverband Kaiserslautern) were interviewed at that time. The five women and three men were between 60 and 86 years old, there was one couple.

[3] One aspect of the survey will be whether and to which extent the voluntariness to participate in the project has an impact on the use of PAUL.

4 SUMMARY AND PERSPECTIVE

The integration of organizations, services and companies in the urban neighborhood form a central aspect of care in old age. Neighborhoods are revitalized and the local economy is strengthened. However, AAL concepts which include a comprehensive range of services have to be considered critically in regard to the acceptance in practice. Our surveys have shown that ordering services with the help of AAL technology might not play a role (yet), because the elderly prefer support from family members rather than professional help and would only accept these services in urgent need and require a bond of trust. Whether and to what extent this can be proved or disproved in the longer term, we hope to show with further research as part of the TSA project.

Although the project is only mid-way through, and not all projected functions have been implemented yet, one can already state that PAUL does his job well as a high tech housemate. Those who do not show fear of contact, enjoy using PAUL. Potential users emphasize its functions in the fields of safety and health; once used, functions in the field of comfort, entertainment and communication are yet as important. As soon as the door camera and the ambient emergency detection system will be installed, further research has to show to which extent the system also contributes to the domains of safety, security and health. First results show that the project design may help to foster neighborly friendships and thus avoid loneliness of senior citizens. Here, talking about PAUL is as important as talking via PAUL.

"Spaces-In-Between" – Reweaving the City along its Inner Edges

Silja Tillner

(Mag. arch. Silja Tillner, Architekten Tillner & Willinger, silja.tillner@tw-arch.at)

1 INTRODUCTION

The continually growing urbanisation inevitably leads to densification of the existing urban fabric in cities worldwide. Land resource for new buildings, especially residential, has become scarce, therefore risen in prices. Residents in well-established neighbourhoods usually object to densification. Higher demand for outdoor activities has increased the pressure on existing open spaces. Therefore, it is essential to locate and secure new open space resources as found in abundance along transportation corridors, due to previous generous land acquisitions in the course of building infrastructure. In the 1950s and 1960s traffic planners allocated these corridors preferably in topographically advantageous locations, i.e valleys between hills. Today, more environmentally friendly modes of transportation further upgrade these longitudinal stretches of land, which now present an unprecedented and highly valuable resource for the residents in inner-city locations. Furthermore, the corridors should be transformed from a dividing barrier to a permeable open space. The sites should be planned with community participation in order to accommodate different needs in a changing society and increase identification with the neighborhoods. This participation process will contribute to mutual understanding of the residents' diversity in the process of re-mixing the city.

The "reweaving process"will be investigated by exploring 3 practical examples from 1994 until 2011. The design proposals were developed bottom-up with active community participation in the case of L.A., interactive and based on a thorough investigation of community needs in the two cases in Vienna.

In future, as an accompaniment to further urbanisation and densification of the existing urban fabric, more open space has to be allocated. The infrastructure corridors present a unique opportunity for this land aquisition for the benefit of the citizens. On one hand, these corridors were conceived generously with future growth in mind - which will not happen any more, as street widening projects have become highly unpopular. On the other hand, infrastructure needs and mobility concepts are currently changing rapidly: parallel train tracks are reduced in width, streets are used more efficiently and multi-modal. The space that can be gained by these future transformations should be used for the benefit of the citizens to create longitudinal corridors of green open space. A special case is traffic infrastructure adjacent to rivers which doubles the barrier effect for the neighboring communities. The generous width of these corridors present opportunities for creative solutions to rearrange the traffic flow and improve river accessibility as well as connectivity for the separated sides of the communities.

2 THE GLENDALE FREEWAY IN LOS ANGELES

The finely grained communities of Echo Park and Silver Lake, prominently located about a mile from downtown L.A. and graced by the natural beauty of the hilly landscape and two lakes, have been divided by the I-2 Freeway since the 1960s. This case study shows the potential of its partial removal.

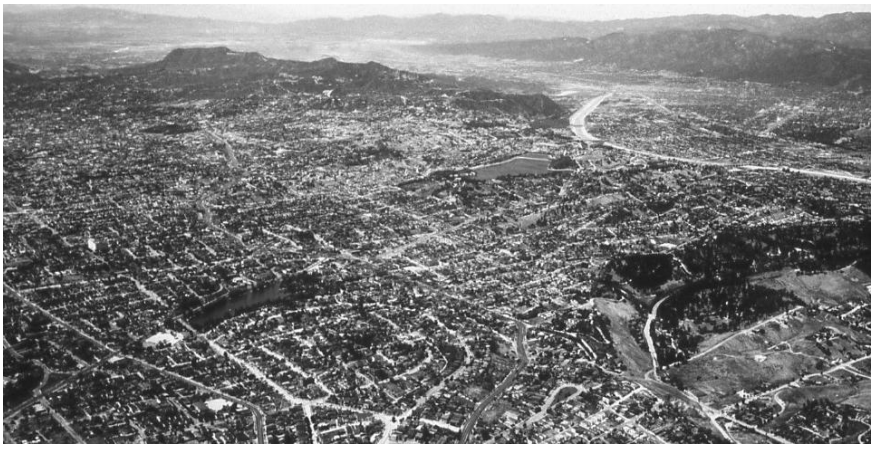

Fig. 1: Echo Park and Silverlake shown on a historical aerial photo in the 1950s

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

This was a time when traffic planners showed little sensibility to the needs of local residents. In spite of massive protests against the necessary evictions in the path of the I-2, freeway construction continued until even CALTRANS, the California Transportation Agency, and local government could no longer ignore the community uproar. The evicted home-owners were given insufficient compensation for their lost property which did not allow them to buy new homes and often led to subsequent poverty. The remaining residents on the edge of the freeway suffered from a severe devaluation of their property due to the negative environmental impacts.

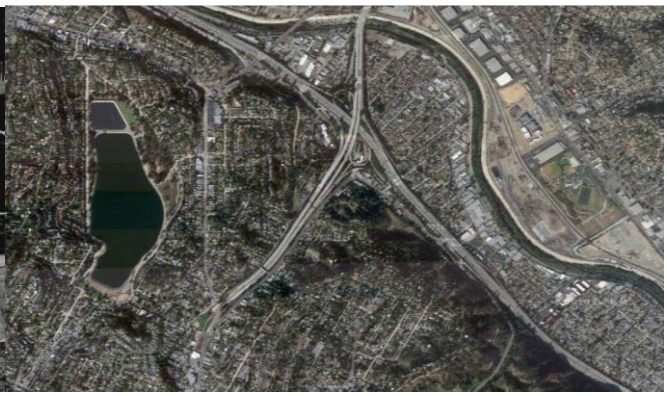

Fig. 2 left: the construction process of the Glendale Freeway Fig.3 right: Echo Park / Silverlake 2011

Fig.4 left map showing the land owned by CALTRANS adjacent to the freeway, right map shows in red the proposed section of the I-2 freeway to be removed

In the mid 1960s CALTRANS halted the I-2 Freeway construction and built an off-ramp onto Glendale Boulevard that was intended for temporary use until protests would hopefully subside. On the contrary, community groups have stayed alert until the present day and became one of the most active in all of Los Angeles.

Fig. 5: The End of the Glendale Freeway in 1990 – a steep off-ramp merges onto Glendale Boulevard towards Downtown L.A. Dangerous and unattractive underpaths are the only safe crossing passages for pedestrians.

Since traffic planers had secured much wider swaths of land than actually needed, the freeway was accompanied by now publicly owned vacant land. A visionary project, developed by the author at GSAUP-UCLA, to remove the controversial off-ramp and realign the traffic flow in order to secure open space for local benefit (community-gardens, a connecting plaza bridge ect.) was welcomed enthusiastically by the community groups. Their support eventually awakened politicians to the potential of the area and inspired them to finance further in-depth planning. As a consequence Gruen Associates and Tillner were commissioned by the LADOT (Los Angeles Department of Transportation) to develop the "Glendale Corridor Plan", a planning document which was awarded the AIPA (American Institute of Planning) Award in 1994. The intention ofthe plan was to increase public transport ridership, allocate space for HOV lanes, reduce traffic lanes for individual drivers and allocate green open space.

Today, the off-ramp still exists, but some improvements were implemented on the adjacent land, since the "Space-In-Between" next to the ramp has been reused as a sports-field. Pedestrian safety has been improved by the installment of additional traffic lights to slow down through-traffic and enable pedestrians to cross the street safely. But the majority of the ambitious plans could not be implemented due to continuous conflicts of interest between CALTRANS, the advocate for individual drivers, and LADOT, the advocate for additional high capacity public transportation corridors and the community groups that favored a more radical reduction of through traffic based on the Tillner plan. Ongoing discussions in the community still consider a more visionary and environmentally ambitious solution. Currently, the Echo Park community has organized an internet forum to improve the situation and increase the safety for pedestrians. The potential to regain the right of way for public transportation and create a "green boulevard" is still intact. Hope remains, the current community efforts will lead to a rethinking at the level of transportation planning and finally to a successful redesign.

3 THE VIENNA GÜRTEL BOULEVARD

In the 1950s and 1960s, the popularity of automobile traffic led to an enormous increase of cars travelling on Vienna's streets. The formerly tree-lined Gürtel Boulevard had reached capacity. Green space was reduced for the sake of street widening, asphalt replaced grass and soon the viaduct had become an isolated island in the center of an eight lane inner city highway. The increase in car traffic led to the further decay of the area: the building stock fell in disrepair and a red light-district spread along the Gürtel street and the connecting roads. The negative image of the whole Gürtel neighborhood led to further erosion and devaluation of the area and the adjacent properties. Negative press in numerous articles criticizing the traffic nightmare, environmental pollution and the social degradation of the red light district, was lamented. The Gürtel area was given up as a "hopeless" case.

3.1 Situation at the beginning of the URBION project in 1995

With over 85,000 vehicles/day, the Vienna Gürtel forms the transportation backbone for an area extending six kilometers with ten municipal districts bordering its busy lanes.

Looking at Vienna's demographic distribution, a possible concept for the western Gürtel emerged. Although the core urban structure of the city is organised along radial-concentric lines, the highest residential density is in the western Gürtel neighbourhoods. Accordingly, the Gürtel could function as a new linear urban "centre" that features a high-performance means of transport, i.e. the Stadtbahn. Instead, in 1995 the neglected western Gürtel assumed the unfavourable traits common to the urban periphery or an access/exit highway: dilapidated buildings, high traffic density, few retail shops or commercial and industrial sites. Thus, the western Gürtel found itself in the paradoxical situation of an inner-city fringe. The Stadtbahn viaduct was no longer a connecting (as in Wagner's concept), but rather a separating element. The explosiveness of this problem was palpable if one examined the failing neighbourhood development and stunted commercial dynamics. What was happening in the western Gürtel areas was in fact a form of commercial blight, exacerbated by increasing motorisation., as seen in Fig. 9.

Fig. 7: The western part of the Vienna Gürtel, highlighted the area selected for urban intervention in the EU-URBAN program

3.2 The main objectives of the URBION project

After numerous and inconclusive planning projects in the 1980s that had proposed expensive infrastructure investments, i.e. tunnels and road reconstruction projects, the City decided against these plans and searched for a novel and more sensitive approach with a different focus. As a consequence, Silja Tillner, who had specialized on similar projects in Los Angeles, was commissioned by the planning department to develop a Gürtel urban design study. The city planners realized that measures taken on the basis of long-term and cost-intensive so-called "hard" location factors, i.e. improving the urban infrastructure, are only one facet. However, measures taken on the basis of so-called "soft" location factors are also important. This refers to the results of Tillner's study in 1994 which included a strategy of image transposition and visual improvement of the Gürtel by means of small-scale, urbanistically active functions in the fields of culture and entertainment. Having acknowledged this, the direction given by the client, the City of Vienna, was to concentrate the planning and urban design on these "soft" factors.

3.3 The URBION Gürtel Financing – EU Funding

In 1994 the City of Vienna applied for EU grants from the community initiative, URBAN, which was set up to aid the improvement of living conditions in problem zones in major European cities. The "1994 Gürtel Urban Design Study" was included in the application.

In 1995 EU grants from the community initiative, URBAN, for the City of Vienna funding mechanism, "URBAN-Wien Gürtel Plus", were approved. As an area with high levels of unemployment, poverty and poor housing conditions the urban districts on either side of the Gürtel, were registered as a "problem urban area". The City of Vienna presented an improvement concept which complied with the principles of "sustainability" and "private-public partnership" and included a total of 60 projects and initiatives to improve the building fabric, attract new small businesses, promote cultural initiatives, social advice centres and improvements to the infrastructure. Silja Tillner was responsible for the URBION component.

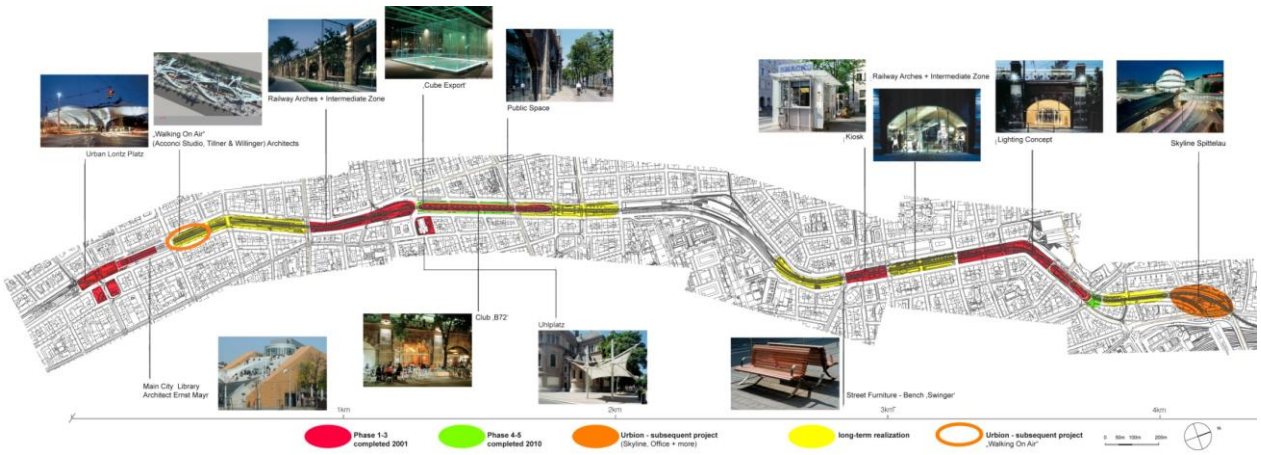

Fig. 8: The Vienna Gürtel map of phased intervention with location and image of implemented projects

3.4 The URBION Gürtel Planning Concept

In 1995 the Vienna Westgürtel, a 6km long and 70m wide 8-lane highway separating the inner from the outer city districts, had become a physical and social barrier. As a consequence, the neighborhoods adjacent to the Gürtel deteriorated, environmental pollution and the red-light district contributed to the negative image. A train viaduct dominated the median of the highway. The percentage of public open space per resident was the lowest in Vienna while many buildings accommodated large immigrant families in overcrowded apartments. This situation qualified the area for EU- co-financing in the URBAN program and was named "URBION", an urban revitalization project with phased small-scale interventions that were responsive to existing conditions. The strategy was on one hand to build on existing strengths, on the other hand to utilize derelict open space and vacant arches. One key problem was the absence of safe pedestrian paths parallel to the subway line and insufficient possibilities for street-crossing. Eliminating deficits was a major goal, i.e. functional defects of the area between the arches and the Gürtel traffic lanes hampered the improvement of this zone. For example, in addition to insufficient lighting of the pedestrian paths and cycling tracks, the use of substantial parts of this zone as partly illegal parking lots massively impeded its rehabilitation as seen in Figure 9.

Fig. 9: The Vienna Gürtel in 1995 before Urban Intervention: left image shows abundance of underutilized space on the edge of the traffic artery due to paving of former streetcar tracks, photo on the right illustrates the occupation of sidewalks for illegal parking.

At the core of the URBION Gürtel concept by architect Silja Tillner was not only the question of how to deal with the architectural heritage of Otto Wagner but above all, how to address the forced co-existence of public space and high traffic loads. By opening the Gürtel median strip and endowing it with a transparent design and connective architecture, the area re-emerged as a space that once again links the outer and inner Gürtel; an area that no longer functions as a barrier, but rather as a meeting-place. An "image transposition" strategy was undertaken to counteract prevalent negative psychological associations of the Gürtel. Fundamental to this strategy was the general improvement of the Gürtel median strip and in particular, populating the "Stadtbahn" arches with cultural and entertainment facilities, restaurants and pubs. The Gürtel Study developed a comprehensive set of measures for a new, low-cost design of the median strip that would respect existing structures and could be implemented in consecutive phases, as seen in map Figure 8.

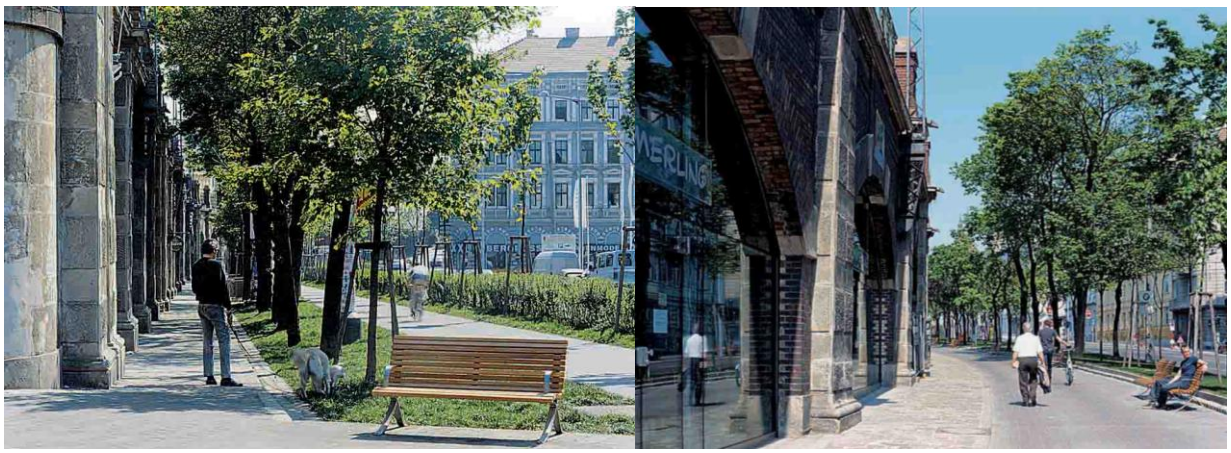

Fig. 10: The Vienna Gürtel in 2000 after Urban Intervention: left image shows the transformation into green open space, a bike-path and promenade, photo on the right illustrates the successful reconquering of public space for pedestrians and the revitalization of the arches.

3.5 Redesign of the Gürtel Open Space – Planning Strategies and Implementation

Redesign of the Gürtel median strip: In certain sections of the Gürtel median strip, public space was redesigned to create attractive open spaces for the residents of the adjacent districts, many of them immigrants. Another goal was to safeguard suitable frame conditions for the commercial success of the numerous private investors in the Stadtbahn arches. Primary objectives for the redesign of these Gürtel sections included both improved pedestrian paths and cycling tracks, additional possibilities to cross the Gürtel and the wish to create attractive open-air zones (e.g. street cafés). A continuous promenade, intensively greened, was established along the Stadtbahn arches by eliminating the side-lane and prohibiting the parking spaces. The improvement of the tree stock by planting new trees and introducing a new automatic irrigation system; enlargement and rehabilitation of green spaces accompanied by a reduction of hard, non-permeable surfaces.

The improvement of pedestrian and bicycle traffic was achieved by providing continuous paths on the median strip along the Stadtbahn arches as well as more possibilities to cross the Gürtel.

An attenuation of the barrier effect of the Gürtel was a major design goal. All newly leased Stadtbahn arches were to be opened up and provided with uniformly glazed façades.

All Gürtel bridges formerly closed with storage space were to be opened up.

A coherent and unifying "look" of the Gürtel median strip was to be achieved by means of a continuous lighting system, newly glazed Stadtbahn arch façades, the installation and design of kiosks as well as urban furniture. The open space was transformed to accommodate newly designed bike paths, pedestrian areas with generous landscaping, squares and parks. The arches were filled with new activity. Image transformation was the key to the success of URBION.

3.6 The present situation and future vision

Today, the barrier effect has been reduced and the districts have been reconnected through the common center, the attractive open space and the active life in the Stadtbahn arches, which have become popular meeting points. Nevertheless, the task has not been completed, because connectivity has been improved only in these sections of the Gürtel that were selected for URBION. These represent only 15 % of the total length of the western Gürtel. In the other areas vacant or underutilized arches and neglected open spaces used for commuter parking dominate the appearance. These deserted open spaces are void of street-life and prevent the reweaving of the city fabric.

In the future, change in travel modes and more environmentally conscientious commuting offer opportunities for a new approach to traffic planning and an open space strategy that favours the pedestrians, cyclists and recreation of the residents over the automobile.

4 THE VIENNA VALLEY

4.1 History and present situation

The Vienna Valley, extending 14 kilometers from the western city limit from the retention basins to the east where the river "Wien" flows into the Danube Canal, offers an interesting cross section of various Viennese urban landscapes, linked by the river, accompanied by an important traffic infrastructure.

Along its length the urban context of the Wiental (River Wien Valley) shows a number of different characteristics, from the scattered development, commercial areas and extensive green spaces in the west followed by a gradual, but at places very abrupt, development to the densely developed inner city areas.

In the course of history the Wiental has developed from a natural river into a regulated urban watercourse and from the mid-20th century onwards, thanks to the intensive development of road and rail connections, it became the most important traffic artery leading into the city from the west.

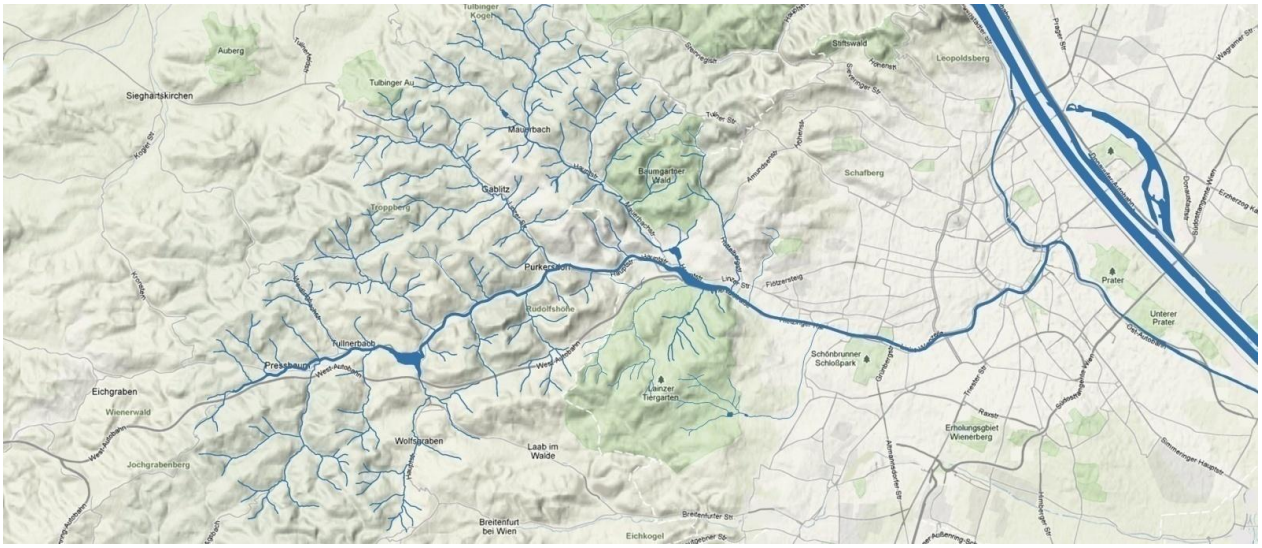

Fig. 11: The Vienna Valley with the river Vienna in its current watercourse

4.2 Planning Study

As part of Vienna's urban development a structure grew up that exhibits highly diverse qualities, deficits and potentials and was identified as one of 13 target areas for urban planning within the framework of STEP05 of the Viennese Urban Development programme. A planning study was commissioned by the City of Vienna, Tillner & Willinger architects collaborated with Auböck & Karasz landscape architects to analyse the current urban situation of the Wiental and, in a comprehensive catalogue of measures, presented proposals for the design of one of the important focal points in Vienna's future as a city.

In historical terms the transformation from a natural river to a regulated watercourse, or the planning of a monumental boulevard from Karlsplatz to Schönbrunn, which Otto Wagner carried out in part by culverting the River Wien in the area of the Naschmarkt, represent important measures that have had a lasting impact on the appearance of the city of Vienna.

Hydrology: To understand the characteristics of the River Wien within Vienna's city boundaries it is necessary to take a regional view of the water economy, especially as regards the flooding caused by heavy rainfall. During a downpour a substantial amount of the surface water in the inner city is led into the River Wien and this can lead to the water level rising by more than a metre within minutes. This fact imposes formidable limitations on urban design, especially as regards the possibility of accessing the river bed.

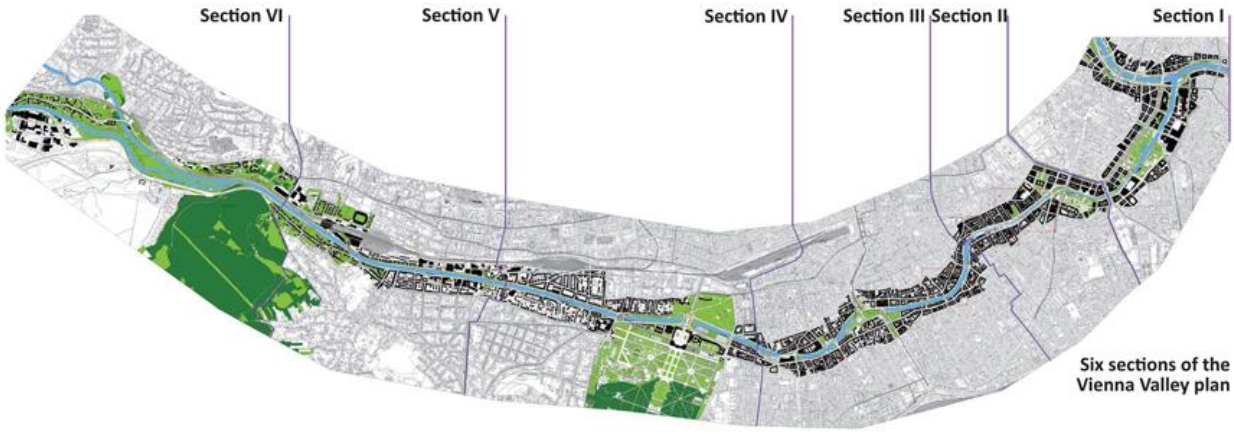

Fig. 12: The Vienna Valley in six sections

At first, a comprehensive planning analysis defined urban typologies and six characteristically similar sections of the Vienna River.

In order to define the most significant urban characteristics , the authors looked at the urban diversity and the development that increases in density towards the inner city, along with the consideration of the most important urban deficits and potential. On examination it is revealed that the urban planning deficits lie primarily in the severe separation of the northern areas of the city from the southern areas caused by the Wiental. Here the use of the Wiental as an axis for road and rail traffic plays a decisive role. The left-over areas and urban wasteland produced at many places by urban planning and the often visually unappealing transitions between individual urban components also represent a serious urban planning deficit.

The design guidelines are formulated by means of goals as well as specific measures.

Important urban design goals are strengthening the awareness of the Wiental and making its experience easier, improving its qualities as a place for recreation and leisure, creating cohesion between bordering urban districts, emphasising the linear identity of the Wiental while creating local identities within. Important measures in implementing the goals are emphasising existing attractors and urban qualities, creating connections and new green spaces, while upgrading left-over and wasteland areas and restructuring them, promoting bicycle and pedestrian traffic, increasing public safety by encouraging activity during all periods of the day.

4.3 Urban Planning Potential

Existing green areas or undeveloped areas that could be used as green spaces play a major role as does the network of bike and pedestrian paths which although well developed could be still further improved, or local accents and linear urban planning elements with a high level of urban quality that could be better integrated within the existing mesh of the city.

The targeted improvements to connectivity have a special focus on important routes, the connections of pedestrian and bike paths including those that need to be optimized, as well as the shortage of crossings over the River Wien.

Principal to the design concept is the general aesthetic improvement of the valley, making it more appealing for the use and recreation of the local residents, while enhancing the distinct urban identities of the different sections along the river.

Critical areas of intervention were selected: The plan identifies locations where existing public amenities can be maintained, brown-field sites regenerated, and new urban measures initiated. The project proposes the conversion of traffic areas into pedestrian zones, novel connections between the districts and the river embankments, and introduces green landscaping. The design of the edges at street level can be implemented in the short term offering a unique chance to upgrade an open space that leads right through the city and changing it from a peripheral zone to a spine. This new identity is to develop at the river banks. To make the river bed accessible flood protection measures would be necessary. On the basis of new technologies and intensive cooperation these could in the future transform this idea from a vision to reality.

13: The Vienna Valley in 2011 – potential for generating new open spaces

5 CONCLUSION AND FUTURE POTENTIAL

Traffic arteries have left scars in the urban grain, often creating "inner edges" that form physical and social barriers. "Space-In-Between" along streets and railways presents an opportunity to reweave the interrupted city fabric and secure urgently needed open spaces – new and environmentally conscientious uses have to be explored for these in the future: pedestrian and cyclists movement, recreation, urban farming, energy farming, ect. New modes of commuting and changing travel behaviour offer unprecedented opportunities to rethink these arteries of the cities.

1 ABSTRACT

Untersuchung über die Fortentwicklung des städtebaulichen und raumplanerischen Methodenrepertoires angestoßen durch technologische Neuerungen im Internet.

Ziel des von der DFG von 2009 bis 2011 geförderten Forschungsvorhabens war es, das Potenzial an Veränderungen des städtebaulichen und raumplanerischen Methodenrepertoires im Zusammenhang mit der Herausbildung des GeoWebs im Internet und mobiler Computersysteme (Mobile Computing) auszuloten. Das Forschungsinteresse widmete sich diesen beiden technischen Entwicklungen in ihrer gegenseitigen Verzahnung. Dabei wurde der Frage nachgegangen, inwiefern und inwieweit die sich im Internet gegenwärtig herausbildenden geobezogenen Informations- und Kommunikationsplattformen zu neuen, für die räumliche Planung wesentlichen Veränderungen der wissenschaftlichen Planungsmethoden führen. Im Zuge der Forschung wurden auch Möglichkeiten zur Fortentwicklung der Planungsmethoden auf – dieser auch als GeoWeb bzw. „Web 3.0“ bezeichneten – Informations-Plattform aufgezeigt. Im zentralen Blickfeld des Interesses standen insbesondere mobile Erfassungs-, Kommunikations- und Rechnersysteme (smart devices).

Innerhalb des Forschungsprojektes wurden die Teilbereiche "Analyse des GeoWebs und des mobilen Computereinsatzes", „Sensorik für das Geoweb“, „Geowebmethoden für die städtebauliche Struktur- als auch Gestaltungsplanung“ sowie „GeoWeb-Methoden und Kommunikations-Plattformen in der Stadtplanung“, die in diesem Paper exemplarisch vorgestellt werden.

2 STAND DER FORSCHUNG

Der Geobezug des Internets wird von namhafter Seite, etwa im britischen News-Magazin Economist vom September 2007, metaphorisch bereits als „Web 3.0“ oder „Geoweb“ bezeichnet (The Economist, 2007). Die zunehmende Bedeutung des Geobezugs zeigt sich u. a. auch dadurch, dass die Browsingtechnologie als eine wesentliche Internet-Funktionalität mittlerweile eine Erweiterung auf räumlich lokalisierbare, geografische Objekte erfahren hat und deshalb „Geobrowsing“ genannt wird. Der Standard dazu, die „Geography Markup Language“ (GML), wurde vom Open Geospatial Consortium (OGC) im Jahre 2007 fixiert. Die „Keyhole Markup Language“ (KML), die Google Maps und Google Earth beschreibende Sprache, wurde im April 2008 zum offiziellen Standard der OGC bestimmt (Shankland, 2008).

Die Potenziale und das Funktionieren des GeoWebs stehen im engen Zusammenhang mit den verfügbaren Sensoren und der sogenannten Sensorik. Die Umwelt wird anhand von aufgenommenen Daten analysiert und in eine Information umgewandelt. Dementsprechend müssen, wenn der Untersuchungsgegenstand der Einsatz von Sensorik im GeoWeb ist, sowohl die körpereigene menschliche Wahrnehmung als auch die technischen Möglichkeiten zur Aufnahme und Analyse von Umweltreizen betrachtet werden. Denn jenseits der technischen Möglichkeiten und Ansätze existiert immer noch ein Messsystem zum Sammeln und Auswerten von Daten, das allen Technologien in seiner Gesamtheit überlegen ist: Der Mensch als „intelligenter Sensor“. Dementsprechend muss das menschliche Perzept, die menschliche Wahrnehmung, zuerst beleuchtet werden, da sie in vielen Dingen das real existierende Vorbild für moderne Sensortechniken darstellt. Dabei wird unterschieden in analoge und digitale Sensoren (Schiessle, 1992; Schanz, 2007), mobile und nichtmobile Sensoren (wie z. B. bei Petschek, 2007), Nah- und Fernsensoren (Stark, 2009), Remotesensoren sowie kollaborative Sensoren und Sensornetzwerke (Hof, 2007). Sensoren können so für Monitoringsysteme in der Raumplanung (Streich, 2005) innerhalb eines induktiven oder deduktiven Monitorings eingesetzt werden. Das sogenannte „Urban Sensing“ (Campbell et al., 2006; Lane et al., 2008) kann so für „Participatory Sensing“ Vorgänge (Burke et al., 2006) als kontinuierliches, städtisches Beobachtungssystem eingesetzt werden. Die Projekte des MIT SENSEable City Labs sind dabei richtungsweisend (Calabrese Ratti, 2006; Outram et al., 2010 und Kloeckl, 2011). Daneben werden auch vermehrt „Menschen als Sensoren“ zur Messung der aktuellen, persönlichen Befindlichkeit im Stadtraum eingesetzt (Nold, 2009). Im Bereich der Strukturplanung und der Anwendung von Desktop-GIS sind die

gängigen Methoden in kommerziellen als auch Open Source Bereich grundlegend bearbeitet (Mitchell et al., 2009; Bill, 2010). In der Domäne des Mobile Webs werden jedoch durch die Verwendung von GPS-Daten immer wieder Bezüge zu den Mental Maps von Lynch (Lynch, 1960) klar, auf denen viele der automatisiert aufgenommenen Elemente basieren. Die Visualisierung punktueller Information basiert auf dem Konzept der Heatmaps, die eine online gestützte und live verfügbare Form der klassischen „Point Density" Berechnung (Berry & White, 2002) darstellt. In der städtebaulichen Gestaltungsplanung haben vor allem Techniken der Augmented Reality (Azuma, 1997; Milgram, 1999) im Bereich der Open Source Desktop Anwendungen eine Renaissance dieser Methoden ausgelöst (Höhl, 2008). Die Verfügbarkeit auf Smartphones schließt diese Entwicklung mit ein. Erste Anwendungsszenarien für die „Augmented City" (Allbach et al., 2011) und den Einsatz als Tourismusinformationssysteme (Althoff et al., 2010) bestehen bereits. Daneben entstanden bildgestützte, internetfähige Methoden, die ganze Kollektionen von Bildern für die Planung bereitstellen können (Snavely et al., 2006).

3 FORSCHUNGSFELDER

3.1 Analyse des GeoWebs und des mobilen Computereinsatzes

Gegenstand dieser ersten zentralen Bearbeitungsphase des Forschungsprojektes war das GeoWeb im Sinne der Erweiterung des Internets mit Bezug auf räumlich-geografisch lokalisierbare Objekte. Das besondere Forschungsinteresse wurde dabei auf den Spezifika, wie man zu räumlich lokalisierbaren Objekten gelangt, diese etwa durch Methoden des Geotagging und der Georeferenzierung ins Internet einspeisen und für die Raumplanung nutzbar machen könnte, gerichtet.

In dieser ersten Phase wurde eine Begriffsanalyse durchgeführt, die die Besonderheiten des GeoWebs in Verbindung mit dem mobilen Computereinsatz analysiert. Insbesondere die Abgrenzung zum traditionellen Desktop GIS stand dabei im Mittelpunkt bzw. dessen Komplementarität. Alle in diesem Forschungsprojekt durchgeführten Untersuchungen haben die besondere Anwendbarkeit in diesem Umfeld des GeoWeb und des Mobile Webs gemein. Dementsprechend bauen alle weiteren Arbeitsschritte auf diesen Besonderheiten auf. Neben einer fundierten Literaturrecherche in diesem Bereich wurden sowohl die Hardware als auch die für den Bereich des GeoWebs und des Mobile Webs verfügbaren Softwareapplikationen, die sogenannten Apps, untersucht. Dabei wurde eine Analyse der allgemeinen Eigenschaften und der Potenziale des GeoWebs, eine Analyse der Organisations- bzw. Sprach-Standards des GeoWebs sowie eine Analyse des Stands und der Entwicklungstendenzen des mobilen Computereinsatzes, insbesondere im Bereich der PDAs und Smartphones, durchgeführt.

3.1.1 Ergebnis

Allgemein ist zu konstatieren, dass eine Evolution im Internet stattgefunden hat: Von der allgemeinen, hardwarekomponenten- basierten Zurverfügungstellung von Informationen im Internet, dem Web 1.0, über die Entwicklung des von Tim O'Reilly titulierten Web 2.0, dem sogenannten Mitmach-Netz bis hin zu dem jetzt entstehenden, geo- und ortsbasierten, mashup- fähigen Web 3.0. Neben der URL, über die die Informationen im Internet abrufbar sind, können Informationen zusätzlich einen Geobezug erhalten. Die Verknüpfung aller bisherigen Daten mit Geokoordinaten sowie deren jederzeitige Verfügbarkeit und Austauschmöglichkeit mit mobilen, handlichen Endgeräten kennzeichnet damit einen neuen großartigen evolutionären Schritt der Technik im Internet. Wenn auch einige Fachleute das sogenannte „Semantic Web" als die neue Revolution im Internet bezeichnen und mit „Web 3.0" etikettieren, so steht nach Meinung der Verfasser eben diese Verknüpfung von Geoinformation und virtueller Information für eine neue Entwicklungsstufe im Internet. Diese sollte, wenn überhaupt diese Begrifflichkeit benutzt wird, als Web 3.0 bezeichnet werden (nach Zeile, 2010 S.97).

Ein Vorreiter, Indikator und auch Brückenkopf dieser Entwicklung ist das für die räumliche Planung so wichtige Webmapping. Schwierig ist mittlerweile die Abgrenzung zwischen reinem Webmapping, Web 2.0-Diensten und Web 3.0-Werkzeugen, da viele der Techniken mittlerweile zusammengewachsen sind nach Zeile, 2010 S.97).

Die Definition des Geowebs kann dementsprechend wie folgt aussehen: Das GeoWeb ist eine Weiterentwicklung von kartenbasierten Diensten hin zu mashup-fähigen Kartendiensten, die sich in einem Art Baukastensystem mit immer anderen Diensten neu kombinieren lassen. Somit verändert das GeoWeb das

Sammeln von Geodaten und deren Analyse durch neue Technologien und beschreibt zusätzlich die grundsätzlichen Konzepte hinter der Neukombination durch die Mashup-Fähigkeit und deren Techniken (Batty et al., 2010).

Die Anwendbarkeit auf mobilen Endgeräten wurde in den Bereichen der städtebaulichen Struktur- und Gestaltungsplanung, des städtischen Sensorings und der GeoWeb-Methoden und Kommunikations-Plattformen in der Stadtplanung Untersucht. Als Testplattformen haben sich nach eingängiger Recherche die Betriebssysteme AndroidOS und iOS herauskristallisiert. Tablet PCs der neueren Generation wurden zwar angetestet, aufgrund der noch nicht ausgereiften technischen Entwicklung in diesem Stadium der Forschungsarbeit jedoch nur am Rande getestet. Als eine sehr offene, mit einer Vielzahl von frei verfügbaren Apps für den Planungsbereich und bedienerfreundliche Plattform stellte sich das AndroidOS heraus, auf das sich in großen Teilen in dieser Arbeit fokussiert wurde.

3.2 Sensorik für das GeoWeb

Die Potenziale und das Funktionieren des GeoWebs stehen im engen Zusammenhang mit den verfügbaren Sensoren und der sogenannten Sensorik. Diese wurden in diesem Abschnitt des Forschungsprojektes näher untersucht.

Die Umwelt wird anhand von aufgenommenen (Sensor-) Daten analysiert und in Informationen umgewandelt. Dementsprechend müssen, wenn der Untersuchungsgegenstand der Einsatz von Sensorik im GeoWeb ist, sowohl die körpereigene menschliche Wahrnehmung als auch die technischen Möglichkeiten zur Aufnahme und Analyse von Umweltreizen betrachtet werden. Denn jenseits der technischen Möglichkeiten existiert immer noch ein Messsystem zum Sammeln und Auswerten von Daten, das allen Technologien in seiner Gesamtheit überlegen ist: der Mensch als „intelligenter Sensor". Dementsprechend muss das menschliche Perzept, die menschliche Wahrnehmung, zuerst beleuchtet werden, da sie in vielen Dingen das real existierende Vorbild für moderne Sensortechniken darstellt.

Innerhalb dieses Arbeitspaketes des Forschungsvorhabens wurden folgende Fragestellungen überprüft: Wie finden die Sinneswahrnehmung und der Einsatz von Sensoren im Allgemeinen statt? Welche Methoden der Datenerfassung mit Sensoren sind verfügbar? Welche Modi des Sensor-Einsatzes sind bekannt? Welche Arten von Monitoringsystemen innerhalb der Stadtplanung sind denkbar? Welche Basissensoren werden für das GeoWeb benötigt? Wie können menschliche Sinne im GeoWeb abgebildet werden? Wie ist der Mensch in diesem Bereich als „intelligenter Sensor" einsetzbar? Wie ist der Zusammenhang von Sensoren in der Raum-Zeit-Dualität? Und welche Probleme treten im Kontext des Einsatzes von Sensoren mit dem Datenschutz auf? Daneben wurde anhand eines Projektes überprüft, ob Methoden aus dem ambulatorischen Assessment und des psychophysiologischen Monitorings Erkenntnisse zum barrierefreien Planen liefern können. Mithilfe von Sensorarmbändern wurde eine Messung mit der Zielgruppe von mobilitätseingeschränkten Personen durchgeführt. Dabei wurden ihr zurückgelegter Weg, ihre Hauttemperatur und ihr Hautwiderstandswerte aufgenommen, um deren Stressreaktionen auf bestimmte Hindernisse im Stadtraum zu ermitteln und dementsprechend der Stadtplanung wichtige Hinweise auf stadtplanerische Mängel zu geben (vgl. hierzu Bergner et al., 2011 u. Zeile et al., 2011).

3.2.1 Ergebnis

Der Bereich der Sensorik kann nach Abschluss der Arbeit in die schon in Kap. 2 erläuterte Systematik erfolgen: analogen und digitalen Sensoren, der mobilen und nichtmobilen Sensoren, Nah- und Fernsensoren, Remotesensoren sowie kollaborative Sensoren und Sensornetzwerke. Zusätzlich können Sensoren für Monitoringsystem in der Raumplanung (Streich 2005) innerhalb eines induktiven oder deduktiven Monitorings eingesetzt werden. Das sogenannte „Urban Sensing" (Campbell et al. 2006, Lane et al. 2008) kann so für „Participatory Sensing" Vorgänge (Burke et al. 2006) als kontinuierliches, städtisches Beobachtungssystem eingesetzt werden. Die Projekte des MIT SENSEable City Labs sind dabei richtungsweisend (Calabrese Ratti 2006, Outram et al. 2010 und Kloeckl 2011). Daneben werden auch zunehmend mehr „Menschen als Sensoren" eingesetzt. Dabei kann mithilfe von Sensorarmbändern die Messung der aktuellen, persönlichen Befindlichkeit im Stadtraum erfolgen (Nold 2009).

Das Prinzip der Menschen als Sensoren wurde innerhalb der Forschungsarbeit mit den Methoden des psychophysiologischen Monitorings (EmbaGIS) umgesetzt. Dabei konnten vor allem die Fehler der Experimente der BioMaps (Nold 2009) und der emomaps (Zeile 2010) beseitigt werden und eine neue

Methodik zur besseren Identifizierung von Stressbereichen innerhalb eines Stadtraumes erarbeitet werden. Mithilfe der neuen Methode konnten barriere-bedingte Sektoren der Stadt identifiziert werden (vgl. . Bergner et al., 2011 u. Zeile et al., 2011).

3.3 Methodenentwicklung in der Stadtplanung für das GeoWeb

Drei Eigenschaften sind es, auf denen das enorme methodische Potenzial der mobilen Kommunikationsgeräte mit Computerfunktion – Smartphones also- beruht. Sie sind klein, mobil und ortbar. In Kombination aller Eigenschaften erlauben diese Geräte völlig neue Konzepte innerhalb der räumlichen Planung.

Um die Potenziale von Smartphones innerhalb der räumlichen Planung zu erforschen, müssen verschiedene Techniken näher betrachtet werden. Neben den Verortungsmethoden, der Sensorik, der in Zukunft möglichen Nahfeldkommunikation und der QR-Codierung ist dies vor allem das Methodenrepertoire im GeoWeb und in geobasierten Netzwerken. Geobasierte soziale Netzwerke und das GeoWeb, - die Kombination von Web 2.0 und Web 3.0, eröffnen diese neue Form der räumlichen Planung.

Das Methodenrepertoire lässt sich ableiten aus den im Forschungsvorhaben durchgeführten Projekten. Um die einzelnen Methoden besser zu identifizieren, sind sie in diesem Abschnitt nochmals im Einzelnen erläutert. Eine Zusammenfassung der Methoden ist auch bei Streich (Streich 2011:235ff) zu finden. Nachfolgend ist dies aber zur besseren Verständlichkeit auch im Ergebnis in Kap. 2.3.3 zusammengefasst.

3.3.1 Ergebnis

Folgende Methoden zeichnen sich in Zukunft für den Einsatz in der räumlichen Planung ab (Streich 2011:235ff):

- Erfassung räumlicher Daten durch Geotagging- das Hinzufügen von räumlichen Informationen bzw. Attributen mit geografischen Koordinaten (Geotags), um zum Beispiel Standorte von Gebäuden oder Bepflanzungen direkt „vor Ort“ zur erfassen und in einem georeferenzierten Kartensystem zu archivieren und auszutauschen;
- Erfassung von räumlichen Daten im „crowdsourcing“- Prozess, bei dem die Organisation eines raumbezogenen Erfassungssystems mit derselben Technik wie eben beschrieben durch synchrone oder sequenzielle Aktivität einer Personengruppe zu einem städtebaulichen Thema erfolgt;
- Beobachtungen von Phänomenen im zeitlichen Verlauf- deduktives Monitoring als die Organisation eines im GeoWeb verankerten Beobachtungsprozesses durch eine Planungsinstitution mit Themen bzw. Phänomenen, die für die betreffende Planung als relevant erachtet werden;
- Beobachtung von Phänomen und dynamische Hinzufügung neuer Beobachtungsphänomene – induktives Monitoring, als die Organisation einer durch die Beobachter (z. B. Akteursgruppen) in Eigeninitiative ergänzbaren Palette von zu beobachtenden Phänomenen der räumlichen Planung im GeoWeb und mit geobasierten Netzwerken
- Analysemethoden, die alle GeoWebtechniken zur Durchführung von räumlichen Analysen wie Distanzberechnungen, Flächenberechnungen etc. verwenden;
- Organisation sozialer Aktivitäten im Planungskontext, bei denen die Nutzung von geobasierten sozialen Netzwerken zu Partizipationszwecken bis hin zu „Smartmob“-Aktivitäten, bei der eine spontane Selbststrukturierung einer sozialen Gruppe durch (mobile) Kommunikationsmedien stattfindet;
- Prognosen durch geobasierte „Prediction Market“-Methoden, bei denen Blogging- Plattformen (mit Geobezug) ausgewertet und als Grundlage für Prognoseeinschätzungen zu Hilfe genommen werden;
- Entwurfsarbeit mit „Augmented Reality“-Techniken, bei denen der zu realisierende Entwurf über mobile Applikationen vor Ort erlebbar gemacht wird;
- Erfolgskontrolle mit geobasierten Weblogs, bei denen Diskussionsforen zu gewissen Planungsaktivitäten ausgewertet werden, um daraus Aussagen zu Erfolg oder Misserfolg herzuleiten.

3.4 GeoWeb-Methoden für städtebauliche Strukturen

Methoden des Planentwurfs stehen im Zentrum der fachlichen Aktivitäten in der Stadt- und Raumplanung. Der Computereinsatz hat hier mittlerweile in großem Umfange und Stil durch GIS und CAD Einzug gehalten. Das GeoWeb bietet neue Optionen der Bearbeitung. Um diese zu nutzen, ist es erforderlich, die computergestützten Methoden entsprechend weiterzuentwickeln. Durch mobile Computersysteme bieten sich zudem Möglichkeiten, ortsunabhängig den Entwurf alleine oder im Team zu bearbeiten.

Die im Forschungsprojekt herangezogenen neuen Technologien des Internets – mobil, klein und geolokalisierbar – sind in der Tendenz dazu geeignet, eine Vielzahl von personenbezogenen Aktivitäten dynamisch zu koordinieren. So ist es vorstellbar, ein Monitoring-System aufzubauen, bei dem die auf ein bestimmtes Ziel ausgerichteten Aktivitäten von vielen verschiedenen Personen zusammengeführt werden. Jeder einzelne Akteur steuert im Rahmen des Monitorings individuelle Fälle bei.

Nach einer Untersuchung der für die städtebauliche Strukturplanung traditionellen Methoden wurden diese auf die Anwendbarkeit im GeoWeb hin untersucht. Dabei sollten folgende Fragestellungen im Einzelnen bearbeitet werden: Wie sind die für die Strukturplanung wichtigen Zeichenelemente wie Punkt, Linie und Fläche zu erfassen und zu organisieren? Des weiteren stellte sich die Frage, ob Mental Map (Lynch 1960) Prozesse im GeoWeb durchgeführt werden können und wie städtebauliche Themenkarten in das GeoWeb zu integrieren sind. Durch zwei Projekte, dem internetgestützten Flächenmonitoring am Beispiel der Gemeinde Altenglan und dem smartphonegestützten Touristeninformationssystem „Alexplore“ wurde die praktische Anwend-barkeit der Methoden überprüft.

3.4.1 Ergebnis

Die Aufnahme von punktuellen und linienhaften Strukturdaten geschieht bei mobilen Endgeräten über das automatisiert erstellte „Logfile“ im GPX- und meist auch im KMZ-Datenformat. Je nach gewählter App sind die Daten auch direkt auf einer Google Maps Oberfläche verfügbar und können auch in klassische Desktop-GIS-Programme übernommen werden. Sowohl bei der Aufnahme von Punkten- als auch Linienelementen eignet sich bei der Überlagerung vieler Datensätze nicht die Visualisierung in absoluter Form, sondern die Darstellung als sogenannte „Heatmaps“. Diese können hohe Dichten der Messwerte für den Benutzer anschaulicher darstellen. Über die Verknüpfung über soziale geobasierte Netzwerke sind diese nutzerbasierten „Hotspots“ einer Stadt über die Verwendung der Javascript Bibliothek „heatmap.js“ (Wied 2012) auch online abrufbar. Mithilfe von Online Services oder Open Source Software sind Punktelemente zu Linienelementen transformierbar, auch der umgekehrte Weg des Konvertierens ist möglich. Nicht funktioniert derzeit die automatische Aufnahme von Flächen über GPS-Logger, jedoch bieten einige Apps die Möglichkeit, zumindest Flächengrößen über Liniensegmente zu berechnen, oder Flächen manuell einzuzeichnen. Somit lässt sich auch nur teilweise der klassische Mental Map Prozess über das GPS-Tracking abbilden. Erste CAD-Programme sprechen die GPS-Schnittstelle an und könnten hier eine techinische Lück schließen. Trotzdem muss (immer noch) eine Kombination aus verschiedenen Apps im Planungsalltag zur Bestandsaufnahme und zur Anfertigung von Mental Maps benutzt werden. Dies zeigt sich auch bei der Integration von eigenen oder von Fremdanbietern zu Verfügung gestellten Themenkarten. Teilweise können Themenkarten über externe WMS- oder WFS-Dienste eingebunden werden, teilweise ist es allerdings sogar ein Problem, eine eigene, gescannte Karte zu georeferenzieren und darzustellen. Alle Möglichkeiten der verschiedenen Apps sind in einer Übersichtstabelle zusammengefasst. In den umsetzungsorientierten Beispielen wurden im Projekt Flächenmonitoring die Potenziale zur Ermittlung und communitybasierter Aufnahme von Flächenpotenzialen erfolgreich umgesetzt. Dabei wurde auf einen Workflow in einer Open Source Umgebung zurückgegriffen, der von Laien innerhalb einer kurzen Zeit erlernbar war, und somit für kleinere Kommunen ohne GIS-Ausstattung adaptierbar ist. Im Alexplore Projekt wurden die Potenziale von crowdsourcing basierten Informationen über die Touristendestination Alexandria untersucht, die den Benutzern die Möglichkeit bietet, eigene Hotspots in der Stadt mithilfe der Google Maps API zu verorten. Gleichzeitig sind auch Bereiche mit einem Wohlfühlfaktor klassifizierbar, die dann live allen Benutzern wieder als Kartendienst mobil als auch auf Desktop PCs zur Verfügung zu stellen (vgl. Körnig-Pich et al. 2010).

Die für die Planung und im Einsatz von GIS- und CAD-Programmen wichtigen Zeichenelemente wie Punkt- und Liniensegmenten sind im GeoWeb problemlos sogar automatisiert über GPS-Logger abbildbar. Die Erstellung von Flächen ist momentan nur manuell möglich. Der Austausch der Daten erfolgt meist über die

GPX- oder KML-Schnittstelle, sodass der aufgenommene Datensatz anschließend entweder direkt auf dem Mobile Client oder desktopbasiert zur Bearbeitung bereitliegt. Dies geschieht teilweise automatisiert. Aufgrund dieser Einschränkung ist die Erstellung von Mental Maps nur halb-automatisch realisierbar. Andererseits können unter Zuhilfenahme der Point Densitiy Berechnungsmethode sogenannte Heatmaps erstellt werden, die die Dichten von Beobachtungsgegenständen im Raum visualisieren. Weiterhin ist es mittlerweile auch möglich, thematische Karten entweder über die WMS- oder WFS-Schnittstelle einzubinden sowie auch die eigen erstellten Planwerke in Form von georeferenzierten Bildern darzustellen. Alle Funktionalitäten innerhalb einer App sind derzeit noch nicht verfügbar.

3.5 GeoWeb-Methoden für die städtebauliche Gestaltung

Städtebauliche Gestaltungsaspekte gehören zum zentralen Gegenstandsbereich der räumlichen Planung. In diesem Forschungsprojekt geht es um die Fragestellung, mit welchen Methoden und Werkzeugen stadtgestalterische Prozesse im GeoWeb und Mobile Web abgebildet werden können.

Um die für das Forschungsprojekt relevanten Methoden zu ermitteln, wurden zuerst die Grundlagen zu Raum und Gestalt sowie die gängigen Methoden der Gestalterfassung und Gestaltbewertung ermittelt. Gestaltprozesse sind durch das Fortschreiten der digitalen Visualisierungs- und Simulationstechniken heute anders zu handhaben als noch vor 20 Jahren. Zudem sind Ansätze im klassischen desktopbasierten Augmented Reality Verfahren (Höhl 2008) zwar als Grundlage zu verwenden, jedoch wurden mobile Web-Methoden bis dato nicht umfassend für den Einsatz in Planung betrachtet. Dementsprechend wurden in einem anschließenden Schritt die Möglichkeiten der fotografischen Erfassungsmethoden im GeoWeb, neue visuelle Simulationsverfahren – besonders im mobilen Augmented Reality-Bereich untersucht. In einem abschließenden Schritt wurden die Erkenntnisse in dem Projekt „Baukulturmonitoring“ praktisch angewandt. Zusätzlich wurden Szenarien im Augmented Reality Umfeld prototypisch definiert, wie und mit welchen Werkzeugen die Umsetzung der „Augmented City“ gelingen könnte.

3.5.1 Ergebnis

Städtebauliche Gestaltungsprozesse sind über Modelle zu kommunizieren. Dabei ist es im Kommunikationsprozess wichtig, dass bei allen am Planungsprozess beteiligten Akteuren die Erkenntnis vorhanden ist, dass das Bild, der Film oder eine sonstige Präsentationsform der zukünftigen Entwicklung immer nur modellhaften Charakter aufweist, und dass die tatsächliche Planungsumsetzung später eventuell anders aussehen wird als das kommunizierte Modell. Als Diskussionsgrundlage sind diese Modelle jedoch ein wichtiges Instrument, um möglichst viele Gruppen in den Prozess mit einzubeziehen. 3D-Stadtmodelle und die Integration von virtuellen Neuplanungen in diese Modelle liefern einen Zugewinn an Transparenz. Zusätzlich entsteht in den planenden Disziplinen ein großes Wissen, wie diese Modelle erstellt werden und vor allem, wie mit diesen über Echtzeitvisualisierungssysteme oder Virtual Earth Systeme die Planungsintention einer Vielzahl an Personen vermittelt werden können. Die Dokumentation von baulichen Zuständen kann mittlerweile über Online Foto-Communities als auch über interaktive Fotokollektionen mit relativer, modellinterner Georeferenzierung erfolgen. Dies erleichtert zum einen stark Bestandsaufnahmeprozesse als auch die Katalogisierung von Bauwerken innerhalb der Baukultur-Diskussion. Neben den schon erwähnten Virtual Reality Methoden können planerische Arbeitsprozesse auch dazu verwendet werden, Inhalte für (Mobile) Augmented Reality Applikationen zu erstellen. Die Einsatzfelder und die jeweiligen auf den Smartphones zu Verfügung stehenden Apps wurden dementsprechend untersucht. Mithilfe dieser Apps können dann Szenarien wie die Überlagerung von historischen Informationen („talking places“), Messwerte, 2D-Karten-Informationen, 3D-Bauten und auch Formen der Partizipation mithilfe von Augmented Reality Tags in Social Communities umgesetzt werden (vgl. hierzu auch Memmel Groß, 2011 und Allbach et al., 2011). Im Rahmen des Baukulturmonitorings hat sich der Methodenmix aus Foto-Communities, die dynamische Visualisierung von Veränderungsprozessen mithilfe von Google Earth, die Durchführung von Social Community basierenden Befragungen sowie die Visualisierung von Neubauprojekten mit Augmented Reality Applikationen als sinnvoll erwiesen. Zusätzlich ist es sinnvoll, Objekte der Baukultur zentral auf einer Plattform zu speichern, bzw. mithilfe dieser Plattform auch Bürger zu aktivieren, eigene Inhalte einzuspielen und zu verorten, wie es im MACE-Projekt (Zeile Memmel 2010) durchgeführt worden ist.

3.6 GeoWeb-Methoden und Kommunikations-Plattformen in der Stadtplanung

In der Stadtplanung ist Kommunikation eine zentrale Instanz. Sie dient dem Informationsaustausch, ist wesentlicher Teil von Partizipation und spielt eine wichtige Rolle bei der Konsensfindung für Planungsentscheidungen, aber auch für die Vermittlung von stadtbezogenen Informationen zum Beispiel für den Tourismusbereich.

Der Umbruch von der Informationsgesellschaft in die Wissensgesellschaft ist im vollen Gange. Dementsprechend sollten auch die planenden Disziplinen diese neuen Wege der Kommunikation bestreiten. Neben dem Speichern von Bildern, Texten, Videos und Audiodateien im Netz entstehen neue Formen des Informationszugangs und der Informationsbeschaffung. Stichworte sind hierbei das „GeoWeb-Blogging", das „Mobile Tagging", „Near Field Communication" und „QR-Codes" sowie die Möglichkeit, diese Techniken miteinander zu verknüpfen. Ziel ist es, alle Techniken miteinander zu einem Informationssystem zu verknüpfen (vgl. Althoff et al., 2010).

Die oben genannten Techniken wurden innerhalb eines Tourismus-Projektes untersucht und umgesetzt. Es sollte ein mobiles Touristeninformationssystem, das an verschiedenen Standorten zusätzliche Informationen in Form von Kurzfilmen mithilfe der QR-Technologie plattformunabhängig dem Besucher zu Verfügung steht.

3.6.1 Ergebnis

Das Konzept wurde erfolgreich umgesetzt und kann in Aalen vor Ort besichtigt werden. Dieser Art der Informationsvermittlung in einem Medienmix aus mobilen Techniken, Film und QR-Codierung kann beliebig erweitert werden und ist so auch bei der Vermittlung von Informationen von Großprojekten oder Ähnlichem denkbar.

4 FAZIT UND AUSBLICK

Die Mashup-Fähigkeit vieler Applikationen, der bibliotheksbasierte Aufbau des AndroidOS und die immer bessere Verfügbarkeit von Daten und des Datenzugangs lassen es in einem weiteren Schritt zu, nun auf besondere Fragestellungen innerhalb der räumlichen Planung entweder maßgeschneiderte Apps zu entwickeln, oder mithilfe von bestehenden mashup-fähigen Kombinationen besondere Bereiche der räumlichen Planung näher zu beleuchten. Die ständige Beobachtung der Trends im GeoWeb ist dabei eine zwingende Voraussetzung in diesem Forschungsbereich. Derzeit kristallisiert sich vor allem die Nutzung der mittlerweile von technischen Fehlern bereinigten Tablet- PCs und die Einführung von Near Field Communication (NFC) als neue Trends heraus. Die dadurch bessere und benutzerfreundlichere Komponente könnte dem Mobile Web für alle Benutzergruppen zum Durchbruch verhelfen.

Der Bereich der personenbezogenen Sensorik, bzw. das Prinzip des „Menschen als Messfühlers" wird in weiter bearbeitet und fortentwickelt werden. Dabei stehen zwei differenzierte Methoden im Mittelpunkt: eine auf Mobiltelefonen zu entwickelnde Plattform für „Urban Sensing" und die Weiterentwicklung des „EmbaGIS".

Darüberhinaus wird eine App entwickelt werden, die ortsmarkenbezogene Tags erstellt, die anschließend als „positiv" und „negativ" bewertet werden können (RADAR SENSING). Hintergrund dabei ist, dass ein Radar-System in Echtzeit entsteht, über das registrierte Nutzer als auch Planer die von den Benutzern aufgenommenen Attribute an ihren verorteten Plätzen in Form von Heatmaps direkt nach Usergruppen und Attributen visualisiert werden können. Ein möglicher Workflow sieht wie folgt aus: Die Benutzer verorten auf ihrem Mobilclient einen Platz in der Stadt und können neben den vordefinierten Attributen „Sauberkeit", „Aufenthaltsqualität", „Stadtgestalt/Architektur", „soziales Umfeld", „Barrierefreiheit", „Beleuchtung", „Sitzmöglichkeiten", „Verkehr", „Flora und Fauna", „Klang/Geräusche" auch eigene Attribute erstellen und diese mit positiv oder negativ bewerten. Jeder Ort/jede Ortsmarke dient so als Grundlage für eine „bewertete, georeferenzierte Tagcloud". Weiterhin sind alle Ergebnisse zu einem Gesamtergebnis aggregierbar und stellen einen „Zustand der Stadt" zu einem bestimmten, frei definierbaren Zeitpunkt oder über eine Zeitspanne dar. Die Ergebnisse sind in Google Maps einsehbar, entweder als absolute Punktwolke mit allen Attributen oder als generierte Heatmap aus den aufgenommen „menschlichen Sensordaten".

Weiterhin sollte das EmbaGIS in praktischen Untersuchungen validiert werden. Dabei steht im Vordergrund, wie die Messmethode in Innenstadtbereichen mentale Belastungspunkte identifizieren und analysieren kann.

Zusätzlich sollen ausgesuchte neuralgische Punkte nach Gesichtspunkten der Barrierefreiheit städtebaulich optimiert werden. Die angedachte Methode sieht vor, dass in Fallstudien die mentale Belastung (der „Stress“) von mobilitätseingeschränkten Menschen mit Ergebnissen aus anderen Zielgruppen verglichen werden sollen (z. B. sehbehinderte Menschen, aber auch Mütter mit Kinderwägen), sowie Probanden, welche nicht-behindert sind und als Kontrolleinheit fungieren können. Auf Basis dieser Ergebnisse der Fallstudien werden besondere Belastungspunkte herausgefiltert und kartografisch dargestellt. Belastungsauslösende Örtlichkeiten werden auf städtebauliche Gegebenheiten nach DIN untersucht und bei Handlungsbedarf optimiert.

Neben der Planung für behinderte Personenkreise können die Messungen auch als Grundlage für die nach EU-Umgebungslärmrichtlinie Identifizierung von Orten mit einer „hohen Eignung für ruhige Erholung“ dienen. Da in diesem Verfahren bis jetzt nur auf die standardisierten ICBEN-Fragebögen zur Lärmbelästigung zurückgegriffen wird, kann die Anwendung von Messungen des psychophysiologischen Monitorings mithilfe von Sensorband-Messungen die subjektiven physiologischen Reaktionen auf die sich dynamisch verändernde Geräuschsituation vor Ort objektiv messen und könnte eventuell eine objektivere Bewertung des Lärms und der Erholung darstellen. Diese kombinierte Erhebung aus Messung und Befragung soll Rückschlüsse auf die schalltechnischen Anforderungen an „ruhige Gebiete in Ballungsräumen“ nach der Umgebungslärmrichtlinie der EU ermöglichen.

Die sich neu bietenden Methoden für die Planung sind durch das Fortschreiten der Technik erheblich erweiterbar. Gerade subjektive Empfindungen der Menschen im Stadtraum können mithilfe von crowdsourcing orientierten Messverfahren neue Aufschlüsse über den „Herzschlag“ oder den „Puls der Stadt“ hervor bringen. Der Ansatz des „Emotional Mappings“ oder des „EmbaGIS“ können auch in diesem Zusammenhang ein probates Mittel sein. Wie die im Kapitel „Sensorik für das GeoWeb“ vorgeschlagenen weiteren Untersuchungen im Bereich des Emotional Mapping und die Entwicklung einer „App“ zur Messung des subjektiven Empfindens in einer Stadt sind auch in diesem Arbeitspaket als die logische Weiterentwicklung zu bezeichnen.

Durch die Ermittlung der Methoden für die städtebauliche Strukturplanung haben sich zwei Arbeitspakete für die Strukturplanung herausgebildet: Auf der einen Seite die Umsetzung eines smartphone- gestützten Leerstandskataster und die Entwicklung eines mobilen Audioguides im Rahmen des „Urban Storytellings“.

Neben dem touristischen Verorten von Plätzen mittels Smartphone und dem desk-topgestützten Erfassen von Flächenleerständen sollen in einem weiteren Schritt auch die Potenziale der crowdsourcing gestützten Aufnahme von Geschäftsleerständen mittels Smartphone untersucht werden. Klassische Ansätze, erwartete Leerstände durch Prozentangaben stadtweit zu verorten, sind zwar aus strategischer Sicht sinnvoll, bringen in der Planungspraxis allerdings nicht den gewünschten Mehrwert mit, da die Suche nach dem richtigen Geschäftslokal doch über den Makler oder den Besuch vor Ort läuft. Die Herausforderung liegt in der Erfassung, des kontinuierlichen Monitorings und eines effektiven Managements dieser Potenziale. Mittels des crowdsourcing sollen so innenstadtnahe, flexible, günstige und nachhaltige Ressourcen für eine kulturelle und soziale Stadtentwicklung aktiviert werden.

Das „Urban Storytelling“ soll die Bedeutung geogetaggter Audiodateien für die Erlebbarkeit der Stadt untersuchen. Dabei werden auditive Smartphone Applikationen untersucht und weiterhin der Frage nachgegangen, inwieweit diese einen Beitrag leisten können, eine auditive Identität der Stadt in Relation zu ihren Bewohnern zu vermitteln. Des weiteren soll aufgezeigt werden, welche Grenzen und Möglichkeiten der Technik in den potenziellen Einsatzfeldern bestehen. In diesem Zusammenhang werden bereits vorhandene „audio tools“ für mobile Endgeräte bewertet, wie auch eine neue konzeptionelle Idee zum Thema „auditives Stadterleben“ in Form von Geschichten, Musik und Hintergründe mit dem Titel „Urban Storytelling“ erarbeitet. Gleichzeitig wird auch das Phänomen der „Überlagerung“ der städtischen Umwelt mit mobilen Abspielgeräten und inwiefern dieses Phänomen zur (Wieder-) Identifizierung mit seiner Klangumwelt durch mobile Applikationen eingesetzt werden kann, unter-sucht. Weitere Fragestellungen in diesem Arbeitspaket können sein: Wie gestaltet sich die akustische Identifizierung der „iPod und Smartphone Generation“ mit der Stadt? Wie sehen bereits vorhandene auditive Guides aus und welchen Einfluss haben diese auf das Stadterleben? Inwiefern können diese auditive Hilfen (Smartphone, Mp3s) eingesetzt werden, um dem Menschen die Stadt (wieder) näher zu bringen? Wie könnte eine mobile Applikation in Bezug auf die auditive Wahrnehmung und Identifizierung konzeptionell aussehen?

Die Szenarien der Augmented City, die in ihren theoretischen Ausrichtungen vielversprechend klingen, sollen in zwei Projekten umgesetzt werden. Dies ist zum einen die Möglichkeit des augmentierten Bebauungsplans 3D und zum Anderen die Nutzung der Augmented Reality als (bau-) kulturelles Nachschlagewerk in Form des Szenarios der „Talking Places".

Im Bebauungsplanszenario soll deshalb neben der zweidimensionalen Darstellung auch die Bandbreite an zeichnerischen Festsetzungsmöglichkeiten, die dem Planer bei der Aufstellung eines Bebauungsplans zur Verfügung stehen, analysiert und (soweit möglich) dreidimensional visualisiert werden. Ergebnis ist eine „3D-PlanzV".Dieser wird beispielhaft für eine bessere Kommunikation zwischen Bürger und Verwaltung umgesetzt. Dabei sollen auch die Inhalte in einer Augmented Reality Umgebung visualisiert werden.

Die „Talking Places" werden anhand der Stadthistorie in Kaiserslautern überprüft. Dabei sollen analoge Daten aus dem Stadtarchiv Kaiserslautern zuerst gesichtet und nach Analyse existierender Standards und Metadatenformate zur Beschreibung digitaler Ressourcen im Kontext der Baukultur mit einem eigenen Repräsentationsformat ausgewählt bzw. definiert werden. Anschließend sollen die Inhalte aus heterogenen Quellen in einer interaktiven Plattform integriert werden. Neben der inhaltlichen Beschreibung sollen auch die Zugänglichkeiten über die entsprechenden Informationen mit einfließen. Die aufbereitenden Daten sollen dabei zwei- als auch dreidimensional aufbereitet und an ihre Originalstelle virtuell und mit Hilfe von Augmented Reality Methoden wieder erlebbar gemacht werden. Neben der Verortung von historischen Aufnahmen sollen zudem aus alten Bauplänen bzw. aus historischen Bauakten Gebäude zumindest in ihrem Ansatz rekonstruiert werden. Ziel ist es, sowohl diese Gebäude als auch die historischen Aufnahmen im digitalen Kontext mithilfe von mobile Augmented Reality, dem vom DFKI entwickelten RADAR System (Memmel 2010), als auch mit Virtual Earth Systemen wieder erlebbar zu machen.

Einige dieser angedachten Weiterentwicklungen sind schon in ersten Projektphasen umgesetzt worden und sind kurz vor Publikationsreife. Daran ist ablesbar, wie schnell die Entwicklungen im Bereich des GeoWebs momentan ablaufen. Andererseits zeigt es auch die Potenziale der Mashup-fähigkeit der Dienste an, denn was gestern noch als Problem galt, ist heute oftmals durch die Neukombination der Bausteine gelöst. Für den Planer heisst dies insbesondere, alle diese Entwicklungen aufmerksam zu verfolgen.

5 DANKSAGUNG

Die Autoren bedanken sich bei der Deutschen Forschungsgemeinschaft (DFG) für die Finanzierung des Projektes „Städtebauliche Methodenentwicklung mit GeoWeb und Mobile Computing - Untersuchung über die Fortentwicklung des städtebaulichen und raumplanerischen Methodenrepertoires angestoßen durch technologische Neuerungen im Internet".

Stadtplanerische Herausforderungen einer funktionalen Durchmischung am Beispiel der Landeshauptstadt Innsbruck

Antonia Roither, Anne Weidner

1 ABSTRACT

Die Landeshauptstadt Innsbruck verzeichnet nach Stagnation und Rückgang in den 1980-er Jahren ab 2001 wieder eine stärke Bevölkerungszunahme, v.a aufgrund einer sehr positiven Zuwanderungsbilanz. Die dem Örtlichen Raumordnungskonzept 2002 (ÖROKO) als strategisches, langfristiges, räumliches Planungsinstrument zugrunde liegenden Prognosen zur Bevölkerungsentwicklung, sagten für die Dekade bis 2012 ca. 130.000 Personen "anwesender Bevölkerung" voraus [1]. Die tatsächlichen Zahlen haben bereits im Jahr 2010, auch aufgrund einer geänderten Berechnungsmethode 145.000 Personen ergeben.

Die räumliche Situation Innsbrucks ist durch die beengte Talkessellage gekennzeichnet, von den 10.500 Hektar Stadtgebiet ist nur ein Viertel von 2.700 Hektar Siedlungsraum. Das Spannungsfeld dieser Rahmenbedingungen - rasche Bevölkerungsdynamik und beschränktes Raumangebot - stellt die Stadtplanung Innsbruck vor große Herausforderungen, um durch entsprechende Strategien die Flächen für Wohnen, Arbeiten, Bildung, Sport, Tourismus, Daseinsfürsorge und Infrastruktur [2] zu sichern.

Generelle räumliche Leitziele dabei sind der haushälterische Umgang mit Grund und Boden durch Ausschöpfung vorhandener Baulandreserven, Verdichtung und Umnutzung bereits bebauter Gebiete, Durchmischung bzw. Mehrfachnutzung bei hohem Qualitätsanspruch, wenig Neuwidmungen, Zurückstellen „strategischer Reserven" und damit Ressourcensicherung. „Mixing the City" bedeutet für Innsbruck konkret im stadtplanerischen Handeln, die Stadt weitestgehend nach innen zu entwickeln, kontinuierlich umzustrukturieren sowie eine konfliktarme und nachhaltige Durchmischung voranzutreiben [3]. Denn durch den stark begrenzenden (natur-)räumlichen Rahmen in Innsbruck liegen auch historisch bedingt verschiedene–oft konfliktträchtige–Nutzungen eng aneinander. Die Herausforderung ist das ständige Ausloten einer noch vertretbaren baulichen Dichte und Intensivierung der Flächennutzung bei gleichzeitiger Sicherung des hohen Anspruchs an die Qualität für Stadtraum und Wohnen.

Durchmischung wird in Innsbruck u.a durch Stapelung verschiedener Nutzungen erreicht. Dabei beweisen mitunter neuartige Mischungen ihre Praxistauglichkeit, etwa bei einer Stapelung von Bildungseinrichtungen und Handelsstrukturen, die zusätzlich als neues Stadtteilzentrum fungiert.

Grenzen der Durchmischung hingegen werden auf ökonomischer Ebene insbesondere durch das Zusammentreffen von Wohnnutzung und Gewerbe virulent. Aber auch Vorgaben aus der Umwelt- sowie Gewerbegesetzgebung und der darin festgeschriebenen vorrangigen Schutzwürdigkeit der Wohnnutzung stellt die Raum- und Stadtplanung vor die Situation, dass ihre rechtlichen Steuerungsinstrumente oftmals eingeschränkt sind. Dem entgegnet die Stadtplanung in Innsbruck einerseits mit der Ausweisung von „Besonderen Entwicklungsgebieten" in der strategischen Planung des ÖROKO und damit der Verankerung planerischer Handlungsspielräume sowie andererseits mit konkreten projektbezogenen, privatrechtlichen Verträgen.

2 AUSGANGSSITUATION

Das Bevölkerungswachstum der Landeshauptstadt Innsbruck liegt im österreichweiten Trend zentraler Orte und ist natürlich positiv zu beurteilen. Dies kann auch dahin gehend interpretiert werden, dass die Unternehmungen sowie Aufwendungen in Zielrichtung einer lebenswerten, attraktiven, ökonomisch und sozial stabilen Stadt erfolgreich waren und auch weiterhin sind.

2.1 Wachsende Ansprüche durch demographischen Wandel an das Wohnen …

Die positive Bevölkerungsentwicklung bedeutet einen steigenden Bedarf an Siedlungsflächen, für Wohnraum genauso wie für soziale und technische Infrastruktur, für wirtschaftliche Entwicklung mit Arbeitsplätzen und nicht zuletzt für innerstädtischen Erholungs- und Freiraum. Dabei ist trotz allgemeiner Bemühungen um Ressourcenschonung des knappen Bodengutes festzustellen, dass der Bedarf an Wohnraum nicht linear mit einem Bevölkerungswachstum korreliert. Vielmehr wirken soziale und ökonomische Effekte des „Demografischen Wandels", dass der Raumbedarf und damit die Flächennachfrage für Wohnen maßgeblich steigen. Ein- und Zweipersonenhaushalte [4] nehmen in allen Altersgruppen in Folge veränderter gesellschaftlicher Rahmenbedingungen und damit gängiger Lebensstilformen zu. Neben den jungen Erwachsenen, deren Gruppe gesamtgesellschaftlich rückläufig ist, hat auch die wachsende Gruppe der älteren Menschen (über 65 Jahre) hierbei besonderen Einfluss. Deren Wohlstandsentwicklung, deren Lebenserwartung und einhergehend deren Verbleib in den oft zu groß gewordenen Wohnsitzen trägt stärker zur Zunahme der durchschnittlichen Wohnfläche je Person bei. Somit steigt letztlich die absolute Zahl der Wohnungen [5].

2.2 … sowie der Flächenbedarf für gewerbliche Nutzung …

Die kurz- und langfristige Verfügbarkeit gewerblich zu nutzender Flächen ist in Innsbruck sehr beschränkt. Das Potential wirtschaftlicher Nutzungen und Entwicklungen liegt aufgrund der topographischen und erschließungstechnischen Voraussetzungen nämlich nahezu ausschließlich im bereits verdichteten, verkehrlich erschlossenen Talboden. Zusätzliche Flächen für wirtschaftliche Neuansiedlungen sind in Innsbruck langfristig äußerst limitiert, auch gibt es keine Reserveflächen, die für einen möglichen Flächentausch im Sinne einer Neuordnung vorhandener Flächennutzungen herangezogen werden könnten. Das übergeordnete, stadtplanerische Ziel muss daher im Sinne einer langfristigen Absicherung der Wirtschaftsleistung der Stadt in der Sicherung all jener Flächen liegen, die für gewerbliche Zwecke geeignet und zum Großteil auch bereits als solche gewidmet sind. Dies unabhängig davon, ob die Flächen aus verschiedenen Gründen (z.B. fehlende Verfügbarkeit oder zu hohe Grundpreiserwartungen) derzeit keiner Bebauung und Nutzung zugeführt werden können. Darüber hinaus sind so auch die bestehenden Betriebsstandorte zu sichern.

2.3 … bei beschränkten Raumressourcen …

Von den 2.700 ha Siedlungsraum in Innsbruck sind etwa 910 ha als Wohngebiet gewidmet, 240 ha sind als Mischgebiete (allgemeines Mischgebiet, Kerngebiet, Tourismusgebiet und landwirtschaftliches Mischgebiet) festgelegt; auf Gewerbe- und Industriegebiete fallen 220 ha. In Summe ergibt dies etwa 1.370 ha Bauland. Hinzu kommen noch rund 520 ha Sonderflächen und 80 ha Vorbehaltsflächen, die teils bauliche, teils freilandbezogene Nutzungen ermöglichen [6].

Die beengte räumliche Situation stellt für Innsbruck eine besondere Herausforderung dar, um die wachsenden Flächenansprüche befriedigen zu können. Hierbei konkurrieren Interessen der Siedlungserweiterung mit den Interessen der Freilandsicherung. Einer - wenn auch extensiven - land- und forstwirtschaftlichen Nutzung kommt durch die Notwendigkeit der Sicherung alpiner Hanglagen und (Kultur-)Landschaften besonderer Bestandsschutz zu; die Erholungsflächen in und um die Stadt sind nicht nur für die Bewohner wichtig sondern auch wesentlicher Faktor für den städtischen Tourismus, etc. Und

[4] Laut vorliegender Prognose steigt die Anzahl der Wohnungen von insgesamt 62.4477 im Ausgangsjahr 2001 auf 67.721 (+8,4%) im Jahr 2011 bzw. 72.218 Wohnungen (+15,6%) im Jahr 2021 an. Diese Steigerung wird in etwa bis 2021 gleichbleiben, ab diesem Zeitpunkt aber eine Stagnation erfahren bzw. nur mehr in geringfügigem Ausmaß bis in das Jahr 2031 (72.442 Wohnungen, +15,9 %) zunehmen. STRUKTURANALYSE 2007 D-14

[5] Die in dieser Publikation zitierten Werte stammen zum größten Teil aus der "Strukturanalyse 2007 – eine Bestandsaufnahme. Aktualisierung des Basis-Informationsberichtes 2001 zum Örtlichen Raumordnungskonzept 2002 (ÖROKO 2002)". In diesem wurden zur Halbzeit der Gültigkeitsdauer des ÖROKO 2002 alle wesentlichen generischen Zahlenwerte die dem ÖROKO zugrunde lagen überprüft und aktualisiert. Aktuell im Jahr 2012 wird an der Fortschreibung des ÖROKO gearbeitet, dafür ist zum Teil bereits neueres Zahlenmaterial vorhanden, jedoch sind – auch aufgrund der Änderungen der Anforderungen an das ÖROKO durch die Novellierung des Tiroler Raumordnungsgesetzes 2011 – diese nicht gesamtstädtisch aufbereitet und stehen für eine Publikation derzeit noch nicht zur Verfügung.

[6] Daten aus der Widmungsbilanz Stand November 2008.

bezogen auf das bestehende und künftige Bauland an sich, das nur in sehr engen Grenzen erweiterbar ist und daher verstärkt verdichtet bebaut werden muss, besteht enorme Konkurrenz zwischen den verschiedenen Nutzungen. Einer Neuerschließung zusätzlicher Siedlungsfläche sind durch die Topographie (keine Anbindungsmöglichkeit der Verkehrswege) ganz grundsätzlich, durch Ausschlussgebiete aufgrund von Naturgefahren (etwa Wildbäche und Lawinengebiete) sowie ökonomischen und ökologischen Überlegungen restriktive Grenzen gesetzt.

Dieser langfristig eingeschränkte Handlungsspielraum im flächenmäßigen Wachstum wird durch das Verhältnis der noch vorhandenen Baulandreserven im Vergleich zum Baulandverbrauch besonders deutlich. Für die zukünftige Entwicklung steht von rund 1.370 ha gewidmetem Bauland in der Stadt weniger als ein Zehntel, etwa 150 ha, an Baulandreserven zur Verfügung [7]. Dies sind jene Flächen, welche als Bauland, Sonderfläche oder Vorbehaltsfläche gewidmet, aber noch nicht bebaut sind. Abzuziehen sind davon ca. 13 ha, die für Grün- bzw. Freiflächennutzungen vorgesehen sind. Auf Wohngebietswidmungen entfallen ca. 95 ha, wovon die meisten Reserven im Westen der Stadt zu finden sind, insbesondere in den Stadtbereichen Hötting-West mit ca. 18 ha und in der Höttinger Au mit 17 ha. Auch die Katastralgemeinde Vill und Igls auf der südlichen Mittelgebirgsterrasse oberhalb der Kernstadt verfügen mit 11 ha noch über einen hohen Anteil an Baulandreserven. Den zweitgrößten Anteil machen Baulandreserven in der Widmungskategorie Gewerbe- und Industriegebiet im Ausmaß von fast 36 ha aus. Diese liegen zum überwiegenden Teil im Osten der Stadt, wobei der größte Bereich das Gewerbegebiet Rossau mit 17 ha und das Gewerbegebiet Mühlau/ Arzl an der Hallerstraße mit etwa 10 ha sind.

Für den Baulandbedarf der letzten Jahre wurden neben Neuwidmungen in großem Ausmaß die vorhandenen Baulandreserven verbraucht (ca. dreimal so viel, wie Neuwidmungen!). In der Periode zwischen der Grundlagenerhebung für das ÖROKO 2002 ab 1999 und der STRUKTURANALYSE 2007 waren das fast 34 ha, wovon allerdings auch ein Großteils für Sondernutzungen, nicht für Wohnnutzung, herangezogen wurde. In einer groben Überschlagsrechnung könnte davon ausgegangen werden, dass bei linear steigendem Wachstum die vorhandenen Baulandreserven für Wohnen noch ca. 20 Jahre zur Befriedigung des Bedarfs ausreichen würden.

2.4 … verlangen nach besonderen Lösungen.

Unter diesen Rahmenbedingungen ist der allgemein gültige Ansatz eines sparsamen Umgangs mit Grund und Boden besonders elementar und muss auf verschiedenen Handlungsebenen verfolgt werden.

Die Landeshauptstadt Innsbruck verfügt über einen sehr geringen Anteil an baulandgeeigneten Eigengrund, Aktionen des aktiven großflächigen Flächenmanagement kommen daher nur untergeordnet in Frage. Die Baulandreserven sind im überwiegenden Maße in Privateigentum, eine steuernde Einflussnahme auf die zeit- und lagegerechte bauliche Verwertung sind kaum gegeben. Umso mehr haben Gespräche, Verhandlungen und Kooperationen mit Investoren und Bauherren daher einen besonderen Stellenwert und sind auch bei "kleineren" Projekten unumgänglich. Sowohl für Bauherren als auch die Stadtplanung ist dies nicht immer eine einfache oder konfliktfreie Aufgabe, es ist aber für die Einbettung des einzelnen Projektes in die gesamtstädtische Strategie notwendig.

3 SPARSAME BODENNUTZUNG ALS ZIEL - DURCHMISCHUNG ALS MASSNAHME

Raumbezogene Grundprinzipien der Tiroler Landesentwicklung sind im Raumordnungsplan „ZukunftsRaum Tirol_2012" festgehalten, so sind *"Siedlungen abgestimmt auf die Bedürfnisse der Bevölkerung und der Wirtschaft* [zu entwickeln] *und auf eine zweckmäßige und sparsame Nutzung der verfügbaren Flächen" zu achten. "Raumstrukturen, die eine gute Vernetzung der verschiedenen Bedürfnisse der Bevölkerung (Wohnen, Arbeiten, Bildung, Versorgung, Erholung, ...) auf möglichst kurzen Wegen ermöglichen"* sollen umgesetzt werden (ATLR, 2001, S. 47) [8]. Umschrieben mit dem Begriff der "kompakten Siedlung" liegt das

[7] Werte aus der STRUKTURANALYSE 2007. Im Zuge der Novellierung des TROG 2011 werden die Baulandreserven zukünftig zentral vom Amt der Tiroler Landesregierung erhoben und den Gemeinden zur Verfügung gestellt.

[8] Die übergeordneten Raumplanerischen Ziele werden in der "Tiroler Nachhaltigkeitsstrategie 2012 - Leben mit Zukunft" (ATLR 2012) programmatisch für das Land Tirol festgelegt. Dieses Strategiepapier ist der derzeit noch in der Begutachtungsphase und liegt als Diskussionsentwurf vor. Bereits von der Landesregierung rechtverbindlich beschlossen ist der Raumordnungsplan "ZukunftsRaum Tirol_2011 – Strategien zur Landesentwicklung" (ATLR 2011).

übergeordnete Ziel in der Forcierung einer Innenentwicklung bestehender Siedlungsräume. Dies soll primär durch die Nutzung des Gebäudebestandes erfolgen und in zweiter Linie durch "Nachverdichtungen, das Schließen von Baulücken, die Mobilisierung bereits gewidmeten Baulandes und Arrondierungen an Siedlungsrändern" realisiert werden. Des Weiteren sollen *"verträgliche Nutzungsmischungen eine 'Raumordnung der kurzen Wege' ermöglichen"* (ATLR, 2001, S. 58). In der raumplanerischen Umsetzung setzt dies eine konfliktminimierende Anordnung der verschiedenen Nutzungen mit einer Reduzierung bzw. Vermeidung von Puffer-, Abstands- und Ausgleichflächen voraus. Auch wäre die Körnung der verschiedenen Nutzungen klein zu halten, um Distanzen zu minimieren. Gleichzeitig ist es erforderlich, die Dichte im Gleichgewicht mit wachsenden stadtplanerischen, architektonischen und raumökonomischen Qualitätsansprüchen anzuheben.

3.1 Planungsrechtlicher Rahmen

Implizit wird die Aufgabe der Schonung der Ressource Boden in den Zielen des § 27 Abs. 2 Lit. a TROG 2011 [9] *„die Erhaltung und Entwicklung des Siedlungsraumes und die Verhinderung der Zersiedelung durch die bestmögliche Anordnung und Gliederung der Bebauung, insbesondere des Baulandes"* angeführt. Die diesbezügliche Umsetzungsebene wäre jene des Örtlichen Entwicklungskonzeptes ÖROKO (vgl. TROG 2011 2. Abschnitt §§31), welches als Verordnung der Gemeinde die übergeordneten Leitziele zur Gesamtstadtentwicklung sowie die strategischen Vorgangsweisen festlegt. So wird mit dem ÖROKO 2002 der Stadt Innsbruck auch hinsichtlich der räumlichen Entwicklung ein haushälterischer Umgang mit Grund und Boden, mäßiges Randwachstum und verstärkte Innenentwicklung bei gleichzeitigem Erhalt eines funktionstüchtigen Frei- und Grünflächensystems innerhalb des bebauten Gebiets verfolgt (vgl. ÖROKO 2002 S.6).

Explizit angeführt ist das Prinzip des Bodensparens in der folgenden gesetzlichen Zielbestimmung des §27 Abs. 2 Lit. b TROG 2011 *„Ausweisung ausreichender Flächen zur Befriedigung des Wohnbedarfs der Bevölkerung und für die Erhaltung und Weiterentwicklung der Wirtschaft entsprechend dem bei einer zweckmäßigen und bodensparenden Bebauung* […]" sowie §27 Abs. 2 Lit. e TROG 2011 *"die Vorsorge für eine zweckmäßige und Boden sparende, auf die Bedürfnisse abgestimmte Bebauung unter Berücksichtigung der Möglichkeiten verdichteter Bauformen einschließlich der nachträglichen Verdichtung bestehender Bauformen"*. Diese Handlungsanweisungen beziehen sich auf den Bereich der Bebauungsplanung.

Die Ebene der Flächenwidmungsplanung, die prinzipiell für Re-mixing beziehungsweise Durchmischung von Nutzungen im Stadtraum wesentlich ist, wird mit dem § 27 Abs. 2 Lit c TROG behandelt: *„die weitest mögliche Vermeidung von Nutzungskonflikten und wechselseitigen Beeinträchtigungen beim Zusammentreffen verschiedener Widmungen,* […]". Darüber hinaus beziehen sich die Definitionen einzelner Widmungskategorien auch auf dieses Thema.

3.2 Die Flächenwidmung bestimmt mögliche Nutzungsmischung

Funktionale Durchmischung wird in den Zielformulierungen des TROG (siehe oben) eher als möglicher Konfliktfall angenommen und nicht als strategische Herangehensweise zur Umsetzung einer nachhaltigen Stadt. Jedoch sind in den entsprechenden Paragraphen die die Beschreibungen der verschiedenen Baulandkategorien enthalten, die rechtlichen Möglichkeiten der Nutzungsmischung explizit angeführt.

Im Wohngebiet (TROG 2011 § 38) können Grundflächen auch als gemischtes Wohngebiet ausgewiesen werden in denen "öffentliche Gebäude, Geschäfts- und Verwaltungsgebäude, Gebäude für Gastgewerbebetriebe […] und Gebäude für sonstige Kleinbetriebe errichtet werden" können (ebd. Abs.2). Die Kategorien der Mischgebiete (TROG 2011 § 40 mit allgemeinen Mischgebiet, Kerngebiet, Tourismusgebiet und landwirtschaftlichen Mischgebiet) beziehen sich auf die unterschiedlichen Anforderungen der Mischung verschiedener Nutzungen. Bei diesen "Misch-Festlegungen" wird als kleinste Einheit das Gebäude herangezogen. Allerdings ermöglicht eine zusätzliche Widmungskategorie, die einer "Sonderfläche für Widmungen in Teilfestlegungen" nach §51 TROG 2011, auch eine kleinkörnigere Mischung, da auf einer Fläche *„die Festlegung verschiedener Verwendungszwecke für einzelne Ebenen von Grundflächen oder für Teilflächen solcher Ebenen"* zulässig ist.

Auf dessen Inhalt und insbesondere die angeführten Einzelmaßnahmen wird in der Tiroler Nachhaltigkeitsstrategie 2012 auch verwiesen.

[9] TIROLER RAUMORDNUNGSGESETZ 2006 in der Wiederverlautbarung vom 28.Juni 2011

3.3 Herausforderungen der Durchmischung

Auf raumplanerischer Ebene steht folglich ein Instrumentarium zur Verfügung, um Nutzungsmischung im Sinne von ressourceneffizienter Bodennutzung zu berücksichtigen und zu unterstützen. Dies ist jedoch nur ein Teil eines komplexen sozioökonomischen Gefüges, das schlussendlich für städtische Vielfalt und stabile/attraktive Quartiere steht.

So können in der Stadt unterschiedliche Phänomene in Zusammenhang mit Nutzungsmischung beobachtet werden. Im Bestand etwa sind zwei fast diametral gegenäufige Entwicklungstendenzen in Innsbruck (wie generell in fast allen europäischen Städten) erkennbar. Auf der einen Seite ist es gelungen, die bis vor 10 Jahren sukzessive Entmischung der Innsbrucker Innenstadt mit dem Verlust als Wohnstandort hintanzuhalten. Bei gleichzeitiger Stärkung als Dienstleistungs- und Einkaufsort steigt die Einwohnerzahl [10] wieder. Dies wirkt stabilisierend auf den gewerblichen Nutzungsmix ebenso, wie auf die soziale Mischung. Maßnahmen dafür waren Förderungen für Revitalisierung des Gebäudebestandes sowie moderate Nachverdichtungen im Bestand (Dachbodenausbau etc.). Auf der anderen Seite schreitet die Ausdünnung der Versorgungsfunktion in Stadtteilsubzentren, der traditionellen Einkaufsstraßen in den Stadtteilen, mit Freiständen bei den Geschäftslokalen voran. Dies trifft in Innsbruck zum Teil auf die Dorfzentren der sechs eingemeindeten Dörfer (Vill und Igls im Süden, Amras im Osten, Arzl, Mühlau, Hötting im Norden) zu. Gewerbliche Nutzung, Versorgung mit Dienstleistungen und Gütern des täglichen Bedarfs verlieren in Folge einer Konzentration von Handelsstrukturen an Stadt(teil-)Rändern und in der Innenstadt bei gleichzeitig steigender Mobilität der Einwohner die Erwerbsgrundlage. Starke Impulse gegen diesen Trend kommen mitunter von den Anwohnerinnen und Anwohnern selber und der lokalen Kaufmannschaft [11]. Die Initiative im Bereich Wiltener Platzl ist erfolgreiches Beispiel für das Zusammenwirken stadtgestalterischer und stadtplanerischer Investitionen die den Wirtschaftsstandort festigen und zu neuem sozioökonomischen Quartiersbewußtsein führt.

Besonders im Fokus der Stadtplanung stehen derzeit jedoch nutzungsdurchmischte neue Quartiere bzw. Gebäudekomplexe [12]. Aktuelle Entwicklungen zeigen positive Beispiele aber auch Grenzen der Zielsetzung einer durchmischten Stadt auf. Der Zwang zur Innenentwicklung mit höheren Dichten führt grundsätzlich zu einer höheren Komplexität in Planung und Ausführung, was auch in höheren Entwicklungskosten resultieren kann. Ökonomische Faktoren wiederum verursachen teils enorme Forderungen hinsichtlich Ausnutzbarkeit einer Baulandfläche und auch starke Verdrängungssituationen. So geraten bei Mischwidmungen gewerbliche Betriebe aufgrund der erzielbaren sehr hohen Grundpreisrenditen durch Wohnen in ein „Hintertreffen". Gewerblich gewidmetes Bauland ist zwar an sich bereits sehr hochpreisig, jedoch noch wesentlich günstiger als Wohnbauland. Die Baulandpreise, die mit einer Mischnutzung und -widmung einhergehen, sind für Betriebe nicht mehr finanzierbar. Im österreichischen Landeshauptstadtvergleich schneidet Innsbruck sowohl bei Miete, Kauf als auch Grundpreis am teuersten ab [13]. Vor diesem Hintergrund besteht, auch von politischer Seite, der Wunsch, derzeit ungenutzte gewerbliche Flächen im Sinne einer Wohnnutzung umzuwidmen. Die notwendige Vorsorge und Sicherung der Flächen als Basis einer langfristig gedeihlichen wirtschaftlichen Entwicklung werden so mitunter zum Politikum.

Darüber hinaus werden raumordnerische Ziele und Steuerungsmöglichkeiten durch Gesetze aus der Umweltmaterie, insbesondere durch die Gewerbeordnung teils konterkariert. Insbesondere bei Nachbarschaft von betrieblicher/gewerblicher Nutzung und Wohnen entstehen große Herausforderungen an Planung und Umsetzung, um gegenseitige Beeinträchtigungen und Unzumutbarkeiten hintan zu halten. Die streng gefasste Definition von "Zumutbarkeit" und des Status des „Nachbarn" in der Gewerbeordnung können leicht dazu führen, dass gewerbliche Nutzungen–egal ob Bestand oder Planung–eingeschränkt oder sogar

[10] Seit dem Jahr 2001 wurde ein Anstieg von fast 14% auf 5.827 EinwohnerInnen verzeichnet. Quelle: Lokales Melderegister, Statistik und Berichtwesen, Magistrat der Landeshauptstadt Innsbruck, 2012.

[11] Dazu sei auf die „Gute-Praxis-Beispiele" aus Wien (Wallensteinstraße), Lokale Agenda 21 Prozesse und Arbeiten der Gebietsbetreuungen verwiesen und auch auf KRAJASITS 2009

[12] Anm. der Autorinnen: Die intensive Auseinandersetzung in der täglichen praktischen Arbeit der Stadtplanung Innsbruck mit den Herausforderungen im Zusammenhang mit Nutzungsmischung war Anlass für die Reflexion in Form des vorliegenden Textes.

[13] Immobilienpreisspiegel der Wirtschaftskammer 2011: "In Innsbruck werden zwischen 800 und 1.200 € bei höheren Baudichten geboten". Stadtintern kursiert mitunter ein Wert knapp unter der 2.000 €-Marke/m² Baugrund. (WKO, 2011)

verhindert werden, indem durch heranrückende Wohnnutzungen die Betriebsbewilligungen nicht verlängert werden können, da Auflagen zur Vermeidung von Emissionen (Lärm, Geruch, Staub etc.) erforderlich sind. Vor diesem gesetzlichen Hintergrund ist also eine Durchmischung von Betrieben und Wohnen raumplanerisch äußerst diffizil und problematisch zu sehen.

Bei neuen Bauvorhaben und Quartiersentwicklungen, die ein Annähern oder Durchmischen unterschiedlicher Nutzungen bezwecken, ist die Stadt daher wesentlich von kooperativen und bereitwilligen Entwicklern abhängig. Auch, da neben geringeren Gewinnen bei der Verwertung durch eine geplante Mischnutzung mitunter auch noch höhere Aufwendungen für Planung und Ausführung entstehen können, um gegenseitige Beeinträchtigungen zwischen Nutzungen zu verhindern. Raum- und stadtplanerische Ziele zur kompakten, durchmischten Stadt treten dann ungewollt in Konkurrenz zu Renditeüberlegungen und Verwertungsinteressen der Grundeigentümer und Bauherren.

4 STRATEGIEN ZUR FUNKTIONELLEN MISCHUNG

Die Phrase “Re-mixing the city” subsumiert eine große Bandbreite an stadtplanerischen Begriffen, die in ihrer aktuellen Bedeutungsinterpretation durchwegs positiv konnotiert sind: Kompaktheit, Dichte, Urbanität / Lebendigkeit, Ressourceneffizienz, Integration, kurze Wege, (Dienst-)Leistungsvielfalt, Wissenskultur, sozialer Zusammenhalt, Nachhaltigkeit und vieles mehr (vgl. BERGHAUSER PONT, 2010 und KLOOSTERMANN 2009). Für die Beschreibung beziehungsweise Analyse einer Durchmischung der Stadt dienen gängiger Weise die Kategorien Körnung (grain), Dichte (density) und Durchlässigkeit/ Vernetzung (permeability) [14]. Die Körnung unterscheidet die Ebene des Quartiers, des Baublockes, des Gebäudes und auch unterschiedliche Nutzungen innerhalb eines Gebäudes. Bei der Dichte ist zwischen baulicher, funktioneller und Bevölkerungsdichte zu unterscheiden. Durchlässigkeit beschreibt einerseits bauliche Nähe aber auch die Möglichkeit der Nutzungsänderung (vgl. NES 2012). Für diese komplexe Vernetzung von räumlicher Struktur und sozioökonomischen Anforderungen bieten die Raumplanung mit Flächenwidmungsplan oder Bebauungsplan nur zum Teil entsprechende Instrumentarien.

Daher ist jedenfalls positiv zu verzeichnen, dass es in Anbetracht der beschränkten Marktverfügbarkeit von Grund und Boden (und einer sehr fragmentierten Besitzstruktur) in den letzten Jahren gelungen ist, auch die bodenpolitische Tätigkeit der Stadtgemeinde zu verstärkten. Trotz oder gerade wegen des hohen Grundpreisniveaus ist auch das politische Bewusstsein gestiegen, in größerem Ausmaß aktiv Grundstücke zu erwerben - nicht nur für kurzfristige Bedürfnisse, sondern auch im Sinne einer großflächigeren und langfristigen Siedlungsentwicklung und auch, um so (wenn auch eingeschränkt) Einfluss auf die Grundpreise nehmen zu können.

4.1 Das Örtliche Raumordnungskonzept enthält Strategien für eine verdichtete, gemischte Stadt

Trotz der grundsätzlichen räumlichen Unschärfe des ÖROKO ist es gelungen, insb. durch die Einführung der “Besonderen städtebaulichen Entwicklungsgebiete” (BE-Gebiet) ein strategisches Instrument zur integrierten Planung zu schaffen, die auch auf die komplexen Zusammenhänge einer Verdichtung und Durchmischung eingehen kann. Als BE-Gebiete wurden größere unbebaute Baulandreserven, städtebaulich unternutzte beziehungsweise nicht standortgemäß genutzte Flächen sowie größere Baulanderweiterungen ausgewiesen. Die BE-Gebiete selber können einem oder mehreren stadtentwicklungsplanerischen Handlungsfeldern zugeordnet werden. Dies sind Stadterweiterung, Umstrukturierung, Verdichtung und Mehrfachnutzung. Bei der Festlegung wurden folgende Strategien verfolgt:

- gesamthafte Planung und Entwicklung der Gebiete (städtebauliche und / oder architektonische Wettbewerbe, ggf. Realisierung in Etappen)
- Vorgabe der grundsätzlich angestrebten Nutzungen (auch Mischungen) und Sonderanforderungen,
- Realisierung höherer baulicher Dichten zu Gunsten größerer Grünflächenanteile
- Berücksichtigung der notwendigen technischen und sozialen Infrastruktur einschließlich der Grünflächenausstattung

[14] HAUSLEITNER 2010 beschreibt diese Kategorien umfangreich für die Voraussetzung städtischer Durchmischung insbesondere in Hinblick auf (klein-)gewerbliche Nutzung.

- gerechte Aufteilung sowohl der „Lasten“ (Infrastrukturfolgekosten) als auch des „Mehrwerts“ zwischen den Grundeigentümern und der Stadtgemeinde Innsbruck
- Festlegung von Zeithorizonten, in welchen eine Realisierung in Abhängigkeit vom tatsächlichen Bedarf und der Verfügbarkeit der Grundstücke erfolgen soll. Der längste ausgewiesene Zeithorizont stellt dabei die strategische Zurückstellung im Sinne zukünftiger Handlungsoptionen dar.

Die Umsetzung erfolgte stets in enger Kooperation der Stadt mit Bauwerbern und Projektentwicklern. Eine Evaluierung des ÖROKO 2002 als Vorbereitung für die Fortschreibung zeigt, dass die verfolgte Strategie sehr erfolgreich war und auch weiterhin beibehalten werden soll.

4.2 Integrative Planung und intensiver Austausch

Die Rahmenbedingungen und die beschriebenen Strategien des ÖROKO führen dazu, dass im stadtplanerischen Alltag intensiv an kooperativen Umsetzungsprozessen gearbeitet werden muss. Die dabei auch in Innsbruck gemachten Erfahrungen und Einschätzungen wurden bereits im Jahr 2000 u.a. in den Ergebnissen des ExWoSt-Forschungsfeld [15] *“Nutzungsmischung im Städtebau” des Deutschen Bundesamtes für Bauwesen und Raumordnung treffend formuliert: „Die Mischung von Nutzungen in einem Gebäude, beispielsweise Läden im Erdgeschoss, darüber Büros und dann Wohnungen, ist bei vielen Investoren unbeliebt. Sie verursacht höhere Planungs-, Bau- und Bewirtschaftungskosten. Die Modellvorhaben belegen jedoch, dass auch vertikale Mischung an geeigneten Standorten wirtschaftlich tragfähig sein kann, da intensivere Grundstücksnutzung, relativ geringere Erschließungskosten und höhere Erträge der einzelnen Nutzungselemente den Mehraufwand ausgleichen. Widerstände der Investoren gegen Nutzungsmischung sind häufiger auf Spezialisierungen und Routinen als auf ökonomische Kalküle zurückzuführen. Eine wichtige Aufgabe für die Stadtplanung ist daher, Investoren von der Wirtschaftlichkeit von Mischprojekten zu überzeugen.”* (BMVBS, 2000 S.5)

4.3 Umsetzung durch Wettbewerbe und Vertragsraumordnung

Um den Herausforderungen durch Lage, Konfiguration und Dichte qualitätvoll und kreativ zu begegnen, wird seit fast 20 Jahren in Verwaltung und Politik der Stadt Innsbruck eine konsequente Wettbewerbspolitik verfolgt. Dies hat nicht nur positive Auswirkungen auf die architektonische Qualität, sondern auch auf städtebauliche Lösungen. Sehr zufriedenstellende Beispiele gibt es im Stadtgebiet viele, etwa die Universitäts- und Landesbibliothek Tirol, die die Topographie und Lage im Stadtraum geschickt nutzt und statt der ursprünglich städtebaulich unbefriedigenden Situation eines Grabens entlang der Straße nun einen belebten Begegnungsraum schafft [16].

Besonders bei Projekten, die Nutzungsmischungen vorsehen, werden auch die Wettbewerbe sehr komplex: beginnend bei umfassenden städtebaulichen Zielsetzungen und Randbedingungen, die hohe Zahl an zu beteiligenden Personen, das Wettbewerbsverfahren selbst, bis zur Realisierung des Siegerprojektes. Um die so gewonnenen Projektqualitäten auch bei der projektbezogenen Widmung und Bebauungsplanung zu sichern, reicht oft die reine Festlegung im Flächenwidmungsplan oder Bebauungsplan nicht aus. Daher haben sich in Innsbruck privatrechtliche Projektsicherungsverträge bewährt. Hierin können unter anderem spezifische Anforderungen an Konzeption, Ausführung und Ausstattung, die aus der Projektentwicklung erwachsen sind, und die wesentliche Voraussetzung für die Umsetzung des Vorhabens darstellen, verbindlich festgelegt werden. Der Vertrag wird in der Regel direkt an die Beschlussfassung des Flächenwidmungs- oder Bebauungsplanes geknüpft, da die hierin getroffenen Festlegungen oft überhaupt erst durch die mit der Projektentwicklung definierten, flankierenden Maßnahmen fachlich und politisch vertretbar werden. Oft können auf diesem Wege auch Konflikten neuer Nutzungen mit bestehenden Nachbarschaften erfolgreich vermieden werden.

5 DIE BANDBREITE AKTUELLER UMSETZUNGSBEISPIELE IN INNSBRUCK

5.1 Bildung und Konsum unter einem Dach? Ein gelungenes Beispiel!

Besondere Bedeutung kommt der Mischung von verschiedenen Sondernutzungen zu. Als Initialzündung kann dabei durchaus die Umstrukturierung und Mehrfachnutzung im Zuge der Innsbrucker Rathausgalerien bezeichnet werden. Die Verschränkung kommunaler Infrastruktur und Verwaltung mit Geschäften, aber auch öffentlicher konsumfreier Nutzung war herausfordernd. Im Alltag hat sie sich bewährt. Die Rathausgalerien werden trotz privaten Eigentums und gewerblicher Nutzung des Erdgeschoßes als Erweiterung des städtischen Straßenfreiraumes gesehen. Die fußläufigen Quer- und Anbindungen bieten für das umliegende innerstädtische Quartier eine hohe Qualität.

Ein neueres, sehr positives Beispiel einer Stapelung verschiedener, normalerweise sehr flächenintensiver Solitärnutzungen ist das Bundesrealgymnasium in der Au mit dem Einkaufszentrum West. Von städtischer Seite war man auf der Suche nach einem Standort für ein Gymnasium im Westen der Stadt, konnte jedoch keine verfügbare und auch ökonomisch vertretbare Fläche finden. Gleichzeitig gab es konkrete private Projektenwicklungen für ein Einkaufszentrum an einem ehemaligen gewerblich genutzten Standort in diesem Stadtteil. Am Verhandlungsweg wurde in der Folge zwischen Investor und Landeshauptstadt Innsbruck mit dem "Bildungs- und Nahversorgungszentrum Innsbruck West" ein gemeinsames Bauvorhaben entwickelt. Für die vielen Partner (Projektentwicklung Signa Holding, Bundesimmobilien GesmbH als Entwickler für Bundesministerium für Unterricht, Kunst und Kultur und Landeshauptstadt Innsbruck) resultierte dies in einer Win-Win-Situation. Eine offene Gesprächskultur und realistische Zielvorstellungen auf allen Seiten, sowie eine integrative Zusammenarbeit überzeugt durch das positive Resultat. Dies wird auch in einer breitangelegten deutschen Studie zur Nutzungsmischung aus 2000 festgehalten: *„Die wichtigsten Elemente eines erfolgreichen Umsetzungsverfahrens sind eine konsequente und innovative Anwendung des bau- und planungsrechtlichen Instrumentariums und informeller Planungsinstrumente, eine aktive Vermarktung des "Produktes" Nutzungsmischung mit einem effizienten Projektmanagement, die Unterstützung durch die Kommunalpolitik sowie eine intensive Information und Beratung der Träger und Nutzer."* (BMVBS, 2000 S.1)

Abb. 1: Einkaufszentrum West und Bundesrealgymnasium in der Au, Bachlechnerstraße, Innsbruck von Arge Reitter - Eck–Reiter. Aktuelle Ansicht von Süden. Das Luftbild zeigt die stadträumliche Situation der Baustelle: im Kreuzungspunkt verschiedener baulicher Strukturen an einer stark befahrenen Kreuzung.

Das aus einem geladenen Wettbewerb als Sieger hervorgegangene Projekt der Arge Reitter - Eck–Reiter fand für die konträren Nutzungen eines Einkaufszentrum und einer Bildungseinrichtung die entsprechende bauliche Form; bei gleichzeitiger Kompaktheit und Einheit wird eine klare und notwendige Trennung der Bereiche sichergestellt. Der kubische Solitärbaukörper realisiert auf insgesamt sechs Ebenen, zwei Untergeschossen und vier Obergeschossen, für die Nutzer jeweils spezifisch für ihre Bedürfnisse entwickelte, komplett getrennt erschlossene Bereiche.

Die Tiefgarage nimmt das gesamte 2. Untergeschoß sowie etwa die Hälfte des 1. Untergeschoßes ein, die andere Hälfte dient als Verkaufsebene für den Lebensmittelhandel mit Kassenbereichen die direkt von der Tiefgarage aus erreichbar sind. Die dreigeschossige Mall hat insgesamt ca. 13.800 m² Kundenfläche mit über 30 Geschäften und Gastronomiebetrieben. Das Gymnasium wird über eine eigene Eingangsterrasse im 1. Obergeschoß erschlossen, welche ausschließlich vom öffentlichen Straßenraum erreichbar ist. Während das Einkaufzentrum mit Schaufenstern Verbindung zum Außenraum aufnimmt, ist die Schule konsequent nach Innen orientiert und reagiert derart auf den verkehrlich intensiven Standort.

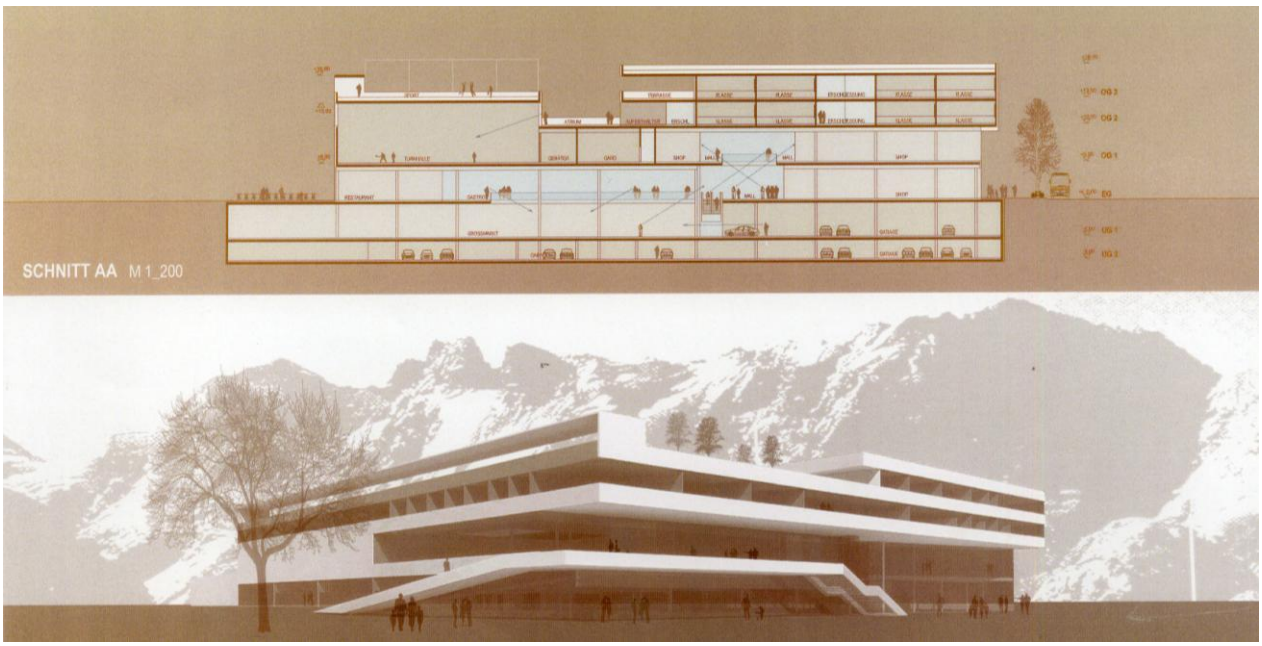

Abb. 1: Einkaufszentrum West und Bundesrealgymnasium in der Au. Abbildungen aus dem Wettbewerbsbeitrag. Der Schnitt zeigt die Verschränkung der Nutzungen in der Gebäudekonfiguration.

Über einem großzügigen Foyer und der Turnhalle befinden sich im 2. Obergeschoß die Verwaltungsräume der Schule sowie die Nachmittagsbetreuung. Durch zwei große eingeschnittene Hofbereiche werden jeweils zweigeschossige „Schuleinheiten" gebildet. Großzügige interne Erschließungszonen mit Aufenthaltsnischen innerhalb dieser „Schuleinheiten" bieten gute Voraussetzungen für Kommunikation, Bewegung und unterschiedliche zeitgemäße Unterrichtsformen. Im südlichen Teil des 3. Obergeschoßes ist über den Verwaltungsräumen sowie der Turnhalle eine Dachterrasse als zusätzlicher Freibereich und Pausenhof angeordnet.

Im Alltag hat sich das ursprünglich sehr kritische gesehene Projekt der Stapelung von Bildung und Konsum bewährt und wird auch durch Mehrfachnutzung etwa der Schulräumlichkeiten immer mehr zum Stadtteilzentrum. Besonders ist auch der ökonomische Nutzen durch Public Private Partnership zu erwähnen.

5.2 Wohnen in gewerblicher Nachbarschaft–Die Herausforderungen!

Die Schwierigkeiten einer Durchmischung zeigen sich dagegen insbesondere bei einer Mischung mit Wohnen. Das hohe Immobilienpreisniveau in Innsbruck verursacht einen großen Druck, Wohnen auf Gewerbeflächen (die über eine entsprechende Widmung, Lage, Nachbarschaft und infrastrukturelle Anbindung verfügen würden) zu realisieren. Dies insb. dann, wenn Gewerbeflächen aktuell nicht genutzt sind und an bereits vorhandene Wohnnutzung angrenzen.

In einer solchen (zum Stadtzentrum orientierten) Randlage eines Gewerbegebietes wurde eine neue Wohnanlage geplant. Das Gewerbegebiet in diesem Bereich weist im Bestand eher mittlere betriebliche Strukturen mit wenig Kundenfrequenz auf. Durch die sehr gute verkehrliche Anbindung sind hier Lagerflächen, kleine Verteilerzentren und spezialisierte Handelsstrukturen zu finden. Es besteht durch zahlreiche Baulandreserven und geringe bauliche Dichten ein starkes wirtschaftliches Entwicklungspotential, dass es langfristig zu sichern gilt. Die Lage für die neue Wohnnutzung konnte zwar nicht als ideal bezeichnet werden, die Entscheidung dafür fiel aufgrund der angespannten Wohnraumsituation und der Möglichkeit, bei der Projektentwicklung spezifische Schutzmaßnahmen ergreifen zu können. Insbesondere zum Zweck der Durchmischung und Innenverdichtung wurde die Wohnanlage daher grundsätzlich auch planerisch vertreten. Durch die bauliche Situierung sollte es gelingen, introvertierte, sich selbst vor Immissionen schützende qualitätsvolle Wohnräume und auch (private) Freibereiche zu schaffen. Zudem sollte ein integriert geplantes Hotel- und Boardinghaus die Puffernutzung zwischen dem bestehenden Gewerbegebiet und der heranrückenden Wohnanlage übernehmen. Der bestehende Bedarf hierfür und das Interesse seitens des Bauherren lies eine gute Lösung erwarten.

Im Projektverlauf, kurz vor Fertigstellung der Wohnungen wurde nun jedoch vom Projektentwickler beanstandet, dass die städtebauliche Situation zu teuer sei, auch die spezifischen Lärmschutzmaßnahmen

(vorgehängte Fassade, etc.) nicht wirtschaftlich seien und dass es ganz grundsätzlich aufgrund der zwischenzeitlich getätigten hohen Investitionssummen nunmehr unmöglich sei einen Investor für die Errichtung und den Betrieb des Boarding-Hauses zu finden. Zusätzlich zeigt sich in der Praxis, dass Bewohnerinnen und Bewohner neuerer Wohnungen - und hier besonders bei Eigentumsanlagen–die hochpreisig verkauft werden, empfindlicher auf mögliche störende Nutzungen reagieren, als dies in bereits gealterten, gemischten Quartieren der Fall ist. Konflikte zwischen der neuen Wohnnutzung und dem bestehenden Gewerbegebiet scheinen daher wahrscheinlich. Hier sieht man - leider idealtypisch - dass Projekte zur Durchmischung nur funktionieren, wenn alle Akteure an einem Strang ziehen, allfällige Restriktionen als Herausforderungen sehen und gemeinsam an evidenten Vorteilen arbeiten.

6 SCHLUSSFOLGERUNGEN

Schien in den ersten Überlegungen "Re-Mixing the City" das Schlagwort für Stadtplanung in Innsbruck zu sein, zeigt die professionelle Reflexion, dass nicht "Wiederdurchmischung" sondern viel mehr "neue Mischung" planerisches Thema ist.

Grundsätzlich basiert und passiert Mischung in unterschiedlichen städtebaulichen Körnungen, vom Quartier bis auf die Ebene des einzelnen Gebäudes. Die Nutzungen regieren unterschiedlich in den verschiedenen Maßstabsebenen. Innerhalb des Gebäudes sind Mischungen von Wohnnutzungen und gewerblicher Nutzung–leider auch mitunter durch die Vorgaben der Wohnbauförderung oder des Umwelt- und Gewerberechtes–oft Herausforderung oder nicht realisierbar und auch im Alltag schwer dauerhaft aufrecht zu erhalten. Im Stadtraum zeigt sich dies in Leerständen von vorher oft mühsam verhandelten Gewerberäumlichkeiten in Wohngebäuden. Grundsätzlich ist daher die *„funktionale Verflechtung zwischen Wohnen und Arbeiten […] gering. Die räumliche Einheit der Lebensbereiche im Alltag existiert kaum."* (BMVBS, 2000 S.5) Positiv bewährt hat sich vielmehr eine "additive Nutzungsmischung" (vgl. ebd.), die Nähe von unterschiedlichen Nutzungen.

Dagegen gibt es gute Erfahrungen bei der Kombination von Sondernutzungen mit gewerblichen Nutzungen. Sowohl in der Planung, der Umsetzung und auch der Verwertung muss eine dauerhafte Nutzung gesichert sein. Denn es sind nicht nur Vorteile mit einer Nutzungsmischung verbunden. Mischung bedeutet generell, sich im positiven Sinne zu arrangieren (vgl. FOORD, 2010). Voraussetzungen für eine Realisierung sind immer ein Interessensausgleich und dieser verlangt Innovation, Kreativität und Mut zu Neuem auf allen Seiten.

Strategic Forecasting and Planning that City Planners can do Themselves: Examples of Simple but Powerful Visual Techniques for Specifying Urban Outcomes in Growing Metropolitan Regions

Jeremy Dawkins

(Jeremy Dawkins, Centre for Local Government, University of Technology Sydney, PO Box Broadway NSW 2007 Australia, jeremy.dawkins@uts.edu.au)

1 ABSTRACT

Where urban regions are growing and changing quite rapidly, effective metropolitan strategies should be supported with quite detailed projections and descriptions of the region's future subregions, districts, centres and neighbourhoods.

These descriptions should include, for instance, detailed and explicit forecasts, targets and specifications of future population densities and distributions, of future patterns of land use, and of the future social characteristics of neighbourhoods and districts. This detail is not a 'blueprint' or masterplan: it provides a meaningful picture of one possible set of outcomes of the present metropolitan strategy. These kinds of pictures are essential if stakeholders are to engage in a meaningful dialogue with the planners and decision makers. Perhaps even more importantly, these pictures can be continuously refashioned and updated as policies change and as the real city evolves. Without such a detailed picture of the future urban region, metropolitan strategies are not only vague and 'broad brush', but also inaccessible, weak, unconvincing and unable to influence the powerful actors who shape the future region through their day-to-day investment decisions.

This paper presents three concrete examples of visual techniques for exploring and anticipating the future spatial characteristics of the urban region, techniques which are quite powerful but simple enough for the planners to use themselves, thus avoiding forecasts, population projections and scenarios which are driven by the practices and demands of other disciplines.

2 MOTHER OF INVENTION

2.1 Challenges and opportunities

The modest ambition of this paper is to present three examples of the visualisation of metropolitan development to support the formulation of strategic metropolitan policy.

Each example begins with standard demographic and spatial data. Through simple manipulations, the data is transformed into 'operational graphs', 'operational charts' or 'operational maps'. In this form, standard metropolitan data is used to present policy issues in a visual form. More importantly, these 'operational' formats can become live tools for shaping and testing policy.

The experiments that led to these tools were prompted by specific problems. Metropolitan planners in Perth, Western Australia, work within a longstanding tradition of strong regional planning. They have comprehensive statutory powers, bipartisan commitment from governments and a high level of community support. (A description and explanation for this happy situation can be found in Dawkins (2009), written when the author was executive chairman of the Western Australian Planning Commission.) Nevertheless, in the mid-2000s the planners had no effective responses to a number of important policy opportunities.

A centre-left state government – effectively the metropolitan government of Perth, almost solely responsible for urban development, hard and soft infrastructure and urban services, and equipped with an integrated land, transport and urban planning portfolio led by a smart and energetic minister – had won the public argument for a 'sustainable' Perth: impeding sprawl, densifying existing built areas, privileging public transport, expanding the well-equipped and well-run urban rail and bus systems, developing new 'activity centres' and 'activity corridors', and adopting stronger measures to protect water resources and biodiversity (WAPC 2004).

This was a historic opportunity to foster new forms of urban development, and to reverse long-term patterns of low-density car-based suburbs, dispersed employment, poorly located centres of intense activity such as university campuses and hospitals, and a demand-led approach to the provision of land, roads, water, power, etc. Given the role of the state government as the funder, regulator or provider of all these things, and given the high level of legitimacy enjoyed by the state's planning agency, the Western Australian Planning

Commission, there were few institutional or political impediments to major changes in policy and performance. Furthermore, the growth of the metropolitan region, propelled by China's appetite for the energy and mineral resources that Western Australia has in abundance, meant that new policies were not only urgently needed but would have a rapid impact. (A reasonable way to characterise the situation was to say that Perth was halfway through a century of growth, and would grow from 1.5 million to 2.5 or even 3 million by about 2050.)

2.2 Opportunities not taken

If they were to lead this transformation of planning in Perth, the planners would need to do a number of things.

- Firstly, the planners would need to propose how the distribution of the population in the Perth region would change with growth. If the inner and middle areas were to resume the growth that slowed and stopped a few decades ago, how soon, at what rate, and to what degree would 'urban consolidation' impact on their current character? If the outer areas were to slow down and stop growing, how soon and at what rate would this happen? The planners would need a plausible method for arriving at population 'targets', and a method for depicting patterns of growth over time.
- Secondly, the planners/policy makers would need to propose concretely how the existing patterns of urban and suburban development would change, and what the new urban living environments would be like. They would then need to find a way to communicate this to all the stakeholders.
- Thirdly, the planners would need to conceptualise the intended structure of the metropolitan region over time, and find a way to depict it and communicate it.

Over a period of years the Western Australian Planning Commission pressed the Department of Planning and Infrastructure, which provided the Commission with planning services, to undertake the above tasks. No progress was achieved. There appeared to be several reasons for this failure to act. The transference of power from heads of technical departments to ministers, a transference which occurred in most countries with 'representative government' systems during the latter third of the last century, weakened the public sector and led to a serious loss of capacity in departments such as the Department of Planning and Infrastructure. In the period examined in this paper, 2004-2008, the very competence and confidence of the minister only made matters worse. Metropolitan and regional strategic planning is a fairly fragile art with few expert practitioners, so the loss of capacity in this area was nearly total. There was no-one to challenge the demographers and other specialists, who operated their black boxes to produce population projections that were largely impervious to policy objectives.

The projects briefly described and illustrated in this paper were my response to this unfortunate circumstance. The projects – part demographics, part new policy, part persuasion, part graphic communication – were undertaken to demonstrate by example the possibilities of new policies and new ways of communicating them through simple visualisation techniques. They are not offered as more than this, and certainly not as a comprehensive set of regional planning tools.

3 DISTRIBUTING FUTURE POPULATION

3.1 First, meaningful pictures of the past

We worked with readily available statistics on population and households: those for each of the local government areas in the metropolitan region. We could have used statistics of a much finer grain based on census collector districts of roughly 400 households each, but such high-resolution data was not necessary or appropriate. We could have created a different geography, for instance a grid of urban cells. As it happened, the number of local government areas in the region, thirty-two, were sufficient to provide a reasonable mid-resolution picture of the region, and in any event were the obvious areas to work with since the politicians and communities of each of the local governments had to be persuaded that our 'targets' were plausible, probable and acceptable.

We worked with census data from 1961 onwards, because that was within a decade of when post-war growth really took off, and was when the national census settled down into a regular pattern of five-yearly censuses. In each presentation we depicted data for the census year until 1996, and then used both census data and

annual intercensal estimates for the years 1997 to 2007. (Due to local government boundary changes, each graph needed two small boxes to explain sudden changes in trajectories: the boxes said, 'From 1991 the population of "Perth area" splits into Perth, Cambridge, Victoria Park and Vincent' and 'From 1998 Wanneroo splits into Wanneroo and Joondalup. Their respective populations are shown from 1991' respectively.)

For those with a deeper interest in how Perth had developed into its present form, we drew the graph for population change over the previous period, showing the actual number of people by which the local government area increased or decreased in each interval (figure 1). The graph shows significant and unexpected volatility (as different areas were developed and the market changed) and presents a visual impression of when local government areas took off – reflecting Perth's planned frontal expansion – or when they started losing population.

We translated the data into growth rates for each of the intervals (figure 2). While the older suburbs were losing population, there is a clear picture of the new suburbs, in turn, experiencing initial high rates of growth, then decaying gradually until a generalised growth spurt in the late eighties, a time of resource-based economic expansion. The graph demonstrates that growth rates can be highly misleading (rates are a ratio related to the base population, and are correspondingly larger in small local government areas) and at the same time revealing: a small council with a modest population increment is still faced with major challenges if the rate is high.

We depicted the extent to which the different local government areas shared in metropolitan growth (figure 3). Again, there are surprising variations and volatilities, at odds with expectations and conventional wisdom, with local government areas swapping places from census to census. Overall, the graph dramatised how, at any one time, the share of metropolitan growth was dominated by a few outer urban areas.

Finally, we showed the total number of people, at each interval, in each local government area (figure 4). Overall, this is a picture of exponential growth, although local government areas started to grow at different times in the past 45 years. The growth curve of individual local government areas rises and then flattens out: this can be seen in the graph. A number of interesting cases stand out: for instance, three fully developed middle-ring local government areas remain largely stable in the twenty-thousands for four decades, yet the distinct upward movement of one of them in recent years can be taken to foreshadow future demand for inner-city living in all three.

This fourth graph depicted the familiar measure of the total number of people in each of the 32 local government areas, that is, population as commonly understood. This became the benchmark for the next phase of the project, exploring desirable distributions of the regional population in the future.

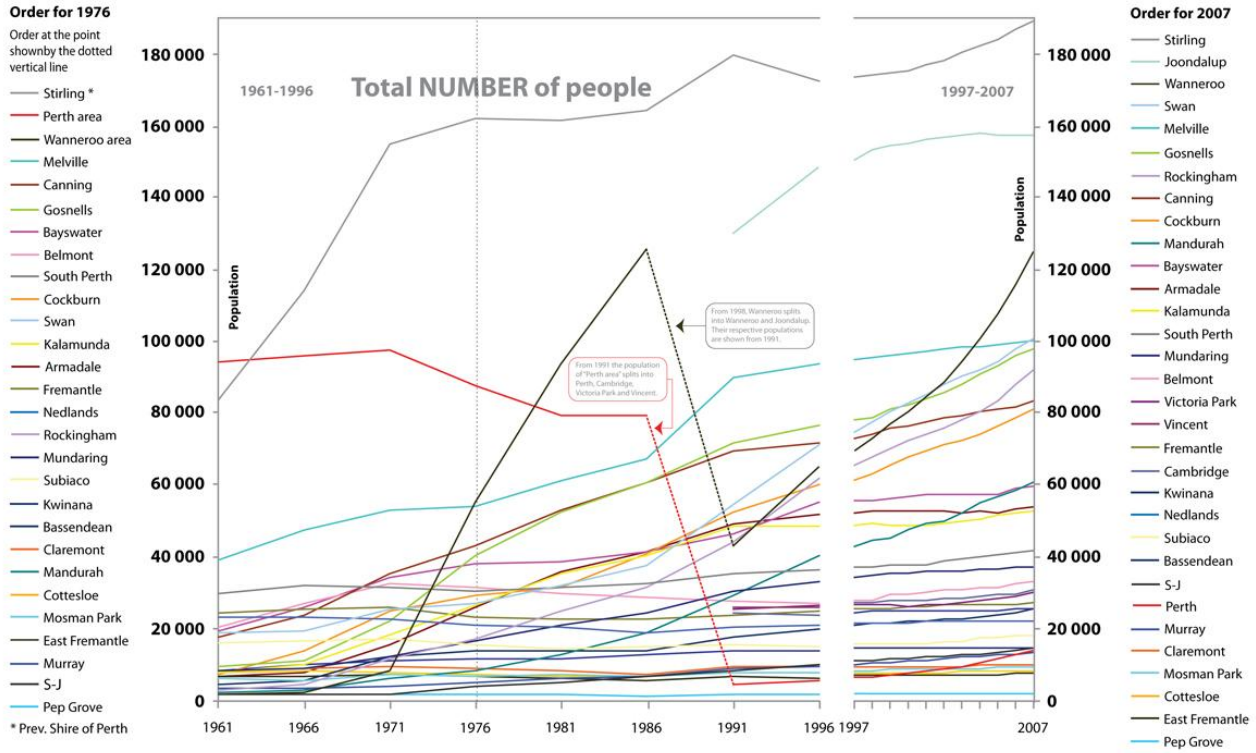

Fig. 4: Population in local government areas in the Perth metropolitan and Peel regions 1961 to 2007 (Dawkins and Matan 2008a, p.13)

3.2 Then, a policy for the future

The demographers in the Department of Planning and Infrastructure used sophisticated methods for allocating the population projections of the Australian Bureau of Statistics to smaller areas, and specifically to Perth's local government areas. They carefully analysed past development and density patterns, and calculated potential capacities based on local zoning and development standards (figure 5). This generated accurate projections only if all these assumptions were correct, and no transformations in policy and performance took place. In other words, the official projections showed us what we did not want Perth to become. Despite this, the demographers regarded any other form of projection as unscientific: they seemed to have no tools with which to assist the planners to project the outcomes of alternative policies, except through mechanical measures such as future zoning changes. Perhaps under this influence, the planners separately attempted to derive various small-area population projections based on simple mathematical formulae, for instance adjusting growth rates down for outer areas and up for inner areas, or applying factors based on, for instance, the number of train stations in a local government area. They were uncomfortable with the idea of subjectively applying a combination of local knowledge and known policy objectives: any projections (no matter how much at odds with commonsense) had to be arrived at by the application of 'objective', numerical methods. The result was a set of projections which, for instance, treated all inner and all outer areas the same, despite fundamental differences in policy terms, and which contemplated sudden step changes in growth rates as a result of the application of notional growth factors.

A novel approach was called for. This could be called a 'planning' approach: subjectively combining a detailed knowledge of the region and its component parts with a clear view of policy objectives. How to apply this approach? The method chosen was a form of reverse engineering, by directly shaping the population curves of each local government area to reflect policy objectives. Specifically, the curves are generated by a table of populations for five-year intervals to 2050 for each of the 32 local government areas. The value of each cell is manually adjusted, with the only hard constraint being no change in the total population for the region in any year: the curves are literally shaped to produce the most appropriate picture of population change across the region. The resulting set of curves in figure 6 has the following characteristics.

- Interval by interval, a plausible change is proposed based on explicit policy objectives (slow outer growth, densify inner areas, intensify future major centres including those on the fringe, recognise

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

growth moving from north to south, strengthen activity corridors, etc) and on a feel for momentum and inertia resulting in development lagging behind policy changes.

- At each of these intervals, for each local government area, the population estimates are based on explicit quantifications of greenfield suburban development, exurban development, intensification of centres, urban infill, and wholesale redevelopment, depending on the nature of the local government area.
- At all times, the total population of the region remains the same as that in the official projections (these are zero-sum redistributions of the population between local government areas).
- Unlike the step projections calculated by other methods, these curves can generate smooth year-to-year, or even month-to-month, population projections (targets).
- The curves are alive: anyone can fine-tune the curves (by adjusting the values in the cells of the table) to propose alternative outcomes, or test scenarios, or to illustrate alternative assumptions and alternative policies.
- At the same time a strict discipline is imposed on the testing of such alternatives: local governments cannot aspire to higher populations (in the case of the booming outer areas) or resist densification (in the case of inner areas) without showing all the gains and losses amongst the other local government areas.

As an aside, it may seem to some readers that the difference between figure 5 and figure 6 is inconsequential. Coming to that conclusion would be to misread the graphs (perhaps because the graphs, admittedly, remain hard to read) or to underestimate the challenges of overcoming momentum, inertia and path dependency in order to reverse current trends in metropolitan growth. The targets depicted in figure 6 are actually bold, even heroic, leading to an ever-widening gap between the intended structure of the region and the business-as-usual region.

For want of a name, figure 6 is an example of an 'operational graph'. Manipulations are carried out by modifying the cells in the associated table of populations, generating a visual and (with a bit of effort) readily understood picture of the regional population over time, and at the same time allowing the population of each local government area for any given year to be read from the table.

This is just an illustration. The same manual-visual technique can be used for larger and smaller areas, for traffic, for housing types, for urban hierarchies, for commercial centres, for the distribution of jobs, etc.

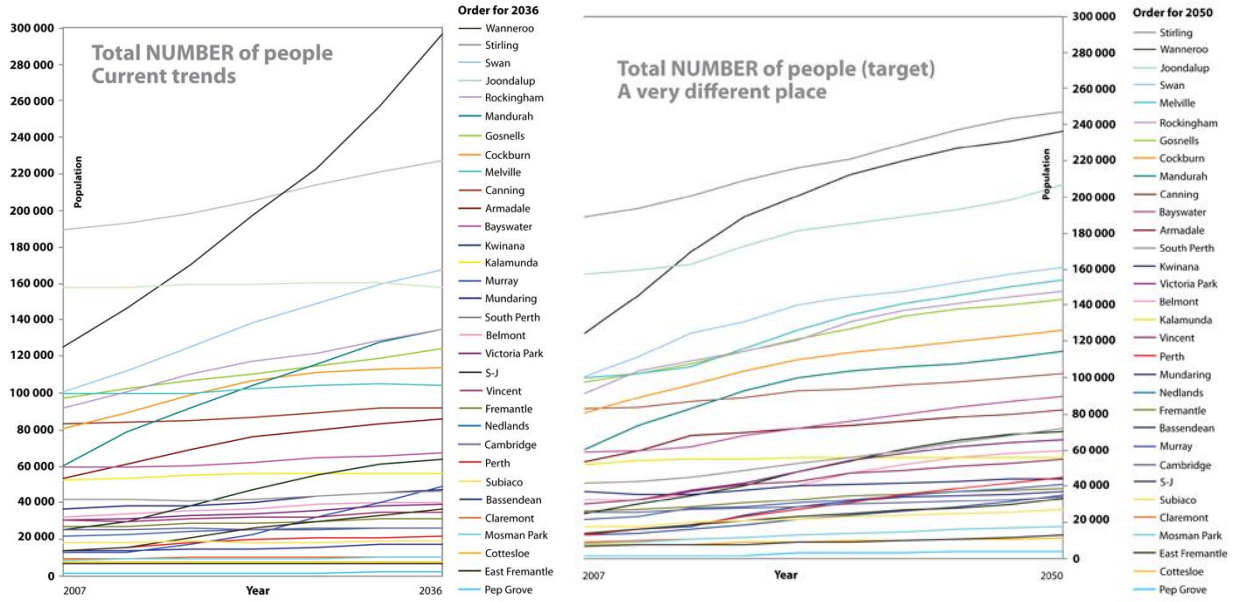

Fig. 5: Official population projections (based on continuation of current trends and policies) (Dawkins and Matan 2008a, p. 14). Fig. 6: Population targets for Perth's local government areas to 2050, (extract from 1961-2050 graph) (Dawkins and Matan 2008a, p. 17)

4 PROFILING URBAN PLACES

4.1 First, x-raying the urban area

In the mid-2000s Perth had an opportunity to begin a significant reconfiguration of the metropolitan region, fundamentally changing the outcomes of the rapid growth that would characterise the next several decades. To better understand the past and present anatomy of the region, and to more concretely describe the forms of urban area that might be possible, it was essential to go beyond averages, norms and generalised patterns. Tradition and habit made this almost impossible: the practice was to write planning rules without feeling any need to first understand the complexity of existing urban areas and processes, to prescribe the future without closely investigating past and present growth trajectories, and to work with coarse tools, such as 'residential', 'commercial centre', '15 dwellings per hectare', etc. (Worse, when measuring or prescribing dwelling density, as in '15 dwellings per hectare', there was no recognition that values can vary by orders of magnitude depending on what kind of 'hectare' forms the denominator of the ratio: site, neighbourhood, local government area, etc.) These practices, which made it nearly impossible to understand the starting point of any development strategy, or to work with the dynamic forces shaping the new built environment, simply meant that regional policies and strategies were not going to change what would happen in any event.

Novel tools were needed to expose the rich complexity of the urban area behind the bland, broad-brush descriptions and proposals. The necessary inputs were readily available.

- Census data was available from the Australian Bureau of Statistics giving household characteristics for each of 3000 collection districts in the region (200-300 households per collection district). For regional analysis this resolution was ideal: both sufficiently fine and sufficiently manageable to reveal the 'DNA' of the region.
- Simple land use data was also available: the state government's Valuer General regularly valued every land parcel in the state, and from field surveys assigned a land use code to every land parcel in their geographic information system.

Accessing the digital and spatially-referenced raw data, we were able to construct tables of broad land use, dwelling density and household size (more strictly, persons per dwelling) for every collection district. To test the methodology, we chose thirteen diverse 'places', each of 53 collection districts. These sample areas constituted an interrupted transect from the northern fringes of the metropolitan region through new suburbs, post-war suburbs and older suburbs to the mixed inner areas and the dense core, the City of Perth.

This analysis was able to provide remarkable insight into the richness of what might have seemed to be a fairly uniform built environment, and to reveal patterns that were otherwise hidden by cruder characterisations of the region. These insights and patterns are presented and discussed in detail in Dawkins and Matan (2008b). There is space here only to provide a glimpse of how the data was presented in a visual form, using data for two of the thirteen places, Subiaco, an attractive, diverse inner area with rich urban, social and environmental resources, and North Joondalup, a newer, more distant area with uniform, low-density residential areas and a planned commercial centre on its way to becoming a subregional CBD (figure 7).

- Land use – the proportion of each collection district used for residential sites, roads and 'other', that is, everything else – was shown in charts for the thirteen places. Each chart became a kind of profile showing similarities and differences between the individual collection districts; the bars at either end gave the resulting land use proportions for the whole 'place'. The charts were assembled on one page so that the similarities and differences in the land use 'profiles' of the thirteen places could be explored and explained.
- Dwelling density was shown in two graphs across the 53 collection districts of each place, one plotting dwellings per residential-site hectare (often inexactly referred to as net density) and the other plotting dwellings per collection district hectare, in other words dwellings divided by the area of the collection district in hectares (equally inexactly referred to as gross density). The graphs also showed, as lines, the averages of these measures, that is, dwellings divided by the total area of residential sites in the place, and dwellings divided by the total area of the place.

- The sizes of households were estimated by showing, for each collection district, the number of dwellings (light blue bars in the lower charts of figure 7) and the number of people (dark blue bars), then resolving this into a graph of persons per dwelling across the collection districts, and persons per dwelling for the whole place.

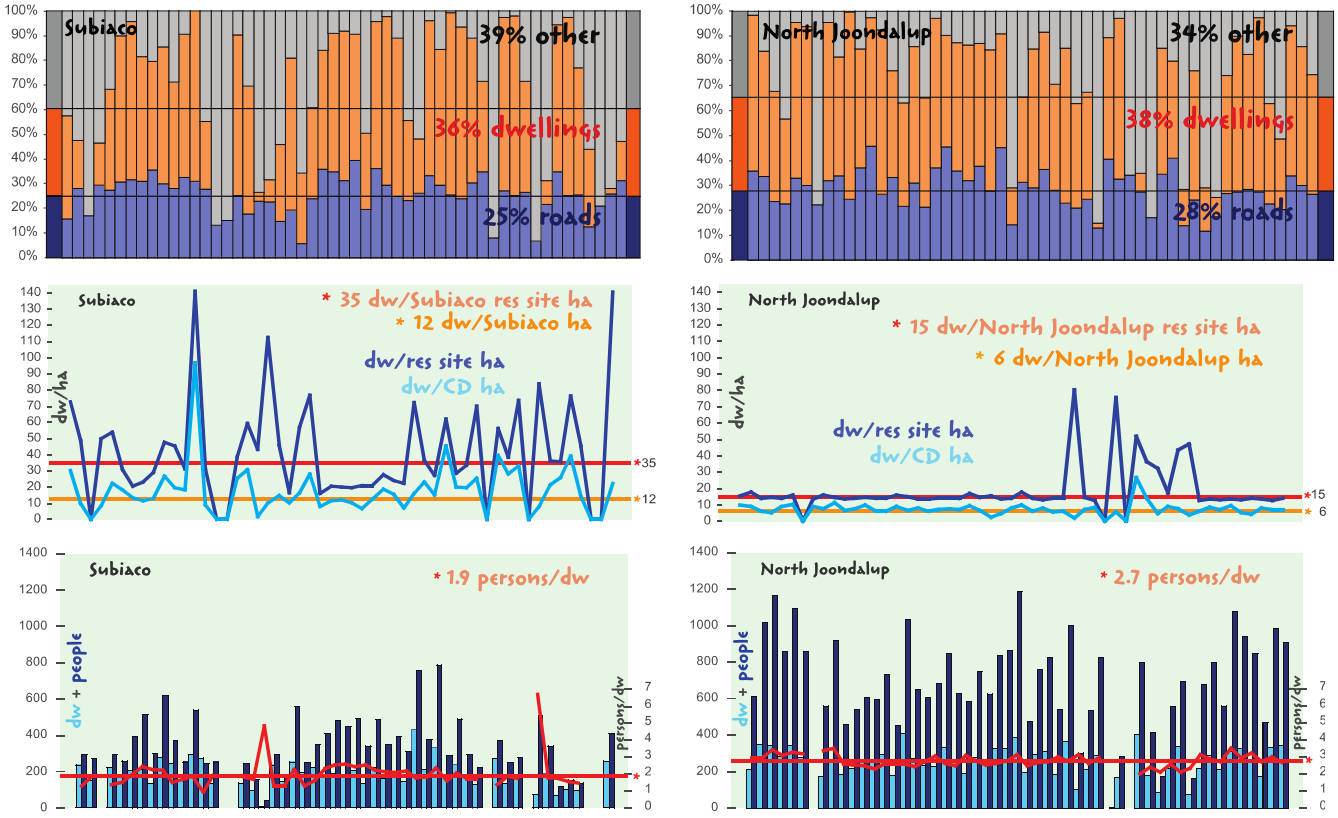

Fig. 7: Land use, density and household profiles for two sample places in the Perth region (Dawkins and Matan 2008b, pp. 13,15, 19)

The three pictures, or profiles, of each place can be read vertically: the collection districts are arranged in the numerical order assigned by the census bureau, so the land use, density and household characteristics of any one collection district correspond vertically. The pictures can be read horizontally, in the sense that the land use, density and/or household profiles of Subiaco can be compared with those of North Joondalup. Assembled on one page, as in figure 8, the pictures present the possibilities of the region, inviting comparisons and the identification of typologies.

Particularly in the case of the density profiles, there is a remarkable convergence between plotting the data and visualising the actual place it refers to. Subiaco is a diverse, mixed inner-city area with areas of high and low density residential use, and diverse areas of non-residential use. The density profile almost allows the cityscape to be imagined. In North Joondalup, much of the place is single-storey, single-family housing, producing the flat lines of most of the area, but it also has the emerging CBD, which is represented by a cluster of collection districts with dense residential development. This convergence is of course most noticeable in the City of Perth, where residential development is confined to high-density enclaves, and produces a pattern that resembles the CBD skyline. The City of Perth also illustrates the potentially large gap between dwellings per site hectare (101 dwellings/site ha) and dwellings divided by the area of the whole place (only 6 dwellings/City of Perth ha) (figure 8).

4.2 Then, designing new urban forms

The findings of this exercise in profiling urban areas included the following.

Even this relatively simple data can provide a typology of places as guides to new and revitalised places. Should East Wanneroo be more like Subiaco, or Vincent, or Joondalup? East Wanneroo should be a new urban form, but how do these places provide models to identify the differences intended for East Wanneroo? What is the broad land use pattern likely to be? What is the diversity of neighbourhoods in terms of land use

mix, dwelling types and densities, and household types and sizes? Plans that do not attempt to answer these questions, even tentatively, are hardly plans at all.

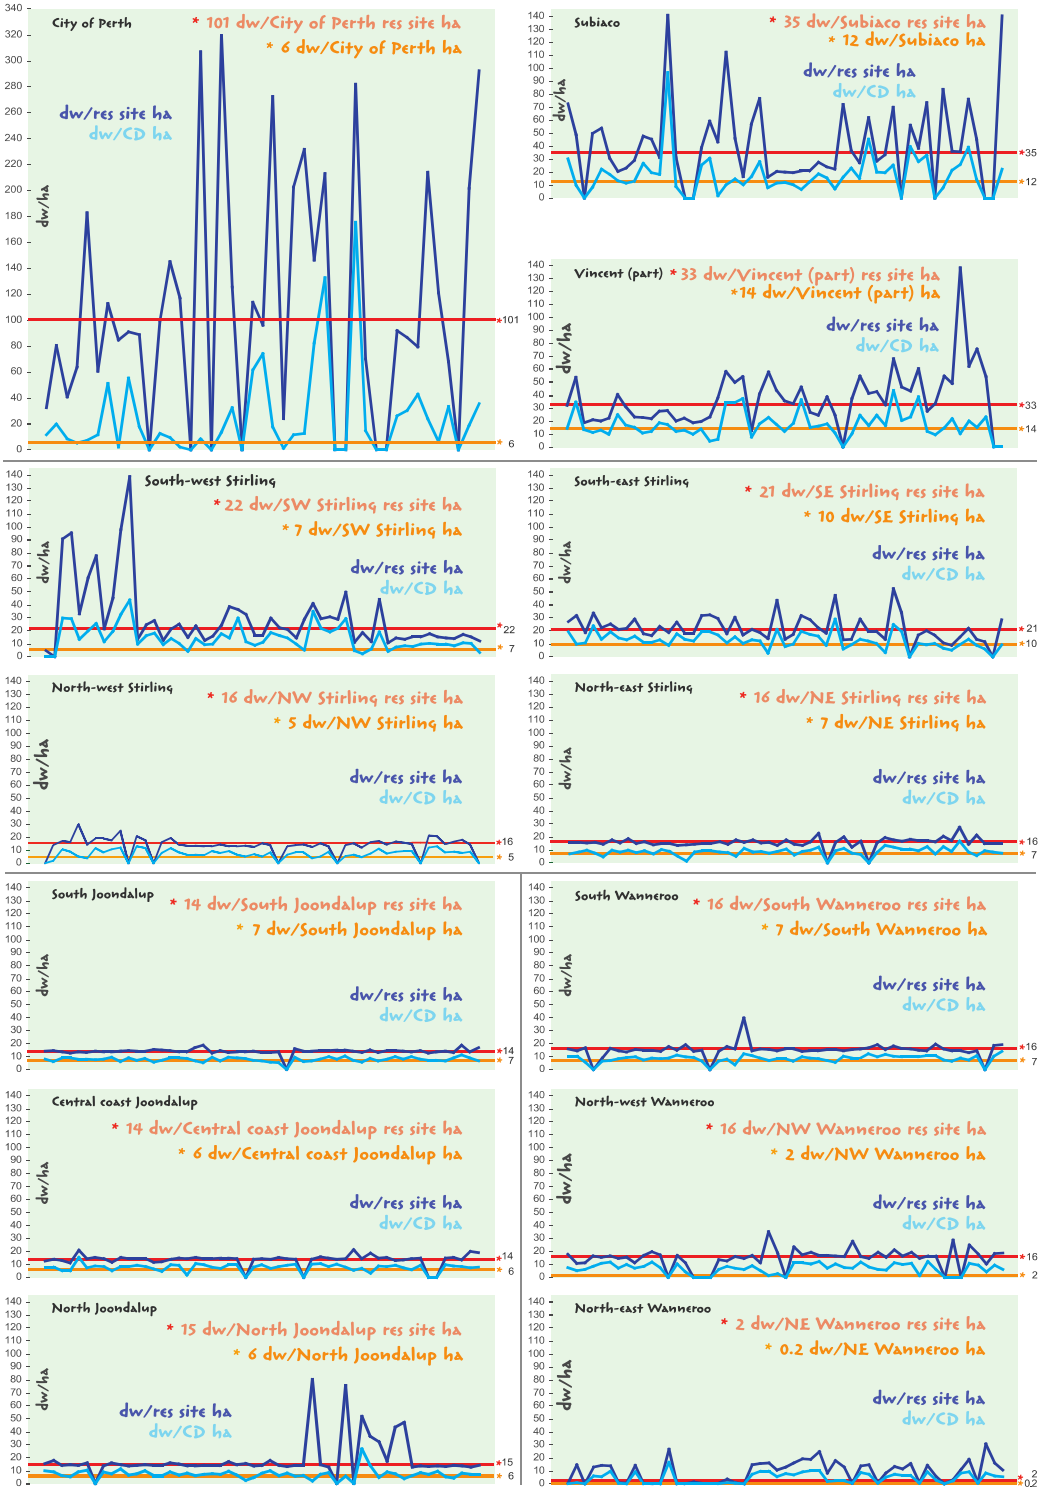

Fig. 8: Density profiles for thirteen sample places in the Perth region (Dawkins and Matan 2008b, pp.15)

What other places in the region can develop some of the characteristics of the City of Perth? Can we reproduce, in other activity corridors and urban areas, some of the land use mix, the dwelling diversity and density and the household patterns of Subiaco? Is Vincent a reasonable model for new and revitalised urban areas? Is it appropriate to see the profile of SE Stirling as a baseline from which to plan new urban areas? Should the precincts being developed around new rail stations have aspects of the profiles of Subiaco, or Vincent, or SE Stirling? How will their profiles differ? Likewise, what should be the profiles for Stirling Highway, Canning Highway, Guildford Road? Which of these profiles are appropriate for the centre and inner areas of Mandurah and for the corridor between Mandurah and Pinjarra? How will the profiles for the Cockburn Coast, Alkimos, Keralup, Wungong, the hills, etc, reflect or differ from the thirteen places in the transect? (Dawkins and Matan 2008b, p. 24)

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

All of these questions invite planners to not only use the profiles as typologies or partial typologies, but to test new alternatives and manipulate the profiles into new forms. In short, these charts and graphs are 'operational', like the population graphs discussed earlier. If planners are anticipating, or designing areas for, specific mixes of land uses, residential forms and households, all this can be depicted – visualised – in this manner. The proposed pattern of uses, densities and households can be created as notional collection districts, then plotted and graphed so that comparisons with existing, profiled places can be made, and further iterations of the notional places can be carried out.

As with the earlier example, this exercise in picturing the characteristics of urban places is just an illustration of technique and potential. The project report said that the 'search for a typology needs to be comprehensive and therefore include more types of places…and the profiles need to include the age, qualifications, occupation and purchasing power of the people in each collection district. These are relatively minor extensions of the matters explored in this paper' (Dawkins and Matan 2008b, p. 25).

5 DEPICTING THE STRUCTURE OF THE METROPOLITAN REGION

The map in figure 9 illustrates a novel way to visualise the characteristics of the metropolitan region. Typically, a regional map which attempts to show policy or strategy uses simplifications such as symbols to represent different centres in the centres hierarchy, uniform corridors, growth paths in the form of arrows or something similar. These kinds of strategy map cannot even hint at the richness and complexity of the real world. Their idealised simplifications, often not even based on an attempt to characterise how the city is presently structured or how it is presently evolving, provide little guidance for action and intervention. Strategies presented in this way are inaccessible to stakeholders, unconvincing and unable to influence the powerful actors who shape the future region through their day-to-day investment decisions.

In contrast, the map in figure 9 attempts, despite its own simplifications, to capture the fuzziness of the urban area, it transitions, its range and spread of denser and more intense areas, none of which have discrete locations and hard edges, and most of which do not conform to idealised notions of the metropolitan structure.

The map is also 'operational'. It lends itself to the building and testing (in a qualitative manner) of alternative scenarios – for instance, more growth north than south, greater or lesser degrees of expansion, this corridor rather than that… Given access to the graphics file, planners can change the parameters, modify the growth patterns, and produce different metropolitan regions. Each is a picture, and can support discussion and debate through semi-realistic images of the future region.

6 CONCLUSION

Planners often lack simple techniques for presenting to the public a meaningful picture of what their locality or district or subregion will be like. To the extent that forecasts and depictions of the future urban region are provided at all, they are generated by demographic and other experts in ways over which the planners have little control, and which often claim to be exact and precise, with little responsiveness to changes in policy and preferences. If the planners had simple visual methods for depicting the future region to the politicians and the public – and if they can show both how those depictions were created and how they can be continuously adjusted and adapted as preferences, priorities and politics change – discussion of the strategy would take on greater reality, and politicians would be less concerned about being trapped in specific promises.

This paper has merely sought to illustrate three such techniques. The salient feature of all three is that they are policy oriented, attempting to translate into visual forms the subtle, possibly abstract, and sometimes complex issues of metropolitan strategy. All three are 'operational', in that they invite live modification, to test alternatives and explore options.

1 ABSTRACT

Before industrial revolution, city's identity was based on their continental specifications and life patterns according those specifications. That is geography that determining economic and livelihood processes, specified social interactions manners and its skeleton sight means architecture and civilizing. But by deploying industry and propounding mass-products, new live advantages were formed that didn't see themselves in limit continental frame. Based on it, new social interactions were formed that in their architectural expression added new organs to a city body. Modern architecture is a product of those conditions. Industry language as a life style and an architecture style encountering to tradition language created new conditions. In some fields like religious spaces, conquest was by tradition language, and in spaces like factories and offices victory was by industry language. City of Shiraz as a city with known cultural and architectural tradition has passed almost one century history in industry experiment. So as one of Iran's industrial poles, presents industry language as a part of its traditional language. In this new situation, how can be industrial symbols symbiosis with traditional symbols in Shiraz view? In this article, by surveying city designing projects, gardens, cultural buildings, industrial museums, restaurants, and houses in Shiraz, we study the role of industry and its encountering methods to traditional symbolic system and survey these buildings success in absorbing tourists and public fortuity. It is memorable that, buildings are studied in this research, as contemporary buildings compete with ancient buildings in absorbing a tourist has come to Shiraz for visiting a traditional place and they have accepted as Shiraz new landmarks.

2 INTRODUCTION

During the agricultural and animal husbandry revolution, continental differences caused economical, cultural and inevitably architectural differences among nations. As after industrial revolution, likeness in economical processes, dictate a universal position to culture and architecture, there have been many different materials and construction style in traditional architecture, vary from herbal stem to mountains, in modern time in all of the geographical latitudes, metal and concrete define contemporary structures. Factories with wide outlets and big but plain programs in planning made the possibility of position and necessity of the new structural techniques at the first of modernism. Bolton and Watt foundry factory was the first building in which spikes and piles made of iron were used simultaneously. That steam engine manufacturer which made the industrial revolution heart to beat. Is one of the reasons of structural innovations that built architectural basis on industry, shows the modern architectural harmony with industry in history beginning of these two constituent elements of contemporary civilization. In fact if we suppose technique as the advantageous juice of industry, visual reopening of that in structural abilities will be occurred. But the 3rd revolution which is called globalization is based on ultra-nation (Fockoyama) economics and unlimited information universe (Mc Luann) besides the preparing of environmental similarities of second revolution and has the capability to conserve differential cultural layers of the first revolution. This position has an international tendency (similar) and regional products (different) in today world architecture. If we look at industrial development pattern in traditional cities, we will know that the construction of any modern building in a traditional background is a modern tendency which produces a post-modern product. Palmist is known as papers of papyrus or skin on which by grazing of original context, a new text is written. But yet there are some sections of the pervious text. So the addressee of a post-modern city such as Shiraz has a view of pervious traditional texture, while he is living in contemporary buildings. A texture which has placed words of concrete and steel among its brick lines by industrial development. In this paper with the consideration of the industrialization process and the development of Shiraz, correspondent tendencies with this process in creation of environments which can reshow the binary architecture, will be studied.

3 INDUSTRIAL CONDITION

3.1 Industrial Iran

The industrial revolution of the west entered Iran with a relatively long delay. According to historic books and documents the most important steps for familiarizing Iranians with modern civilization and European culture took place during the Qajar era. However its weakness and dependence on foreign powers not only prevented the government from managing and developing industrial projects it also kept from supporting the initiatives of Iranian investors, and therefore, Iran's industrial growth during this time was extremely limited and slow. Iranian entrepreneurs tried very hard to compete with foreigners in the realms of industry, transport, and communications, but with little success. In the beginning of the Pahlavi era, the central government became more powerful, and as a result the roads became safer, highway robbery was reduced, and the costs of transport and trade were lowered. The start of oil grilling increased the foreign exchange earnings of the country as well as its domestic demands, and improved its overall economic condition. Therefore Iran's industrial development began in earnest in 1930 as one of the main objectives of the government. This development was so rapid that in 1931 around 20% of the countries entry budget was allocation to the creation of industries. With the start of World War II, like most other activities, industrial production also came to a standstill and was only resumed after the war, with the establishment of the 2nd Pahlavi dynasty. In the next few years the increase in the price of oil was also a great help industrial development of Iran. The material of the section is an overview of the most important factories built in various cities during Iran's rapid industrial growth at the time of the 1st Pahlavi dynasty.

3.2 Shiraz, Yesterday

Old Shiraz can be known as an axis from Isfahan gateway (Darvazeh Isfahan) to sanctuary Shahcheraq. An axis which has been considered as the main morrow of commerce, industry and transportation. In Shiraz market like the other traditional markets, goods arrived caravans from neighbouring cities and then with the production parallel with market axis, they were offered. In fact, industry in its pre-modernism concept was a long coat covered market axis. From old industries of Shiraz, we can imply to inlay, pottery, glazier, calico, carpet-weaving, fretwork, miniature and wadding. Generally Shiraz has a special tradition in different kinds of weaving and decorative works on wood, metal and glass.

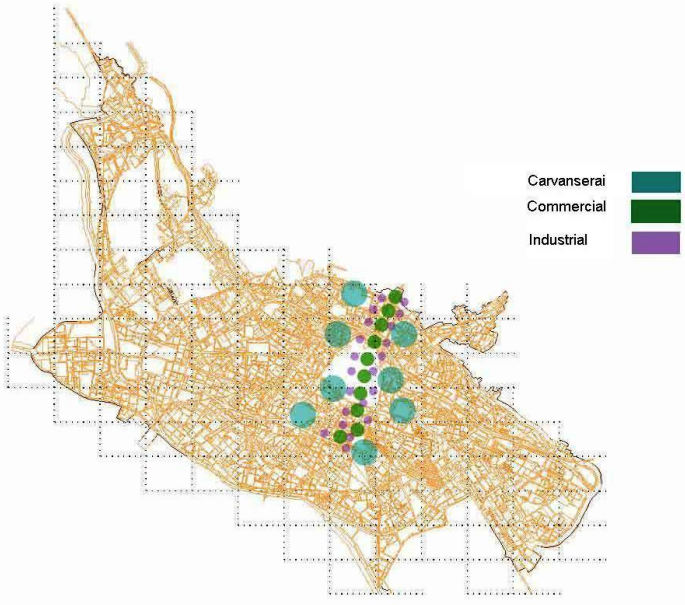

Fig. 1: Old Shiraz Urban Skeleton

3.3 Shiraz, Today

With the entrance of modern industry in 19th century, different factories of electricity production, armoury production and advanced weaving workshops and agricultural products were appeared in Shiraz. These urban functions according to their requirements to space and communications were located in wide land by which car usage will e available. By the creation of car-streets which made the network of residential and

traditional textures of city, commercial advantages of main axis disappeared and other industrial and commercial axis appeared according to urban changes.

3.4 The Correspondence between Traditional and Modern Layers

New buildings which have been formed with different logic from their traditional texture background were like heterogeneous seeds in traditional urban texture. From the other hand the appearance of new materials such as metal and concrete made the visual language of these buildings different. So according to different visual patterns, different criteria and different urban relationships appeared which were developed according to commercial advantages and were distributed as a cancer along the city. By passing of decades from this event, Shiraz is now a complex with traditional and modern layers in which the urban links network connects the blood vessels of this biological complex of these two bodies to each other.

Fig. 2: Palimpsest of contemporary Shiraz

From one hand by the development of oil commerce and the dominance of import on production from the other hand and formation of industrial towns around the big cities and according to urban problems of industry and factories, the master plan of Shiraz transformed an important part of factories and workshops to out of the city and introduce the entireness of Shiraz as a tourism city. But according to passing around a century from citizens' common life and industrial sites, we can't ignore the urban organs and we can't make decisions without caring about their analogy and their urban background. Because of this most of the buildings which are documented in following, are buildings based on the correspondent point of two layers, traditional and modern or direct dependence on industrial sites have been evacuated. According to this fact that Shiraz has a strong artistic background in different fields and traditional crafts were most decorative and also the urban planning based on tourism development, this tendency was created so that the facing with industrial sites will be based on decorations and also the representation of these sites. In other words by the highlighting and symbolizing of industrial aspects of these sites, some kinds of industrial aesthetics have been introduced as a standard which has been common during around a decade.

4 SHIRAZ STYLE

4.1 Symbolism

Any phenomenon introduces itself in relationship and companion with other phenomenon. So any component in its context is a part of a whole and receiving the message from the addressee happens. But if a component separates itself from the main context, according to its visual history in addressee's mind, it can be the sole reminder of general concept. The positive advantage of this tendency is that without any necessity the existence of all components which is costly, a limited component transform not only that concept, but also shows this concept transformation in other levels with its unique visual flash and make the addressee to think deeply about that lost wholeness. In many recent buildings of Shiraz, the symbolic attitude with industrial elements and taking advantage of them in a new totality cause the previous concept of industry, besides the new concepts to create a new level of conceptual relationship with addressee and imply to historical, social and cultural themes.

In weaving museum, which revive traditional building of Shiraz weaving factory, metal and concrete elements show aesthetics and weaving philosophy and tattering of universe by showing the lost mechanism of production and by fixing a dynamic movement in a static statue form, the possibility of addressee's thought about weaving, not as an industrial event during the past century, but as an ideology.

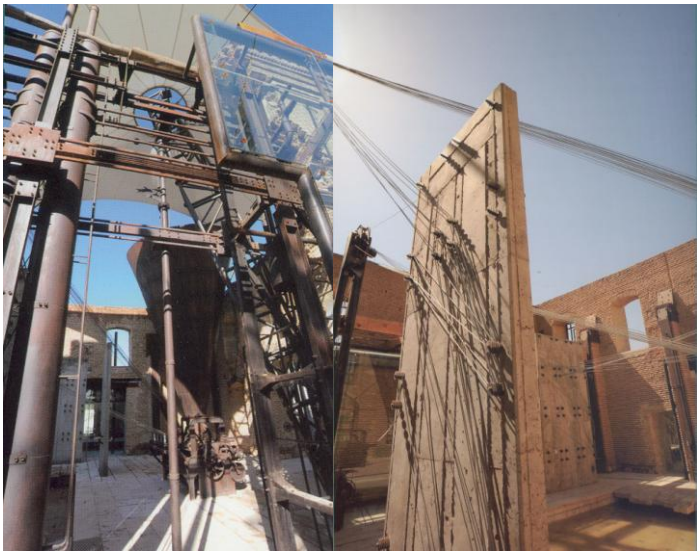

Fig. 4&5: Weaving Museum, Mehrdad Iravanian, 2008

Fig. 6&7: Weaving Museum, Mehrdad Iravanian, 2008

In some urban designs such as Shiraz water mills by aesthetics representation of old mills which are in current location of element, historical background of pattern is introduced and on the other hand, platonic

geometry of wheels versus natural geometry of current water, shows the relationship between human and nature.

Fig. 8: Shiraz Water Mills Monument, Mehrdad Iravanian, 1994

Fig. 9: Gas Company, Mehrdad Iravanian, 1998

Fig. 10: Sanat Tower, Soroush Saberi, 2007

4.2 Framing

Looking at any phenomenon is happened based on viewers coordinates. The mental time of addressee and the view which he chooses to look at, will be both his looking tools and also the effective elements on

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

received concept. The look of contemporary human, who passed the industry experience, occurs from a historical glasses to his traditional past. This museum view in any moment separate traditional theme from surrounding phenomenon and also by emphasizing on modern framework which is covered by, declare our relation with that phenomenon. Framing of themes by modern industrial and architectural elements is one of the most common tendencies in considered buildings of this study.

Fig. 11: Tourist information, Ali Sodagaran, 2003

Fig. 12: Amini House, Ali Ghahremanpour, 2004

Fig. 13&14: Mostaghimi House, Ali Ghahremanpour, 2006

4.3 Conflict

Any building, in its materials or it's from has a timely quality. A quality which shows the formation mechanism and also introduce it's cultural and aesthetics features to represent it's time ideology. Adjacent of two different qualities and two different architectural languages, beside introducing each of them, cause the

possibility to review historical and cultural roots of them in addressee's mind during comparison and to reread the passed direction.

Fig. 15: 13# House, Mehrdad Iravanian, 2005

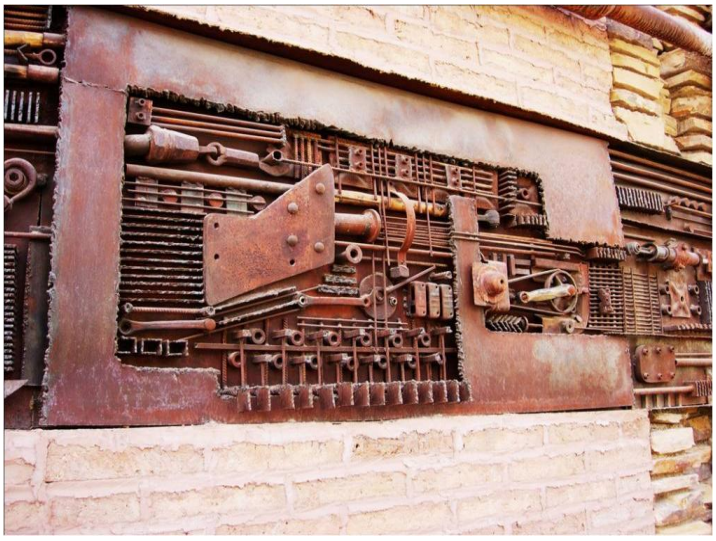

Fig. 16: Haft Khan Restaurant, Mehrdad Iravanian, 2010

4.4 Transformation

Any component has highlight features in addressee's mind as a visual sign which can show that phenomenon. According to this capacity, any component can has some changes which is responsive of new needs, and also shows its previous meaning. In this tendency, form can be changed while the original substance is fixed. In this way industrial elements are used in new usages and the background of cultural facing of addressee in new context is played.

Fig. 17: 13# House, Mehrdad Iravanian, 2005

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

By relative success of this tendency in Shiraz and taking advantage of it in projects in direct relation with people, such as restaurants, hotels, museums, and commercial centres, public favorites tend to them too and apply this attitude in smaller fields like residential apartments.

Fig. 18: Mostaghimi House, Ali Ghahremanpour, 2006

5 CONCLUSION

Development of on aesthetics tendency in architectural and urban planning of shiraz which is formed based on traditional and modern needs of this city has a root in gaining of formation from historical organization happened in city field. In other words, all of the effective components in this analyzing, means traditional architecture, industrial and modern architecture and the pattern of their exchange are based on the biological experience of people from Shiraz in 3rd millennium. A human who has yet roots in his language and region traditions and his economy is based on modern world and industry, inevitably in global background of today world; express all of his properties and his experiences, so that his unique experience can make a unique future for him. This local tendency with a global look caused the development and success of tourism in Shiraz, as the statistics if visiting from recent buildings is not less than ancient and historical places. This economical success changes the development and repetition of this experience to an architectural style in a city scale. A style which its success is base on its correspondence with life style of Shiraz.

Testing the Resilience of Underground Infrastructure Solutions through an Urban Futures Methodology

Dexter Hunt, Ian Jefferson, Chris Rogers

1 ABSTRACT

Resilience engineering is about building in sufficient flexibility whist ensuring that outcomes are robust. As such it is a measure of the ability of Urban Engineers to provide solutions today that can cope (i.e. adapt) to real world complexity ensuring they remain relevant no matter what the future holds. Success in this area is undoubtedly related to the ability of Urban Engineers to define current operating conditions and anticipate more fully how these may change in the future. In so doing, risk of failure or breakdown within any given solution is reduced, a better understanding of what might trigger such threats to occur is highlighted, and necessary adjustments (either now or in the future) are identified; in short the resilience of the solution is improved.

This paper presents an Urban Futures (UF) methodology that facilitates testing the future resilience of any underground water infrastructure solution (e.g. potable and non-potable mains water, wastewater and stormwater). Through the use of 5 scenarios (1 baseline and 4 plausable futures each considering increasing technological water efficiency in the home) the resilience of localised rainwater harvesting infrastructure is tested at four city locations within Europe (i.e. Birmingham - UK, Lancaster - UK, Barcelona – Spain and Malmö – Sweden). In so doing a methodological approach to robustly test the resilience of any underground infrastructure asset is defined, and it is shown that so called 'sustainability' solutions may provide varying degrees of resilience in each scenario and location.

2 INTRODUCTION

Urban water provision and investment are predicated on trend analysis, where future demand forecasts rely upon what we know now. Unfortunately, the future is never certain and rarely conforms to set trends, therefore the infrastructure which is being adopted today in the name of sustainability may be vulnerable in a future which resides outside the limits of current predictions. Moreover an infrastructure solution that has been optimised for sustainable benefits today may not be resilient (or even sustainable) if operating conditions dramatically change. In responding to this challenge it is suggested that Urban Engineers might seek to provide infrastructure solutions today that can cope (i.e. adapt) to real world complexities ensuring they remain relevant no matter what the future holds. Some engineers would advocate that built-in flexibility (or redundancy) will always propogate robust future outcomes (O'Rourke, 2007). Although this is reliant upon Urban Engineers defining current infrastructure operating conditions and anticipating more fully their potential for future change (i.e. for better but also for worse). Through the use of a worked example this paper presents a five-stage Urban Futures (UF) methodology (Section 3) that can be used to explore a variety of ways in which the operating conditions of a localised underground infrastructure solution (i.e. non-potable rainwater harvesting - RWH) may change in the future and helps evaluate how this could trigger threats/risks not only to its own resilience but also the resilience of other adjoining infrastructure networks (e.g. mains potable water supply, wastewater and stormwater systems). A better understanding of what might trigger such threats to occur is highlighted, and necessary adjustments (either now or in the future) are identified; in short the resilience of the RWH solution is improved. Allied to this process is the application of an UF tool, initially developed to test the performance of water-based solutions - through scenario-based analysis (i.e. normative or explorative) where social, technological and environmental changes are considered.

3 URBAN FUTURES (UF) METHODOLOGY

The Urban Futures (UF) methodology, as originally described by Rogers et al. (2012), consists of five discrete stages that are for the most part linear (Figure 1). In this paper the methodology has been adapted for testing the resilience of underground infrastructure solutions and shows clearly where the UF tool is applied. Stages 1 to 5 are explained through the use of a worked example.

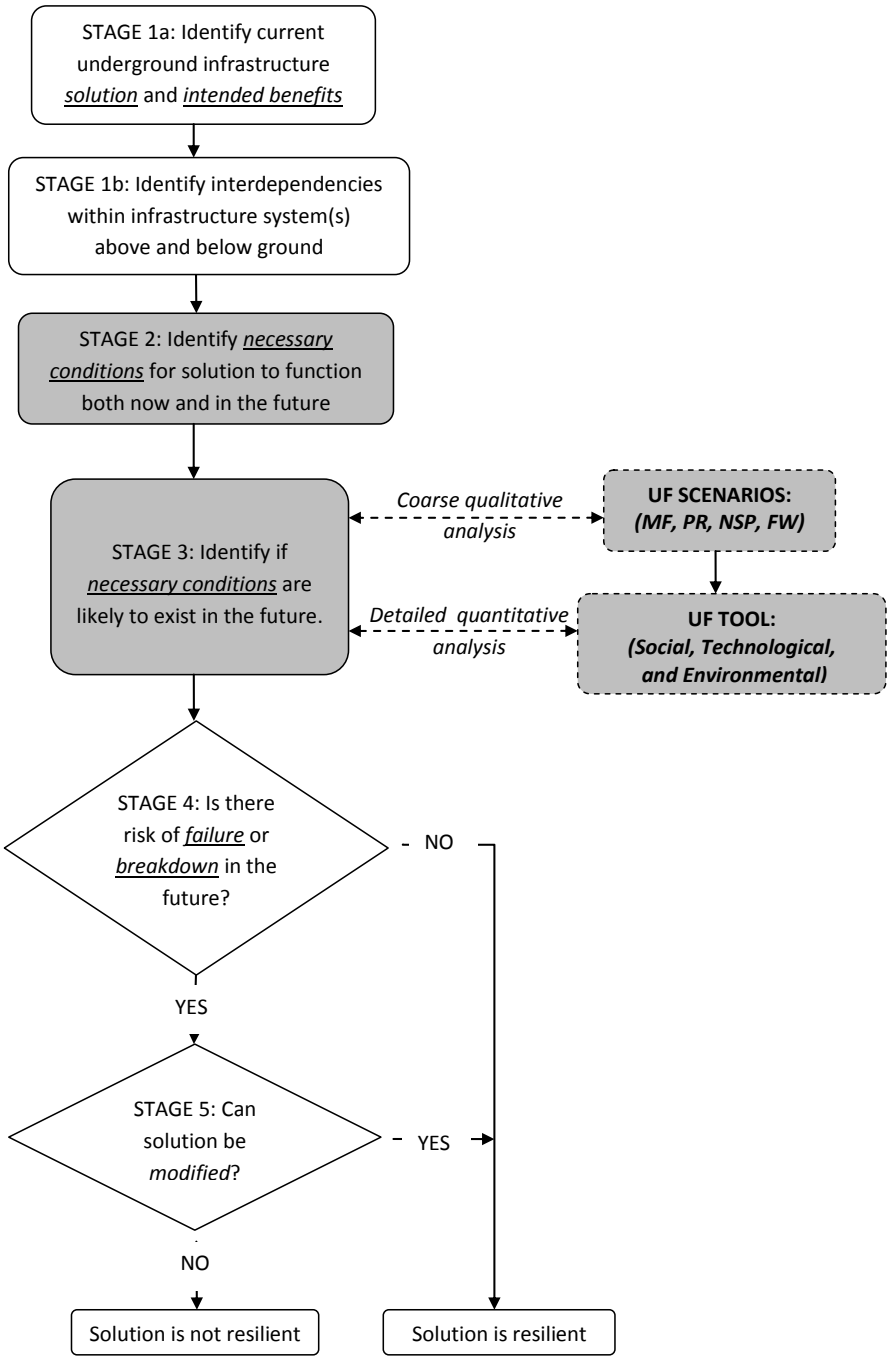

Fig 1: Urban Futures methodology as applied to urban infrastructure

3.1 Stage 1a – Identify underground infrastructure solution(s) and sustainability benefits.

Underground infrastructure solutions can be selected in one of two ways; either planners/developers/infrastructure engineers are aware of a specific problem(s) within urban areas and seek sustainable solution(s); alternatively solution(s) have been adopted without any prior knowledge of their sustainability function/benefits and/or current and future problem(s).

In this example urban engineers have proposed the introduction of an underground non-potable water supply network (i.e. rainwater harvesting – RWH, Figure 2) in order to achieve the following sustainability benefits within the local area (Hunt et al., 2012a):

- Reduced consumption of potable (i.e. drinkable) mains water;
- Reduced requirements for stormwater outflow;
- Increased water storage in times of drought and mains water failure;

- Increased pluvial flash flood protection.

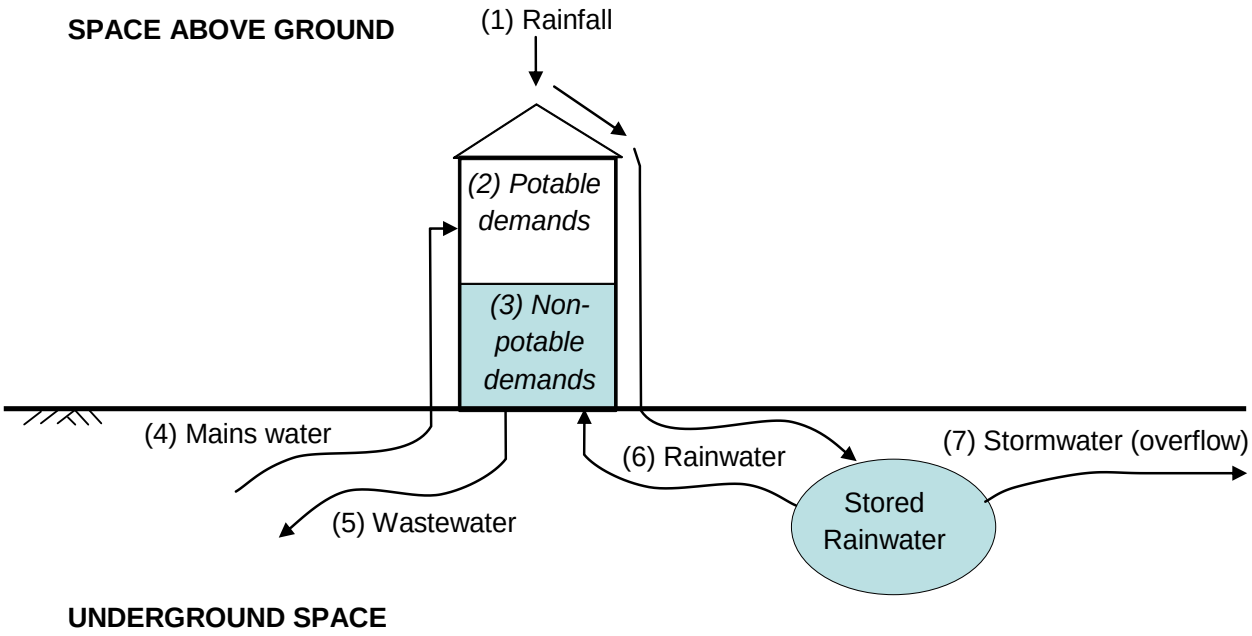

Fig 2: Key elements for RWH infrastructure

3.2 Stage 1b - Identify interdependencies above and below ground

By narrowing down the analysis to the scale of an individual domestic dwelling (Figure 2) we can easilly identify key interdependencies that are directly related to the adoption of an RWH system. Each of these interdependencies will ultimately impact upon the use of space above and below ground, which in urban areas is becoming increasingly compact.

- Within the house the numerous daily water related demands per person (e.g. cooking, washing, cleaning) are dependent upon the technologies adopted (e.g. a shower with 12l/s flow rate), the frequency of use (e.g. once a day) and longevity of use (e.g. a 5 minute shower). The total household demand is directly dependant on occupancy rates. Changes to any one of these influencing factors will impact greatly upon all inflows and outfloes therefore related infrastructure requirements (4 to 7 in Figure 2). In turn this will influence the resilience of localised and non-localised utility infrastructure which is conventionally placed underground.
- Potable demands (2 in Figure 2), e.g. showering, are met through drinking quality water and are therefore dependent upon mains water supplies (4 in Figure 2). Conversley non-potable demands (3 in Figure 2), e.g. toilet flushing, are dependent upon harvested rainfall supplies (6 in Figure 2). Wastewater capacity (5 in Figure 2) is directly dependent upon both of these.
- The performance of an RWH system is highly dependent upon rainwater being collected (from a domestic roof) and stored within an underground tank, from where it is pumped to the point of demand. Any changes in rainfall (1 in Figure 2) will impact greatly upon the volumes of water that can be collected/stored. Subsequently this effects the ability of the RWH system to meet non-potable demands. When the tank reaches its capacity excess rainwater will overflow into the stormwater system. The volume and frequency of overflow (7 in Figure 2) is highly dependent upon how much water is coming in (i.e. rainfall), how much is being drawn off (i.e. non-potable demands) and the size of the RWH tank and roof. Correctly sizing these is important, because one requires a significant amount of underground space (~1-2m3 per household) and together a dual resilience role is served (i.e. to maximise potential for non-potable supplies and minimise stormwater outflow).

The most important point to highlight here is that any of these interdependent properties will change with location and are likely not static in the future. Therefore difficulties will undoubtedly arise when trying to understand (and quantify) what is happening to all inflows and outflows within a highly interdependent and somewhat complex system where changes in one area can have repurcussions in another. This is why the development and application of the UF tool is so very important. Whilst the example of a single domestic

house is given here for simplicity outputs can be scaled-up within the UF tool (i.e. multiple dwellings of numerous types) so as to be representative of a (re)develeopment site or ultimately as part of a city.

3.3 Stage 2 - Identify necessary conditions for solution(s) to function.

This stage identifies the necessary conditions (NCs) that allow an RWH solution to function both now and in the future. Whilst in some cases these NCs will be straight forward to identify, others may require expert opinion (including validation through detailed modelling). However, in nearly all cases it is likely that NCs will be derived from (and subsequently influenced by) the following list of key drivers (Hunt et al., 2012a):

- **S**ocial (e.g. demographics, values, equity, public attitude, user-behavior)
- **T**echnology (e.g. type, efficiency)
- **E**nvironment - Natural and Built (e.g. climate, local resources, built form)
- **E**conomic (e.g. cost, affordability, payback)
- **P**olitics and Governance (e.g. regulations, laws, standards)

These NCs include, but are not limited to, the following list:

NC1 - Non-Potable demand must remain

NC2 - Enough water must be collected

NC3a - Enough water must be stored for supply

NC3b - Enough water must be stored for pluvial flash flood protection

NC4 - System must be economically viable

NC5 - System must be publically acceptable

NC6 - Policy for adoption of systems must remain in place

NC7 - Systems must be maintained

Some of these NCs are likely to be generically applicable anywhere in the world whilst others will be influenced greatly by, or simply explicit to, a particular location. This forms an obvious link with the theme of sustainability, where it is necessary to look at local, national and international requirements and impacts within economic, social and environmental spheres.

3.4 Stage 3 - Identify whether necessary conditions will exist in the future.

This stage determines whether the solution is likely to be effective in the future and forms a critical part of the resilience testing process (Rogers et al., 2012). In the UF methodology the future is envisioned through the use of four scenarios (Market Forces - MF, Policy Reform - PR, New Sustainability Paradigm - NSP and Fortress World - $FW_{HAVES\ (H)}$ or $FW_{HAVE\ NOTS\ (HN)}$) that are plausible, yet significantly different from each other and well-grounded within academic literature (Hunt et al., 2012b, Boyko et al., 2012). Rogers et al., (2012) showed that it is possible to identify whether NCs are vulnerable in the future through the use of contextual scenario-based narratives that include consideration of key drivers (Stage 2). Hunt et al. (2012a) found that this level of analysis was sufficient for identifying vulnerabilities in some NCs (i.e. NC5 to NC7) and would allow the user to confidently pass from Stage 3 to Stage 4. However, within NC1 to NC4 they highlighted that more detailed analysis may be required in order to understand better the vulnerabilities that exist. As such the generic excel-based UF tool (Figure 1) was subsequently developed in order to consider more easily the effect of making changes to social, technological and environmental drivers - all highly influential considerations within UF research. As described in Section 3.2 household water demands (hence water inflows and wastewater outflow) are influenced directly by a mix of technological efficiency and user-behaviour which in the future are relatively unknown quantities. By using these ‘axes of uncertainty‘ we can produce a defined parametric space (Figure 3) within which to test the performance (and therefore resilience) of an RWH solution. Therein we can see that future demands may stay constant (anywhere along the dotted line), increase in value (area above dotted line) or decrease in value (area below dotted line). The UF scenarios (grey ovals) are shown within this parametric space and it can be seen that they allow us to test extremes, moreover they allow us to consider the case where households have the same demand values (NSP and FW_{HN}) although for very different reasons. The 5 scenarios being considered here (A to E) allow us to

better understand the resilience implications along one axis of uncertainty (i.e. where technological efficiency alone is changing). In this case A refers to a scenario where technologicial efficiency is reduced compared to the Baseline B, whereas C, D and E refer to scenarios where progressively more water-efficient technologies are being adopted. The various input values for Scenarios A to E are shown in Table 2 and Table 3, a broader discussion of which follows.

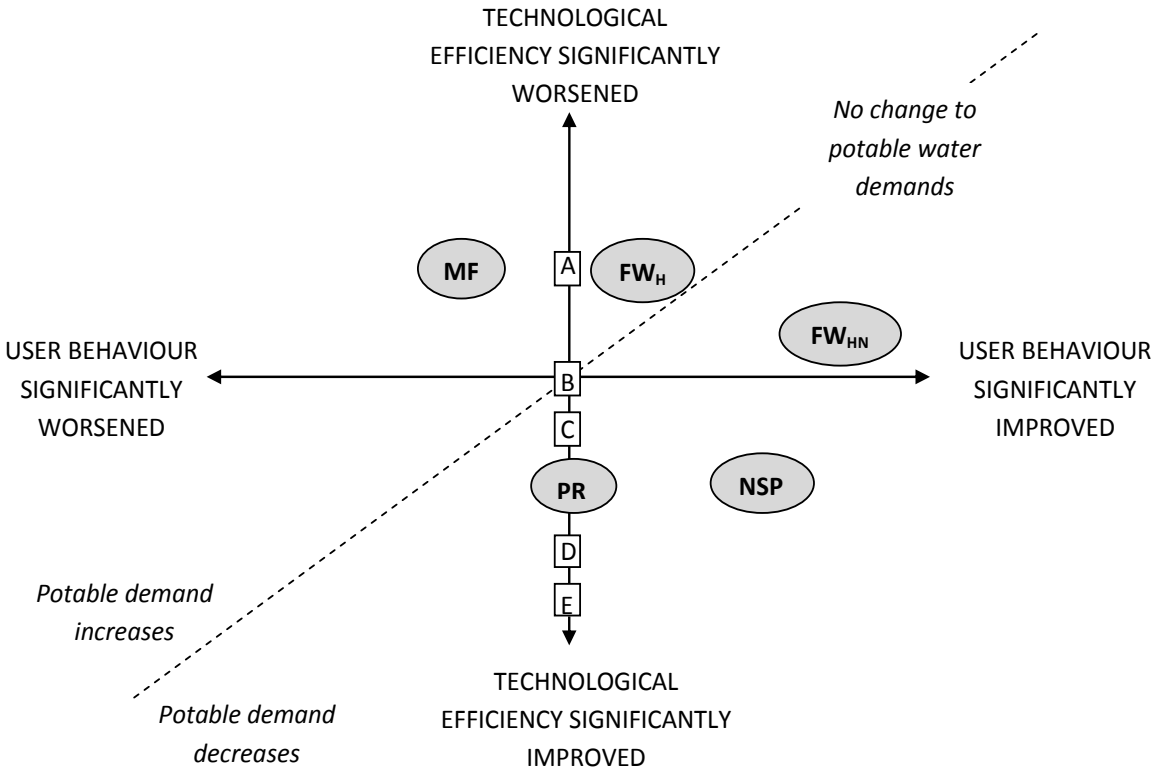

Fig 3: Parameter space required for resilience testing in UF analyses

3.4.1 Environment: Natural and Built

Local climates (e.g. rainfall, temperature, irradiance, wind speeds, etc.) are influenced greatly by geographical location and certainly within Europe can vary considerably throughout the year. In most respects this leads to reduced rainwater availability in hotter climates and during summer months. This paper uses the example of four European urban locations: Lancaster (UK), Birmingham (UK), Barcelona (Spain) and Malmö (Sweden), where climates vary markedly as shown in Figure 3a-3d. All aspects of roof design may be specific to a certain location and/or be dictated by local policy and this will influence how much rain can be collected. In order to limit the amount of variables within the analyses presented here it is assumed that roof types in all four locations are identical sizes (50 m2), pitched and tiled (Table 2). Therefore rainwater collection is merely a function of changing rainfall patterns in each location rather than roof design. The UF tool allows the user to generate any type of scenario and change potable and non-potable water demands and environmental operating conditions (Table 2). The impact on water infrastructure at various locations at different times in the year can then be assessed; this includes water inflows (i.e. mains water), water outflows (i.e. stormwater and wastewater), and tank storage (i.e. size of tank and water volumes stored). As stated previously all of these have implications for the use of underground space.

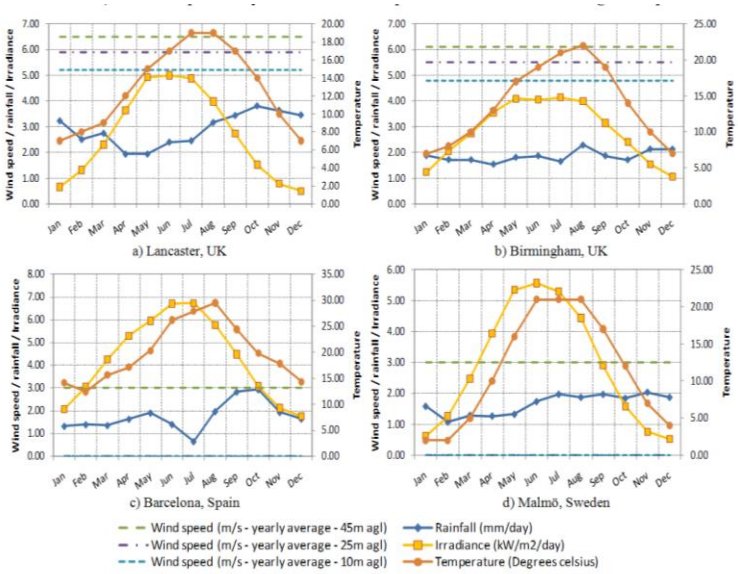

Figure 3. Local weather conditions in different locations

Location	Demand type	*Units of measure* (hh = household)	Scenarios				
			A	B	C	D	E
UK	Potable	*l/hh/day*	418	311	246	212	160
	Non-potable	*l/hh/day*	113	113	101	86	50
Spain	Potable	*l/hh/day*	517	385	299	270	198
	Non-potable	*l/hh/day*	140	**140**	125	107	62
Sweden	Potable	*l/hh/day*	398	296	230	208	152
	Non-potable	*l/hh/day*	108	108	96	82	48

Table 3: Influence of occupancy rates on total household potable and non-potable demands.

3.4.2 Social

User behavior will impact considerably on future water demands within and outside the home. For example it is well reported that showering within the home is the largest consumer of water; showering for an average of 4.4 minutes in a 12 l/minute flow rate shower will consume 52.8 liters of mains water. Therefore changing shower times by 1 minute will change total demands by more than 10 liters. If the flow rate of the shower is changed also the cumulative effects would be considerable. This is true of many water-using appliances within the domestic home. In addition water-using behavior can be influenced greatly by climate, i.e. more frequent showering or car washing in warmer months (Roebuck, 2007) and if vegetables/plants/flowers/shrubs are grown at home (perhaps adopted in an aim to be more sustainable) significant water demands (i.e. >> the highest value of 199 l/person adopted in Scenario A) will be required during these periods. Occupancy rates, vary according to location (Table 2) and leed to highest demands (potable and non-potable) in Spain, followed by the UK and then Sweden (Table 3).

3.4.3 Technology

Future technologies adopted within the home form a significant contribution to total future water demands. As the efficiency of water-using appliances increases total water demands (including non-potable) will reduce and vice versa (Table 2, 3). Hunt et al. (2012a) showed that increases in domestic water demands from 149 l/person/day (Scenario B) to 199 l/person/day (scenario A) occurred through the adoption of power showers alone (24 l/minute flow rate), whereas reductions to 76 l/person/day (scenario C) required improved efficiency measures over a broader range of technologies including reduced flow rate showers (Table 2).

3.4.4 Politics, Economics and Governance

Whilst economics, policy and governance are important drivers their influence in this case is secondary. For example, a road map of policy requirements (gradually increasing in strength over time) could require that domestic demands to be decreased from 148 l/person/day to 80 l/person/day by 2014 and seek to implement this by rewarding uptake of more efficient technologies (and assuming behaviour is unchanged). In fact scenarios C, D and E do exactly this and are directly in line with Levels 1, 3 and 6 specified within the Code for Sustainable Homes in the UK, see Hunt et al., (2012a). Rather than addressing behavioural issues the preference in these scenarios is to enforce metering only. Alternatively policy may be extremely weak and inadvertantly encourage inefficient technologies to be adopted (Scenario A) or simply rely upon peoples‘ conscience to evoke a step-change in behaviour (e.g. In Feb, 2012 residents in South East UK were asked to reduce shower times by 1 minute due to fears of ensuing drought, but without strict policies in place how effective would this actually be?). Likewise economics (i.e. the rising cost of water) might influence the uptake of efficient technologies (for those who can afford the investment and will see a payback) or incentivise more water-efficient user-behaviour (for those who cannot). In such cases Government incentives can be used to bridge these gaps. Therefore when all influences are considered, it can be seen that water demand within a domestic home will always be directly dependent upon technological efficiency and user behaviour operating within spheres of environment constraints (i.e. availability of natural resources), policy requirements (i.e. those that seek to push or pull change) and economics (i.e. cost/value of water).

3.5 Stage 4 – Identifying future risks

In Stage 2 a range of NCs were identified. In this stage associated future risks to these NCs will be highlighted in order that their vulnerability (and therefore resilience of the solution) in all four locations are better understood. Table 2 shows that non-potable demands remain in the future, therefore there is likely to be a demand for non-potable water in the future, although to differing degrees in each scenario, hence NC1 is fulfilled. Provided that rain falls and RWH systems are implemented and working the ability of each location to collect rainwater (NC2) is fulfilled. However, the subsequent implications for water storage to meet demands (NC3a) and spare tank capacity to allow for flash flood protection (NC3b) is unclear and will vary drmatically within each scenario and within each location. In this paper we consider further risks related to NC3a and b. Risks associated with NC4 to NC7, are discussed further in Farmani et al. (2012). The effect of adopting the various demand profiles (Table 3) within each location is investigated through the use of the UF tool. Tanks (Table 4) are sized according to standard methods throughout (i.e. the greatest of 5 % annual rainfall and 5 % annual demand – BS8515; BSI, 2009).

Location	**Scenarios**

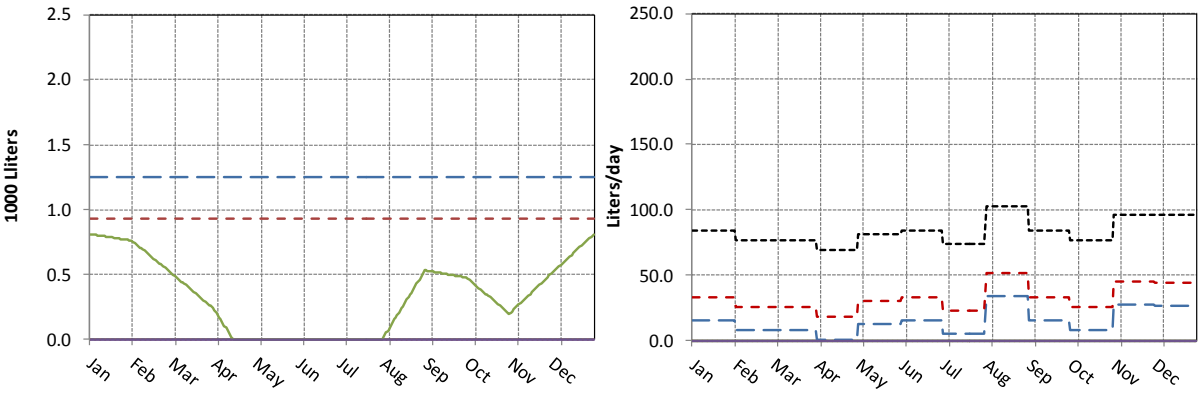
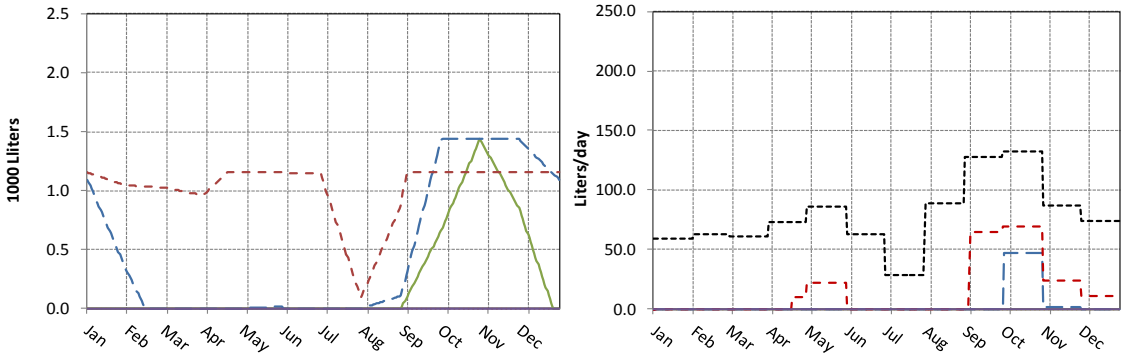
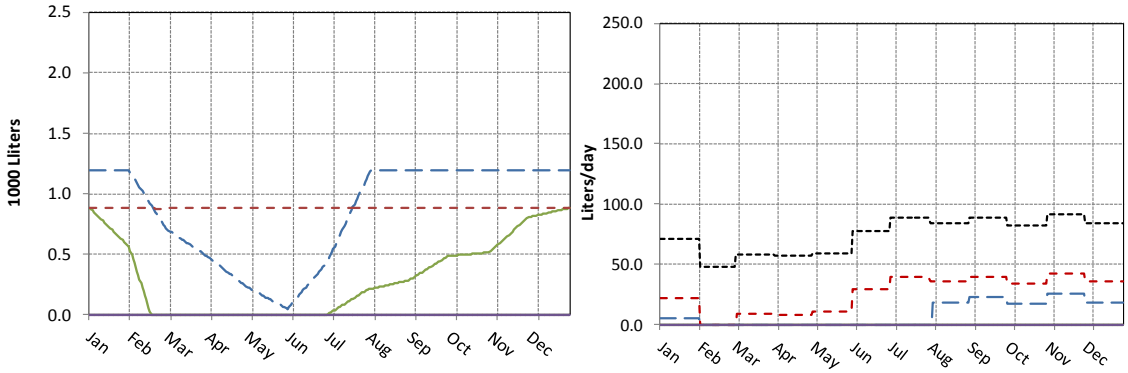
a) Lancaster, UK



b) Birmingham, UK



c) Barcelona, Spain



d) Malmö, Sweden

Fig. 4. RWH tank storage volumes (lhs) and related outflows to stormwater system (rhs) in different scenarios and case study locations.

Fig 5. Influence of RWH roof size in Barcelona (a) 1436 liter RWH tank (b) RWH tanks sized for 5 % annual rainfall.

Figure 4a to d show the corresponding yearly water levels with RWH tanks and respective stormwater outflows within Scenarios A to E within all four case study locations. It is assumed that yield before storage occurs (Mitchell, 2007) and that tanks are installed in January. The data are presented for the 2nd year of installation thereby allowing tanks to fill and reach a steady state. However it should be recognised that average daily values of rainfall are used (calculated from monthly average values in Figure 3a to d), therefore results, whilst indicative, should be treated with care. Intuitively it can be seen that significant risk to NC3a will occur when RWH tanks are empty (i.e. not enough water to meet demand) and significant risk to NC3b will occur when the RWH tanks are full (i.e. not enough spare capacity for flash flood protection). In Lancaster it can be seen that RWH tanks are empty for 3.7 months (May through to August) within scenario A and B. [N.B. In all cases data for scenarios A and B are identical as non-potable demands are equal, Table 3.] However, they are full for different time periods in all five scenarios; 5.5 months (mid October to end March) in A and B; 6.9 months for C; 11 months for D and 12 months for E. When considering the three other locations RWH tanks only ever fill in Scenario D and E, i.e. 12 months in each scenario for Birmingham and only 2 months and 7 months in Scenario D and E respectively for Barcelona. RWH tanks in Scenario C are empty for 4 months (April to July) in Birmingham; 4.5 months (mid-February to July) in Sweden and 8 months (January to August) in Spain. In scenarios A and B it can be seen that RWH tanks are empty year round in Birmingham, Barcelona and Malmö. Therefore an RWH solution poses least risk to NC3a in Lancaster because tanks are fullest year round in all scenarios, this is attributed to a much higher rainfall within this region. The opposite is true of Spain where most risk occurs. The least risk to NC3b occurs in Spain, followed by Sweden, Birmingham and then Lancaster. The risk in Lancaster is highest in winter months and lowest in summer months, where spare capacities of up to 2000 liters occur in scenarios A and B. The corresponding related outflows, from RWH tanks to the stormwater system, are also shown in Figure 4 (rhs). It can be seen how the adoption of RWH tanks significantly reduces stormwater outflows (per household) in all scenarios, in all locations, during the year. In Birmingham, Spain and Sweden stormwater outflows (from roofs) has deceased in Scenarios A, B and C, which could have implications for future infrastructure resilience (i.e. it may be oversized) or more simply in planning terms this would allow for more houses to be connected without modification. Scenario D is interesting because it is assumed to be the most sustainable solution in terms of reduced mains water demand and wastewater outflow, yet it offers least protection against fluvial floods and least reduced capacity requirements for stormwater infrastructure.

3.6 Stage 5 – Modification of solutions

In this stage solutions can be modified in order to change their performance and increase their resilience, e.g. if rainwater supplies are insufficeint to meet demands it is not possible to increase rainfall. Although we might consider increasing collection areas. Table 5 shows a range of collection areas back-calculated from non-potable demands and expected rainfall. Scenario B (Barcelona) suggests a 89 m2 collection area (i.e. an additional 39 m2) should be sufficient to meet yearly non-potable water demands – 140 l/hh/day (Table 3). However, by also increasing the roof area above this value (Figure 5a), whilst maintaining at 1436 liter RWH tank (Table 4), we can see that more water is collected year round, i.e. a 110 m2 roof area leads to surplus water over 11.5 months (4.5 months more than when using a 90 m2 roof). If we then increase tank capacities (Figure 5b) in line with the 5 % annal rainfall design rule, surplus water will occur for 12 months with the 110 m2 collection area. Another alternative would be to use water collected from other rooftops (e.g. shopping centers, commercial or office roofs) where demand is much lower than potential rainfall supply. It is worth recognising that, under identical conditions, 80 % more rain can be harvested from pitched tiled roofs than from flat gravel roofs (Leggett et al., 2001); moreover rainwater availability per occupant will be higher in low occupancy dwellings with large roofs than high occupancy dwellings with small roofs (e.g. high rise buildings). Alternatively other solutions could be adopted (e.g. greywater recycling), however the benefits may not be identical and will have to be considered carefully and perhaps even traded-off.

Location	**Scenarios**				
	A	**B**	**C**	**D**	**E**

4 CONCLUSION

Through the use of an urban Futures methodology this paper has shown how it is possible to test the resilience of solutions that are being adopted today in the name of sustainability. By looking specifically at technology, user behavior and location through the use of a UF tool the close relationship between actions above ground and infrastructure requirements below ground can be better understood and tested in terms of sustainability performance and resilience provision. The methodology helps to raise questions that wouldn't normally be asked and enhances the solution that is put into place. The capabilities of the UF tool has far reaching implications (beyond what is presented within this paper) and can be used to inform decision-makers, planners and urban engineers alike. A future publication will describe the UF tool in detail.

5 ACKNOWLEDGEMENTS

The authors wish to thank the UK Engineering and Physical Sciences Research Council (EPSRC) for their support during this second round of sustainable urban environments (SUE2) funding under grant number EP/F007426.

1 ABSTRACT

Purpose: Wheelchair users have much more problems than other disabled people. The only way for them to participate in social activities is through using wheelchairs. On the other hand, if urban facilities aren't convenient for them, wheelchairs won't be useful. We studied the ability of wheelchair users to enter urban facilities without helps.

M&M: The study was done in summer 2011. One hundred and forty wheelchair users were selected. The questionnaire consisted of 20 statements starting with the phrase: "I can use… without help". Answers in 4 scales of "almost always, usually, sometimes and rarely" were equivalent to getting nil to 3 points respectively. Reaching the points 40-60, 30-39 and <20 was considered as "easy access", "rather easy access" and "no access" respectively. Content validity was achieved by expert consultation. The reliability of the checklist was attained by retesting the 20 people in 2 weeks (Pearson Correlation Coefficient, r= 0.89). Questionnaires were totally anonymous in order to participant feel free to express their opinions. Descriptive statistics were reported using SPSS (16) software.

Results: One hundred and twenty (80%) of participants responded. Eighty percent stated as "no access" whereas 20% were "rather easy access". One hundred percent could not get in public buses, the beaches, clinics, religious places, registration offices and libraries.

Conclusion: Despite international and national codes, the majority of urban facilities are not appropriate for wheelchair users.

2 INTRODUCTION

As wheelchair users are dependent to others in most of their needs, access to social facilities should be as such that they could use them without help or with minimal help one. The United Nations General Assembly (UNGA/GA) adopted resolution 31/123 of 16 December 1976, proclaiming 1981 the International Year of Disabled Persons; It is a cornerstone towards recognizing the rights of the disabled and enhancing the understanding of their needs and appreciation of their capabilities (1). A major outcome of the "International Year of Disabled Persons" was the formulation of the World Program of Action (WPA) concerning Disabled Persons, adopted by the General Assembly on 3 December 1982, by its resolution 37/52(2-4). The WPA is a global strategy to enhance disability prevention, rehabilitation and equalization of opportunities, which contributes to full participation of the disabled in social life and national development. The WPA also emphasizes the need to approach disability from a human rights perspective (3). In its resolution 37/53 of the same date, the General Assembly proclaimed the period 1983-1992 the United Nations Decade of Disabled Persons. These actions enhanced considerable activity in the field of disability at international, regional and national levels (1). Among the major outcomes of the decade, dedicated to meet the needs of disabled, was the adoption of the standard rules on the equalization of the opportunities for the disabled by General Assembly on 20 December 1993 (resolution 48/96 annex). Equalization of opportunities is a central issue in the WPA and its assisting philosophy for the achievement of full participation of persons with disabilities in all aspects of social and economic life. An important rule underlying this theme is that issues related to persons with disabilities should not be treated in isolation, but within the context of normal community services (3). The Ministry of Social Affairs is cooperating in the area with the National Committee for the Disabled in an integrated approach and a program that includes: quality of services suggested, ease of procedures followed, current legislation, and standards to be adopted for training and rehabilitation. The approach is to progress into the present of accessibility for the disabled, a design manual for a barrier- free environment (1). A barrier-free environment is a space that allows free and safe movement, function and access for all, regardless of age, sex or condition, a space or a set of services that can be accessed by all, without obstacles, with dignity and with as much independence as possible(5). Barrier-free design includes a design that removes those barriers that obstruct the social participation of disabled people. It started in 1953

as a movement to remove barrier for the disabled, which is referred to as "welfare community development" in Japan, began in Machida city in 1974(6). The developing countries can apply this manual as a reference and guideline. They should consider their environment and try to renovate the existing buildings and inspect new spaces so that every person could utilize urban facilities without segregation. All people have equal rights to use urban facilities and enjoy life.

The Declaration on the Rights of Disabled Persons with the International Covenants on Human Rights, The Declaration on the Rights of Mentally Retarded Persons in the Universal Declaration of Human Rights stated that all people have equal right to utilize various urban facilities without discrimination. The Declaration on Social Progress and Development remarked the necessity of respecting the rights of physically and mentally disabled people and assuring their welfare and rehabilitation. All urban facilities such as the physical and cultural environment, accommodation and transportation, social and health services, educational and work opportunities, cultural and social life, including sports and recreational facilities must be accessible for all (2-3). The developing countries can apply this manual as a reference and guideline. They should consider their environment and try to renovate the existing buildings and inspect new spaces so that every person could utilize urban facilities without segregation. All people have equal rights to use urban facilities and enjoy life.

The Conference on the Capabilities and Needs of Disabled Persons in the United Nations Economic and Social Commission for Western Asia (ESCWA) Region was held in November 1989. Their purpose was attention to urban facilities for disabled persons. They recommended that city planning and construction legislation, should consider the conditions that ease the movement of disabled persons and ensure their safety, including in the design of infrastructural services, transport and the entrances and interiors of buildings (1). There are more than 500 million persons with different kinds of disabilities. They have the same rights and equal opportunities like other normal human beings (2). Researches show the world's population is going toward aging in such a way that number of the elderly over 60 years old will reach 1.2 billion in 2025 and the necessity of attention to these group increases (7). It is inevitable that human is base of sustainable development and attention should be paid to all strata of society. In a healthy society, all citizens have equal rights to its services. (8). Disabled persons should have job opportunities to be active members of the society (1, 4). Disabled persons especially wheelchair users have lots of physical problems. They need especial medical and rehabilitative care so that they can participate in society actively. Accessibility of the environment is that of the "trip chain". It means they are able:

- to go from home to a working place
- to go from home to sidewalk or pathway
- to enter in a vehicle
- to go out of the vehicle to sidewalks or pathways near the working place
- to reach the entrance of the building
- to enter the building
- to move around in the building
- to enter the office or other kind of place for work
- to reach the working station

If only one link is not accessible, then the journey becomes impossible. Each link must be considered and improved as necessary (6). Poor socio-economic conditions contribute significantly to disability in developing countries. The United Nations states that poor nutrition, dangerous working and living conditions, limited access to vaccination program, and to health and maternity care, poor hygiene, bad sanitation, inadequate information about the causes of impairments, war and conflict, and natural disasters all cause disability (9-10). People who use wheelchair have lots of problems. Typical problems include maneuvering through narrow spaces, going up or down steep paths, moving over rough or uneven surfaces, using toilet and bathing facilities, reaching and seeing items placed at conventional heights, and negotiating steps or changes in level at the entrance/exit point of a building(11). In this study we tried to survey the ability of wheelchair users in utilizing urban facilities without helps.

3 MATERIAL & METHODS

The study was done in summer 2011. One hundred and forty wheelchair users were selected. Questionnaires were totally anonymous, therefore participants filled free to express their opinions. The questionnaire consisted of 20 statements starting with the phrase: "I can use …….without help". Answers in 4 scales of "almost always, usually, sometimes and rarely" were equivalent to getting nil to 3 points respectively. Reaching the points 40-60, 30-39 and <20 was considered as "easy access", "rather easy access" and "no access" respectively. Content validity was achieved by expert consultation. The reliability of the checklist was attained by retesting the 20 people in 2 weeks (Pearson Correlation Coefficient, r= 0.89). Questionnaires were anonymous in order to participant feel free to express their opinions. Data were reported using SPSS (16) software.

4 RESULTS

One hundred and twenty of participants (80%) responded. All of participants were man and between 35-60 years old. One hundred percent could not go to bus station and get in; As well as beaches, clinics, religious places, Registration offices, libraries and public toilets. Eighty percent of participants stated as "no access" whereas 20% were "rather easy access" (Table1 and Fig. 1).

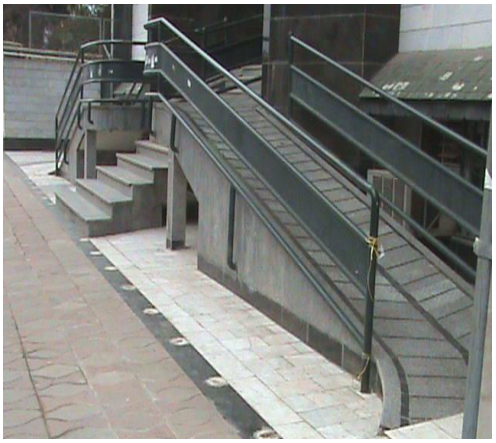
How can disabled persons take advantage from urban facilities when they cannot get into the buildings and areas? (All photos have been taken by author, Sari, September 2011)

Picture 1: The ramp isn't standard and wheelchair users could not go to beach. Picture 2: There is no ramp in the beach.

Picture 3: The ramp is not standard and suitable for the disabled



Picture 4: An entrance to a general hospital, the slope of ramp is not standard and is unprotected border. Picture 5: Ramp of inappropriate slope for access into a clinic.

Pictures 6 and 7: A not standard ramp to a bank.

5 DISCUSSION & CONCLUSION

The study showed almost all of urban facilities were not appropriate for wheelchair users. In another research that was performed on private and public buildings in Sari, we found that they were not suitable for these people (12). In spite of the existence of law since more than 11 years in the country, the majority of urban areas didn't meet the urban designs criteria (13). Some research showed in many areas of Tehran in Iran, there aren't the minimum amenities for the disabled and no appropriate welfare amenities and facilities based on their needs are considered. Streets, sidewalks, shopping centers, educational centers, hospitals and other urban facilities still are far from global standards. In most European and American countries that number of their disabled and elderly are far less than Iran, attention to this stratum of society is enormous. There is direct relationship between levels of development of countries; citizenship rights and considering all strata of society especially disabled persons (8, 14). There are international and national legislations for the disabled and many countries especially the developed countries performed them so that the people with disabilities could work and attend in the society (15-25). We all may experience some types of disabilities in different periods of our life. Every person has ability to be an active member of society. Disabled people have equal rights and duties. The authorities and government should provide career and vocational opportunities for them. They should try to renovate the existing buildings and inspect new spaces so that every person could utilize urban facilities without segregation. The urban facilities should help them to put their abilities in beneficial way because they have right to live and feel pleasure like normal people. Because almost all of cities in Iran don't have standard designs for people with disabilities, we recommend the international conventions observe Iran as a pilot country so that all can take advantage of the same facilities in the society.

1 ABSTRACT

The Action Programme "effizient mobil" of the German Energy Agency is funded by the Federal Ministry for the Environment. It aims for a further dissemination of Mobility Management (MM), as this concept is so far mainly implemented on an ad hoc basis. MM measures promote environment friendly transport modes and an efficient use of the existing transport systems. By shifting trips from cars to environment friendly transport modes noise exposure, pollutant emission, land consumption and separating effects on people´s living space can be reduced. The programme supports the uptake and the effective implementation of MM, both within the municipalities and for different sites and organisations. In the first phase of the programme 15 regional networks are established to address municipalities and companies and to involve different regional actors. In the second phase more than 100 municipalities and companies get free of charge consulting that leads to a specific concept taking the framework conditions into account. The programme has a special focus on possible CO_2 reduction in order to point out the positive outcome of MM on the climate. For MM in companies the possible CO_2 reduction has been estimated by analysing the mobility concepts and data about the staff's mobility behaviour and the current site characteristics and quality of available mobility options. For estimating the possible CO_2 reduction a two-step approach was developed. It takes different factors in regards to the possible effect into account and calculates in the first step a theoretical potential of CO_2 reduction based on more objective factors. The second step looks at the more realistic potential due to the share that can be achieved in relation to the planned measures.

By extrapolating the data obtained in the staff surveys conducted as part of the consultation sessions it can be seen that there are, in the companies surveyed, around 53,000 people driving to work by car. About 28 % of these cannot use other forms of transportation (bicycle / public transport / car pools) due to their individual circumstances. However, 72 % could, at least in theory, shift to other means of transport. To what extent this potential is tapped depends on the proposed measures and on the local quality of the alternative means of transport. An analysis of 85 concepts showed that on average 26 % of the theoretical potential is being tapped. A full implementation of all concepts of the participating companies could lead to a total CO_2 reduction of 23,600 t/a.

2 INTRODUCTION AND BACKGROUND

Even though Mobility Management is more and more seen as a suitable approach to meet the challenges of mobility and transport, a nationwide and top down strategy has been missing in Germany so far. The action programme "effizient.mobil" of the German Energy Agency (dena) (present runtime 01/2009–12/2010) is the first attempt to go a more systematic way to foster Mobility Management strategies and implementations.

It is funded by the Federal Ministry for the Environment (BMU). It aims for a further dissemination of Mobility Management, as this concept is so far mainly implemented on an ad hoc basis. The programme supports the uptake and the effective implementation of Mobility Management, both within the municipalities and for different sites and organisations. Effective structures shall be established which support a better institutional anchoring and a better integration into suitable strategies and programmes. So far more than 100 municipalities and companies got free of charge consulting that leads to a specific concept taking the framework conditions into account.

A special focus is laid on possible CO_2-reduction. It is estimated by analysing the mobility concepts and data about the staff's mobility behaviour and the current site characteristics and quality of available mobility options.

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

In detail the programme aims at the following:

- Initialisation and encouragement of conceptual design and implementation in order to support concrete Mobility Management strategies and measures on the municipalities' level as well as on the site level.
- Creation of a nationwide network of stakeholders to concentrate the knowledge and to use it for an area-wide implementation of Mobility Management.
- Anchoring of the subject in politics and the public
- Evaluation of the effects on a structural and organisational level and development of a standardised method and tools to estimate the expected CO2-reduction of the programme.

The ISB-Institute for Urban and Transport Planning and the ILS-Research Institutes for Regional and Urban Development are assigned with both the evaluation of processes (mainly ILS) and the estimation of effects (mainly ISB). That is why the paper concentrates on the last bullet point and here mainly on the method and tools to estimate the excepted CO_2-reduction of the programme. In addition first results relating to potential CO_2-reductions are presented.

3 GENERAL APPROACH OF THE EVALUATION

The evaluation of the processes takes place throughout the whole project duration. Therefore results will be available at the end of the project runtime (until end of 2010). The process evaluation looks at all relevant procedures and processes within the action programme. With the help of interviews and surveys with the regional coordinators the effectiveness of the coordination offices for the regional networks in regards to their networking capabilities and the dissemination of the concept of Mobility Management will be deeply analysed. A survey of all mobility advisors and beneficiaries will generate findings about factors of success in the consultation processes.

The estimation of possible CO_2 reduction will be described in detail in the following chapter.

4 ESTIMATION OF THE POTENTIAL OF CO2 REDUCTION

Mobility management is a concept to promote sustainable transport by the use of "soft" measures like information, communication, organisation and coordination, as well as an accompanying marketing. Thereby different fields are distinguished. Mobility management for cities and regions is mainly strategically. At this level measures aim to create the basis for further mobility management measures, linking the policy level with the management level in order to ensure the support of the responsible authorities or management and create new offers like car sharing or new public transport tickets. Mobility centres offer intermodal information about travel options. Mobility management for target groups or locations develops concepts based on the individual demands and conditions of the group or location, e.g. mobility packages for new citizens. Accordingly mobility management in companies focuses mainly on employees. Measures aim at the promotion of environment friendly transport modes such as adjusting the public transport schedules to the working time at companies, establishing job tickets or participate in action programmes such as "Cycling to work" [1].

Within the framework of the project the development of a method to estimate the CO_2 reduction focuses on mobility management in companies, because most of the mobility management concepts within the programme are made for companies. Due to the strategically focus of mobility management for cities and regions the benefit of these concepts cannot be estimated by the reduction of CO_2.

The base for the development of a standardized assessment of soft measures and the estimation of CO_2 reduction for these measures is complex. On one hand mobility management combines many different measures, which have different effects and can be combined in different ways in concepts in order to adapt the services to the specific individual needs and demands. On the other hand there are just a few mobility management measures or concepts which have been verified due to their effect on modal shift.

[1] ILS, ISB (2000)

Examples for scientific evaluated measures are the Dialogue Marketing Campaigns for New Citizens [2] or the mobility management for companies at Infineon in Dresden [3].

Mobility management measures have effects on different target fields (see fig. 1). With the aim to promote the environment friendly transport modes and an efficient use of the existing transport systems mobility management has an important effect on the environment. By shifting trips from cars to environment friendly transport modes noise exposure, pollutant emission, land consumption and separating effects on people´s living space can be reduced. Another target field of mobility management is health. The modal shift from car use to non-motorized transport leads to more exercise and therefore to a better health. The safety of transport can be described by the number of accidents due to transport modes. As each mode has a different accident rate (the risk of an accident is higher for nonmotorized modes) modal shift has an impact on safety. In addition mobility management has an influence on costs. On the one hand the measures can lead to decrease mobility costs of people, if trips are shifted from car to environment friendly transport modes. On the other hand companies or authorities need to carry the costs of the measures.

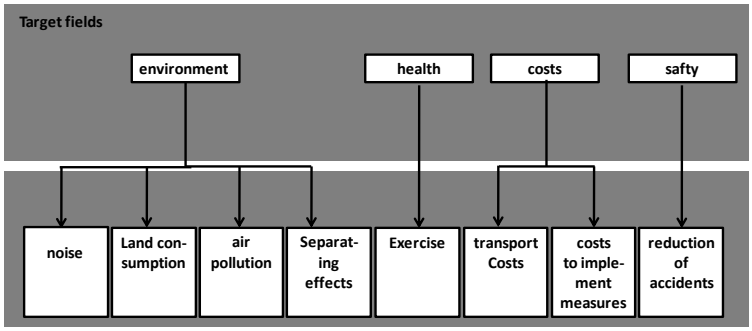

Fig. 1 Target fields of Mobility management Within the framework of the project the focus is on the estimation of CO2 reduction in order to point out the positive outcome of mobility management on the climate.

5 REQUIRED DATA

The essential factor to estimate effects is the available data on which the method can base on. Therefore the survey of the parameters which have an influence on the effects of mobility management measures plays a crucial role.

- The outcome is in general influenced by:
- Conditions of location and surroundings
- Activities of the companies and
- the travel behaviour and opportunities of the employees

As part of the project these data are measured with different survey tools. The conditions of location and surroundings are recorded trough a standardized profile of the companies. This profile consists of collected data of the location and the circumstances of the companies. This includes the existing accessibility to public transport, the existing bike infrastructure in the surroundings, the situation for pedestrians, the existing accessibility for motorized transport and the situation of stationary transport. In addition information about the activities of the company are recorded through the profile such as if sustainability is already an issue in the company. In order to determine the travel behaviour and the opportunities of the employees an employee survey is carried out. For this a questionnaire was developed based on the data needed to estimate the CO_2 reduction. The data collected is for example the frequency of use of transport modes of the employees, the availability of transport modes and the reasons for car-use.

In addition to this survey the distances from residence to workplace of the employees is calculated by using residence location data. This is the basis to determine the distance travelled of trips to and from work.

[2] ISB (2009)
[3] PGN, BiP (2003)

6 METHOD TO ESTIMATE THE CO_2 REDUCTION OF MOBILITY MANAGEMENT MEASURES

The estimation of the potential of CO_2 reduction of trips to and from work is based on the reduced distance travelled by motorized private transport. The kilometres of motorized private transport are calculated by today's distance travelled and the estimated distance travelled after the implementation of the measures proposed in the concept. The change in CO_2 emissions by public transport is more difficult to calculate because there is no information about the occupancy rate in public transport in the different regions. Therefore it has been neglected in this method.

Today's distance travelled by motorized private transport is calculated by the distance between residence and workplace of the employees and their use of motorized private transport. The estimation of the distance travelled made by motorized private transport after the implementation of mobility management measures is based on the collected data of conditions of location and surroundings and the travel behaviour and opportunities of the employees. Figure 2 shows an overview of the steps of the estimation. In a first step a theoretical potential is determined. This is defined by the proportion of car-users that could be shifted to different modes of transport, based on their personal conditions. The conditions of the location determine the level of this potential which can be obtained by the measures proposed in the concept.

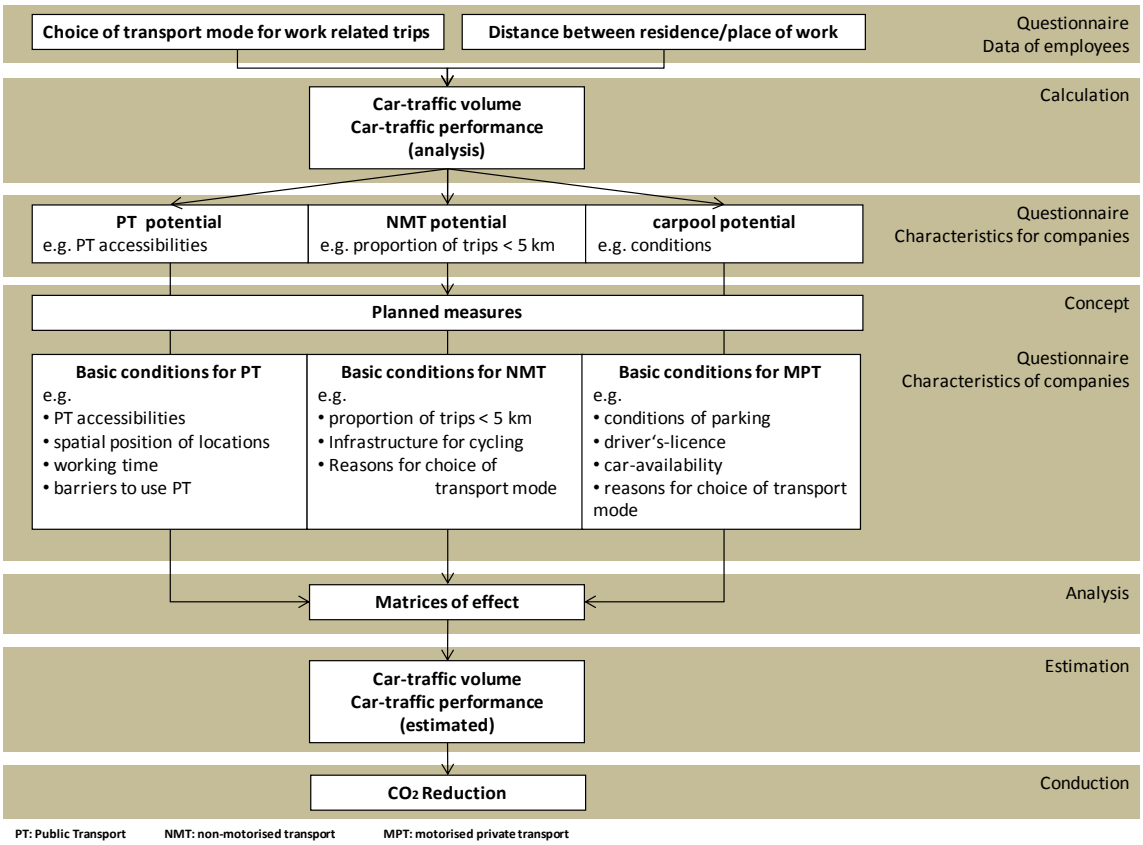

Fig. 2 Overview of the estimation

The determination of the theoretical potential is carried out on the basis of the car-drivers. This group of people is divided based on their personal circumstances weather they can be shifted to other modes of transport or not. The group of car users is divided into those who can theoretically use a bike or walk, those who can use public transport, those who are willing to use car pooling and a group of car users which have to use the car due to their personal circumstances.

This classification of people is carried out based on the data collected from the employee survey (see figure 3). In a first step the group of car users is divided in potential pedestrians and cyclist and potential public transport users based on the distance between residence and workplace. Those people whose trips to work are less than three kilometres are fully added to the potential of non-motorized transport, those whose trips have more than five kilometres are fully added to the potential of public transport. Car users with trips between three and five kilometres are divided into the potential of non-motorized transport and public

transport due to the quality of the location for public transport and non-motorized transport. The result is a clear assignment of each person to one potential group. The interaction of public transport and non-motorized transport can be neglected in this context, since the CO_2 estimation is based on the change of distance travelled by car.

In a second step the potential groups of cyclists and pedestrians as well as public transport are further divided by different parameters such as the availability of transport, the working time model, the ownership of a bike or the reasons for car use. People, who for instance live in an area with no public transport service to their workplace, are split off at this point. The result is a number of car users who can theoretically be shifted to public transport and non-motorized transport. The remaining persons are divided into a car pooling potential and those, who cannot be shifted to other transport modes based on their circumstances and their personal attitude towards car pooling.

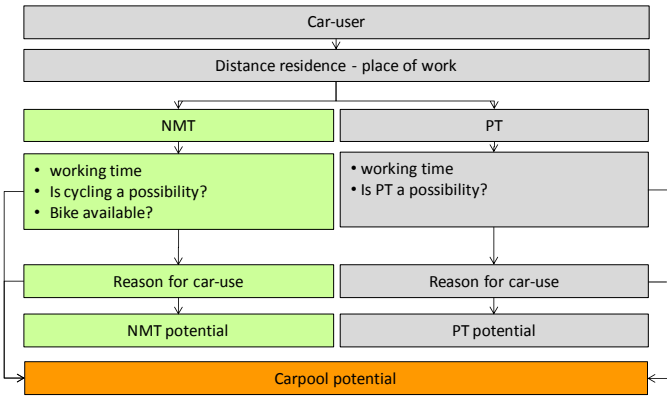

Fig. 3 Simplified description of the determination of the theoretical potential

The rate of the theoretical potential which can be realized is estimated depending on the proposed mobility management measures of the concept and the conditions at the location for different modes of transport. As mentioned before there is only little knowledge about the effects of mobility management measures. Therefore calibration and validation of the estimation method can only be made based on these few conclusions. In general it may be said, that the presented method needs to be calibrated and developed further with additional empirical data that needs to be generated.

The measures proposed in the concept for the companies are classified in three categories by their probability to obtain a modal shift. It is hereby considered that, for example a job-ticket with a high cost-reduction compared to a monthly ticket has a higher effect on the modal split of the employees than information about public transport service in general. The classification of the measures is based on a Delphi survey carried out with the regional coordinators of the programme.

To take into account the conditions at the location for different modes of transport the quality of the location for the different transport modes is classified.

Due to the effect of restrictions in stationary traffic these types of measures are separately taken into account. The restriction of motorized private transport at the location of the companies is classified based on the following factors:

- number of company-owned parking spaces
- authorization for use the company-owned parking spaces
- fees for company-owned parking spaces
- utilization of company-owned parking spaces
- parking space management in public space
- utilization of parking space in public space

Measures that increase the restriction of motorized private transport such as the increase of fees are considered in the classification of the location. Each factor is weighted according to its influence. The specifications of each factor are marked with points. According to the total mark the total restriction of motorized private transport of the location can be ranked.

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

The quality of a location for non-motorized transport and public transport is classified by the influencing factors such as location of the company and existing infrastructure and service. To classify the quality of public transport at the company`s location the following factors will be considered:

- location/spatial position of the company
- existence of a rail network
- existence of a tram or subway network
- distance to the next public transport stop
- travel time to the city centre
- travel time to the next rail station
- number of arrivals between 7 and 9 o'clock or in a two-hour-range at start of work (if working hours start differently)
- accessibility to company grounds

Each factor is weighted according to its influence. The specifications of each factor are marked with points. According to the total mark the quality of the location for public transport can be ranked.

To evaluate the quality of the location for non-motorized transport the attitude towards cycling is taken into account on the basis of the proportion of urban bicycle traffic. In addition the opportunities to park bikes, the infrastructure and the accessibility to company grounds is considered. In particular the following factors will be considered:

- proportion of urban bicycle traffic
- quality of bicycle racks
- utilization of bicycle racks
- existence of showers and dressing rooms
- quality of bike infrastructure in the area of the company
- accessibility to company grounds

The factors are weighted due to their influence and marked with points. Based on the total mark the quality of the location for non-motorized transport can be ranked.

The quality of the location for car pooling is not classified since there will be only little influence on the effect of the measures due to small differences in quality for motorised private transport.

Based on the classification of the location for different modes of transport and the proposed measures of the concept the rate of the theoretical potential which can be realized is estimated. By multiplying the theoretical potential with the rate which can be realized the estimated number of shifted car users is calculated. The distance travelled by motorized private transport is obtained by multiplying this estimated number of shifted car users and the distance of trips to and from work.

7 RESULTS OF THE CLASSIFICATION OF LOCATION

The companies that took part in the programme differ by number of employees, business sector, location and accessibility for different modes of transport. So does the classification of their locations. The classification of non-motorized transport and public transport is classified in the three categories good, moderate and poor, whereas the classification of motorized private transport is classified in the three categories strong restriction, moderate restriction and poor restriction.

The analysis is based on data from 85 companies. It shows that with 64% of all locations a major proportion is well accessible by public transport only a few locations are difficult to access. The classification of location for non-motorized transport is in the upper and medium range. At many locations there is already a high restriction of motorized private transport (47 % of the locations). At 18% of the locations though is only little or no restriction (cf. figure 4 and 5).

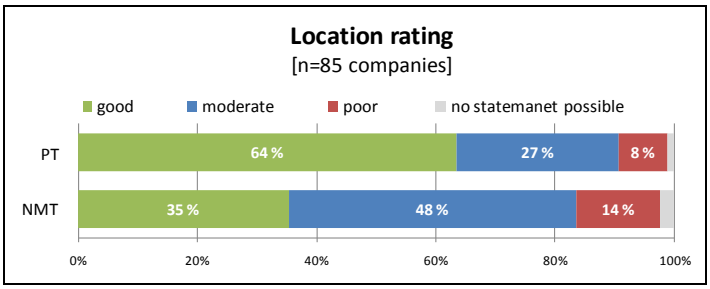

Fig. 4 Results of the classification of location–non-motorized und public transport

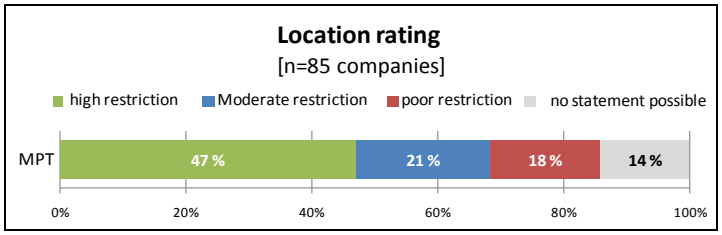

Fig. 5 Results of the classification of location–motorized private transport

By examining the classification of location with regard to the spatial position of the company in town it is obvious that, with exception of few locations, urban locations have a better accessibility for public transport due to their higher-valued offer. The classification of non-motorized transport is in the middle range for urban locations while locations at a periphery position are distributed across all ranges with tendency to good location for non-motorized transport. As expected the restriction of motorized private transport is in urban areas relatively high due to lack of parking spaces and the related management and utilization fees of these (cf. figure 6 and 7).

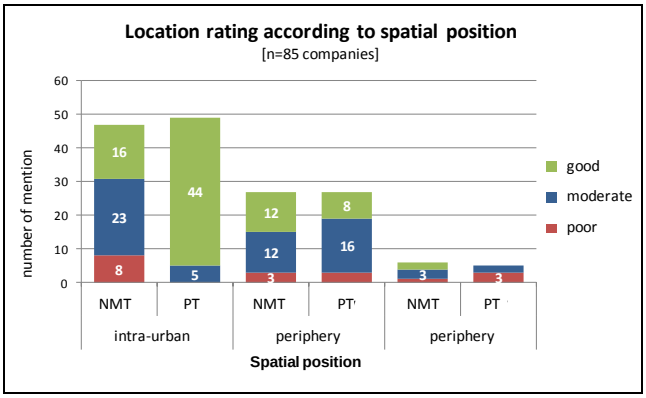

Fig. 6 Results of the classification of location–acc. to spatial position–non-motorized and public transport

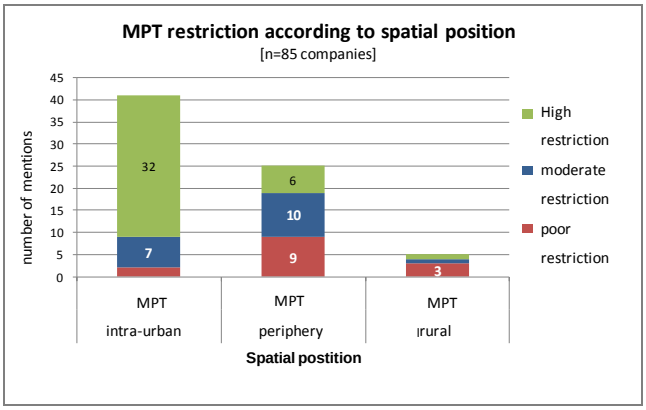

Fig. 7 Results of the classification of location–acc. to spatial position–motorized private transport

The analysis of the classification of location according to the business sector shows a heterogeneous dispersion. At first it is noticeable that public institutions are well accessible by public transport and the restriction of motorized private transport is high. However the explanation of this correlation is that most of

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

public institutions are situated in the urban area. The classifications have no correlation with the size of the company, measured by the number of employees.

8 RESULTS OF THE THEORETICAL POTENTIAL

Based on the employee survey about 53.000 people out of 102.794 employees can be identified, who use a car for their trip to and from work each day. About 28% of these people cannot be shifted to either environment friendly transport modes or car pooling due to their individual circumstances. The majority of the remaining car users, 33%, could be shifted to public transport. In addition about 13% could be shifted to public transport if the travel time with public transport could be reduced due to measures improving the public transport supply (additional PT potential). The theoretical potential of non-motorized transport is about 6%, this seems to be relatively low compared to today's car-users (cf. fig. 8). But it shall be taken into account that the potential of non-motorized transport is based on a distance of max. 5 kilometres between residence and workplace. This distance may be considered to be, manageable by bike especially for those who are used to go by car to and from work each day.

The theoretical potential of those people, who use a car between one and three times a week for their trips to work, is rather similar. But in comparison to the high proportion of daily car users only a small number of people drive to work 1-3 times a week by car, therefore only daily car users are depict in the following analysis.

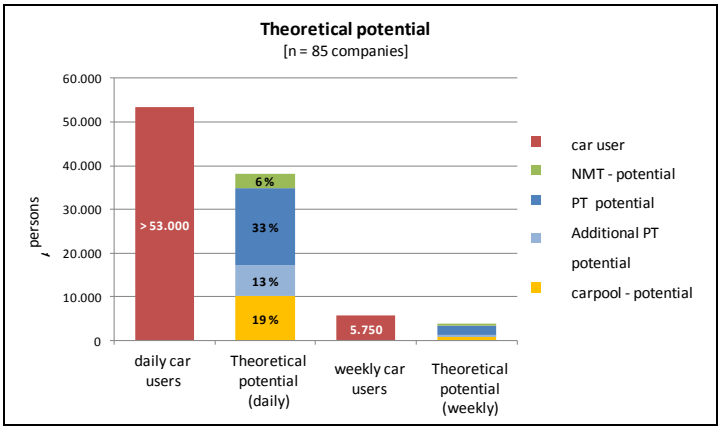

Fig. 8 Results of the theoretical potential

Car-drivers who are employed at a company in an urban area or in the periphery could be easier shifted to non-motorized transport than those who are employed in rural areas. In rural areas, due to the lack of public transport offer, only few car-users could be shifted to public transport, however they could be shifted to car pooling (cf. figure 9).

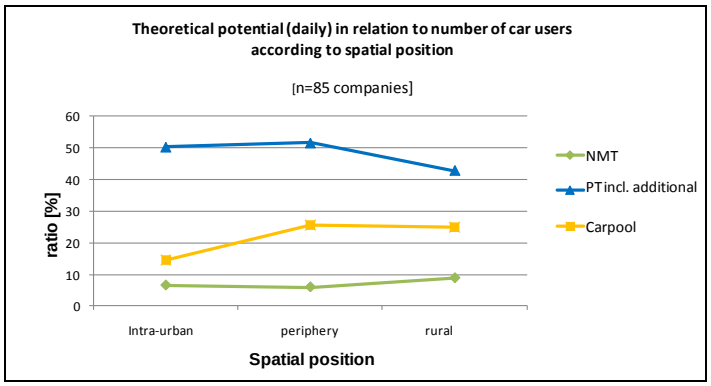

Fig. 9 Results of the theoretical potential–acc. to the location

8.1 Modal shift due to the measures proposed in the concepts

The level of the theoretical potential which can be obtained by the proposed measures depends on the quality of location for each transport mode. The better the public transport quality of a location and the higher the restriction of motorized private transport is, the higher is the proportion of the theoretical potential that can

be obtained. The calibration of this method is made on basis of evaluated examples. Since there are just few examples available which have been evaluated it is necessary that the calibration continues with further empirical data.

The estimation of the 85 concepts shows that on an average 26% of the theoretical potential could be obtained. Averaged 119 daily and 17 weekly car users of each type of location could be shifted (see figure 10).

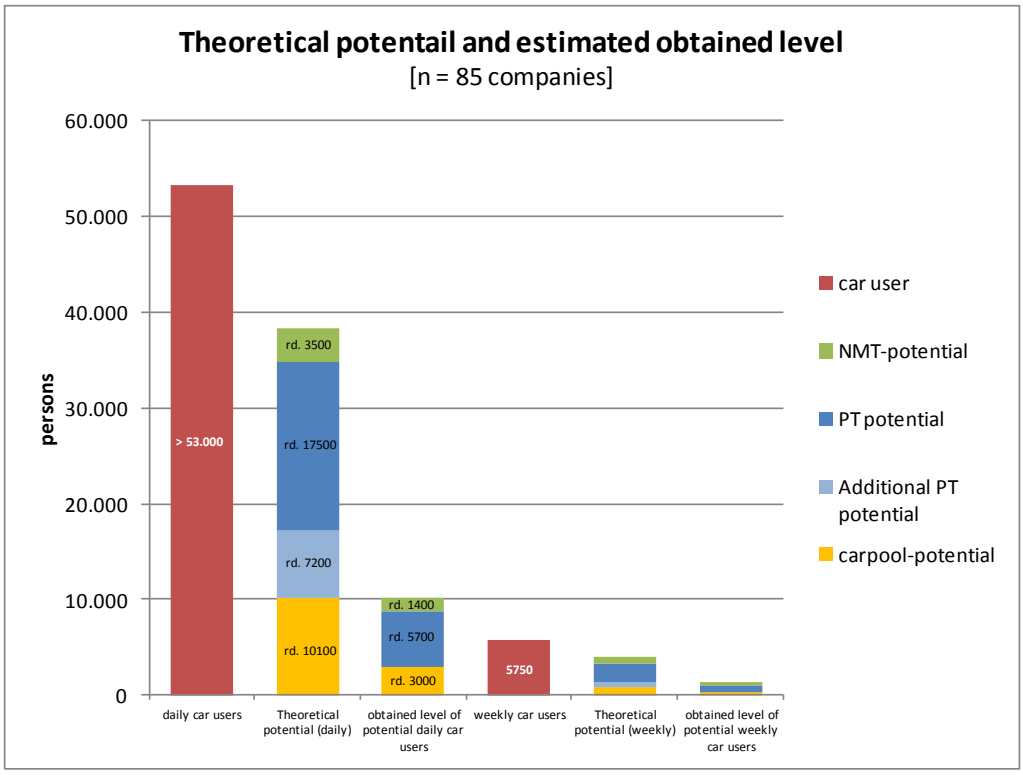

Fig. 10 Part of the theoretical potential which can be obtained

8.2 Potential of the concepts to reduce CO_2

To determine the reduction of CO_2 the estimated reduction of car distance travelled is multiplied by an average CO_2 value for cars (177 g/km).

A full implementation of the concepts of these 85 evaluated companies would lead to an average CO_2 reduction of 0.19 t/a for each employee and an average reduction of 248 t/a for each company. The total CO_2 reduction of these 45 companies is about 23.000 t/a.

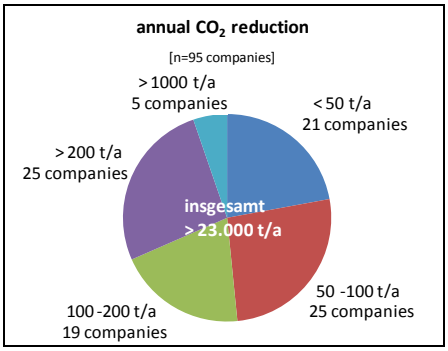

Fig. 11 Annual CO_2 reduction

9 CONCLUSION AND PERSPECTIVE

By extrapolating the data obtained it can be seen that there are, in the companies surveyed, in all some 53000 people driving to work by car. Some 28 % of these cannot use other forms (public transport / car pools) due to their individual circumstances. However, 72 % could, at least in theory, shift to other means of transport. To what extent this potential is tapped is dependent on the proposed measures and on the locational quality

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

of the alternative means of transport. An analysis of the 85 concepts showed that on average 26 % of the theoretical potential is being tapped.

As mentioned at the beginning it is not possible to calibrate all possible combinations of locations and measures with existing examples, since there is only little knowledge about the effects of mobility management measures so far. Therefore the different combinations of measures may, with regard to their potential of shift, only be classified roughly. In general it may be said that there is only little empirical data available, so that the presented method needs to be developed with additional data. This data needs to be generated.

With the standardized survey tools the programme offers the opportunity to carry out a comparison of the situation before and after the implementation of the concepts and evaluate the effect of realized measures.

1 ABSTRACT

Urban design is mainly about connecting people and places, movement and urban form, nature and the built fabric. Hence, one of the aims of urban design should always be that humans lie in the focal point of the design and not only technical infrastructure or buildings. Egyptian public spaces play an important role to activate demonstrators socially and even politically, inspiring the whole world. Public squares were and still are playing a valuable role in political changes all through the country.

Urban spaces have different impacts on humans' feelings and perception. Those feelings are affected directly and indirectly through urban settings, human masses or crowds, topography, distance, weather, etc. This leads to the need of developing new methods to measure the feelings of people in urban spaces. "SMART-Bands" are ambulatory assessment devices that measure how people feel in their city and how they react to the surrounding built and non-built environments. These devices can measure body parameters in real-time, like skin temperature, skin conductance and heart rate, as indicators for human emotions.

This paper presents a human urban experience on one of the protesting events in Alexandria using "SMART-Bands" as a tool for collecting protestors' feelings. The case study covers one of the major arteries of the city, with its variations of width, topography, and street furniture. It documents the whole experience of two different participants walking within the crowds, and living the whole experience with changing weather conditions, crowd density, and street settings.

This experimental research is considered as a pilot stage for similar in-depth studies that could lead to a new way of thinking about urban planning and public participation.

2 INTRODUCTION

For a long time in Egypt, younger generations were often perceived to be arrogant or spoiled when expressing their ideas. Being unaccepted from the elderly forced them to seek shelter in the virtual world for articulating themselves (Youssef, C. 2011). However, starting from 2008 groups of youngsters (such as 6 April Movement) started to switch from the virtual to the real world, and started going on strikes and demonstrations opposing the old regime. The call for January 25th demonstrations were first initiated by those groups, and then followed by the rest of the population (Shabab 6 April, 2012).

When masses of young Egyptians flowed into the streets during the revolution days in Cairo, Alexandria, and allover Egypt, it has been learned that the "virtual streets" for demonstrating that were percolating on various social media web sites were not entirely separated from actual, physical ones. Hence, public streets began to be the most motivated arteries in Egypt (Figure 1). At that time the unprecedented scene of streets and squares packed with people became an urban brand for Egypt and an icon for liberty and freedom for both Egyptians and Non-Egyptians.

Figure 1: El Tahrir Square, Cairo (BBC, 2011), El Corniche Boulevard & Port Said Street, Alexandria (author)

Public open spaces can take the responsibility as key design elements for enhancing urban life quality and to reduce the negative effects of urbanisation. For that sake, open spaces must meet the expectations of

potential users and offer the suitable mix of environmental, economic, social, and even political conditions (Bruse, 2007; Raslan, Bakr, & Ayad, 2011).

Designing public spaces, which are accepted and used by pedestrians, is a challenging task for urban planners as it deals with a multitude of different disciplines. There are several factors that directly and indirectly affect the pedestrians' behaviour in public open spaces, such as the right mix of sun and shade, the presence of windy and calm areas, spaces and streets conditions, topography, multitude of different materials used in the urban fabric and the arrangement of buildings, trees, and other urban objects besides the surroundings situation and crowd characteristics.

3 OBJECTIVES

Conventionally, urban planners depend on data gathered by professionals to aid them through their different design and decision making processes. Even when they tend to interview the different stakeholders, the process is deliberate, and tends to neglect intangible parameters that stakeholders find difficult to spell out. Hence, it is of great importance to make use of state-of-the-art technologies to effectively and efficiently collect feelings sensed by users of those urban spaces.

The presented research investigates the use of "SMART-Bands" as a newly developed tool to collect demonstrators' feelings while parading one of the major arteries of the city of Alexandria. If the tested tool and technique proves to be useful, it can easily be implemented on many study areas to facilitate the tasks of urban decision makers for collecting users' attitudes towards urban spaces.

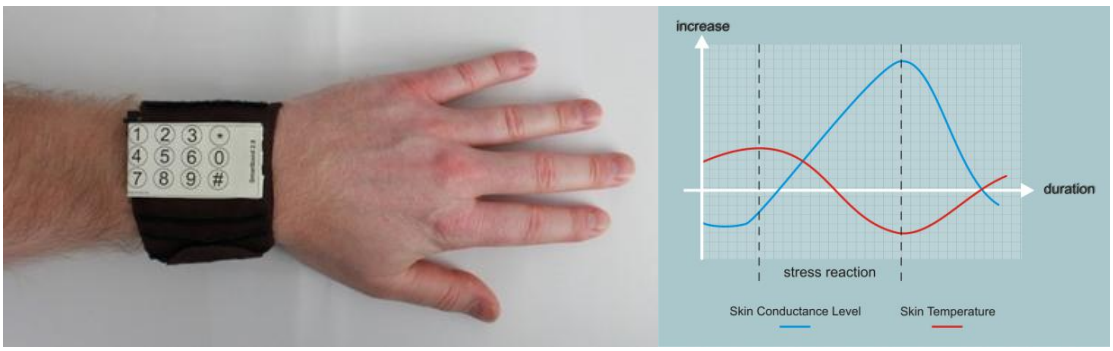
4 METHODOLOGY

This research is a pilot study to test how useful "SMART-Bands" can be for urban decision makers. Although the sample size is not representative, however, such a research pinpoints potentials and limitations for upcoming, more elaborate studies using the same tool.

4.1 Emotion measurement with physiological vital data

Emotions can be observed in many different ways. In the research at hand a new technical device, the sensor wrist-band called SMART-Band (Figure 2), is used to measure changing body physiology as a consequence of the actual feelings and emotions of the participants. Based on previous research in the new field of Affective Sciences (NFS Affective Sciences, 2011) and classical emotion research, emotional reactions are reflected in changes in the activity of the autonomic nervous system. As a result of this activity, specific physiological parameters (e.g. skin conductance and skin temperature) show different values depending on the actual emotion (Kreibig, 2010). These parameters are classified as vital data of the individual. In this context, the so-called method of the psychophysiological monitoring implies the recording of objective vital data in real-time and for every instant. With the help of this data unswayed affective emotions are derived. For the measurement of the participants' feelings during the Egyptian demonstrations, the identifying of mental load (stress) with the help of physiological indicators is obvious. Stress can be understood as a product of anger and fear, both considered as highly negative emotions (Bergner et al. 2011). In this explicit situation the actual surroundings, the pressure of the crowd or the imminent danger of conflicts arising can elicit stress reactions.

A negative emotion is given, when the skin conductibility increases and shortly afterwards, the skin temperature drops (Bergner et al. 2011). The following graphical curves illustrate this process (Figure 3). The slope values of the curves can be used for statistical analysis. The mathematical function of these parameters and their curves is simplified with the first derivation. The method of using scoring points (increase in skin conductibility = Scoring +1; decrease in skin temperature = -1) was previously used in several studies (Bergner et al. 2011).



Figures 2 and 3: The SMART-Band (own source) and Physiological Stress Reaction (Bergner et al. 2011)

Due to recording the data for every second during the study, it can be coupled and synchronized with GPS- and video camera data without difficulty. This offers new perspectives to understand the participants' feelings and emotions in the context of their actual surroundings. This approach was already pursued in several project studies. First test series were done in the emomap-project (Zeile, 2010). Furthermore, the so-called EmBaGIS (Emotional Barrier-GIS)-studies were conducted in the context of urban spatial barriers for handicapped (Bergner et al., 2011). Only recently studies concerning the correlation of stress and noise load and also emotional sensing of urban green areas were carried out (Bergner et al. 2012). In all these studies, the SMART-Band (SMART-BAND by www.bodymonitor.de), developed by GESIS, the Leibnitz-Institute for Social Science in Mannheim/Germany (Papastefanou 2009), was used.

4.2 The selected path

While demonstrations in Cairo take place in El Tahrir-Square and neighbouring streets as an agglomoration space, in Alexandria the situation is different. Rather than staying in one place, demonstrators prefer walking in parades, circulation Alexandria's streets (Figure 4). During the first 18 days of the Egyptian Revolution, demonstrators marched from both east and west sides of the city (blue nodes) towards the small square across Sidi Gaber train station in the centre of Alexandria (green node). Another path, but less frequently used, was from Quaed Ibrahim Mosque towards Ras El Tin Palace (one of the Presidential Palaces in Alexandria) located further to the west edge of the city.

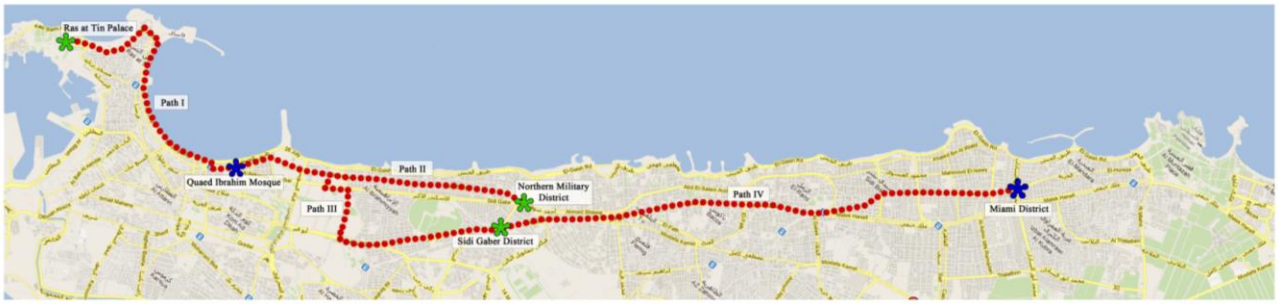


Figure 4: Map of Alexandria Showing the Different Paths Demonstrators Took During 2011/2012

However, after Hosni Mubarak stepped down, demonstrators switched their destination towards the Northern Military District, since their dispute switched from being directed to the former ruler of Egypt (i.e. Hosni Mubarak) towards the current one: the Supreme Council of Armed Forces (SCAF), which is represented by the Northern Military District. Hence, demonstrators switched to the path studied by this research, a 4.34 Km strip stretching from El Quaed Ibrahim Mosque in El-Ramleh Station and ending by the Northern Military District in Sidi Gaber District. For research reasons, this path was sub-divided into ten sections (Table 1 & Figure 5) according to major intersections and presence of squares along the path.

4.3 The event description

Similar to previous calls for demonstrations that take place on Fridays, this experiment took place on Friday, 18th of November 2011. It was another call for a million-participants-demonstration, where Moslem Brothers and Salafis were joining as well. Demonstrators agglomerated after noon prayers at the place across El Quaed Ibrahim Mosque and started their march around 1:15 pm towards the Northern Military District. The march lasted for almost three hours, with one pause made during that period for after-noon prayers. The weather was pleasant at the start of the march, but it started to drizzle after 2.5 hours, and to pour in the last 20 minutes. Two female participants took place in this experiment. They were equipped with one video camera and one GPS tracker for them, as well as one SMART-Band for each. Only one video camera was used, although two were available due to the long duration of the march and the fear that the capacity of one video camera might not cover the whole duration.

Table 2: Average Pedestrian's Speed & Stress Response Count and Values per Street Section

Generally, participant A showed a higher amount of stress responses than participant B. Although the minimum and the average values of stress responses of both participants are pretty close, participant A again showed a higher maximum response during most of the demonstration path, except at the start and while approaching the destination. This can be due to different reasons; if the test person knows that she is approaching the destination, this can reduce the stress. Another reason might be that the test person got used to the situation and stopped showing high stress responses; or that the situation was not as stressful itself as in the middle of the path. Since there was only one test conducted during that research, one cannot determine which of those reasons caused the relaxed stress levels.

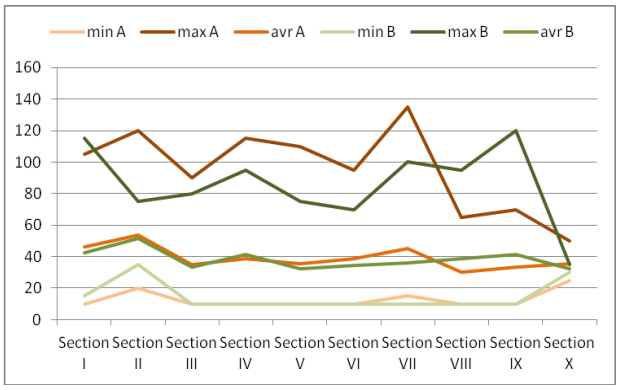

Figure 6: Min, Max, and Average Stress Values

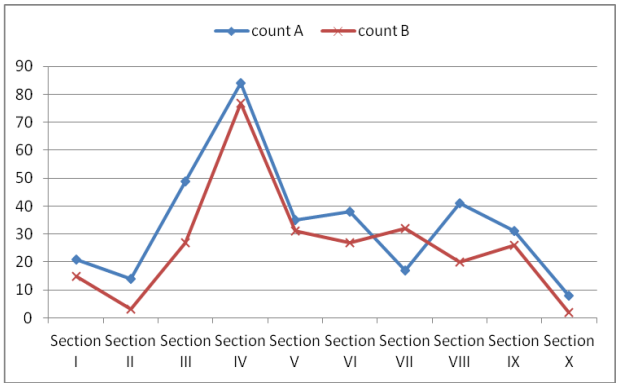

Figure 7: Amount of Stress Points within Each Street Section

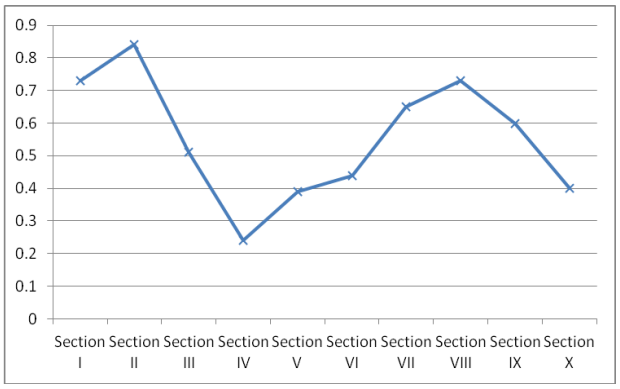

Figure 8: Average Pedestrian's Speed for Each Street Section

By comparing the amounts of stress points (Figure 7) with the pedestrians' average speed (Figure 8) within each street section, it is noticeable that generally whenever the amount of stress points rises, the slower the pedestrians' speed gets. For example, street section IV has the highest amount of stress reactions for both participants: 84 and 77; it also has the slowest speed: 0.24 m/s (Table 2). From reviewing the video data for this street section, it was noticed that during the 42 minutes needed to pass this 617m section, the density of the crowd got higher. This was due to the street profile getting narrower than the preceding section (Figure 10), as well as due to the parked cars on at least one side of the street. Hence, the demonstrators were slowed down, and sometimes even completely blocked, which caused the stress charted in street section IV.

If we neglect the first two street sections, where demonstrators were still fewer in number and still physically fitter, section IV showed the highest amount of stress reactions, while sections VII and IX showed the highest values of stress response (Figure 6). As clear from Figure 8, sections VII, VIII, and IX also represent the highest pedestrian speed: 0.65, 0.70, and 0.60 m/s respectively (Table 2). During this phase, the weather had changed dramatically and it was raining. This caused several things: first, many of demonstrators left due to the bad weather and the streets started to get less crowded; second, the remaining demonstrators had better chances to walk faster because of the less crowded street and also to get away from the rain, as well as people usually getting a boost of power while approaching their destination.

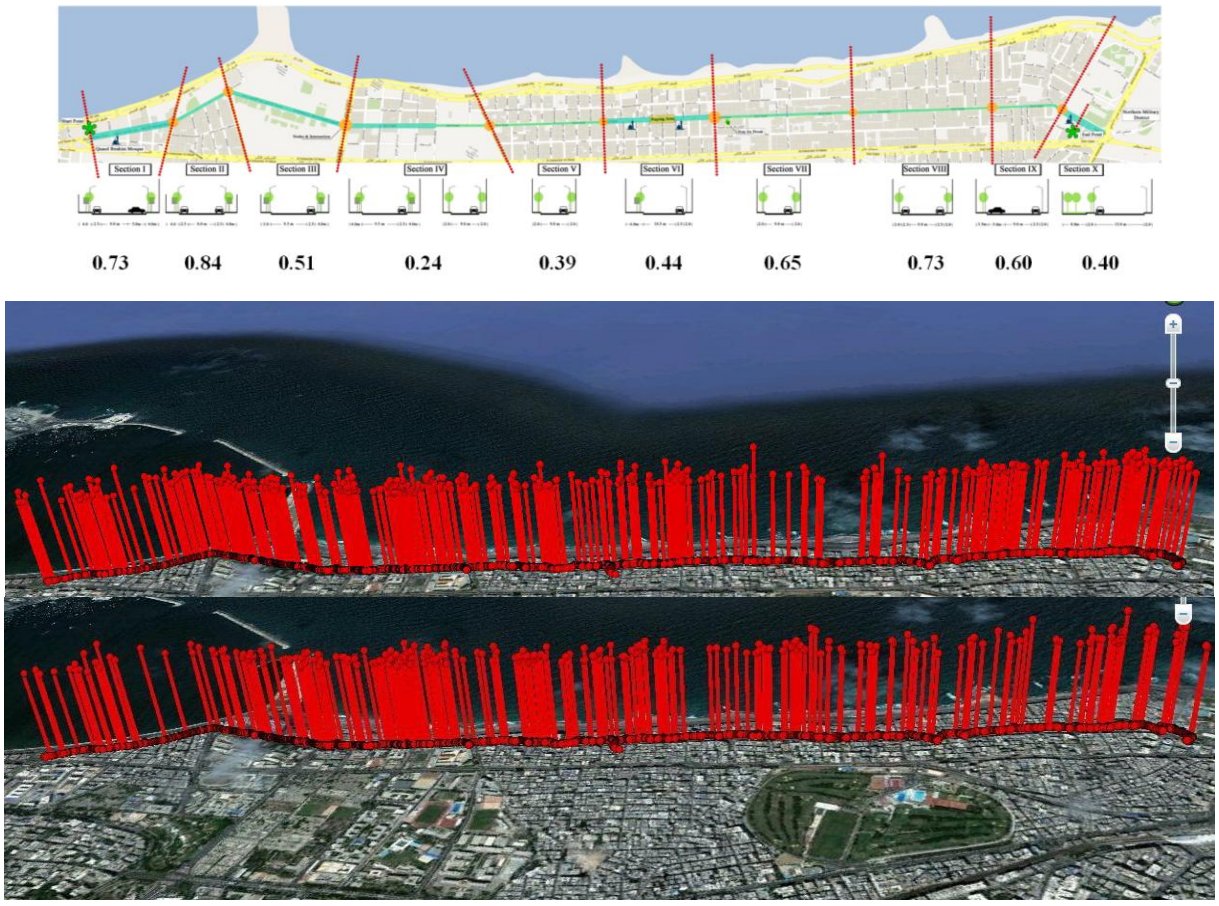

Figure 9: Street Profiles and Pedestrians' Speed at the Different 10 Street Sections along with Stress Profiles for Participants A & B

It was also clear that the pedestrian's average speed was proportional to the width of the path. The narrower the street the slower pedestrians got and vice versa (Figure 9). The only exception is in street section VI. Although the Street was 13m wide, with sidewalks of 6 and 2 meters width, the average speed was only 0.44 m/s. This is due to the time the demonstrators came to a complete stop for after-noon prayers, which drastically increased the amount of time for crossing this 480m stretch of path.

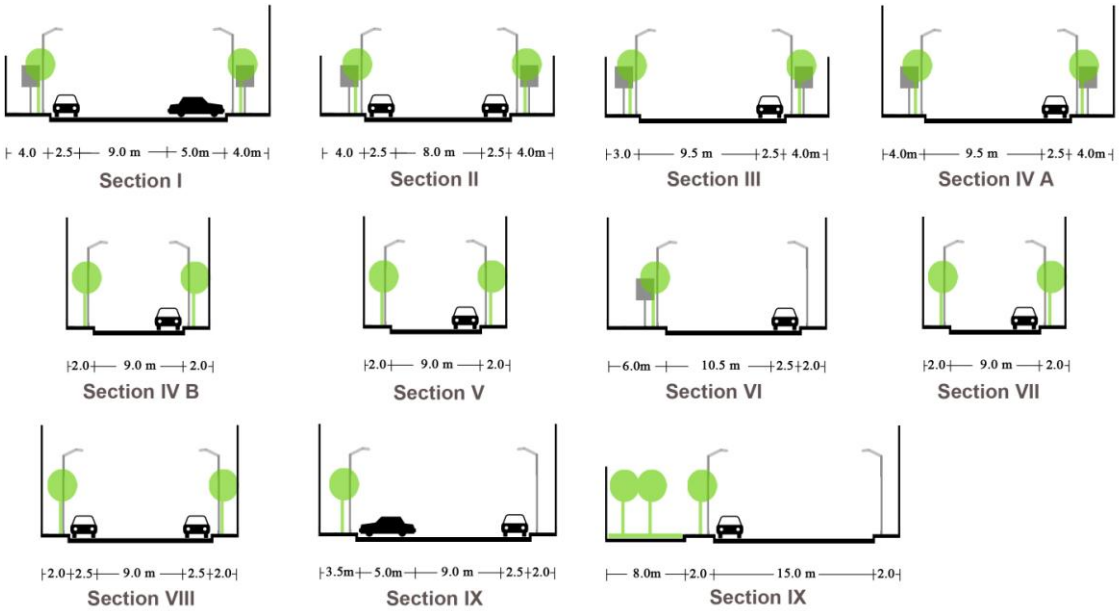

Figure 10: Detailed Street Profiles at the Different 10 Sections

Obstacles faced on the path also triggered stress responses. Such obstacles can be water patches on the streets due to bad pavements, clusters of garbage partially or completely blocking the sidewalks, shops

trespassing on sidewalks and hence reducing the usable part for pedestrians, as well as bad or missing pavements of sidewalks (Figure 11).

Figure 11: Different Obstacles that Trigger Stress Responses along the Path (author)

Just before major street intersections as well as right after squares, there were always high valued and high intensity stress responses charted (Figures 12 and 13). Both situations triggered stress reactions due to the increased intensity of crowds at those points. In the first case, cars crossing the intersections blocked the path of the demonstrators, forced pedestrians at the front to a stop and therefore blocked the rest of the march. In the second case, streets get almost triple in width at squares, so pedestrians spread out over the whole square, and then they had to squeeze again to fit into the regular street width, if not moreover blocked by any trashcans, street vendors, or parked cars.

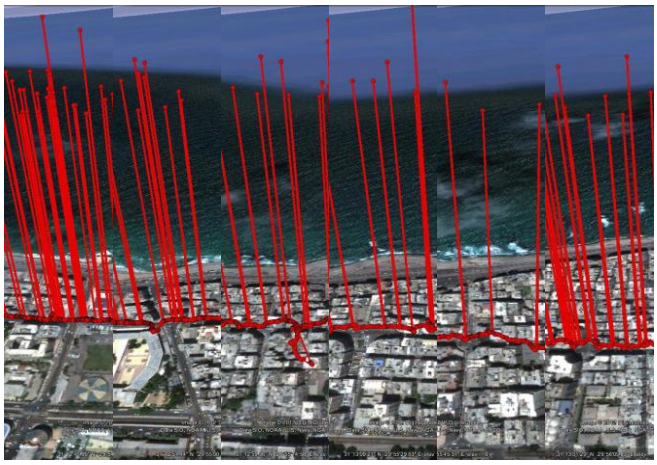

Figure 12: Stress Responses for Pedestrian A at Street Intersections and Squares

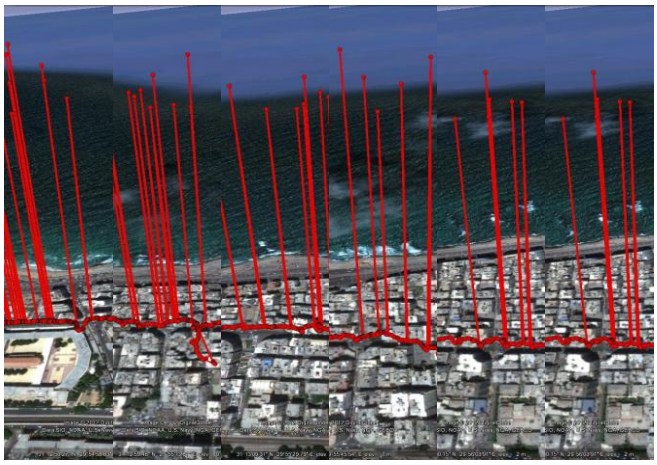

Figure 13: Stress Responses for Pedestrian B at Street Intersections and Squares

6 CONCLUSION

Unlike Cairo with its El-Tahrir Square, Alexandria lacks an open space of a proper size and a central location. Hence Alexandrians tended to marching demonstrations rather than agglomerating ones. The walk itself, along with the street conditions and people densities had their effects on demonstrators.

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

The personal space is defined as an invisible bubble that surrounds an individual, and serves to maintain proper spacing between individuals. The size of this bubble varies according to different cultural, social, personality, and environmental dimensions (Hall, 1966). Stress values rose proportionally with the density of surrounding demonstrators. These rates rose higher, when the surrounding crowd was basically of the opposite sex due to the conservative culture still dominating in the region. Other reasons for triggering stress responses were the various types of obstacles blocking the path, the bad weather condition by the end of the path, as well as getting enthusiastic and cheering along with the rest of the demonstrators.

Because this experiment was limited in its number of testing subjects and testing locations, no definite results can be reported from it in a final manner, but it still provides useful knowledge about the usefulness of "SMART-Bands". It was adjudged that these devices are easy to handle, to wear comfortably during outdoor use, and provide useful information concerning how people perceive and react towards their built and non-built environments.

7 ACKNOWLEDGEMENT

The authors are grateful to the support of the University of Kaiserslautern for financing the "Laboratory for Monitoring and Spatial Sensing", including the sensor equipment for this international research project. Also, the authors would like to express their gratitude to the German Research Foundation (DFG – Deutsche Forschungsgemeinschaft) for supporting the project "Development of methods for spatial planning with GeoWeb and Mobile Computing (Städtebauliche Methodenentwicklung mit GeoWeb und Mobile Computing)".

(Farhad Amiri Fard, Islamic Azad University, Bandar Anzali Branch, Department of urban planning, Bandar Anzali, Iran. Farhad_amirifard@yahoo.com)

1 ABSTRACT

Developments of transportation system and asphalt roads network during the recent years, has been resulted in simple and quick accessibility toward Rasht city. Along with unique placement of population centers in this region, these developments have led to modern urban communicational systems between central city and these population centers. It considers that lots of daily traffics are flowing as "home-work-home" so that major structural changes have been arisen in communications and interaction among them. After evaluating and surveying daily urban system of Rasht city, it has been concluded that existing traditional planning such as Master Plan of Rasht City do not practically benefit from required function as strong interactions have not been considered among Rasht city and other urban and rural areas located in this region. Thus some suggestions have been proposed, so that all areas affected by this daily urban system may be controlled by a unified planning and urban management as well and also they may be managed and planned as an integrated complex in all cities whose populations are not as much as metropolises' but they have functions beyond a city.

2 INTRODUCTION

Generally, central region of Guilan province is a smooth and flat plain and Rasht city is located in this region so that it benefits from a very suitable condition for trafficking by individuals and vehicles. Short distances along suitable topography led to particular and unique condition for this region so that it exceptionally has linked population centers located in this region together during a gradual process unlike qualitative and quantitative development of asphalted road and considerable increase of vehicles as well. This process arose structural changes in urban system of the considered region. The present research has attempted to evaluate this daily urban system. It shows that function of Rasht city in this system is beyond a central city exerting a metropolitan impact and a strong traffic process in its periphery. Thus, it is significant to present a new definition for such cities in the state urban planning system.

3 METHODOLOGY

The research method is descriptive-analytical and data collected through different recourses. The data have been employed in this research including reports and literature reviews after extracting data, they were classified and organized in forms of maps, images and so on. Finally, data were analyzed as descriptive statistics, inductive test and so on.

4 THEORICAL FRAMEWORK AND DEFINATIONS

Urban system is, generally, "a set of related cities which creates structure of urban settlements system in an area, region, land and world". Urban system is not limited to a physical set of urban settlements but it also includes streams and relations among these settlements. These streams are population, investment, factors of production, ideas, information and innovations. Based on this definition, studying about urban systems which are open systems requires studying on their extensive relations with their surrounding area (Azimi, 2002).

4.1 Daily urban System

This system includes daily commuting (home-work-home), thus hierarchical system is not concluded. This kind of urban system includes a wide range of central city and all its surrounding and rural areas which are daily in relation with them regarding social-spatial or in other word functional issues and it also includes a wider range of urban assembly (Bertangolle et al, 2002). Laan has proposed a distinct classification of multi core urban structure use a classification of daily urban systems in four categories rather than drawing a distinction between mono centric or polycentric urban areas

(1) *Centralised*: these resemble monocentric systems in which morning peak-hour commuting is primarily directed towards the core city of the DUS.

(2) *Decentralised*: many morning commuters are attracted to the suburban parts of the system, where much employment is located.

(3) *Cross commuting*: these structures resemble the classic polycentric region consisting of relatively independent, self-contained development nodes. Suburban commuters tend to work in the suburbs; core-city residents often work in the core city.

(4) *Exchange commuting*: these systems have many reciprocal relationships between the suburbs and the core city. Many suburban commuters work in the city, while many central-city residents work in the suburbs (Laan, 1998).

4.2 Christaller Classic Urban System

The theory of core-periphery considers each geographic system as two spatial subsystems which one of them is dynamic core and the other is periphery centers which are dependant and submissive to the center. Theoreticians assert that these relations exist in intra-region areas and even in continental and global levels. According to this theory two forces are received by periphery from the core; favorable force that involves movement of investment from core to periphery and providing first materials for industries by the core.The consequence of this force is emergence a new core and its peripheries.(Andrew K. Copus 2001; Christaller, W 1933).

4.3 Definitions in Existing Theoretical Texts:

4.3.1 Central City

The largest city within a limited area of an urban system enjoying from a population of at least 200,000 inhabitants according the last census. It has a high economic, social and service integration with at least 2 other cities within its functional area as well. Functional area of a central city is at least 35 km.

4.3.2 Urban system

It is a geographical area that is made up of a central city and at least its 2 surrounding cities and rural areas around them. All surrounding areas have high economic, social and service integration with the central city.

4.3.3 Metropolitan Area

Metropolitan area refers to a large population center comprising a large city and its immediate sphere of influence or several cities and town and areas connected to them so that one or more large cities act as its center. Metropolitan areas usually comprise conurbations (areas constructed near each other) and its surrounding regions which do not have necessarily urban nature but are highly depended on central city regarding employment or business.

4.3.4 Urban Region

Urban region is urban centers' sphere of influence which is created from total influence sphere of various functions of an urban center. Range and form of an urban region for a particular function are depended on the following factors:

- Closeness of considered settlements to those settlements with the same function, especially settlements with the same size or larger.
- Nature and pattern of existing communication and transportation system and as a result accessibility of surrounding areas to central city.
- Number and size of existing functions in central city.
- Geographic status of central city and physical geography of surrounding areas.

4.4 Classifying Urban System in Iran

Urban system are classified in 3 main groups in Iran:

- While population of central city of an urban system according to the last official census is between 200,000 to 500,000 inhabitants, the urban system is called median urban complex.
- While population of central city of an urban system according to the last official census is between 500,000 to1,000,000 inhabitants, the urban system is called large urban complex.
- While population of central city of an urban system according to the last official census is 1,000,000 inhabitants or more, the urban system is called metropolitan region.

4.5 Background of the Research

Rasht city and the limited area which is presently interacting with it under a daily urban system were considered about more than 30 years ago in studies conducted in the second period of long-term strategy of land preparation in 1977 by Setiran consulting engineers and was called "SEFID RUD URBAN REGION".

"Delimiting an urban region is arbitrary to a large extent. The territory of the present study is lands of Guilan which includes Rasht, Bandar Anzali and Lahijan. Also it includes west of Fouman and Someesara and it is extended near langroud from east as well. Therefore, order of geographic field in the present study is an area which neither is beyond 90 km from east to west nor 45 km from north to south. This area covers approximately a total area of 3300 square kilometers and it is almost conform to divisions of the civil: Rasht city, Bandar Anzali city, rural districts of Tolam and Someesara (from Someesara city), Fouman city except rural districts of Masouleh, Gasht, Ahmad Sar Goorab, Lahijan city except a large part of Siahkal district (rural district of Siahkal, Fararoud) and Shir Jo Posht rural district. As cities located in this area are complementary for each other and due to closeness of the cities, expression of "Urban field" is induced: Rasht: administrative center, Bandar Anzali: Port and tourism center, Fouman: rice farming center and Lahijan: Tea farming center.

In 2008 we studied daily urban system rules in central region of Guilan and its limited areas. Firstly, entry and exit stations of Rasht city that were the major places of entrance and exit for daily passengers were identified for initial field research. Then mentioned stations were referred and data were collected. This stage cleared a general view of limited area of DUS (Daily Urban System). In addition, it showed that to continue research and to complete data it is possible to go directly toward daily passengers' place of employment so that the second stage of the research were conducted through direct refer to some of offices, companies and factories and so on where had daily passengers. By the help of people, some of daily passengers were identified and research was conducted without administrative process.

In the third stage of census in 2006 and based on raised question all villages of Guilan province which provide their basic requirements from a city or other village and finally all villages of Rasht city which introduced Rasht as the first provider city for their basic requirements, considered as DUS region. Based on studies in these three stages, it was clear that DUS region generally includes Shaft, Fouman, Someesara from East, Lahijan. Langroud, Koomleh, Siahkal, and … from West Bandar Anzali, Khoshkebijar and … from North and Sangar, Shaghaji and … from South.

At the end, in order to determine accurate DUS area whose general view was obtained at the end of three previous stages, it was directly referred to likely borders. In this regard, based on obtained experiences from the previous stages and also based on knowledge obtained from the region and also by referring to Islamic Councils of Villages, departure of daily passengers to Rasht or from Rasht were dealt with. Therefore, limited area of DUS region was completely determined at the end of this stage of the research. In the Fig 1, total DUS region is depicted and curves of stimulus accessibility and accessibility to central city based on time limitations, through personal car, in route without traffic and also the starting point were drawn from exit ways of Rasht cities.

DUS region identified in this research covered a total area of approximately five thousand square kilometers. Regarding total area of Guilan province, DUS covered about 36% of total area of it which is more than 1/3 of the province's total area. This is while that, based on obtained population for DUS region which is more than one million people, this region has 73% of total population of Guilan province that is more than 2/3 of the population of Guilan province. Therefore, based on statistic of DUS region and in compare with the province, DUS region has twice as much population as its area. This region has 24 cities which are 50% of total cities of Guilan province. These cities cover 80% of urban population of total population of Guilan province.

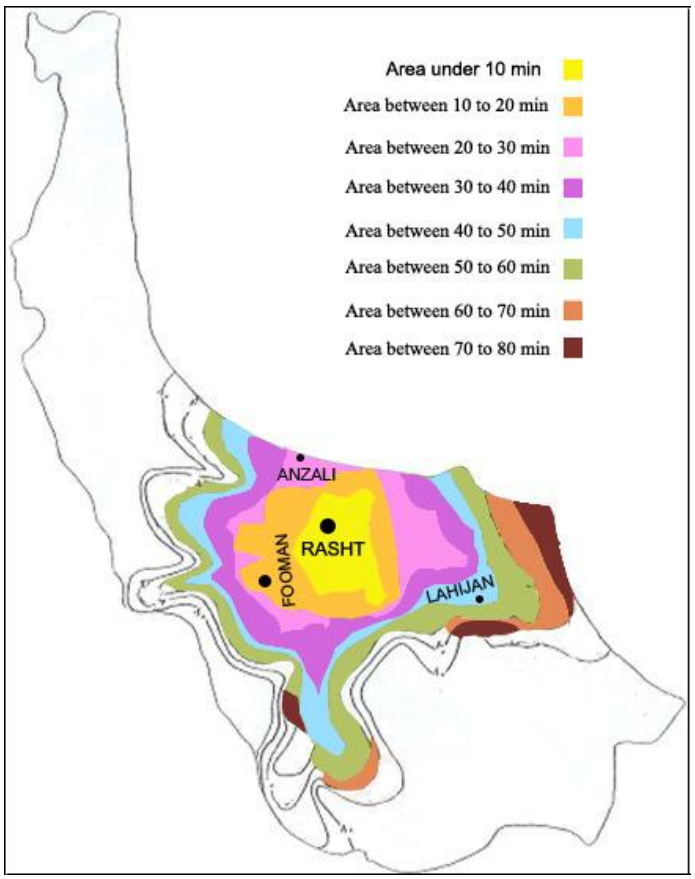

Fig. 1: DUS region and drawing curves of stimulus accessibility on it.

5 COLLECTING DATA AND ANALYSING

5.1 Introducing the Study Area

Guilan province is one of the northern province of Iran with an area of fourteen thousand square kilometers. Its length is 235 kilometer from northwest to southwest and its width varies from 25 to 105 kilometer. Based on the last division of the civil in 2006, Iran has 49 cities, 43 districts, 109 rural district and 2935 villages. Guilan province has 16 cities including: Astaneh Ashrafieh, Amlesh, Bandar Anzali, Talesh, Rasht, Rezvanshahr, Roudbar, Roudsar, Siahkal, Shaft, Soomesara, Fouman, Lahijan, Langroud and Masal. Guilan economy is based on agriculture and it has 253,403 hectares agricultural land so that 198,456 hectares of them are arable land and 54,946 hectares of them are gardens and nurseries.

In order to survey limited area of the considered region and its geographic particulars, it should be said that Guilan province, generally, has two complete different areas (plain areas and mountain areas). If we consider that up to 150 meters height from sea level are plains of Guilan, about 1/3 of total area of Guilan will be plain areas (Fig. 2).

As we described, plains of Guilan (and more cities of Guilan) are almost smooth and flat, it means that they have a very little slope. We could say that slope of the land in all plain areas of Guilan province is approximately less than 1% (Azimi, 2002).

Regarding that, we proposed to survey and evaluate daily urban system of Rasht city and its planning and management and generally surveying these kind of cities, we just study limited areas where this daily urban system is going on and almost all of this limited area is located on plain area of Guilan (only some parts of a few rural districts are located on mountain areas). Limited area of this daily urban system, as it was mentioned above, is a smooth and flat land which has provided a suitable condition for commuting peoples and vehicles. These short distance and suitable topography is by itself a main reason of creation this daily communicational system. As it is clear, this communicational system has been not able (or hardly) to effect mountain areas. Of course, creating and constructing bridges in mountain areas were a great help for communications and transportation systems. However, in fact, this daily system is limited in mountains which surround south, east and west of this smooth and flat land.

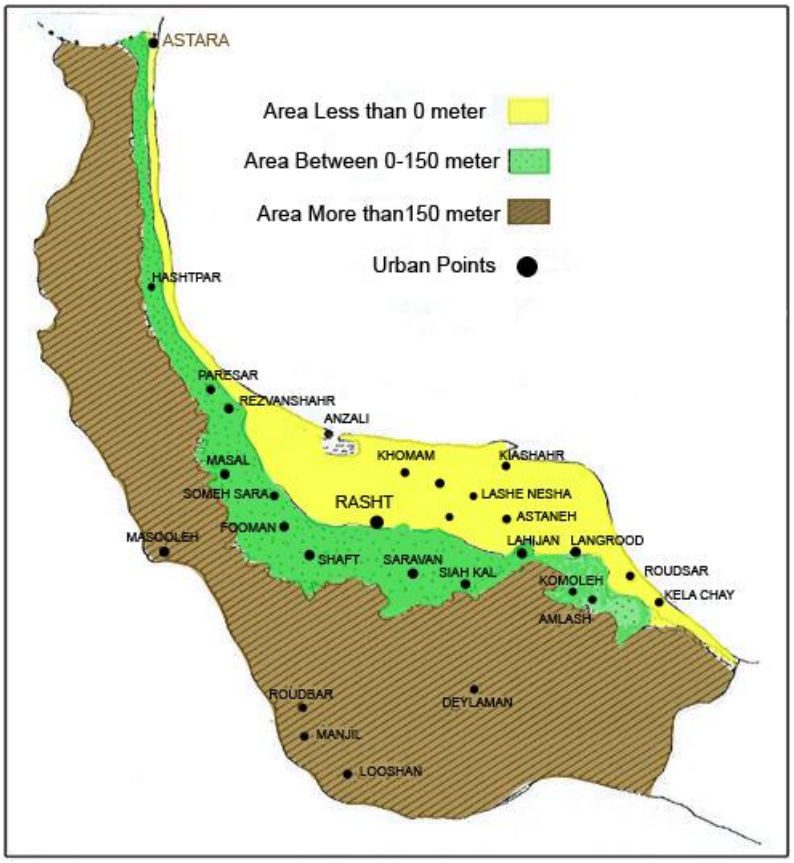

Fig. 2: Urban areas and plain areas of Guilan Province

5.2 Urbanism pattern of Rasht and its interactional region

Generally, based on existing evidences, the study area which had previously pre-industrial economy relying completely on agriculture and running fully by self-reliance followed classic hierarchical system. In fact movement system of people toward applying required facilities and services was hierarchical so that those who were resident in a village or a small city came to more intermediate cities in which they could benefit from higher facilities in compare with their place of residence to meet their basic needs. They also traveled to more important cities to meet their more important and rare needs and they finally traveled directly to central city for specific issues. However, there were two important events from late of 1990s. The first was that qualitative and quantitative daily growth of asphalted road in one hand and increasing personal and public cars which bring quick, inexpensive and simple accessibility to central city which practically transformed existing communicational system to Daily Urban System (DUS) on the other hand. The second event was related to quick growth of rural asphalted roads and also qualitative improvement of asphalted roads and highways construction which increased demands for daily trips to central city. As a result of increasing demands for daily trips to central city, regular commuting service systems to central city and vice versa were arranged so that it assured passengers about daily trips regarding accessibility to vehicle.

Therefore, regarding to the four kinds of Daily Urban System discussed in theoretical principles (Centralized, Decentralized, Cross commuting and Exchange commuting) this system in Rasht daily urban system is a compound of Cross commuting and Exchange commuting which represents interactions among central city and other existing cities and villages in target region in one hand and interactions among suburbs in the other. In fact, modern communications dismantled previous hierarchy and has replaced it by direct and mutual communication between central and other population areas located in this region. Current daily system is not certainly the previous hierarchical system, although it is not completely consistent with a daily urban system. However, this consistency is relative and is integrating day by day. In fact, it does not yet portray a complete real and virtual communicational network but this performance is going toward more integrity and this integration and its performance system are completing day by day to be a very compact and integrated daily system through qualitative and quantitative development of asphalted roads. If we survey curves of stimulus accessibility to central city (Map 4-1), in order to understand better and to analyze daily

urban system in Rasht city, we find that an area which has a distance of less than 30 minutes to Rasht and is almost consistent with Rasht functional area (a 35-km distance), has about 16% of total area of Guilan province measuring 220 km/sq and has more than 50% of total population of Guilan province it means more than 1,200,000 inhabitants whose 70% is city dwellers. It also surrounds 30% of total cities of Rasht. What is obvious is that, all settlements located in this 30-minute area have a unique potential for common economic, social and … performance. Obviously, this area has a powerful interaction with central city and Rasht city is immediate center of urban system of the study area which at least is not considered or performed in urban-regional planning.

5.3 Suggestions:

5.3.1 New definitions have been proposed for central cities of daily urban system considering existing definitions and current structure of Iran urban planning system:

- While a metropolis is considered as a center of an active daily urban system so that its total population of functional area along with population of the central city is not less than two million inhabitants, the region is considered as a metropolitan region. For example, Tehran will be a metropolitan region because it places unlimited daily trips in one hand and in the other hand, cities of Damavand, Rey, and Karaj are located in this area and the total population of it is approximately nine million inhabitants.
- While population of central city in any urban system according to the last official census is between 500,000 to 1,000,000 inhabitants, the urban system is called large urban complex. If these systems meet the following particulars, they will be considered as urban region:
- If central city of a large urban complex has a population of 750,000 to 1,000,000 inhabitants and is located in distance of 35 km from legal boundary or census boundary of central city (the minimum functional area of a city according to the description), and has at least 2 cities with more than 10,000 inhabitants, it is called urban region.
- If central city of a large urban complex has a population of 500,000 to 750,000 inhabitants and it is located in distance of 35 km from legal boundary or census boundary of central city and has at least 5* cities with more than 10,000 inhabitants, and total population of the 35-km area along with population of central city is not less than 1,000,000 inhabitants, it is called urban region.

It the mentioned above suggestions come to implementation, Rasht city will be subjected in Paragraph 2 of the suggestions because based on census of 2006, Rasht has a population of 550,000 inhabitants and 13 cities are located in its 35-km area which 6 of them has a population of more than 10,000. These six cities are Khomam (12,901 inhabitants), Lashtenesha (10,871 inhabitants), Bandar Anzali (109,687 inhabitants), Astaneh Ashrafieh (36,298 inhabitants), Fouman (27,763 inhabitants) and Someesara (36,522 inhabitants). In addition, total population of this area is more than one million inhabitants. In this case, Rasht and its 35-km area would be an urban region.

*The average number of surrounding cities in functional area of current central cities (2008) in Iran is 5.85.

5.3.2 Obviously, these kinds of urban regions will require a new form of urban planning and management.

In fact, Iran urban planners are faced with metropolitan populations which are settled detachedly and different from what they knew. Therefore, we need an urban management different from management of a usual city or even a metropolis. What is suggested is arranging a responsible system for urban region. This unified urban management could be held as a council including authorities of a central city and other existing population centers in this urban region chairing by the highest executive authority. Planning system of an urban region is in fact a strategy to reach proportional distribution of urban development among different cities and generally parallel growth of all regions. It is obvious that this aim will not be achieved unless total urban region is permanently considered by a system which exclusively concentrates and regards toward this urban region and issues such as all new industrial settlement, projects to determine paths of transport infrastructures and large separation of lands must be consulted. In fact this regional council must firstly deals with studying and ratifying regional plans as a superior project for its urban region so that all comprehensive and directory projects for cities and villages located in the considered region are formed and ratified within

their framework considering particulars of total urban region in order that no existing population system in this urban regions being planned and managed as a single member and separate from its family.

6 CONCLUSION

Authorities, planners and specialist believe that as physical differences between these kinds of cities exerting metropolitan impacts, with other known cities and metropolises in Iran were hidden up to now, urban problems and difficulties of these population centers surpass specialists and planners regarding time and facilities. It is obvious that if this negligence continues, the city and citizens will be subjected to all-embracing damages. This issue, at first, declines citizens' quality of life which is certainly the most important issue for planners and specialists in urban affairs. Therefore, it is required to consider this fact in planning as soon as possible as it seems necessary particularly in the region's spatial arranging and especially in its communicational network and in arranging its settlements and so on. It also may be the purpose of experts and planners. In fact, all planning up to now and in future regardless the revolution taking place and consuming time and money, will be incorrect and we have uselessly have consumed our time and resources as the special condition of this region has not been regarded. For example, all planning arranged for Rasht city and its complementary system, regardless to structural revolution have considered it as a single city while its requirements, facilities and other conditions are completely different in two classical and daily systems so that planning considering classical system will deviate the city far from direct way and finally creation of abundant problem in the future which are glaring by now will lead us to acceptance. It is necessary to propose a new description for planning system of those cities located in centrality of a daily urban system having large commuting (or will be developed in the future) and then a new type of urban and regional management and planning may be considered for them.

The Netherlands in Transition. The Planning of Low Carbon, Sustainable and Liveable Cities in the Utrecht Region

Martin Dubbeling

(Ir. Martin Dubbeling, SAB Office for Urban and Regional Planning, Urban Design, Landscape Architecture, Ecology and the Environment, Arnhem, The Netherlands, martin.dubbeling@sab.nl)

1 INTRODUCTION

The Netherlands is world renowned for the way in which urban planning, infrastructure, ecology and the environment form an integral part of the practice of spatial planning and urban design. The country has a vigorous and open economy, an entrepreneurial society with its metropolis situated on a compact delta which is vulnerable to climate change. The Netherlands has four layers of public administration, the State (central government), the provinces and the municipalities which, together with the regional water boards, are responsible for spatial planning and the future development and structure of the Netherlands' cities, infrastructure and national landscape. At the start of 2011 and following a change of government the responsibilities of each of the three tiers of government and how they can work together was re-evaluated and set out in the 'Administrative Agreement 2011-2015' . Central government, the provinces and the municipalities are almost constantly working on strategies, policies and plans for the development and redevelopment of low carbon, sustainable and liveable city regions and cities for the coming decades.

All three tiers of government are charged with the task of making Dutch cities ready to face the future: less dependent on fossil fuels, with reduced emissions of greenhouse gases, and able to cope with the expected rise in sea level and climate change. Policy and targets in the area of reducing CO_2 emissions and energy transition are more likely to succeed when they become an essential part of spatial policy and planning. The Province of Utrecht and the larger cities in this region, in particular, are taking major steps in this area. This article describes how the newly elected central government, the Province of Utrecht and the six larger towns in Utrecht are turning their climate and energy targets into spatial policy, strategy and physical planning. This stands in sharp contrast with the situation as reported in the ISOCARP Review 05 Low Carbons Cities , especially in the way the responsibilities between the state, provinces and municipalities are redefined and redivided.

2 THE ADMINISTRATIVE AGREEMENT

The Netherlands faces a major challenge: cutting government spending while at the same time strengthening the economy. The Administrative Agreement between the State, provinces, municipalities and regional water boards is supposed to help to create a government apparatus which is lean and efficient with a clear division of tasks between the four levels of administrative authority. The underlying principle of the Dutch Government apparatus of the last decade 'decentralize whatever can be, centralize whatever has to be' is put into practice. This means that, wherever possible, the implementation of tasks is devolved to the municipalities or provinces. Central government is responsible only for national concerns such as national defence and foreign policy, but is also involved, alongside other levels of administration, in the spatial economic structure, public health, flood defences, the nation's unique landscape features and cultural heritage, plus the national and international transport networks. Central government set out this vision in the draft National Policy Strategy for Infrastructure and Spatial Planning .

The core tasks of the provinces will lie in spatial development and the physical surroundings. The provinces will act as regional coordinators for the development of integrated development strategies, the interplay of interests as well as promoting and safeguarding complementarity between the cities and city regions within the province. The municipalities will be responsible for creating a safe and pleasant environment in which to live and work, and their tasks will lie in the social, economic and spatial domains. In the spatial domain this will be spatial planning in the widest sense, in which it will be important to find the right balance between the environment, nature, water, the economy and housing, etc. This policy will be laid down in policy strategies and zoning plans. The task of the regional water boards is to manage water quality and quantity in the regional water systems. As part of this task the water boards are responsible for the flood defences and for ensuring that there is sufficient clean water.

The Administrative Agreement states that the public authorities will work together to ensure coherent spatial policy and task allocation across the administrative layers and levels of scale in the areas of housing, water, mobility, economic activity, the climate, energy, the environment and cultural heritage. This spatial policy must ensure that the Netherlands:

- Can develop further economically, so that investing in the Netherlands continues to be attractive to national and international businesses;
- Continues to be accessible by land, water and air;
- Puts its energy supply in order and ensures that energy is available for the future;
- Is protected against flooding and surplus water, and continues to be safe even under climate change;
- Is a pleasant, healthy and attractive place to live and work, where people can enjoy nature, culture, and recreation, with a good balance between all these functions .

3 THE ENERGY REPORT 2011

The Administrative Agreement refers to the goals set out for economic innovation and making the energy supply more sustainable as formulated in the Energy Report 2011 published by the Netherlands Ministry of Economic Affairs, Agriculture and Innovation. Central government continues to work towards achieving the EU climate target, reducing 80-95 % of CO_2 emissions in 2050 by comparison with 1990. The provincial authorities, municipalities and water boards too are dedicated to creating more sustainable energy and achieving climate targets. Based on their own goals and resources, they are continuing to work towards energy conservation and increasing the share of sustainable power generation. The provinces and municipalities are adjusting the spatial criteria for this, while fostering economic innovation and change. The underlying principle of the Energy Report is a form of energy management which is more sustainable and less dependent on increasingly scarce fossil fuels. The state wants to benefit from the strength of the Dutch energy sector. This will bring growth, jobs and revenue. The energy policy has three main concerns: transition to a cleaner energy supply, the economic outlook for the energy sector and the need for a reliable energy supply.

The Energy Report sets out the aspiration of achieving a low carbon economy by 2050. It indicates that the best way of doing this will be through an international climate agreement and it will be necessary to make the transition to a more sustainable form of energy management. This transition should be good for the Dutch economy. Under the motto of "not 'green' or growth, but 'green' and growth" the Energy Report advocates capitalising on the strength of the energy sector and encouraging cooperation with research institutes and industry in the development of new energy technologies. This is the only way that the Netherlands will be able to further develop renewable energy and maintain its international position as an energy producing country. This will bring growth, jobs and revenue. The Energy Report further assumes a balanced mix of national and international green energy and grey (i. e. fossil) energy. It describes the present reality which, for the time being, means that Europe will continue to be dependent on fossil fuels and that the Netherlands' position as a gas producer and world leader in the technological field of capturing and storing CO_2 will be important for the Dutch economy. It further assumes that, in the near future, the Netherlands will also need nuclear energy because this will help to further diversify energy sources and does not lead to CO_2 emissions. The Energy Report sets out five main pointers for the future:

- A modern industrial policy based on innovation, the development and commercial viability of renewable energy technologies, the positioning of the Netherlands as a knowledge-based economy and as a gas exchange for North-West Europe. This will not only create jobs and economic activity, but also help to safeguard supply;
- Increasing the share of renewable energy, provided that the energy supply becomes more sustainable, in a way which is economically viable and that renewable energy becomes a standard part of the internal European energy market;
- Keeping all energy options open as we move towards a low carbon economy in 2050 with a balanced mix of green and grey energy in an integrated energy market together with CO_2 reductions brought about through an increased share of renewable energy, energy conservation, and nuclear energy, together with CO_2 capture and storage;

- Based on the principle of 'green growth', making a 'Green Deal' with society with the aim of taking real steps towards a sustainable society. A sustainable society will not happen by itself, it is a joint process involving both society and government. Energy conservation and renewable energy will be important elements in the Green Deal;
- Investing in a properly functioning European energy market with an adequate infrastructure which facilitates cross-border integration of national grid operators. An adequate energy infrastructure is vital for an energy supply which is clean, secure and affordable.

The Energy Report clearly shows that the built environment and transport take up a very large proportion of the total energy consumption in the Netherlands and that these constitute a major source of CO_2 emissions. There is also considerable potential for savings in both these sectors. Policy and targets in the area of reducing CO_2 emissions and energy transition are more likely to succeed when they are made an indispensable part of spatial policy and planning. However the Energy Report does not go much beyond the development of intelligent transport systems, promoting electric cars, and improving the energy labelling of new and existing buildings. The Energy Report keeps all the options open when it comes to green, grey and nuclear energy, and makes no credible choice. The Energy Report therefore falls short when it comes to formulating adequate and effective policy on the necessary changes to be made in the built environment. The aim of moving towards a low carbon economy and society in 2050 will require a revolution in the area of smart public transport and an entirely different way of organising and planning urban regions and cities.

4 NATIONAL POLICY STRATEGY FOR INFRASTRUCTURE AND SPATIAL PLANNING

In the spring of 2011 the Dutch Government presented its draft National Policy Strategy for Infrastructure and Spatial Planning. The subtitle 'Keeping the Netherlands competitive, accessible, liveable and safe' already indicates something of the document's nature and goals. After its adoption, this Policy Strategy will replace the Spatial Planning (2006) and Mobility (2004) Policy Documents and the Randstad 2040 Structural Vision (2008) in order to provide room for the provinces, municipalities, citizens and businesses to take the initiative and continue to develop economically. Central government has made it clear that it cannot and does not wish to continue to do and control everything. The Policy Strategy specifically notes that the spatial differences in the Netherlands are widening. The rapid population growth in previous decades is now behind us. In the next 25 years perhaps another one million or so Dutch citizens will be added to the cities, mainly in the west of the Netherlands. More than half of the country's municipalities will soon start to feel the effects of a shrinking population and an ageing one. In most areas the demand for more offices, industrial estates and residential areas will be much less than it has been in recent decades. As a result, obsolescence and vacancy levels will become an increasingly apparent problem.

In many respects, especially in the way the responsibilities between the state, provinces and municipalities are redefined and redivided, the draft National Policy Strategy for Infrastructure and Spatial Planning constitutes a break with the past and with the policy of the last few decades. Central government is focusing on strengthening the international position of the Netherlands and promoting the interests of the country as a whole. These interests concern the main networks for the transport of passengers and goods, energy and the environment, flood defences and environmental quality (air, noise, soil, water and external security) and the protection of world heritage sites such as the Waddenzee (Wadden Sea), and the Nieuwe Hollandse Waterlinie (New Waterline defences). These three main goals have been subdivided into 13 themes of national importance and included in national commissions for seven designated so called MIRT regions under the Long-Term Programme for Infrastructure, Spatial Planning and Transport, along with the North Sea coast. The seven MIRT regions are North-West Netherlands including the Amsterdam metropolis region (the northern wing of the western conurbation known as the Randstad), the southern wing of the Randstad, the South Western delta, Brabant-Limburg, East Netherlands, Utrecht and North Netherlands. In this way central government has indicated what it is responsible for and the results it wants to achieve. While at the same time, the state gives the provinces and municipalities room to act in response to their own regional and local situation, make their own decisions and tailor their activities accordingly.

It should be noted that developing low carbon, sustainable and liveable cities and regions will mainly become the concern of the provinces and municipalities, possibly in concert with one another. The stated ambitions and themes of the Energy Report 2011, such as a low carbon economy by 2050 and entering into a "Green Deal" with society are hardly, if at all, reflected in the draft National Policy Strategy for

Infrastructure and Spatial Planning. It is recognised, however, that the transition to more sustainable fuels will take up more space. To ensure that the Netherlands sets aside enough land for wind energy, central government, together with the provinces, has designated preferred areas for large scale wind farms. Alongside this, international energy relations will be strengthened and the energy infrastructure made more suitable for decentralised electricity generation.

The ex ante evaluation of the National Policy Strategy for Infrastructure and Spatial Planning by the Netherlands Environmental Assessment Agency (PBL) advocated careful steering of the energy transition. The evaluation further emphasized that the built environment can contribute to the energy targets. The heating and cooling of buildings demands a great deal of energy and a lot can be saved by connecting the heat flows between individual buildings, and using waste heat from industry. There is also an enormous benefit to be gained through better insulation of existing homes and commercial buildings, because a large proportion of the buildings that will be standing in 2050 have already been built. This means that it is vital to look at the restructuring of the existing building stock in order to meet energy targets. In other words, it is a matter of improving the heat management in towns and cities in innovative ways, with information and clear rules, such as energy labelling for buildings, and by linking projects, for example, in heating networks.

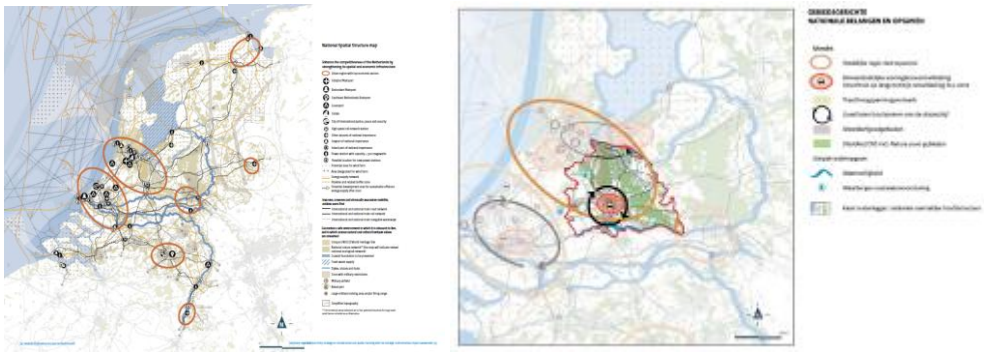

Figure 1 (left): The National Spatial Structure Map from the (draft) National Policy Strategy for Infrastructure and Planning illustrates the way that the Netherlands is enhancing its competitiveness by strengthening its spatial and economic infrastructure. Figure 2 (right): The Utrecht Region is part of the Amsterdam metropolis region. The (draft) National Policy Strategy for Infrastructure and Spatial Planning states that the proper functioning of the Utrecht region as the Dutch 'hub' with its complex intersection of road, rail and waterways is one of the primary tasks of national importance.

5 THE UTRECHT 2040 MISSION

With 1.2 million inhabitants, the Province of Utrecht is one of the most densely populated and at the central point of the Netherlands. It forms part of the northern wing of the Randstad, one of Europe's strongest economic centres. Utrecht lies at the centre of one of the country's largest metropolitan networks which will drive economic and social developments over the next few decades. It is here that the motorways, railway connections and waterways converge which connect other parts of the Netherlands with one another. In this way it acts as a logistical hub for the major development axes along the A1, A12 and A2 motorways. With the trend from 'main ports' to 'brain ports', the Utrecht region is increasingly becoming a meeting point for know-how and creativity. Utrecht owes this opportunity to the three mainstays of the region: its leading position in terms of knowledge-based activities and culture, its central position, and the quality of the cities and surrounding landscape.

In its strategy and mission 'Utrecht 2040: sustainable and attractive', the Province of Utrecht states that it intends to be a province which does not shift the burden to other places on earth and later generations. Making choices with a view to the consequences elsewhere and later is seen as a moral duty and a strategic task. Within the overall picture of maintaining and strengthening the three mainstay qualities of the region, six goals are set; these indicate where the major societal issues and spatial tasks will lie in the coming decades. The Utrecht 2040 strategy is the prelude to the draft policy strategy for the period 2013-2025 and describes a province:

- Where there is for room for a good quality of life (housing, work and nature);
- With an innovative knowledge-based economy;
- Which is accessible by car, bike or public transport in a better environment;

- Which is climate neutral and able to cope with climate change;
- Where everyone counts and can participate at school, in their neighbourhood and in their profession;
- With more diversified nature and an attractive landscape.

The economic strength of Utrecht lies as much in its central location as in its highly educated population, the knowledge-intensive sectors (such as Utrecht University, the Royal Dutch Meteorological Institute (KNMI) and the National Institute for Public Health and the Environment (RIVM) research institute) as well as the creative sectors, business and financial services and the life sciences (Utrecht Science Park). The particular features of the surrounding landscape, including key areas of the National Ecological Infrastructure (EHS) and the presence of cultural heritage features in the form of the 'Roman Limes', representing the border line of the Roman Empire at its greatest extent in the second century AD, and the Nieuwe Hollandse Waterlinie which are candidates for the list of World Heritage Sites, also contribute to this strength. On the edge of the Randstad, Utrecht acts as a buffer zone between the metropolitan dynamism on the one side and the peace and spatial tranquillity of the East Netherlands on the other. This position gives the region the relaxed urban atmosphere and quality of life which makes the area so attractive. These are its past and future critical success factors.

In the 2011-2015 Coalition Agreement of the Provincial Council of Utrecht, the provincial executive designated as its core tasks economic and spatial development, nature and the landscape, accessibility, as well as cultural and historical heritage. Sustainability forms an integral part of these core tasks. The Province of Utrecht is well aware of its position and responsibilities as a hub and its central position in the Netherlands. Policy tasks include restructuring and making more intensive use of existing work sites in combination with energy conservation and reducing CO_2 emissions, together with inner city development and strengthening the quality of the rural area, as well as the flood defences, energy transition and accessibility.

The Coalition Agreement also addresses how to make sustainable energy possible in the spatial context. The accommodation of wind power is thought to be constrained by landscape quality considerations. The preliminary draft Provincial Spatial Planning Policy Strategy 2013-2025 document nevertheless includes wind energy sites. If accepted by the municipalities and if the market takes the lead, the plans for wind energy could be further developed. However, other forms of sustainable energy are preferred, such as solar energy, waste heat, thermal energy storage, geothermal energy, biomass and farm energy, which have less impact on the quality of the landscape.

The draft National Policy Strategy for Infrastructure and Spatial Planning states that the proper functioning of this Dutch 'hub' with its complex intersection of road, rail and waterways is the primary task of national importance. Other tasks in the draft Policy Strategy include building and maintaining the flood defences along the Lek and Lower Rhine rivers and the freshwater supply via the main water system, implementing and protecting the (revised) National Ecological Infrastructure (EHS), including the Natura 2000 areas, making the main energy network robust and complete and accommodating the exploitation of geothermal energy and thermal energy storage in the region. The redevelopment and urbanisation of the A12 zone in the urban landscape between the towns of Utrecht, Nieuwegein and Houten is also designated as a task of national importance. The Utrecht region experiences considerable pressure on its space because of the heavy demand for housing in combination with the limited space available for this.

The economy and the number of households in Utrecht is expected to continue to grow until 2040. Until 2040 there will be continuing demand in the Utrecht region for more than 100,000 homes, alongside the need to replace some 20,000 homes. Given the complexity and scale of the inner city task and the relationship between this task and the function of the 'Utrecht hub', central government and the region have reached agreements about this. They have furthermore agreed that, in principle, some of the demand for housing in the Utrecht region (15,000 homes) will be met in Almere.

Box: Definitions and Ambitions

The following three ambitions are often voiced in the Netherlands: CO_2 neutral, climate neutral and energy neutral. These terms are often used interchangeably as if they mean the same thing, though this is most certainly not the case. CO_2 neutral is understood to mean: a situation where fossil energy consumption (and related CO_2 emissions) measured throughout a year is no more than zero and no energy is consumed that is

not put back into the system from a renewable source. Climate neutral refers to a situation where the above definition of neutrality encompasses all greenhouse gasses. Energy neutral goes one step further because in this case the total energy requirements of a company or a whole area must come from renewable sources and the storage of CO_2 in new forestry areas or underground is not permitted.

6 THIRD INDUSTRIAL REVOLUTION

For the further development of the task set out in the Utrecht 2040 strategy as well a climate-neutral and climate resilient province which is dependent only to a limited extent on fossil fuels, the Province of Utrecht in 2010 called in the US economist and energy strategist, Jeremy Rifkin. In his report Rifkin outlines a path in which economic development and the realisation of climate goals go hand in hand. Rifkin expects that, given the finite nature of fossil fuels, in the longer term a worldwide energy transition will start to take place, together with a huge demand for all kinds of products and services. Rifkin, who is also an advisor to the European Commission, makes a clear link with the economy and for his reports and recommendations draws on a large network of people in the private sector, such as Philips, Cisco and Kema. Rifkin's recommendations, with the grand title 'Utrecht Roadmap to a Third Industrial Revolution', provides building blocks for a clean economy in 2040. These involve the consistent pursuit of an energy conservation policy and the application of new, sustainable energy sources. Rifkins 'Third Industrial revolution' is based on five principles:

- Energy efficiency;
- Use of renewable energy resources;
- Use of buildings as power plants;
- Development of hydrogen and other energy storage technologies;
- Shift to smart grids and electric plug-in vehicles.

According to Rifkin, it will be impossible to end CO_2 emissions in Utrecht completely within 30 years. This is because a large proportion of these emissions are related to the old housing and building stock and the infrastructure. Only at extremely high cost would it be possible to become completely climate neutral within 30 years for heating and other purposes. In addition, many new technologies would have to be applied and a new generation of technicians and engineers would be necessary to manage them. This is not something which can be achieved in one generation. To become climate neutral it will therefore be necessary to find compensation elsewhere.

In his report Rifkin makes an important link between the energy transition and the economic opportunities which this offers. He even calls it an 'Economic game plan'. This is precisely the approach adopted by the Province of Utrecht. It is not a separate programme in which the province will steer the energy transition, but one linked to the economic policy of the Province of Utrecht. In the economic policy plan for the province of Utrecht three essential elements are identified: life sciences, the creative industries and economic sustainability. The last theme is still in its infancy, but with such centres of knowledge as the University of Utrecht, the University of Applied Sciences Utrecht, the Utrecht Sustainability Institute (USI), KNMI, RIVM and TNO, the Province of Utrecht has a lot to offer in terms of a starting point for an economic sustainability cluster. The focus of the province in the coming period will be mainly on creating the right conditions to strengthen this cluster, for example, by combining demand and creating economic added value by encouraging innovation. This means that the province intends to take steps to reduce CO_2 emissions in the restructuring of commercial estates and make sustainability and quality of life a visible part of the inner city task. Through the Ontwikkelingsmaatschappij Utrecht (OMU – Utrecht Development Agency), the Province of Utrecht will take part in projects to break the impasse surrounding these tasks. When it comes to the energy issue, the province supports initiatives with a team of energy experts that delivers first aid for technical, financial, legal and organizational bottlenecks. Other examples in which the province is involved are knowledge and innovation in the area of deep geothermal energy, facilitating biogas hubs to support transport and supply of biogas, project management group for smart grids and administration for a guarantee fund.

In his report Rifkin also makes another import link between the issue of the energy transition and its spatial impact. He has made a rough estimate of what would be required to achieve a climate neutral region by

2040: importing 120,000 freight vehicles a year carrying biomass or 1600 large-scale wind turbines in the beautiful open landscape. Given the spatial complexity of the Province of Utrecht previously referred to (densely populated intersection of road, railway and waterway network, nature/landscape) this is not a realistic prospect. But providing the room for energy and other forms of innovation and for large scale generation of sustainable energy is probably the most important pre-requisite in relation to the province's core task in the spatial domain. The province itself cannot develop any sustainable or conventional energy projects. It will be the market players, such as project developers, power generation companies, housing associations and groups of residents who will do that. The task of the province will be to provide clarity at an early stage for these parties regarding where they can develop their initiative. This is what the Provincial Spatial Planning Policy Strategy is intended to do.

Figure 3 (left): This diagram of a smart grid illustrates in which way local energy sources, buildings and electrical vehicles are interconnected. Figure 4 (middle): The common situation of a house that is connected to the power grid only to consume energy might be outdated in the near future. A smart home connected to the smart grid will be able to upload, store and download energy in a way similar to the internet. Figure 5 (right): According to Rifkin, geo-thermal energy is one of the renewable energy resources necessary for a clean economy in the Utrecht Region 2040

7 UTRECHT'S SPATIAL PLANNING POLICY STRATEGY

The preliminary draft of the Provincial Spatial Planning Policy Strategy sets out spatial policy for the period 2013-2025. This document centres around the question of how to ensure that the region remains an attractive place to live and work and for recreation, while maintaining the balance between people, the environment (planet) and the market (profit). The spatial planning policy strategy sets out three main development themes: a sustainable residential environment, bustling villages and towns and an attractive rural area. These themes will contribute most to the attractiveness, liveability and spatial quality of the province.

With the development of a sustainable environment in which to live, the province is preparing for climate change. The spatial planning policy strategy restates the province's goal of being a climate-neutral province and climate-resilient by 2040. To achieve this goal the province already needs to take this into account in its spatial planning. Part of this will include increasing the share of sustainable energy sources. This is desirable not only to achieve this aim, but also from the point of view of becoming less dependent on fossil fuel sources. To cope with climate change it is important that the soil, water system and flood defences are sustainable and robust. Where water levels are too high, the excess has to be safely channelled away and the dikes are intended to further reduce the likelihood of flooding. The Province of Utrecht wants its towns and cities to continue to be attractive, healthy and safe places to live and work and recognizes that a sustainable living environment is also a factor in the decision where to locate a business, one which is expected to become even more important in the future.

Sustainable energy is considered to be a 'provincial concern'. This means that the province can address this concern in various ways. The goal of making the territory of the Province of Utrecht climate neutral by 2040 not only involves reducing CO_2 emissions but also achieving a situation where the province is no longer dependent on the finite supply of fossil fuels. The spatial task here is to provide space for the sustainable generation of energy and the facility to bring together those functions which supply or demand heat or energy. For this purpose the Province of Utrecht will aim for energy self-sufficiency in its regional development. The province will ask the municipalities and developers to include a section in spatial plans on how the plan takes energy conservation and the application of sustainable energy sources into account. The province also intends to stimulate the use of all forms of sustainable energy: wind energy, biomass, deep geothermal energy, thermal energy storage, solar energy, hydropower and the use of waste heat. Spatial frameworks have been drawn up for wind energy and biomass. The basic principle here is that, in view of the spatial impact of wind turbines, preference will be given to other forms of sustainable energy. Besides the

Spatial Planning Policy Strategy, the province will also draw up a strategy on the theme of the subsoil which looks at the opportunities for and threats to thermal energy and geothermal energy storage.

Besides low carbon and fossil fuel independence, a territory which has been organised to be climate-neutral by 2040 has the added benefit of better air quality. It further provides opportunities to maintain and even improve the quality of the physical surroundings. Energy conservation and the generation of sustainable energy also offers opportunities in relation to Utrecht's sustainable economy. To attain climate neutrality the task is to greatly reduce energy consumption through conservation and innovation on the one hand, and to generate the energy that is needed in a way which is sustainable on the other. This relates to both central power generation of large amounts of energy as well as bringing together various functions which demand heat and energy and can supply heat and energy. The province has estimated the spatial capacity for the production of sustainable energy until 2020. If all the realistic options for biomass, solar energy, geothermal energy, etc. were to be used and the province achieves the nationally agreed goal of 50 MW in wind energy, then this will provide for the sustainable generation of 10 % of the Province of Utrecht's energy needs. This means that the province will not meet the goal of 20 % of sustainable energy generation as intended in the Spatial Planning Framework . The transition to a sustainable energy supply is expected to progress slowly during the period of the Policy Strategy document (2013-2025). The Province of Utrecht does not expect that this will influence the objective for 2040 to be climate neutral. A characteristic of a transition is a slow start with several small scale innovations, followed by a 'take off' and acceleration phase where visible structural changes take place. In the period between 2025 - 2040 the province expects the many innovative initiatives and projects that already take place, to develop into a fully grown sustainable economy that is independent from fossil fuels.

The Province of Utrecht does not consider wind energy to be the most suitable option in this transition. The goal in itself and the related sites for wind energy are limited essentially to the agreement made with central government to provide for 50 MW of wind energy on land. When it comes to biomass the province is much more generous. Considerations such as fitting the necessary plant into the landscape and the effect of increasing traffic are, of course, also critical factors. The province wants to make the processing of biomass spatially possible based on a positive land use ratio. In the urban regions the responsibility will rest mainly with the municipalities and the same goes for energy conservation and the application of sustainable energy.

8 PLANS AND INITIATIVES IN THE LARGER TOWNS AND CITIES OF UTRECHT

More than half the residents of the Province of Utrecht live in the six larger towns and cities of Utrecht (311,250 inhabitants), Amersfoort (146,500 inhabitants), Veenendaal (62,250 inhabitants), Nieuwegein (61,000 inhabitants), Zeist (61,000 inhabitants) and Houten (49,000 inhabitants). Utrecht and Amersfoort are the larger and older cities with a historic centre. Nieuwegein, Houten and Zeist are satellite towns of Utrecht and the town of Veenendaal is more closely linked to Ede and Wageningen in the Province of Gelderland.

The two larger municipalities in the Province of Utrecht, in particular, are highly ambitious when it comes to the areas of climate, reducing CO_2 emissions and the energy transition. The municipality of Amersfoort has laid this down in a Climate Action Plan and the policy document 'Amersfoort: a city that cares about the future' , while the Utrecht municipality has this in its planning and implementation programme 'Utrecht's Energy'. These include the goals to make the municipality of Amersfoort a CO_2 neutral municipality by 2030 and Utrecht a climate neutral municipality by 2030 (see Box 1). These goals have not been plucked from the air, but are the result of preparatory policy and research over the years. The programmes of the two councils (last elected in 2010) see CO_2 reduction and sustainability not only as a necessity but also as an opportunity for the economy and a way to improve the environment we live in. The two programmes emphasise largely the same things, specifically the building and renovation of existing and new residential areas and commercial estates in a way which is CO_2 neutral, intensive use of space, the sustainable and local generation of power, clean air through sustainable mobility and creating a green and pleasant living environment.

The planning and implementation programme 'Utrecht's Energy' is solid and full of such aims and policies. Given that 80 % of CO_2 emissions come from the cities, the programme assumes that the emphasis of the drive to reduce CO_2 emissions will lie in the existing stock of housing and industrial buildings, in the private sector and in mobility in the cities. Major CO_2 reductions can be achieved by improving the relatively old stock of housing, offices and commercial premises. In mobility too, there are general opportunities for CO_2

reduction: in a compactly built city like Utrecht, those opportunities are even greater. The distances involved are small as a result of which quieter, cleaner, safer and more sustainable mobility options (e.g. bicycle, public transport, electric transport) would appear to be the more natural choice.

Thus, there is all the more reason to get to work at the urban level. This can be done, among other things, by improving and extending the district heating which started being laid as long ago as 1923, partly in the historic centre, and in 2005 provided for a quarter of the city's heating needs. The heat supplied is the waste heat from two power stations in the city, combined with auxiliary (stand-by) district heating plants. This results in a reduction of 50 % of CO_2 emissions compared with traditional individual heating systems in every building. The heating network has branches not only into the post-war residential areas of Kanaleneiland and Overvecht but also extends to the neighbouring municipality of Nieuwegein and the eastern part of the Leidsche Rijn urban development. By adding biomass as source of energy in the two power stations, the district heating network becomes more sustainable.

Figure 6, 7 and 8: Masterplan and artist impression for the redevelopment of Utrecht Central Station

Another key objective is to reduce energy consumption in the extensive historic inner city of Utrecht, where there are over 4.500 large and impressive historic buildings like churches, museums and university faculties. The municipality is investigating the feasibility of deploying a combination of interventions to reduce energy consumption without damaging the historic cityscape and the listed buildings. For the time being, the focus is on renovation and careful insulation, together with smart building services, smartly utilizing the district heating network and the use of thermal storage in the ground. In this way the municipality considers not only individual buildings but also looks at connected parts of the extensive historic inner city. It is working on a number of key sustainable projects, such as the Science Park on the Uithof university campus, the station area and the Rijnenburg urban development district with 7,000 homes, the master plans for which provide for them to be made more sustainable. These projects also derive to some extent out of the strategy policy for the period 2015-2030 drawn up by the municipality in 2004. This strategy sets out tasks such as optimizing and intensifying the use of the urban space and making the urban water system more sustainable, although measures related to the areas of climate, reducing CO_2 emissions and energy transition are more recent innovations.

Amersfoort municipality has a policy strategy for 2030 in preparation in which sustainability constitutes one of the important themes. Indeed, under the course which the municipality has set for itself, sustainability will be the guiding principle in the further development of this bustling city. Moreover, it is one of the main tenets of the 2010-2014 Coalition Agreement. This concerns the interpretation of the broad term sustainability: the coherence between socio-cultural, environmental and economic measures (people, planet and profit), such that the effects elsewhere and on later generations are recognized. The positioning and strength of the city of Amersfoort is at the heart of its ambition to further develop into a vital and sustainable city as part of the northern wing of the western conurbation known as the Randstad, with a central role for the Amersfoort region. Another related task is the renewal and more intensive use of the existing urban area.

The Steering Document which provides the essential starting point for the Amersfoort Spatial Policy Strategy 2030 sets out eight spatial planning goals and looks more closely at the context and dilemmas which will arise in drawing up the policy strategy. One of the eight spatial planning goals, a specific response to climate change, aimsto facilitate a CO_2 neutral city as far as is spatially possible by 2030. The municipality is fully aware of the scale of this task. To achieve this goal energy consumption will have to be reduced as far as possible. Realistically, however, the likely gains in that area will be limited. Most can be achieved in the built environment and through sustainable mobility. This is why an energy transition is needed, i. e. switching from the use of fossil fuels to the generation of sustainable energy. All promising forms of

sustainable energy must be utilized in order to meet this goal. Examples include solar roof panels, energy storage in the ground, utilizing biomass and wind energy. It is important to create the right conditions to ensure that optimum use can be made of these opportunities. Some forms of sustainable energy, such as wind turbines, are at odds with other spatial planning goals, such as the aim to create an attractive green city which is a pleasant place to live in.

Figure 9 and 10: Experimental low energy houses in Nieuwland in Amersfoort, built in the early 1990s, demonstrated all kinds of techniques and systems. The sustainable residential area Nieuwland in Amersfoort consists of 4,500 houses. One thousand of them are covered with solar cells.

In recent decades, Amersfoort has made a name for itself with its Nieuwland sustainable residential district with 4,500 homes. This residential area is one of the first of its kind in the Netherlands, where the principles of sustainability have been applied right down to the smallest details. The Nieuwland district was built in the period 1995-2002 and is the world record holder in the area of active solar energy. The electricity generated by some 12,500 m2 of solar panels on more than 1,000 homes and other buildings is enough to meet 40 % of the total demand of the households living in those 1,000 homes . The experience gained in Nieuwland was then applied to Vathorst, the urban district currently in development with roughly 11,000 homes and all attendant facilities, such as healthcare, education, sport, culture, shopping centres and its own train station. The focus over the coming years and decades will be on completing Vathorst and on the sustainable re-development of existing residential districts such as Soesterkwartier and Bergkwartier.

The four other major towns in the Province of Utrecht, the municipalities of Houten, Nieuwegein, Veenendaal and Zeist each have specific climate programmes and ambitions. These municipalities' goals in the area of climate, energy conservation and reducing CO_2 emissions are less ambitious and far-reaching than those of the Amersfoort and Utrecht municipalities. Nevertheless, all four of these municipalities have realised remarkable projects worth following or have such in preparation. The municipality of Houten is a world renowned new town, one of the satellite towns of Utrecht to meet the needs of the growing Utrecht region. From the start, in the 1970s, Houten is a classic and successful example of Transit Oriented Development (TOD). The urban design of Houten is entirely oriented towards cycling. The car infrastructure has been made subordinate to this. The new centre is closely linked with the modern transport hub for passengers by train, bus and taxi, and readily accessible too by cyclists and pedestrians. Its TOD role will be further reinforced by the track widening along part of the railway link between Utrecht and 's-Hertogenbosch. The new town has already started to retrofit its oldest residential neighbourhoods in order to make 8,000 houses more energy self-sufficient and healthier.

Nieuwegein is situated next to Houten, but actually its opposite with an urban layout mainly planned around car use. But like Houten, the municipality of Nieuwegein would like to become much more of a cycling town. The most notable project is its renovated town.centre, This is made up of the town hall, theatre, library, housing and retail outlets. The energy supply for heating and cooling the town centre is largely provided by heat pumps, together with underground thermal storage. Sustainability, climate programmes and ambitions are well integrated in the Spatial Policy Strategy 2030 of Nieuwegein. Its plans show the main pipeline routes of the district heating network with a connection to neighbouring Utrecht, and the areas around the stops and corridors of public transport that are to receive more intensive housing. Between Nieuwegein and the A27 motorway, there is to be a sustainable industrial district and a 13 MW windfarm, providing a quarter of the provincial target.

Sustainability is not specifically mentioned in either the Strategic Plan 2025 or the Spatial Policy Strategy 2025 of the Veenendaal municipality, although the documents do include the usual spatial planning goals and aspirations. The Veenendaal urban development 'Buurtstede' with 1,250 homes, the first part of a larger development of 3,200 homes in Veenendaal East, is being built with a sustainable energy system which

makes use of a combined heat and power plant, underground thermal storage at a depth of 85 metres and heat pumps. The heating or cooling is distributed to and from the homes via the pipes of the distribution system. The energy system also provides the necessary heat for warm tap water, together with the heating to five exiting apartment blocks nearby. One innovative element is that the Veenendaal municipality, two local housing associations and two project developers have joined forces to establish a local energy company that runs the energy system.

Zeist houses the office of the World Wide Fund for Nature (WWF) of the Netherlands. This renovated laboratory and office building dates from 1954 and in 2006 was converted to the first building in Europe that supposedly emits no CO_2. In the recently produced Spatial Policy Strategy 2020 of Zeist, sustainability is one of the principal themes, but it lacks any relation with climate programmes and ambitions. The main aims of the municipality are the sustainable redevelopment of the surroundings of the Driebergen-Zeist public transport hub and the sustainable and energy efficient redevelopment of Kerckebosch, one of the older residential neighbourhoods with 1.250 houses.

9 THE A-12 ZONE CONNECTING UTRECHT, HOUTEN AND NIEUWEGEIN

An overview and discussion of the most promising projects and activities in the field of sustainable spatial development and design across all the individual municipalities shows that these projects and activities surpass the administrative borders of the municipalities. The overview shows that a large proportion of these projects and activities is closely related to the central location and the national motorway, railway and waterway hub. To be able to accommodate the constantly growing demand for mobility in the Netherlands and the Province of Utrecht, central government, the Province of Utrecht and the six major towns of Utrecht are investing in various forms of infrastructure to meet future needs. This involves building the A2 and A12 motorways underground, so that the now divided urban areas are better connected, as well as expanding the light railway between Utrecht, Nieuwegein, Leidsche Rijn and the Uithof, the university campus, and improving the areas around the stations in Amersfoort, Utrecht, Driebergen-Zeist, Houten and Veenendaal.

Within the foreseeable future the underground section of the A2 motorway (Eindhoven-Amsterdam) will provide a barrier-free connection between the existing city (Utrecht) and Leidsche Rijn situated to the west, the largest urban development area in the Netherlands with more than 30,000 homes and 80,000 inhabitants forecast for 2025. A more urban-style underpass is envisaged for the A12 motorway (Arnhem-The Hague) for 2025-2040. The zone on both sides of the A12 offers good opportunities to develop an essentially mono-functional, extensively used, urban fringe area into a multi-functional, dynamic commuter area at the centre of a continuous metropolitan region. An area which is no longer only easily accessible by car, but also by tram and bike. The zone makes a substantial contribution to the economic strength of the region in the centre of the country and its positioning as a culture and knowledge-based region. The area lends itself well to the planned demands of the future. It is expected that in 2040 people will want to live and work in mixed urban areas, with spaces to meet and with multimodal accessibility. Some 2,500 to 7,500 additional jobs will be created, and there will also be room for 10,000 to 20,000 homes and a number of regional facilities.

There are four guiding principles underlying the development of the A12 Zone which is intended to link the municipalities of Utrecht, Nieuwegein and Houten. These are: Utrecht-like urbanity, meeting, sustainability and green/blue. Utrecht-like urban living represents the link with the essence of Utrecht, the qualities on which the success of the Utrecht region is based. Key concepts here include high density, mixed use, green corridors, the human dimension and meeting spaces. Meeting stands for the new way of working in the heart of the Netherlands. At the intersection of the A12 and the A2 between the urban centres in the region, in a compact and mixed urban area with tram, car and bike on the doorstep, a bakery in the neighbourhood and a pavement cafe around the corner. Sustainability is first and foremost about a more intensive and multifunctional use of existing locations, the choice of the location, the spatial planning and design of the zone, the economic basis as well as how the residents and visitors to the area act. The area will be designed such that users are continually invited to act in ways which are as sustainable as possible. Key concepts here are tram use, bike, CO_2 neutral, energy generation and climate resilience. As with sustainable economic growth, there is a new way of working and economic activity in low environmental categories. Green/blue refers to the specific features which make the region so attractive, such as the residential area and maximum use of the natural features already present in the A12 zone, the linking themes being the special elements of the Hollandse Waterlinie and the strength of the water corridors running through the area that were once

Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

flooded as defences. By connecting the Green Heart of the country with the greatly valued landscape features in a way which is environmentally-friendly, the green/blue concept can bring added impetus to the region.

10 CONCLUSION

The Utrecht region has made considerable steps in planning low carbon, sustainable and liveable cities. The Province of Utrecht and the six larger towns and cities in the Utrecht region are doing their very best in translating very tough climate and energy ambitions into special policies and a low carbon and sustainable build environment. The Province of Utrecht has wisely transformed climate issues into economic challenges and spatial policies. The cities of Amersfoort, Houten, Nieuwegein, Veenendaal, Utrecht and Zeist are doing the same, with smaller budgets and mixed success. The effort needed to meet the proposed reductions are greatly underestimated. Becoming a CO_2 neutral municipality by 2030, for instance, means an average reduction of 5 % CO_2 every year. The Energy Report of the WWF demonstrates that this can be done and that by 2050 almost all the energy we need (95 %) can come from renewable sources. The report shows that such a transition is not only possible, but also cost effective, providing energy that is affordable for all and producing it in ways that can be sustained by the global economy and the planet.

Climate and energy ambitions have spatial impacts and consequences. In order to actually fulfil these ambitions, we need to plan and built our cities in a more compact way and more based on public transport and high speed trains than on cars. It is generally accepted that we require almost a complete retrofit of the build environment, a transformation of the energy infrastructure, carpeting roofs with solar cells, harvesting geothermal energy and building wind farms in almost every possible location. And planning low carbon, sustainable and liveable cities requires a transformation of the planning profession.

1 ABSTRACT

The future challenges for urban planning and urban governance are often far more observable within the context and complexity of urban agglomerations in countries of the Global South like Vietnam. Here urban development is dynamically changing both urban form and function. More attention therefore should be placed on documenting, mapping and comparing the spatial distribution of urban structures and population over time. This however would require conceptual and methodological clarity to go beyond simplistic assumptions and to arrive at spatial planning recommendations, which effectively direct urban growth and redevelopment priorities and patterns. Rapid urbanisation is a manifestation of the ongoing modernisation process in Asia accompanied by rapid economic and social development. The environmental dilemma, as the major risk component of urbanisation, stresses the negative side-effects of urban-environmental processes. Urbanisation and environmental change is seen to shape the basic prerequisites for urban resilience to climate related hazards. In one sense, the local urban environmental risks themselves can be seen to reflect the challenges of such changes through global climate change and its impacts on population.

2 URBAN GROWTH MONITORING - CASE STUDY HO CHI MINH CITY, VIETNAM

Coastal Asia is facing an urban century in which not only the growth of population in their cities will ultimately determine their resilience and sustainability, but also their patterns of development. The empirical interrelationship between rapid urbanisation processes in coastal Asia and the associated increases of risk to weather and climate-related disaster hazards cannot be fully explained solely in terms of changes in population. Much more important however, is the consideration of the spatial distribution of people and economic assets in risk-prone areas, primarily as a result of rapid urbanisation. Here the sensitivity of both the exposed population and assets—can be used as an indicator for the ability to cope with and reduce risk. There can be little doubt, that a dominant factor contributing to increased vulnerability is urbanisation itself. How this dynamic pattern of urban development assists or hinders risk adapted planning and management is the critical issue that will be highlighted in our indicator-based assessment.

The southern Vietnamese city of Ho Chi Minh City (HCMC) is a rapidly emerging megacity and represents one of the most dynamic examples of urban development over the last few decades. The city is precariously located on the banks of the Saigon River, 60 kilometres from the South China Sea and northeast of the Mekong Delta, in an estuarine area of Dong Nai River system. In a short space of time, the city has grown into Vietnam's largest and most populous settlement, becoming an important port city for Southeast Asia and beyond and contributing a dominant share to the national economy. The official population of the city as of 2009 was 7.2 million, spread over a total administrative area of 2095 square kilometres (STORCH& DOWNES 2011a).

Originally founded on relatively higher grounds, the city has densified through the infilling of open spaces or the redevelopment of existing buildings. However of greater concern is the rapid expansion into lower-lying and former wetland surroundings, primarily at the expense of urban greenscape and valuable multifunctional natural areas. The city is currently incised by a dense network of rivers and canals of around 8.000 kilometres in length, which account for 16 percent of the total area. These waterways are affected by a semi-diurnal tide. In coincident with annual rainfall peaks a significant percentage of the city's neighbourhoods regularly experience floods, due to a combination of tides, heavy monsoon rains and storm surge floods. The dimensions of this flooding are however constantly changing due to the ongoing rapid urbanisation (STORCH& DOWNES 2011b).

2.1 Urban development trends and problems in HCMC

The official population forecast estimates that HCMC will become a megacity and reach a population of 10 million by 2020. According to the official urban development strategy, HCMC will be developed in the future based on a multi-centre pattern along the northeast, south/southeast, north/northwest, southwest

directions. As a result, HCMC's planning administration has recently established so-called new urban areas as focal points for new satellite development, which will integrate fringe areas in the currently more rural outer city districts. The city's current radial development structure is still to some extent impractical, resulting in insufficient land available for public services and for open space.

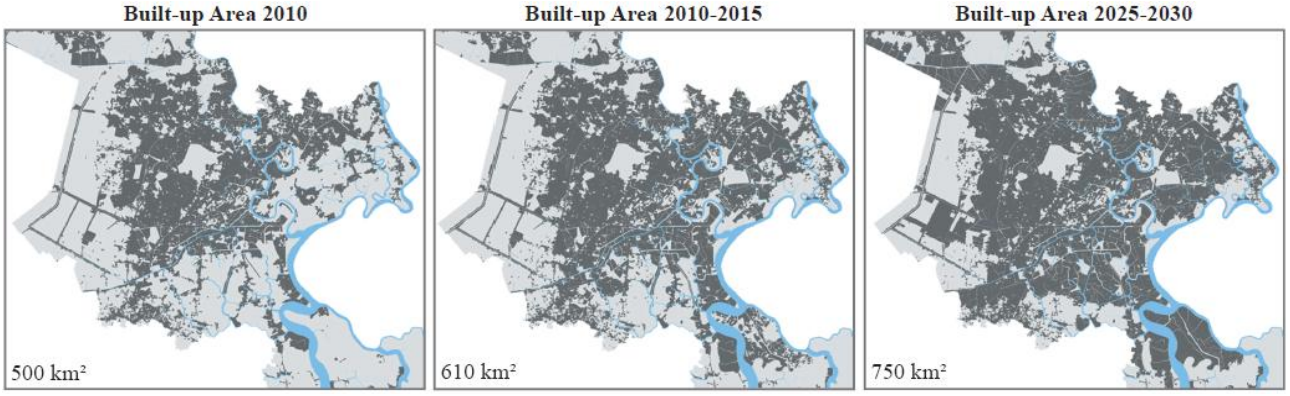

Fig. 1: HCMC's official urban development scenario up to 2025/30

Figure 1 illustrates the future urban growth process of HCMC based on the official land-use plans for the next planning period. The implementation of the land-use plans for the years 2010 up to 2025 will increase the total built-up area to 750 square kilometres (an increase of 50 percent). In order to accurately define the precise spatial extent of the current built-up area, the digitalised version of the official land-use map 2010 at a scale 1:25,000 provided the common spatial geometry based on which a 'current land-use' map for the year 2010 was compiled. Current land-use was determined from the visual interpretation of high resolution panchromatic satellite imagery; the classification was based on our urban structure type classification for the entire HCMC urban area (STORCH& DOWNES 2011b). A limitation of simple urban growth scenarios is that the simplified mapping of built-up areas over time fails to show real land-use densities, ignoring the structural changes and alterations of the current and future urban settlement typologies over time.

2.2 Urban structural indicators to analyse development patterns

Urbanisation is an extreme case of land-use change. For HCMC, rapid and dense urban expansion and inner-city redevelopment has primary direct impacts at the local scale in changing the visible urban structures and form and indirect secondary affects in for example alteration of the urban climate and increasing the need for indoor cooling or modifying the urban water-cycle. The following questions will be explored for climate-related impacts in the urban environment of HCMC (STORCH 2007):

- Where and how does urban development change the land-use pattern of the metropolitan area of HCMC, and to what extent does this affect climate change related impacts on the urban environment?
- Which urban structure typologies can be distinguished (DOWNES ET AL.2011), and what is the relation between their characteristics and the assessed level of resilience against climate-related impacts?
- How adequate are the existing land-use planning and urban-environmental management approaches to the relevant governance structures; to what extent do they contribute to an urban development that takes climate-related urban-structural indicators into account?
- Which hotspot areas can be identified for predominant climate-related impacts in HCMC, like inner-urban flooding caused by high-degrees of imperviousness, and affects to urban climate caused by high-dense building structures?

An important first step in the estimation of hotspot areas is to describe the observable indicators related to both urban form and structure (STORCH ET AL. 2011). The most dominant feature of the urbanisation process in HCMC is the rapid growth of the city itself and the surrounding urban agglomerations. Urban population growth due to birth surplus and in-migration has caused high land demands. In HCMC, urban growth and land consumption indicators are just about to be recognised in planning decisions, while a more regulating use of core urban indicators is still limited. Until recently the available information is often

inadequate or spatially not explicit enough for assisting urban policies like indicator-based planning regulations.

In general, the ratio between built-up and non-built land provides a good overall first impression of the spatial character of the city. Built-up areas typically include residential areas, industrial, and commercial areas. However, in emerging Asian megacities like HCMC, the monitoring of the building footprint alone is not sufficient. Therefore, in order to analyse urban land-use, urban density and spatial development trends over time typically a stepwise indicator approach is used. Here, an initial indicator framework is composed of core sets of indicators measuring different aspects of urban land-use and building density. The first step in assessing the existing urban structure and land-use efficiency is to evaluate changes of the urban form and housing structure and their relation to building densities and land utilisation efficiencies (GILL ET AL. 2008). The indicator framework leads from basic land-use indicators to building density measurements and finally to a combined analysis of population densities and land-use intensities. The most important efficiency indicator pattern is the ratio between built-up and non-built areas.

2.3 Urban Indicators describing the built-up structure of HCMC in 2005

The total area of HCMC is about 2095 square kilometres, divided into 24 administrative districts, hosting in the year 2004 an official population of 6.2 million. 5.2 million of which lived in the 17 urban districts occupying an area of 494 square kilometres and displaying an average population density of around 11,000 inhabitants per square kilometre. The inner-city urban areas are concentrating on an area of 140 square kilometres more than half of the population resulting in an average density of 26.000 inhabitants per square kilometre, with peak values in inner-city informal settlements with up to 80.000 inhabitants per sq km (GSO HCMC 2006).

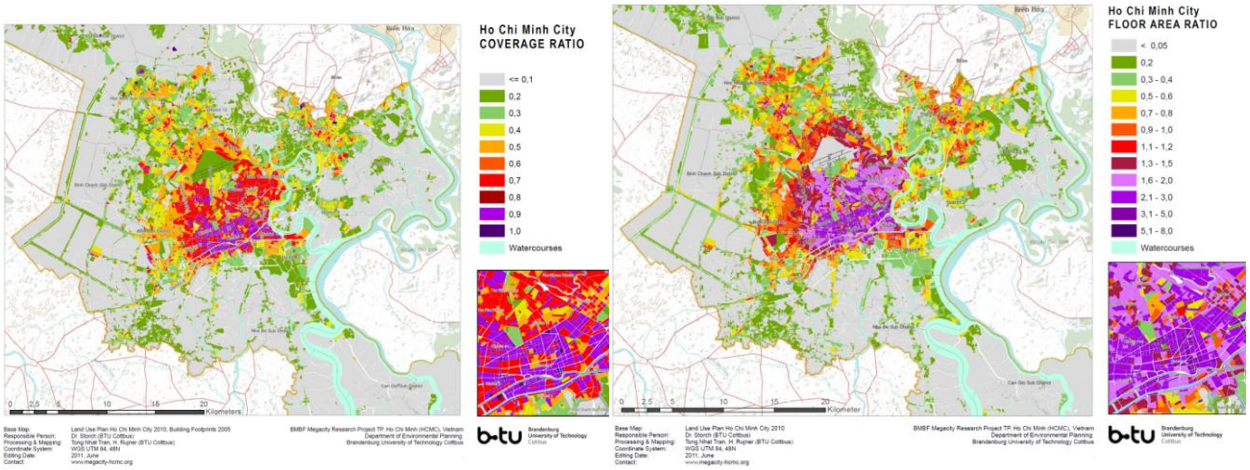

Fig. 2: Coverage ratio and floor area ratio in HCMC's urban core for the year 2005

The extremely high-dense inner city development, with built-up (coverage) ratios of more than 0.6 (i.e. 60% ground coverage) and floor area ratios equal or greater than 1.5 (Figure 2), is predominately realised by the infamous shophouse typology. This typology consists of a flat-roofed row house with a plot size of approximately 4 x 20 metres. The shophouse typologies are the dominant structure in HCMC, accounting for 95% of the seen residential urban structure types (Table 1). Furthermore, with typical building heights of between two and five floors (Table 2), very high density levels are achieved, while the remaining open space is often only represented by the public street areas.

Residential category	No. of sub-division into urban structure types	No. of blocks	Surface Area (km²)	Percentage utilisation category	Percentage of total HCMC surface area
Residential (total):	25	6.717	446	100	21
Shophouse-based	12	6.346	425	95	20
Villa based	04	107	8	2	<1

2.4 Urban indicators describing the change of built-up structures of HCMC over time (2005-2010)

Our core indicator set (STORCH ET AL. 2007), measures the issues linked to the extent and growth of built-up areas and the efficiency of the land utilisation (floorspace), in relation to the common spatial unit of the

official land-use block. The following urban growth and (re)development oriented aspects are measured by comparison of the core-indicators themselves over time. This describes more specifically the growth rate at which built-up areas and floorspace have expanded and evolved over the time period of between 2005 to 2010.

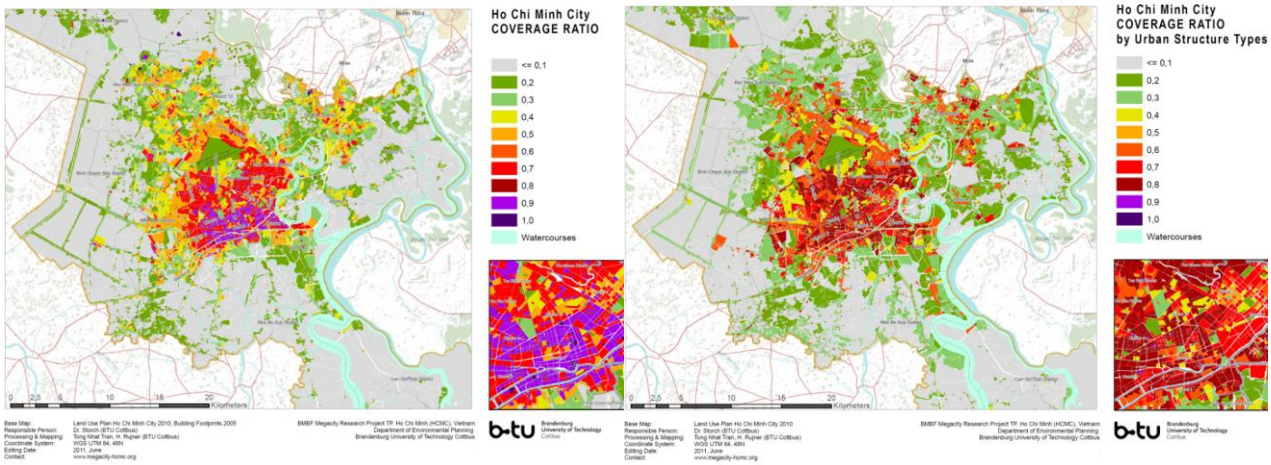

Fig. 3: Comparison of the indicator "coverage ratio" between the years 2005 and 2010 (Note: the map for the year 2005 (left), is based on building footprint data, while the map for year 2010 (right), is based on urban structure type mapping)

Figure 3, illustrates the urban development for the period 2005 to 2010 for built-up areas based on the indicator ground coverage ratio. Seen are the ongoing sprawl developments taking place along the main transportation routes on agricultural land, counteracting the official development according to the satellite urban model. Recent and current residential areas are dispersing towards eastern (District 2, 9 & Thu Duc), southern (District 7, Nha Be) and western directions (District Tan Phu, Binh Tan, Binh Chanh).

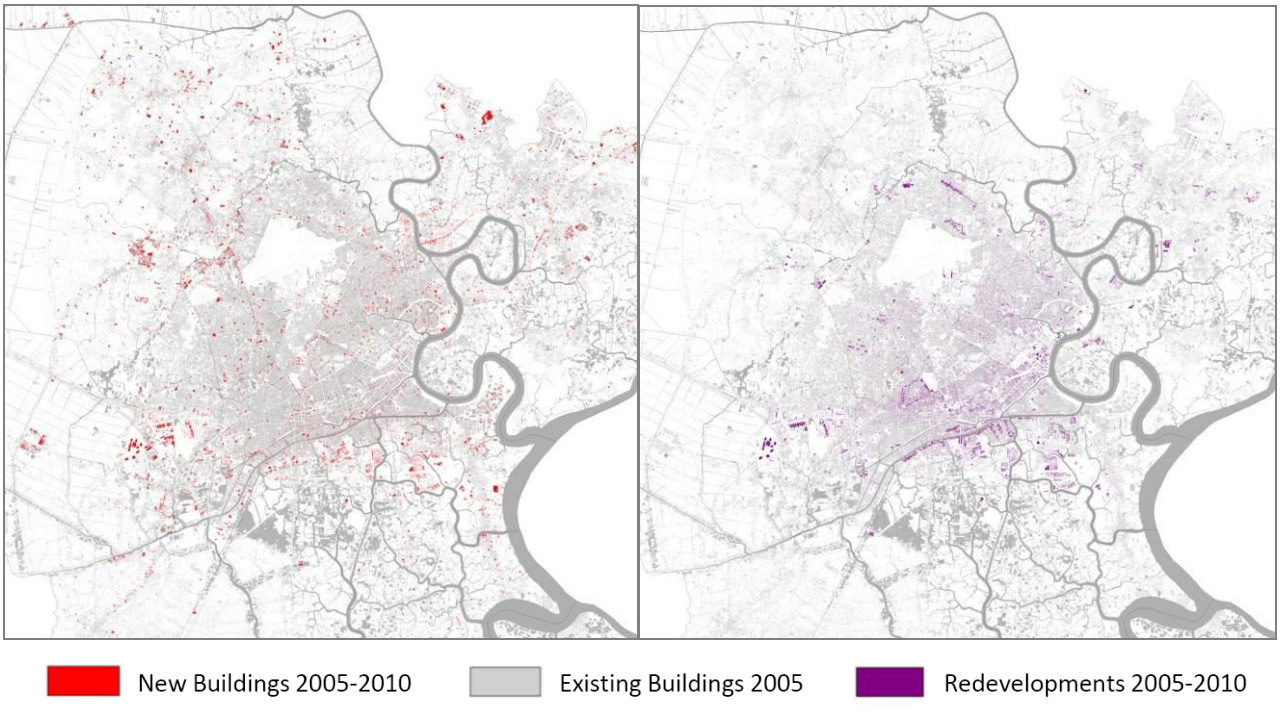

Fig. 4: New developments (left) and redevelopment Activities (right) between the years 2005 and 2010 (The Analyse is based on the detailed mapping of building typologies, shown in Table 3, at a scale 1:5000 in 2005 and 2010)

Interesting to note is that even within the existing urban core (District 6, Binh Thanh) (re)development activities are high. Caution should be exercised however as an overdevelopment in the existing urban core will result in an overload to the limited basic urban services and infrastructure. For a sustainable development scenario, it is important to understand and not lose track of the future urbanisation challenges and the requirements for the provision of basic urban services and technical urban infrastructure preparation. Besides sprawling new urban developments, the ongoing continuous compacting and densification,

horizontally as well as vertically, of the existing settlement structures is a visible trend in HCMCs recent development pattern.

Figure 4 illustrates that new developments and redevelopment activities—mapped on the level of building types (Table 3) —between 2005 and 2010 that lie within the current urban core. Visible are the concentrated new developments seen focused in new urban areas in the outer districts. However also visible and rather surprising, is the great number of construction activities on single construction sites at the building level in the inner city core. This activity is seen to counteract the official development strategy.

Building Type		Coverage (ha)	Floorspac (ha)	Height (flrs)	Coverage (ha)	Floorspace (ha)	Height (flrs)	Coverage (%)	Floorspac (%)	Height (%)
		2005			2010			Change 2005- 2010		
Apartment		113	569	5,0	166	890	5,3	48	57	6
High-rise		19	120	6,4	28	223	7,9	51	86	23
Detached		2149	2824	1,3	2872	5893	2,1	34	109	56
Semi detached		317	334	1,1	458	724	1,6	45	117	50
Temporarily-built and others		37	41	1,1	17	21	1,2	-54	-50	8
Terraced		3496	7001	2,0	7154	18001	2,5	105	157	26
Villas		893	1504	1,7	897	1777	2,0	0	18	18
Wood-framed, thatch- roofed		54	56	1,0	52	53	1,0	-5	-6	-1
Markets		8	29	3,5	17	66	3,8	108	126	9
Hotels		39	160	4,1	45	226	5,0	16	41	22
Office building		113	593	5,3	131	777	5,9	16	31	13

Table 3: Urban structural changes in HCMC from 2005-2010—Core indicators for dominant building types.

Table 3, additionally underlines with the comparison of urban structural indicators (ground coverage and floorspace) the ongoing densification trend between 2005 and 2010. Except for the more informal building types, all building types have significantly increased in both built-up (coverage) and in floorspace density. Particularly the dominant shophouse-related building types show a doubling of their total ground coverage and—due to an increase in their average heights – the floorspace for this type can be seen to have increased by more than 150% in only 5 short years.

3 CONCLUSION

Planning for risk and uncertainty for future urban growth will not just be a challenge for high-flood prone areas; it will be a broader challenge impacting on the very nature and location of future urban developments, particularly when planning for climate change. There is a strong correlation between urban vulnerability and physical exposure. Here land-use planning that takes into account disaster risks can be seen as the single

most important adaptation measure for minimising future disaster losses. The spatial planning frameworks and subsequent urban planning decisions, as currently applied, do not attach sufficient importance to both the physical exposure and the actual rate of urban growth. Urban growth does not increase exposure of population to risks per-se. In general, urban governments are responsible for regulating either building or development in a way that reduces risks. For high-dense Asian megacities, the complexity of risk and vulnerability requires high resolution spatial information systems, in order to identify hazard patterns, vulnerability and risk at a scale that can provide information for urban land-use and development planning. Urbanisation does not necessarily have to lead to an increasing hazard portfolio and can, if managed properly, contribute to reduce risk. Yet, there are a number of key characteristics of the urbanisation process that do directly contribute to the configuration of risk. Spatial and physical exposure alone does not explain nor directly lead to increased urban risk. If urban growth in risk-prone locations is redirected by adapted land-use zoning and guided by adequate building standards, resulting risk patterns can be effectively managed and reduced. It is the very 'spatial dimension', the form and structure of urban settlements that concerns urban and regional planning.

4 ACKNOWLEDGMENTS

The contribution is based on results of the research project ''Integrative Urban and Environmental Planning for Adaptation of Ho Chi Minh City to Climate Change'' which is funded as part of the research programme ''Sustainable Development of the Megacities of Tomorrow'' by the German Federal Ministry of Education and Research (BMBF). The authors would like to express their gratitude to Thong Nhat Tran and Hendrik Rujner who partly supported the geoprocessing and Kiduk Moon who assisted with the illustration of urban typologies.

The Way to Plan a Sustainable "Deep City": From Economic and Strategic Aspects

Huanqing Li

(Huanqing Li, PhD student, Swiss Federal Institute of Technology Lausanne, Switzerland, huanqing.li@epfl.ch)

1 ABSTRACT

Facing the challenges of population growth, energy crisis, land pressure and environmental deterioration, modern urbanization is calling for governance innovation to facilitate flexible spatial transformations and to promote creative city redevelopment. Developing Urban subsurface as a sustainable option for renewing congested urban centers and for updating public infrastructures, should be economically viable and institutionally feasible.

Optimization of urban underground space use has to take into account social-economic demand and supply capacity of geo-space resources. A framework research is put forward, with a functional classification of subsurface project typology, as well as a zoning system of subsurface integrated quality, which includes engineering constructability and development value. Based on the macro-zoning of urban underground space (UUS) at a city scale, an economic model is developed to perform micro-analysis for specific project evaluation. The economic analysis will take into account direct and indirect costs generated along the project life cycle, business benefits and social benefits for the whole community, opportunities for synergetic resources exploitation (e.g. geothermal energy use), and risks induced by sectorial development pattern (e.g. groundwater damage). These main criteria of cost, benefit, opportunity and risk are useful for decision-makers to plan urban subsurface projects in a sustainable way. At the end, a multi-criteria decision-making process will be demonstrated, in order to guide strategic development and policy making.

2 INTRODUCTION AND PURPOSE

2.1 Urban problems and integrated solutions

Cities are economic growth centers hosting nearly 50% of world population and having the capacity to provide best services for high quality of life. These centers, in forms of different scale of metropolitans, are getting more and more congested with expanding occupation of production, service, living space, public infrastructures and decreasing greenery amenities. While the era is going from industrial style to post-industrial trend, the quality of urbanism is playing an important role in city development and governance. While maintaining the basic service of infrastructures, investing on urban quality is becoming an essential concept among city governors. Big cities facing population immigration have to provide more living space and related services, making urban land and other resources more and more valuable and scarce. In order to enable a city to survive and to sustain economic growth, a rational management pattern of land and other resources should be on urban development planning agenda. Urban sprawl is a signal to constrain a sustainable growth, causing higher infrastructure investment to maintain the sprawling area function (larger transport and utility networks), as well as higher energy consumption for low-density living (enhanced use of cars). Obviously, cities are facing "limits to growth" and calling for innovative development strategies and sustainable renewal.

Urban growth is facing two problems: 1) shortage of resources, due to unsuitable exploitation process; 2) lack of value chain to create growth, due to inappropriate policy making or insufficient capacity building. Therefore, ways to support urban growth could be resources-oriented or institution-oriented. *Resources-oriented management* focus on protection and optimal exploitation of basic resources (land, water, energy, material), establishing a self-sufficient society and value-protected environment. Resources-oriented management is a development pattern giving priority to respect "supply limit of resources". On the other side, *Institution-oriented management* focus on value creation and revenue generation by enabling project opportunities, facilitating participation of all interest groups and implementation of constructive action plans. Institution-oriented management is another development method which gives the importance to "satisfaction of people's demand". Since the concept of "sustainable development" goes beyond the simple environmental protection or the sectorial economic growth, our urban governance in the new era has to combine resources-oriented management with institution-oriented management. This integrated approach meets the need of sustainable urban growth.

2.2 New urban forms with "undergroundisation"

2.2.1 Underground infrastructures

Along with the rapid development of metro systems in big cities, urban underground space (UUS) has been exploited as part of urban land resources, providing protective space for infrastructures such as road tunnels, water system, sewage system, energy supply network and cable network. With technological advancement on renewable energy utilization, deep geothermal system will begin to emerge in urban area (Figure 1).

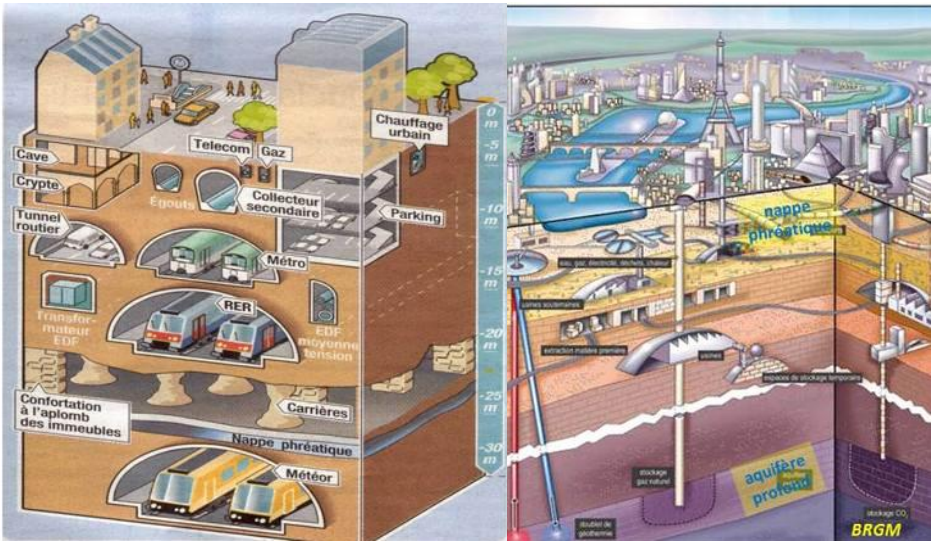

Figure 1 underground space functions illustration for the city of Paris, France (Duffaut 2010)

"Undergroundisation" trend of urban infrastructures is driven by various surface development forces:

- *Land use pressure:* the unbalanced allocation of construction land and facility land forces more and more facilities to be placed underground, since they are often large scale facilities, being underground can release more freedom over ground (Don V 1996; Tajima 2003). The "undergroundisation" volume is highly related to the urban population density causing increasing demand for land, as show in Figure 2.

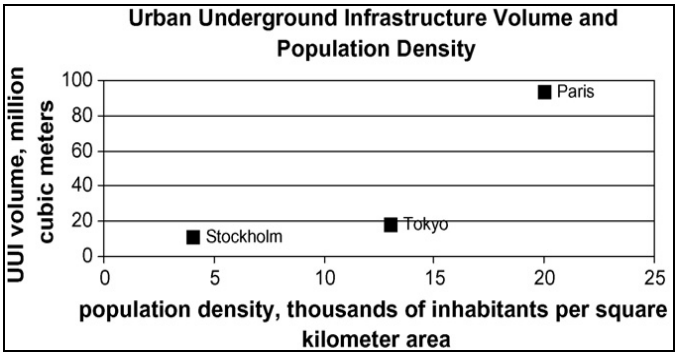

Figure 2 Relationship between population densities in urban areas and volumes of Urban Underground Infrastructures (UUI) (Bobylev 2009)

- *Increasing land prices:* real estate property development is creating huge cash flow in cities and making less and less land available for public use. Moving public facilities underground helps to reduce the land costs, sometimes even no land costs for deep facilities (Figure 3). The price factor has also contributed to the emergence of new legal system for deep space (50m depth) in Japan (Nishioka, Tannaka et al. 2007).

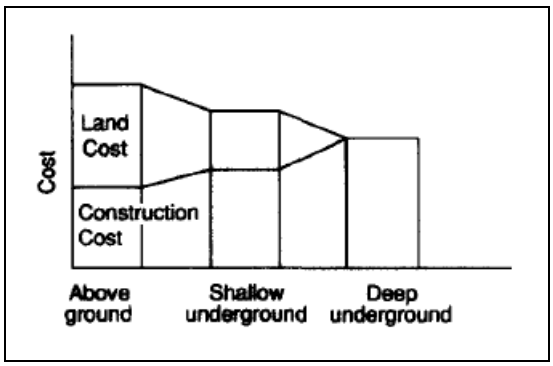

Figure 3 Comparative land and construction costs of above-ground, shallow underground and deep underground facility, Japan.(Tetsuya 1990)

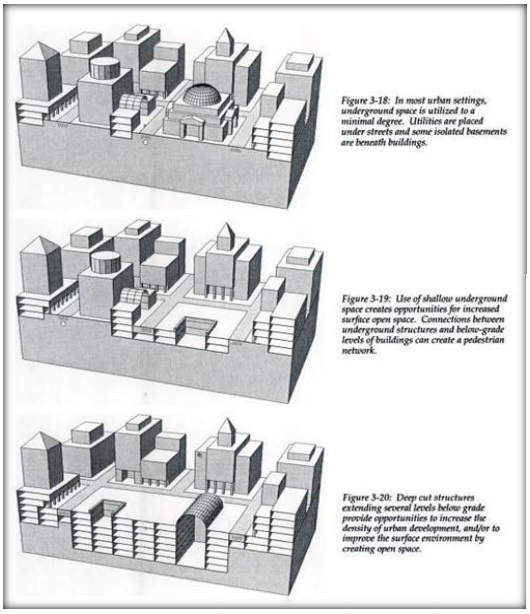
- *Environmental impacts:* due to high isolation capacity in the subsurface, belowground transport system causes less noise and less smoke than surface transport (bus, car) during its operation time, reducing pollutions in the city (Girnau and Blennemann 1990)

2.2.2 Underground buildings

Underground commercial centers become common in central business districts, for example, subterranean shopping centers in Japan have become its major business space (Japan Tunnelling, Takasaki et al. 2000). Montreal city's "indoor city" network connects subterranean commercial area with metro stations, its comfortable underground pedestrian network enable citizens to pass through the center freely during severe weather (Daniel J 1991; El-Geneidy, Kastelberger et al. 2011). Although the construction cost for construction subterranean space is higher than the surface building, it can offset a great part of surface land investment, creating more commercial and service space while saving land occupation costs. Revealed by several empirical researches, external benefits of these spaces could be considerable (Nishi, Tanaka et al. 2000; Lin and Lo 2008). Driven by increasing urban demand, "undergroundisation" process of buildings in business districts is illustrated by architects and planners (Figure 3).

Energy consumption of underground building during operation will be lower than surface building (heating and cooling consumption), due to better thermal isolation capacity (Monnikhof, Edelenbos et al. 1999; Maire 2011). This long-term benefit will encourage the future promoters to invest on underground building projects, for the reason of reducing considerable power expenses.



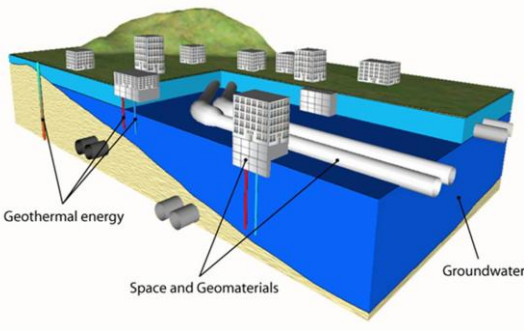


Figure 3 Underground space configurations in urban center (Carmody and Sterling 1993). Figure 4 "Deep City" model (Parriaux, Blunier et al. 2010

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

2.3 Subsurface development integrated with surface city growth

The aim of this research project is to put forward a new management methodology for urban underground space (UUS) development, taking into account its economic potential and its global benefits to urban quality. As subsurface is part of urban land resources, a new approach of "3D land use" is the primary idea of implementing 3D urban projects. "3D urbanism" concept is to couple resources-oriented management with institution-oriented management, integrating the supply scheme of resources with the demand scheme of human society.

Resources-oriented 3D urbanism is to give priority to underground resources protection (including land, water, energy and material Figure 4), by identifying future resources use potential and zoning to a "development reservation area". For example, reserved area for drinking water exploitation, reserved area for material mining, and reserved area for deep geothermal system. These legalized areas are out of construction authorization scheme.

Institution-oriented 3D urbanism is to focus on social demand of development projects, located outside "development reservation area". The aim is to find an optimal way to develop underground projects. By analyzing economic values and social values, decision indicators will be developed to lever the interests of different stakeholders in public sector and private sector. Through multi-criteria decision making process, project scenarios will be evaluated and assessed for their performances. Feedback from the decisions will give implications on policy making, in order to adapt the development demand.

3 CONCEPT AND METHODOLOGICAL DEMONSTRATION

3.1 Interdisciplinary basis

(a) Information gap:

Subsurface environment is known by geologists and civil engineers, whose knowledge and experience give supports to resources mining and underground construction. However, there is a gap between geological sciences with modern underground construction practices. Examples can be seen from tunneling accidents due to insufficient geological survey (Paul, Chow et al. 2002). Information and expertise regarding risk management are also critical factors to succeed larges underground projects such as subway construction (Degn Eskesen, Tengborg et al. 2004). "3D urbanism" requires a new representation of urban territory with a three-dimensional form, in order to visualize real potentials and clear development visions for deep urbanization.

(b) Capacity building:

Different from conventional urban planning, subsurface urbanization needs a profound understanding of deep environment and an integrated approach linked to surface development demand. In another word, capacity of urban planning is supposed to extend to a "3D urban planning" level, by engaging the competences of environmental management, economic planning, and infrastructure construction bodies. The action plan of surface-subsurface codevelopment can be materialized into existing Master Planning practice by introducing strategic procedures (Bobylev 2009).

(c) Urban land market restructuring:

The value of underground in cities has not yet been incorporated into the existing land market system, for the reason that the quality of these exploitable deep spaces is unknown among city governors and land owners. Their future value for complementary land development can not be forecasted without holistic research of resources' supply capacity (relatively static) and urbanization's demand context (variable along time).

(d) Business scenario analysis:

Existing best practices for underground space development can be collected to form an urban case catalogue, to show success factors and to give future improvements. Urban underground projects can be divided into typologies as: typology by depth (shallow independent use project; deep public use project) and typology by aim ("exclusive type", e.g. metro, utility; "density type", e.g. multi-use building; "revital type", e.g. building under parks). Business cases could be simulated and analyzed, using performance evaluation.

(e) Policy-making:

Urban policy aims to facilitate good development practices. Understanding interactions between public sector and private sector help to reformulate positive instruments and to improve the existing governance mechanism. Underground urbanism should be initiated through public sector by introducing instruments promoting development synergies; independent underground projects could grow from the policy framework by applying sustainable investment scenarios (e.g. densification or revitalization).In addition, these interactions enable the policy-makers to go around the management improvement loop (Table 1), making demand dynamics incorporate into the contextual big picture.

3.2 Process-oriented management system

Current development of underground space in cities is facing coordination dilemmas: on one side, public infrastructures are growing fast and going deep, congestions and disorder hinder future development (Sterling 2005); on the other side, private developers play a major role in property development but lack of cognition of subsurface potential and comprehensive decision-making. The process proposed below (Table 1) is an ideal facilitating procedure to frame a comprehensive decision platform, linking public and private sectors into new subsurface urbanism plans. It is also an "undergroundisation value chain" to reorganize multi-disciplinary functions for creating economic growth, meeting urban demand while optimizing the use of underground space in the city.

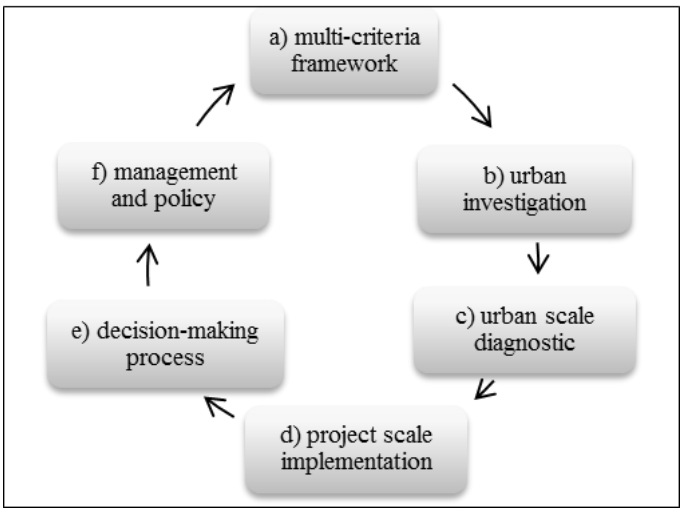

Table 1 Analysis improvement loop of research steps

3.3 New management methodology for subsurface urbanism

3.3.1 Macro-criteria system for land valuation (at urban scale)

Urban projects are developed based on economic attraction and social demand. For real estate projects, locating on high price land indicates higher property price for commercialization, if construction prices remain the same. However, if we take into account the economic potential of urban underground space (UUS), the existing land value distribution will be different. Underground land quality determines construction costs, meaning that, a parcel of high price land can have lower value for "undergroundisation", due to bad quality for excavation engineering. For abandoned industrial land with low land price, it can be exploited by developers for its good soil quality, who built underground parkings or subterranean logistic centers with creation of a green park above, bring revenues for the land owner and good renewal environment for the community. Two macro-indexes (supply and demand) will be integrated through multi-criteria evaluation to map the different levels of urban land parcels (Table2). Detailed procedure with a considerable number of parametrs can be found in another paper of the author (Li, Parriaux et al. 2011).

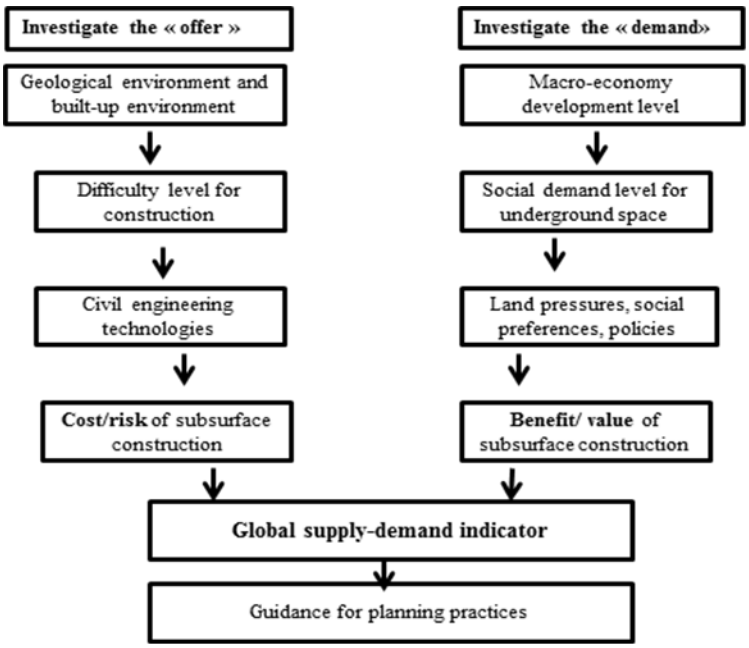

Table 2 Multi-criteria (macro-index) framework for UUS potential evaluation

This macro-zoning system is to classify the urban land into development levels: high potential, moderate potential and low potential. *High potential area* can be short-term development target, using underground to create more urban growth; *moderate potential area* can be reserved for long-term exploitation land resource; *low potential area* is prohibited zone due to sensitive condition or highly protected resource reservation (e.g. water, mine). With future demand dynamics, distribution and mapping of these zones can vary and can be re-affected.

Results of case study: central city of Suzhou, Yangtze region, China (Figure 5, blue color for high potential area)

The structure of macro-zoning favors rational selection of priority development zone to be investment target. As different land use type has different underground use value, commercial land and mixed use land having higher development potential for "undergroundisation". The tradable land parcels on the market can be restructured according to their land price and their exploitable underground potential, a coefficient can be created to lever the integrated value variation (explained in session 2.3.2).

This land value restructuring helps to incorporate the economic potential of using underground space into market land price, and gives implication to the land owners about how to develop an underground property project in a rational way.

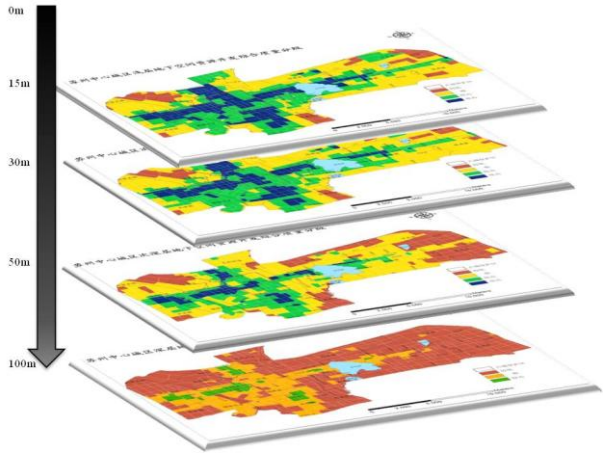

Figure 5 macro-zoning of UUS, layered approach (Deep City project in China (Li, Parriaux et al. 2011))

Analysis of case study: Forecasting exploitation of urban underground space (UUS) along with urban growth

Evaluation of central city area covers 280km2, including a famous historic town, a CBD and a new development district. Current state of deep development reaches 15m below the surface, and short-term growth of its UUS is supposed to extend to the depth of 30m below ground level. With contribution of *underground densification*, city can afford more future construction space without causing urban sprawl.

Status of 3D land use supply: for the 30m deep urban land, total effective constructible floor space is about 413km2, designing sub-floor height of 4m for better architectural effect (Ernst von Meijenfeldt 2003). (Table 3)

integrated supply-demand indicator	0-15m	use coefficient	15-30m	use coefficient	total volume by level	useful ratio by level
very high potential area	3.11	0.6	2.50	0.4	5.61	8.03%
high potential area	3.54	0.4	2.78	0.2	6.32	9.04%
moderate potential area	2.30	0.2	1.89	0.1	4.19	6.00%
low potential area	0.24	0.1	0.15	0.05	0.39	0.55%
useful volume_100mio m3	9.20		7.31			
total volume_100mio m3	27.95		41.92		69.87	
useful ratio by depth layer	32.90%		17.43%		50.33%	
equivalent floor area_km2	230.00		183.75		413.75	*(if floor height = 4m)*

Table 3 forecasting the exploitable UUS supply in short-term, development to 30m below

Variation of 3D land use demand: densification helps to rebuild a compact city (Jenks, Burton et al. 1996), a density index (floor area ratio [1]) can represent this urban trend. Step-forward "undergroundisation [2]" helps to alleviate land use pressure by high-density development. Under proximate simulation, by attaining density level of 6, a 47% "undergroundisation" share needs to place nearly 400km2 construction spaces below surface(Table 4).Compared to the supply quantity of 413km2, this demand can be met.

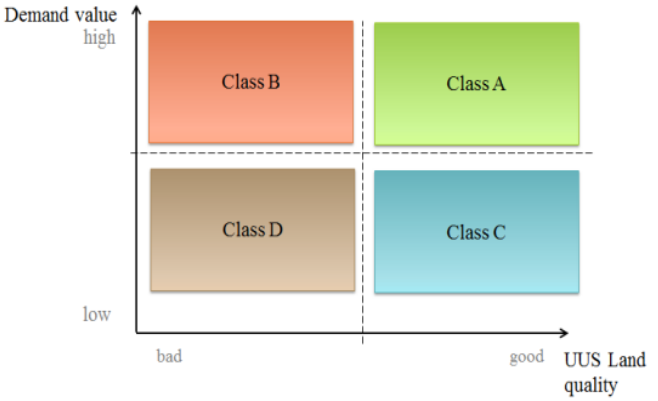
Floor Area Ratio	1.00	2.00	3.00	4.00	5.00	6.00
total urban area (km2)	279.50	279.50	279.50	279.50	279.50	279.50
construction land use (50%)	139.75	139.75	139.75	139.75	139.75	139.75
floor space demand (km2)	139.75	279.50	419.25	559.00	698.75	838.50
"undergroundisation" rate	0.02	0.10	0.20	0.29	0.38	0.47
underground floor space (km2)	2.80	27.95	83.85	160.25	263.20	391.30

Table 4 forecasting the UUS demand in short-term, density development for a compact city

3.3.2 Micro-analysis with business scenarios (at project scale)

The careful diagnostic at urban scale leads to identify high potential area for priority development planning of underground space. Further economic analysis can be performed based on land valuation and project assessment:

Step 1 Land valuation:



Class	A	B	C	D
Land price	10'000	10'000	5'000	5'000
UUS quality included value	+(10%) 11'000	-(10%) 9'000	+(10%) 5'500	-(10%) 4'500

Figure 6 integrated land valuation approach

[1] Floor area ratio = floor space area / land area.
[2] "Undergroundisation" rate = total underground floor space/total urban construction floor space.

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

For high potential area in general, their land parcels to be developed can have different interpretation of real value. The hidden value of developing subsurface can be incorporated into existing land price (here is about commercial land or mixed use land), with a coefficient/premium to reveal the differences of integrated value. Low "UUS land quality" indicates higher construction costs for underground space, decisions on land acquisition can combine UUS quality indicator with business potential of the location, developers can also adapt the real estate project plans to the land value class (Figure 5). With regulated building height, a deep commercial center in the CBD should be built on land class A rather than B, whose subsurface maybe congested, inducing compensation in utility relocation.

Step 2 Project scenarios:

Project type / Land class	Density type	Revital type
Class A	Scenario 1	Scenario 2
Class B	Scenario 3	Scenario 4
Class C	Scenario 5	Scenario 6
Class D	Scenario 7	Scenario 8

Table 5 Project scenario analysis scheme

The research scheme will only focus on underground building in urban area, as its project viability has not been well researched in academic world, although its value to renovate urban centers has been documented (Barles and Jardel 2005; Maire 2011). A sustainable city is an efficient compact city and a livable city. Development of underground buildings can bring density gains or revitalization benefits. Therefore, two project scenarios can be assessed: "density type": multi-use combined building; "revital type": underground building under open space (Table 5). A cross-analysis can be performed by coupling the project type with the land class, assessing advantages and disadvantages of each scenario and levering facilitating and constraining factors. Project performance indicators include cost, benefit, opportunity and risk.

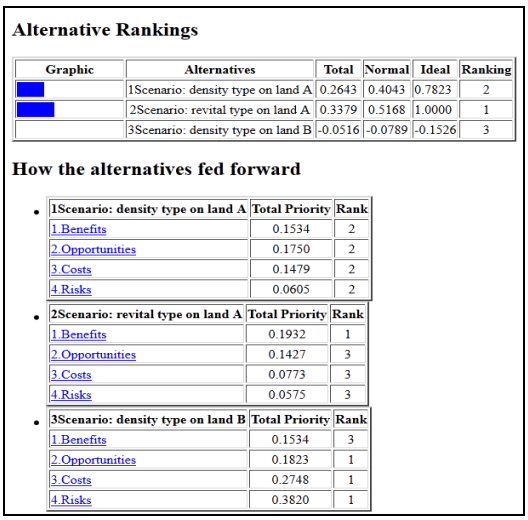
Step 3 Performance assessments:

Example is showed below to lever project viability of scenario 1, 2 and 3: (Table 6, Figure 7)

This decision-maker (environment authority) considers Scenario 2 (a revitalization type built on land class A) as the best alternative, because of a need to renew urban environment (benefit) and to protect groundwater quality (risk). Decisions of all the other stakeholders can be assessed, in order to reveal the challenges and synergies, guiding new development strategies.

Performance indicator	Criteria
Cost	• Construction • Energy consumption • Compensation payment
Benefit	• Business revenue • Environment renewal • Social welfare
Opportunity	• Geothermal system • Material recycling
Risk	• Groundwater quality

Table 6 Criteria for performance assessment



Alternative Rankings

Graphic	Alternatives	Total	Normal	Ideal	Ranking
	1Scenario: density type on land A	0.2643	0.4043	0.7823	2
	2Scenario: revital type on land A	0.3379	0.5168	1.0000	1
	3Scenario: density type on land B	-0.0516	-0.0789	-0.1526	3

How the alternatives fed forward

1Scenario: density type on land A	Total Priority	Rank
1.Benefits	0.1534	2
2.Opportunities	0.1750	2
3.Costs	0.1479	2
4.Risks	0.0605	2

4.Risks	0.3820	1

Figure 7 Part of the full report (by Super Decisions)

4 CONCLUSION

Rethinking the urban growth innovation by introducing sustainable concepts is current policy trend (Programme 2009). During this renovation process, social capital and natural capital have to be well integrated. The research concept and methodology put forward in the project "Deep City" tried to demonstrate a freedom for urban growth and resources consumption. Through case studies and international discussions, this third-dimension freedom could serve the future society within a participative platform, for learning, collaborating, investigating, discovering, improving and contributing. The decision platform enables a smooth process of urban restructuring, upgrading, transforming, renewing and sustaining.

The "Open Cities" Approach: a Prospect for Improving the Quality of Life in Alexandria City, Egypt

Mai M.Abdo, Hany A.Ayad, Dina Taha

(Mai.M.Abdo, MSc Candidate, Department of Architecture, Faculty of Engineering, Alexandria University, Egypt, mai.m.abdo@gmail.com)
(Prof. Hany.A.Ayad, Department of Architecture, Faculty of Engineering, Alexandria University, Egypt, hany.m.ayad@gmail.com)
(Dr. Dina Taha, Department of Architecture, Faculty of Engineering, Alexandria University, ditaha@alexu.edu.eg)

1 ABSTRACT

On one level, sustainable urban development has been the focus attention of most of the planners for the past few years. It is a huge field of interest that needs not only being well studied, but also being implied to all cities all over the world. On the other level, the concept of "Open Cities" is a prospect within the planning domain, which aims at providing equal services and infrastructure to its citizens as well as making cities more attractive to foreign population, may they be migrants, visitors or investors. Hence, cities should be planned in a way to welcome a diversity of people and cultures.

This research is concerned with the introduction of sustainable urban development factors into cities to achieve the concept of "Open Cities". It aims at developing a plan that targets most of the problems facing cities, be it on the demographic, climatic, residential, commercial, social or political levels. It is believed that by combining the factors that affect "Open Cities" with the factors of Sustainable Urban Development, one could conclude the specific factors that should be tackled in order to achieve "Sustainable Open Cities".

The proposed concept and methodology of combining the factors of Sustainable Urban Development to those of "Open Cities" will be applied on the city of Alexandria as a case study. This will pinpoint and highlight the strengths and weaknesses of such an approach.

2 INTRODUCTION

"Open Cities" have become an international trend that could be applied to cities all over the world. An Open City is one that is open to new ideas and innovation; welcoming to a diversity of people and cultures. It is a city of equal opportunities for all, a city that is open for the combination of lifestyle, creativity, scale, population, cultural and commercial diversity that enables it to become a 'magnet' city alongside cities. "Open Cities" require an open approach by city planers.

Alexandria has a lot of characteristics that greatly help it to be compared with all the successful "Open Cities" all over the world. The challenge is that it is needed to find the right way to benefit from these characteristics and points of strength in the most efficient way in order to make Alexandria a successful open city and achieve its vision as a cosmopolitan city and an attractive place to live in.

The paper will focus on the research's case study of applying the methodology of combining the factors that affect both Sustainable Urban Development and those of "Open Cities" to be used in Alexandria urban development. It aims at exploring the "Open Cities" approach in achieving a sustainable urban development. It analyzes the spatial, socio-economic and administrative opportunities that could assist in the regaining of Alexandria cosmopolitan role in the 21st century. Finally, the paper suggests guidelines on how to incorporate the approach in the city planning and management processes in order to improve its quality of life.

3 METHODOLOGY:

Through the analysis of "Open Cities" factors and combining them to the factors of Sustainable Urban Development we will reach the factors that should be taken into consideration in planning the city of Alexandria to make it an Open City. Moreover, with analyzing the current state of the city planning and the challenges that face the city's sustainable development, we could suggest certain steps that could be applied on the city to make it open and improve the quality of life of the city's inhabitants.

4 OPEN CITY AND SUSTAINABLE URBAN DEVELOPMENT

Both "Open Cities" and Sustainable Urban Development are delimited by several factors that describe their physical and socioeconomic characteristics; by the analysis of these factors we will attempt to find/analyze

the relation between both types of factors, in order to use sustainable urban development to achieve the concept of "Open Cities".

4.1 "Open Cities" Factors:

The British Council and URBACT (2009) stated that Openness is a multidimensional and complex phenomenon which has to be measured by more than one factor and also by a large number of individual indicators which measure different aspects of openness. These indicators can be grouped thematically into nine key factors, where each factor represents one of various dimensions of the quality of life of all inhabitants with special attention paid to international populations who are important for the attractiveness and openness of the city. These factors are:

(1) Groups of international populations

(2) Governance and leadership

(3) Regulatory

(4) Economic

(5) Social and societal

(6) Cultural and amenity

(7) Internationalization

(8) Connectivity and accessibility

(9) Environmental factors.

4.2 Sustainable Urban Development Factors:

Sustainable Urban Development incorporates planning for transportation systems and land use to improve the structure of a town or city. Urban development includes urban renewal, which addresses issues like lack of investment in specific regions. Factors like land use, aesthetics, safety, unkempt buildings and transportation all affect how cities are planned.

In this respect, Colantonio (2007) stated that"as a framework or unifying set of principles to be applied across all towns and cities. The core components of sustainable communities present a vision which has gained the commitment of many stakeholders. However, turning the vision into reality raises key questions of delivery. The success of Sustainable Communities policies will depend on the effective interaction of spatial planning, transportation, the economy, the environment and a number of other policy interventions".

Based on Nyakaana (2010), Fallaw (2010), Kishiue et al (2005), Ottensmann (2003), one can summarize the factors affecting sustainable urban development into the following: I suggest that the main factors affecting Sustainable urban development are as follow:

1)Network and infrastructure, 2)Geographical, 3)Political and safety, 4)Residential and planning,

5)Demographic, 6)Economic, 7)Environmental, 8)Social Factors.

4.3 The relation between "Open Cities" and Sustainable Urban Development:

There are several relations between each factor of those of "Open Cities" and the suggested factors of the Sustainable Urban Development, by analyzing each of these factor's characteristics one could conclude the diagram of relations below:

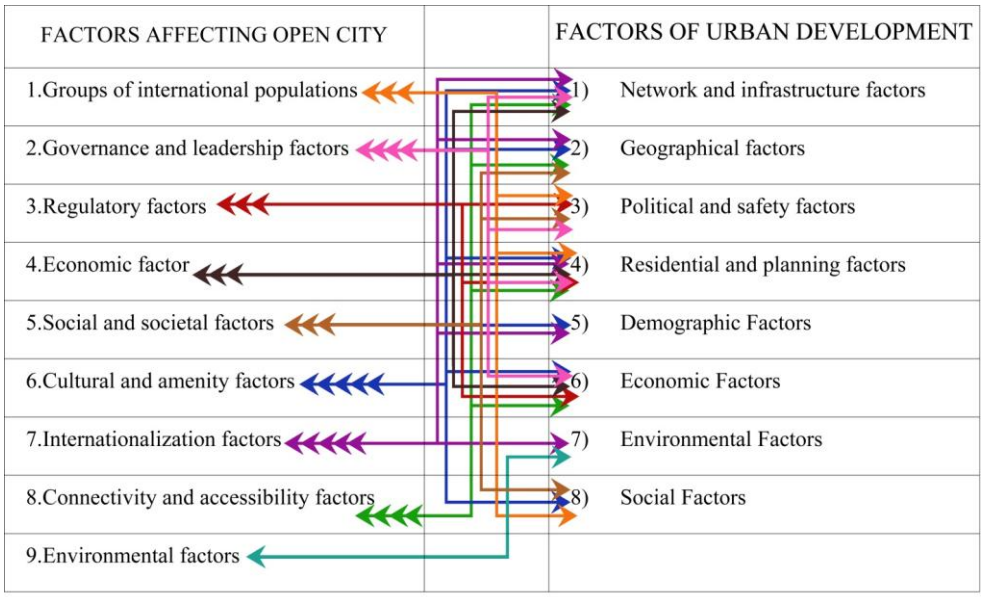

Figure.1: The relation between factors affecting "Open Cities" and factors of Sustainable Urban Development

The analysis reveals that these factors affect each other but in different weights. The factors of Sustainable Urban Development shown below are selected to be examined on the case study of Alexandria as the major effective factors on the city openness, as their effect is more than that of the other factors and also they are affected by the city openness too.

(1) Residential and planning factors

(2) Demographic and economic factors

(3) Social factors

(4) Network and infrastructure factors

(5) Environmental factors

(6) Political and safety factors

5 APPLICATION ON ALEXANDRIA

Alexandria, with a population of about 4.1 million, is the second-largest city in Egypt, and is the country's largest seaport, serving about 80 % of Egypt's imports and exports. Alexandria is also an important tourist resort (CAPMAS,2006). The city extends about 32 km along the coast of the Mediterranean Sea in north-central Egypt. It is home to the Bibliotheca Alexandrina, and is an important industrial center.

Figure.2: Shots of Alexandria Beach

5.1 Residential and planning factors

5.1.1 Housing indicators

The most populous districts (qism) of Alexandria, as indicated by the results of the 2006 census, are Montaza, El-Ameriyah and El-Rammil. However, Moharam-Bek, El-Manchiyat, Mena El-Bassal El-Labban and Karmooz are indicated as zones with high population density, as they constitute the old areas of the city. Residential densities of Alexandria all over its different districts are relatively high as presented in Table 1.

Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

Zone/District (Qism)	Population	Area (feddan[1])	Density (persons per feddan)	
			Gross Density	Residential Density
Bab Sharq	179,729	1,349.34	133.20	721.22
El-Ameriyah.	491,373	100,389.13	4.89	207.95
El-Attareen	343,836	6,934.52	49.58	321.64
El-Dekhiyla	40,605	441.88	91.89	308.55
El-Gomrook	85,192	840.87	101.31	623.66
El-Labban	36,750	264.80	138.78	348.34
El-Manchiyat	23,616	136.76	172.68	415.77
El-Rammil	752,371	7,510.47	100.18	538.18
Karmooz	120,062	850.63	141.14	774.59
Mena El-Bassal	254,986	2,465.56	103.42	704.97
Moharam-Bek	299,401	1,307.79	228.94	807.01
Montaza	1,173,803	20,833.33	56.34	523.67
Sidi Gabr	226,304	2,778.47	81.45	565.90

Table.1: Alexandria, Population, Area and Density, (CAPMAS, 2006)

The majority of households that belong to the upper income bracket reside Sidi Gabr, Montaza, Bab Sharq and El-Dekhiyla districts, while lower income families reside Karmooz, Mena El-Bassal and El-Gomrook districts, Table 2. Judging from the densities of those districts, one can confirm that there is a negative association between gross densities and income levels. In other words, areas with high gross densities are more likely to be the residence of low income families. This can have its implications on the quality of housing, the quality of the residential area, as well as on residents' satisfaction.

Zone/District (Qism)	Income	
	Upper	Lower
Bab Sharq	45.76	25.42
El-Ameriyah.	30.99	13.06
El-Attareen	22.03	37.29
El-Dekhiyla	45.45	27.27
El-Gomrook	15.46	35.05
El-Labban	4.69	32.81
El-Manchiyat	21.43	28.57
El-Rammil	20.89	11.97
Karmooz	1.52	63.64
Mena El-Bassal	3.15	40.16
Moharam-Bek	8.16	34.69
Montaza	46.19	7.42
Sidi Gabr	80.66	2.21

Table.2: Alexandria, Population stratified according to income, (%), NUO Survey, March 2008

5.1.2 Planning indicators

Alexandria is an urban governorate that includes the city Alexandria and the new industrial town, Borg El Arab. The City of Alexandria consists of six districts (Hai): Al-Montaza, East (Sharq), Central (Wassat), Gomrok (Customs), West (Gharb) and Ameriyah. The city can be divided into four major zones:

From the western side of the city that extends from Borg el Arab to downtown, Shallaat (Waterfalls) Gardens then to Montaza, Mamoura and Abu-Qur (East). The built-up area of Alexandria is 73,800 feddan (309,960 sq km). Residential use is the most dominant land use occupying almost 46 % of the total built-up area. Regional roads and railways comes in second place, where almost 29 % of the built-up area is dedicated to

[1] 1 Feddan = 4200 m^2

transportation purposes to facilitate the flow of commodities into and out of Egypt through the port. Industrial uses comes third, with almost 19 %; other uses include military, services and open areas figure 3.

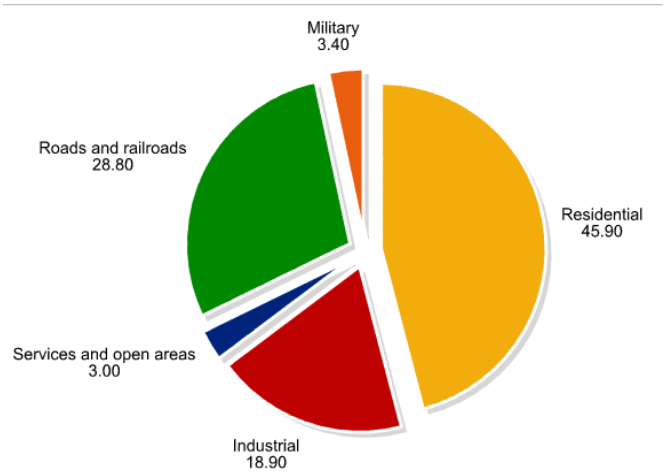

Figure.3: Alexandria, Land uses (%), (CAPMAS), 2006

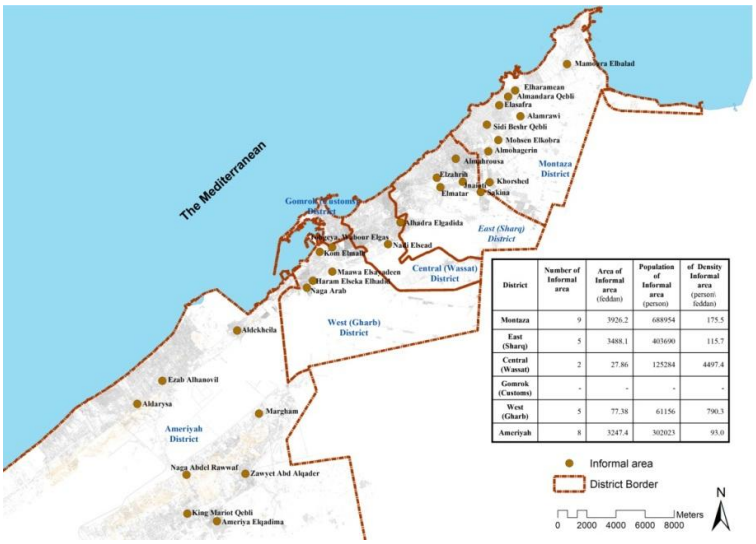
According to the Ministry of State for Local Development, there are 29 informal areas within the City of Alexandria (figure 4). This represents about 2.9 % of the informal settlements of Egypt. An estimated 1.4 million persons, representing about 35 % of the residents of Alexandria, live in these informal areas (GOPP, 2007). They represent an estimated nine percent of those living in informal areas in Egypt. An estimated EGP 275.5 million during 1992/93 to 30 June 2004 had been spent to improve conditions in these informal areas by providing sewerage, electricity and paving streets. Mmost of these slum areas that are located in the old town in the western side of the city are distinguished by their compact patterns. These areas lack many amenities, such as open spaces and green areas; the streets are narrow and unpaved.



District	Number of Informal area	Area of Informal area (feddan)	Population of Informal area (person)	of Density Informal area (person/ feddan)
Montaza	9	3926.2	688954	175.5
East (Sharq)	5	3488.1	403690	115.7
Central (Wassat)	2	27.86	125284	4497.4
Gomrok (Customs)	-	-	-	-
West (Gharb)	5	77.38	61156	790.3
Ameriyah	8	3247.4	302023	93.0

Figure.4: Alexandria, Informal and slum areas, (GOPP, 2007)

5.2 Demographic and economic factors

CAPMAS (2006) stated that the population of Alexandria reached around four million. It is the second most populous city in Egypt. Population annual growth rate from 1996 to 2006 was 2.1 %, which is near the national rate. Male population represented 51 % of the total population. The percent of illiterate adults declined from 24.8 % to 19.3 % from 1996 to 2006. The percentage of educated literates with secondary and technical diploma are the majority representing almost 55 % of the literate population; while those with university and/or post graduate degrees represent almost 15 % of the literate population. Those who are economically active and participate in the labor force are only 31.2 % of the population. Those who are not part of the labor force are students, housewives, physically disabled, etc. The local economy of Alexandria depends on manufacturing as a major commodity production sector, as well as service production sectors, particularly trade and transportation (figure 5).

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

Unemployment is on the rise. In 1996, those unemployed represented seven percent of the labor force, while in 2006, they represented 10.22 %. Accordingly, the dependency rate in Alexandria can be significant since only 31.2 % are economically active.

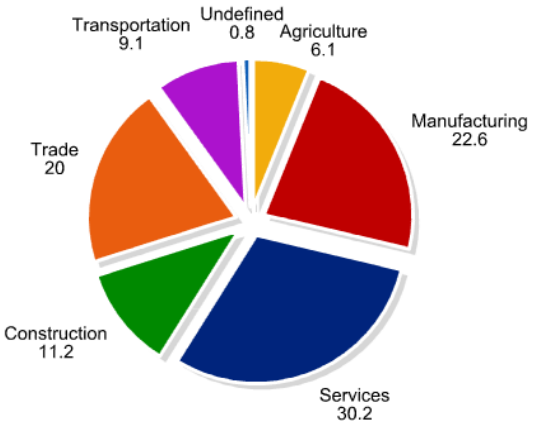


Figure.5: Alexandria, Employment rates by sector (percent), (CAPMAS, 2006)

5.3 Social factors

According to the GOPP (2006) studies, Alexandria needs additional educational services as the planning requirements indicate that the number of students has to be limited to 40, 38, and 36 students per class in primary, preparatory and secondary schools, respectively (Table3).

Alexandria Social Services: Schools

School Type	Number of Schools 2009/2010	Number of Students 2009/2010	Students per Class	School Deficit	Number of new Schools 2032	Total Number of Schools 2032
Primary	787	526,901	43	50	361	1,148
Preparatory	437	210,810	38	-	271	708
Secondary General	163	65,560	32	-	87	250
Secondary Business	26	14,350	36	-	13	39
Secondary Industrial	23	29486	30	-	11	34
Total	**1,436**	**847,107**		**50**	**743**	**2,179**

Source: Information Center of the Governorate of Alexandria (2010), calculations by AS&P

exceeds the standard of 40 students per class

Table.3: Alexandria schools, AS&P/ (2010)

The calculated needs for educational services by 2022 mount to 275.2 feddan to build an estimated 323 schools, as Table 3 indicates. Most of that land is devoted to primary education to meet the growing needs of a growing population.

Health services are also strained. The current services rate is 1.4 beds per thousand persons, which is beyond the planned requirement (3.0 beds per thousand persons). The estimated needed health service by 2022 is 3,751 beds, which will require about 44.66 feddan of land.

Currently, there exists one youth centre for every 114 thousand persons, which is considerably too low when compared with the normal average. The planned requirement is one youth centre for every 50 thousand persons. The future need of sporting facilities is then 25 sporting facilities that require about 25 feddan of land (GOPP, 2006).

Alexandria has 17 police stations, and 55 police precincts. The Governorate has one fire fighting department that includes 46 fire fighting houses distributed among the six districts and Borg Al Arab City. The planned requirement is one fire house per 30 thousand persons. The current rate in Alexandria is one fire house per 89 thousand persons. The needed service then is 91 fire houses that require about 5.4 feddan of land (GOPP, 2006).

5.4 Network and Infrastructure factors

According to GOPP, 2008, Alexandria is well connected to other parts of Egypt via a number of routes. The Cairo-Alexandria Agricultural Road connects the city to other cities within the Delta region. The Cairo-Alexandria Desert Road connects the city with the new developments, such as Sadat City and Nubaria City. The Alexandria-Matrouh Coastal Road extends towards the west, serving a number of summer resorts, such as Marina, and connects the city with other towns, such as Alameen and Marsa Matrouh. This road extends to the Egyptian-Libyan borders. Alexandria is also well connected to other northern settlements, such as Rosetta, Damietta and Port Said through the International Road. Furthermore, the city has an international airport, and is connected to other areas of the country by railroads.

The street pattern of Alexandria takes the form of grid-iron, where major roads, such as the Hurreya st. , El Geish st, stretch from the east to the west. Other important streets, such as Suez Canal Street, go from north to south.

Alexandria Water Company is responsible for providing drinking water to the residents of the Governorate. The company depends on Nubaria and Mahmoudia water canals as sources for fresh water. The company produces about 2,927 million cubic meters a day. Amounts of consumed drinking water are 1,757 million cubic meters, which means that lost drinking water is about 40 % of the produced drinking water.

An estimated 99.5 % of the residents of Alexandria (including Borg al Arab) are connected to sanitary system. Some treatment plants provide primary treatment; other plants provide secondary treatment to the wastewater. The treated wastewater is then discharged to Lake Maryut. There are four power generation plants that provide Alexandria (including Borg al Arab) with electricity. The city is well served with communication network.

5.5 Environmental factors

According to the reports of Egyptian Environmental Affairs Agency (EEAA), there are nine hotspots out of 13 locations for monitoring along the coast of the Mediterranean. El-Max, El-Dekhiyla, Western harbour and Abu-Quir are among these nine sites. The coasts of Sidi-Gaber, El-Anfoushi, El-Shatbi and Eastern harbour experience moderate levels of pollution. El-Agami, El-Montaza and west of Abu-Quir experienced less pollution compared to other polluted locations.

Lake Maryut, is one of the shallow lakes of northern Egypt. It constitutes the southern natural border to the city. Lake Maryut is heavily polluted. There are three drains connected to the lake: al Qala'a (Citadel), al Ummoum (Commons) and old estuaries to the north of the lake. These three drains are responsible for dumping liquid and solid wastes from the city districts into the lake.

In Alexandria the total generated municipal wastes ranges from 2,600 to three thousand tons a day. A private sector is responsible for collecting wastes and cleans the streets. There are three transit stations, and a sanitary landfill in Borg al Arab that receive these wastes. There are three composting plants that transform the municipal wastes into compost to be used as soil conditioner and/or organic fertilizer.

5.6 Political and safety factors

Egypt 2011 Crime and Safety Report stated that, the current overall situation has improved in Egypt, however, in late January and early February 2011, Egypt experienced a dramatic revolution and massive political upheaval. The country is still in a state of flux and the future stability of the nation remains unpredictable. In late January and early February 2011, massive protests swept the nation and hundreds of thousands of demonstrators converged on Tahrir Square and other areas throughout Egypt to include, but not limited to, Alexandria, Suez, Mansoura, Menufiya, Assuit, Qena, Tanta, and Mahallah in a successful effort to topple the regime. During these demonstrations, violent clashes between protestors and police ensued that resulted in the deaths of many demonstrators and police.

Police stations throughout Cairo and other cities were burned, and an unknown number of weapons were stolen from the police stations as well as uniforms which have yet to be accounted for. According to unconfirmed reports, up to 23,000 prisoners have escaped from police stations and prisons, and approximately 10,000 are still at large. There was widespread looting before neighborhood "watch" groups and vigilantes reestablished a tenuous calm. In the days following the initial protest, police resources were exhausted and depleted, and the result was minimal, if any, police presence throughout most of Egypt.

Intercity roads are generally in good condition, but unmarked surfaces, stray animals, and disabled vehicles without lights or reflectors are among the many hazards that can be encountered on highways, especially after dark. Embassy personnel in Egypt are prohibited from traveling outside Cairo by motor vehicle after sunset and are encouraged to travel between cities via air or train. Although rare, petty crime is a growing concern in Egypt. These crimes range from pick-pocketing and assaults to more frequent and aggressive female sexual harassment. Also, a steady increase in various types of crimes and criminal behavior. Residential burglaries are on the rise.

The police in Egypt are generally very concerned about the welfare of foreigners, tourists, and business interests. In practice, foreigners who are crime victims often receive more support from the police than do Egyptians. Tourism and antiquities police are stationed in hotels and tourist sites throughout the country.

Now aday, the police and military forces are working on keeping all the country with its cities more safe and politically stable. They are doing great efforts in order to keep the cities attractiveness not affeceted with these crimes and keep all the tourists and foregin investors safe whenever they are visiting the cities.

6 DISCUSSION

Albert Speer, 2012 stated that Alexandria by its size and geographic location has got the potential to establish itself as the quality of life alternative to Cairo. However, in order to fully exploit this potential it needs to gain attractiveness and tackle vital problems like cleanliness and solid waste management, environmental pollution, traffic congestion and partially poor or lacking utility infrastructure. Alexandria will also have to take care of its architectural heritage and its archaeological treasures. They need both, protection and investment to make visiting the city more appealing to tourists (not only domestic and Arab tourist but also international travellers) and businesses. These development steps would help Alexandria to reach the concept of being Open City in-order to achieve the city vision and goals.

6.1 Residential and planning factors

Albert Speer, 2012 said that Alexandria in particular features in its core districts very high residential densities of up to 500 persons per feddan in areas like Raml 1st. In positive terms this means that high densities are already embedded in the genetic urban code of Alexandria, and reaching an appropriate density will not be the problem, especially not in core area expansion zones. On the other hand, it has to be understood, that excessive densities like in the Raml sub-district cause serious overcrowding-problems and have to be avoided in new developments for health and safety reasons. Based on their international expertise and on a survey of average density figures in Alexandria's core districts the consultant-team recommend not to exceed a gross residential density of 250 persons per fedan and employ considerably lower densities in suburban extension areas.

In the Alexandria 2032 city profile report it was suggested to make alexandria a green city as the residential quality is closely linked to the availability of nearby green open spaces for leisure and recreation, which also fulfill important micro-climatic functions. Alexandria today is underperforming in terms of amount and accessibility of green open spaces, which is why newly planned extensions should include public parks and greens.These new areas for recreation have to be linked to the existing urban fabric as well and should be interconnected through a network for non-motorized mobility. New open spaces should be introduced alongside with innercity brownfield site developments wherever possible.

Alexandria has to devise an urban housing policy, which meets the demand in all strata of society and provides a well-balanced offer on the rental and ownership market. Every Alexandrian household, especially young married couples, shall find an adequate units in price ranges compatible with their income and adaptable to changes in family size. The city will successfully create a wellfunctioning and transparent

residential realestate market and achieve this by controlling unplanned building activities and by legalizing properties in existing unplanned areas.

By means of foresighted land-use planning and a stricter zoning regime, Alexandria will manage to avoid conflicts between residential and industrial land uses and limit the environmental impact of new developments. For inner-city areas along the Mahmodeia Canal and in Gomrok, a relocation of industrial enterprises and the conversion of disused and underused industrial sites to higher value uses will open up new perspectives. The adjacent residential neighbourhoods will benefit from this process of brownfield development.

6.2 Economic factors and Demographic factors

Albert Speer, 2012 mentioned that Alexandria faces the challenge of accommodating about 2 million additional residents by 2032. It is clear that such an increase in Alexandrian citizens cannot be absorbed by the existing urban fabric, but will result in a massive expansion of the city's built-up area. Population growth will have to be redirected away from the already overcrowded core area of Alexandria to new settlement centers either on Alexandrian territory or in the Alexandria Urban Region, especially down the North Coast Strip of Marsa Matrouh Governorate.

For the education facilities it would be better to decrease the literacy rate and improve education and training centres quality, also we should make the density of the students in their classes according to the international standards and never let it increase even with the increasing of the population rate.

Unemployment is on the rise so it should be carfully studied when trying to develop Alexandria in order to make it economically active and decrease this huge rate of unemployment, that could be reached easily when the city becomes more open. Also, we should work on increasing the FDI rate in egypt as that will help in providing extra spaces for egyptian employment and by increasing the city openness and attractiveness we could easily solve the problem of un empolyment and to attract FDI, Alexandria needs to examine what investors want. The primary objective for investors is to have transparency and political stability, easy access to, and easy communication with their investment projects. In all of these areas, Alexandria has room for improvement.

Alexandria shall take advantage of its existing diversified economic portfolio and build its future positioning on three concurrent streams of local economic development. The Natural Growth stream capitalizes on the existing strength of Alexandria in manufacturing industries, the Euro-Mid-Eastern Hub development stream focuses on logistics and related activities, and draws upon the existing seaport, road and river transportation infrastructure. As a third and most ambitious endeavour, Alexandria will embrace the City of Enlightenment stream for boosting the development of knowledge-based businesses. All of the aforementioned streams of local economic development will be linked to specific projects in urban development. Be it a research centre in Sharq, an office park dedicated to business process offshoring in Wasat, Smart City Campus in New Borg El Arab or the extended Al Nahda industrial zone in Al Ameriyah - there will be numerous high-profile investment opportunities for foreign and domestic companies in Alexandria.

With 60% of Egyptian foreign trade passing through Alexandrian Ports, the city seems naturally set to assume the role of a Euro- Mediterranean cargo hub. Substantial investment will be required to expand the already good logistical capabilities. Furthermore such endeavours should be closely coordinated with nationwide development plans for the logistics networks as Alexandria faces strong competition from Damietta and Port Said.

6.3 Network and infrastructure factors

Albert Speer, 2012 , in Alexandria 2032 planning mentioned that The railway line operating between Borg El Arab and Alexandria city centre has to play a pivotal role in this respect. Each new urban centre will have to be fitted with an efficient and affordable internal circulation and transportation network structure. Technical utility infrastructure networks have to be implemented in all devised urban expansion zones taking into consideration aspects like sustainability and reduced resource consumption. Decentralized power generation from renewable sources will complement these endeavours by stabilizing the distribution network.

Urban upgrading will be the key to improving the quality of life for the majority of Alexandrians in the coming two decades. This encompasses ensuring electricity supply, potable water supply and sanitation by extending and upgrading the networks, investing in healthcare, social and educational services, as well as offering better and more connections in public transportation. Spending half of one's working day commuting in traffic jams on clogged main roads seriously affects the quality of everyday life in Alexandria and negatively impacts the economic performance of the city. A remedy will be a set of measures, which includes massive investment in public transportation systems to increase their level service and availability throughout the city, as well as upgrading and extending the existing road network infrastructure.

6.4 Geographical factors and Environmental factors

Albert Speer, 2012 , in Alexandria 2032 planning stated that, as far as tourism is concerned, Alexandria has to take advantage of its natural topographic properties, the most prominent of which are certainly the Mediterranean Sea shore and its inland water bodies like the canals and lakes. Especially the Corniche – as yet dominated by the only viable major North-South arterial road – bears a significant potential for further upgrading and adding new points of touristic or commercial activities. Also Lake Mahmoudeya with its shores partly occupied by unplanned settlements and the heavily polluted main basin of Lake Marriout are in need of strategies for environmental upgrading opening up opportunities for future development.

Alexandria since its beginnings has been an urban hub, a port city strategically located between Orient and Occident, open to people of various beliefs and to merchants, goods, and ideas from foreign countries. Today, of course it is no longer the sea-routes and ports of Alexandria alone through which ideas are exchanged, but modern means of travelling, which themselves get more and more substituted by modern media and the intangible data-highways of the internet. Internationalism and open-mindedness are deeply routed in Alexandria's urban genome, and the city will seize the opportunity to reinvigorate its once colourful and diverse cultural life taking on and blending – like in former times – influences from Egypt, Northern Africa and Europe into a unique cosmopolitan atmosphere. However the strong positioning of Alexandria as a physical hub on the Mediterranean remains and shall be further reinforced by expanding logistics infrastructures like ports airports, road and rail networks.

6.5 Political, safety and Social factors

Albert Speer, 2012 , IN Alexandria 2032 planning said that Alexandria is a great city with public-spirited citizens so, it will be a city promoting a sense of community and active citizenship through public awareness programs and participatory actions. Alexandrians shall take responsibility for their natural, built and social environment. The Governorate's administration can only support such public spirit, yet the major changes will have to be brought about by the Alexandrian people who have to revise their personal life-styles and attitudes and finally agree upon the way they want to live in their mother city. Alexandrian home owners and potential builders should understand that unplanned development without proper roads and sanitation, without enough space for social and educational facilities in the long run jeopardizes the quality of life of every citizen and start gaining trust in coordinated public planning.

Also, Alexandria is a city promoting socialinclusion and gender equality as it will have at least double female workforce participation during the next two decades alongside with providing its youthful population with enough employment opportunities and thus seize the demographic dividend. Social inclusion has a long-standing tradition in Arab cities, which Alexandria – especially in its new residential neighbourhoods will adopt by providing adequate housing for all income levels. Infrastructure provision in all unplanned areas will be implemented according to a comprehensive plan improving residential quality all over the city. Furthermore all neighbourhoods in the urban fabric of Alexandria shall be designed and upgraded considering gender issues like adequate street lights, safe public spaces, access to affordable public transportation and informal employment opportunities.

The political and safety factors are affected a lot with the post revolution in 2011 and this should be solved very fast to make Alexandria be a safe and friendly city to all its visitors as it was. The country political forces are working hard to make the city always safe and solve any political problems as soon as they could. But the Alexandrian residents are always helping all the visitors and protecting them and their safety is the city main concern.

7 CONCLUSION

Improving the quality of life in Alexandria is not only key to the well-being of Alexandrians, but will also support the city's positioning as an important economic and touristic hub in Egypt and on the Mediterranean.

Alexandria is blessed with three waterfronts offering plenty of opportunities for sustainable expansion and development, if environmental problems are solved.

"Open Cities" is a perfect trend that will help Alexandria greatly to reach its future development vision by using Sustainable Urban Development ways of planning. The deficiencies in the urban and socioeconomic structure of Alexandria would need to be solved by the city decision makers and planners in order to reach the city openness.

Finally, Alexandria could be successful Open City by limiting the average gross residential density, redirecting urban growth to the west, linking urban nodes efficiently and providing utility infrastructure, improving quality of life and environmental quality, making Alexandria a greener city, reducing visual as well as noise and air pollution, stimulating successful socio-economic development, providing sufficient building land for economic growth, increasing alexandria's touristic attractiveness and establishing alexandria as a euro-mideastern hub for logistics, trade and business.

Tischlein, deck dich! Über städtische Gastronomielandschaften und was Stadtplanung damit zu tun haben könnte

Ricarda Pätzold

(Dipl.-Ing. Ricarda Pätzold, TU Berlin, Institut für Stadt- und Regionalplanung, Hardenbergstraße 40a, 10623 Berlin, r.paetzold@isr.tu-berlin.de)

1 NACHDENKEN ÜBER … GASTRONOMIE?

„Der Tresen eines Cafés ist das Parlament des Volkes." (Balzac)

Essen–und darunter Gastronomie als eine Spielart der Außer-Haus-Verköstigung–findet nur selten Niederschlag in deutschsprachigen Fachpublikationen [1] oder auch Fachdebatten [2]. Über die Gründe für den Befund der mangelnden „Beforschung" kann nur spekuliert werden, vielleicht ist Essen (gehen) als Alltagspraxis einfach zu banal? Die vorherrschende materielle Rezeption von Essen und Gastronomie (z.B. Regulierung, Ernährung) lässt die kulturellen und repräsentativen Funktionen, die auch in hohem Maße raumwirksam sind, weitgehend außen vor. Auf der anderen Seite legt die Prominenz der Themen in Populärpublikationen [3]–wie Reiseführern, Stadtmagazinen, Tageszeitungen etc.–nahe, dass sich die Kultur einer Stadt oder Region nicht zuletzt im Essen offenbart. Jeder weiß, in Paris isst man *Froschschenkel*, in Brüssel *Pommes Frites* und in Berlin *Curry-Wurst*; London ist eine großartige Stadt, aber die britische Küche…; eine Zeile in Rainald Grebes wohl bekanntesten Lied lautet: „Nimm Dir Essen mit, wir fahr'n nach Brandenburg". Regionale Küchentraditionen prägen das Image von Städten und Regionen, auch wenn viele der Urteile und Vorurteile nur wenig Substanz aufweisen. Z.B. kann man in Marseille kaum noch *Bouillabaisse* essen, da die Zutaten für das einst einfache Fischergericht mittlerweile astronomische Summen kosten; in London haben u.a. migrantische Kochtöpfe *Fish 'n' Chips* oder *Yorkshire-Pudding* sukzessive verdrängt, in Paris wird der Niedergang der klassischen Bistrokultur beklagt–und inzwischen gibt es auch in Brandenburg vereinzelte kulinarische Oasen.

„However, food is not only a functional good, but also a cultural object–consumed not only for this nutrients, but also for its symbolic and aesthetic value." (Neal 2006) Die mannigfaltigen positiven Effekte der Gastronomie, wie urbanisierende Wirkung, Imagefaktor, Alleinstellungsmerkmal von Städten, soziale Funktionen etc., müssten sie eigentlich zu einem *everybody's darling*–auch von Stadtplanern–machen. De facto wird Gastronomie aber auch hier nur vereinzelt und meist als *sidekick* des Einzelhandels betrachtet. Handlungsnotwendigkeiten werden vor allem reaktiv gesehen, d.h. wenn die Nebenwirkungen einer zunehmenden Kneipendichte, wie Lärmemissionen durch nächtliche Straßengespräche oder Parksuchverkehr, zu Konflikten mit den Bewohnern führt. In dem Artikel werden grundlegende Trends der Gastronomie eingeordnet, empirische Befunde zu Kneipenvierteln in Berlin vorgestellt und die stadtplanerische Praxis sowie Optionen diskutiert.

2 STARBUCKS, MC DONALDS ETC. VERSUS REGIONALE TRADITIONEN

Von den deutschen Unternehmen gehören ca. 6 Prozent zum Gastgewerbe. Davon sind 96 Prozent Kleinstunternehmen mit weniger als 10 sozialversicherungspflichtigen Beschäftigten [4]. Anders als in anderen Branchen [5] entfällt auf diese Unternehmen mit 60 Prozent auch ein großer Teil des Umsatzes. 19 Prozent der

[1] Z.B. erschien die Dissertation des Ethnologen Thomas Kochan 2011) über die Trinkgewohnheiten in der DDR im Aufbauverlag, was einerseits ein „Ritterschlag" im Sinne eines breiten Interesses an der Arbeit war, sie andererseits aber ein Stück weit außerhalb der Scientific Community stellte. Grundlegende Studien liegen zum Teil schon Jahrzehnte zurück, z.B. Dröge/Krämer-Badoni 1987; Schwibbe 1998; Teuteberg 1997; Wedemeyer 1990).

[2] Eine Ausnahme war die Konferenz „So ist die Stadt. Esskultur und die Eigenlogik der Städte" vom 6.-7. Mai 2011 in Darmstadt (LOEWE 2011).

[3] Das spiegelt sich natürlich auch in den zahllosen Fernseh-Kochshows von „Nachfahren" Alfred Bioleks. Allerdings geht es hier in der Regel um das Selbst-Kochen, bzw. um die Selbst-Inszenierung von Sterneköchen. Ein Sonderfall: Auf ARTE wird in der Sendung „Zu Tisch in …" ein Blick auf die häuslichen Kochtraditionen in verschiedenen europäischen Regionen geworfen (ARTE 2012).

[4] Insgesamt wies das Gaststättengewerbe 2011 ca. 673 Tsd. Beschäftigte auf. Der Bedarf schwankt in Abhängigkeit von saisonalen Gegebenheiten und auch Wochentagen (umsatzstärkster Monat ist der Juli, schwächster der Februar). Im Vergleich zur Gesamtwirtschaft werden fast dreimal mehr geringfügig Beschäftigte eingesetzt.

[5] So lag z.B. der Anteil der Lebensmittelgeschäfte unter 400 qm 2004 bei 60 Prozent, deren Umsatzanteil aber bei nur bei 11 Prozent (KPMG/EHI 2006)

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

Erwerbstätigen im Gastgewerbe sind selbstständig. Als Indiz für eine mangelnde Professionalisierung der Branche kann die hohe Insolvenzrate–10 Prozent der bundesweiten Unternehmensinsolvenzen entfallen auf das Gastgewerbe–gewertet werden (Stöver 2011). In den Jahren 2010 und 2011 lag die Zahl der Betriebsaufgaben mit jeweils 17 Prozent deutlich über den Betriebsneugründungen. Insgesamt sinkt die Zahl der Unternehmen im Gaststättengewerbe seit Jahren–bundesweit existierten 2002 noch 190.760 Unternehmen, 2009 nur noch 175.576; das entspricht einem Rückgang von 8 Prozent (DEHOGA 2011b; 2012).

Tiefe und Intensität des Umbruchs in der gastronomischen Landschaft zeigt sich aber deutlicher im Detail. Verlierer der Entwicklung sind Schankwirtschaften, Restaurants und Eisdielen; klare Gewinner Imbisse und Cafés (vgl. Abbildung 1). Analog zum Einzelhandel sind Filialisierungstendenzen und Systemkonzepte auf dem Vormarsch, auch wenn der Anteil lokaler Betreiber in der Gastronomie vergleichsweise immer noch sehr hoch ist. Die 100 größten Unternehmen der Systemgastronomie in Deutschland betreiben insgesamt „nur“ 16.833 Betriebe [6]. Die einzelnen Typen der Gastronomie [7] sind dabei ganz unterschiedlich betroffen. Unter „Fullservicegastronomie“–also die Konkurrenz zu den klassischen Restaurants–fallen nur 18 Unternehmen mit insgesamt 312 Betrieben.[8] Die meisten Systemkonzepte (10.121 Betriebe) sind in der Kategorie „Fastfood, Imbiss, Home Delivery“ zu finden. Die dahinter stehenden 30 Unternehmen bedienen ganz unterschiedliche räumliche Radien: So sind 8 global (3.561 Betriebe), 5 multinational (921 Betriebe), 11 national (4.465 Betriebe) und lediglich 6 ausschließlich regional (1.174 Betriebe) ausgerichtet. Das umsatzstärkste Unternehmen ist mit Abstand McDonald‘s (DEHOGA 2011a).

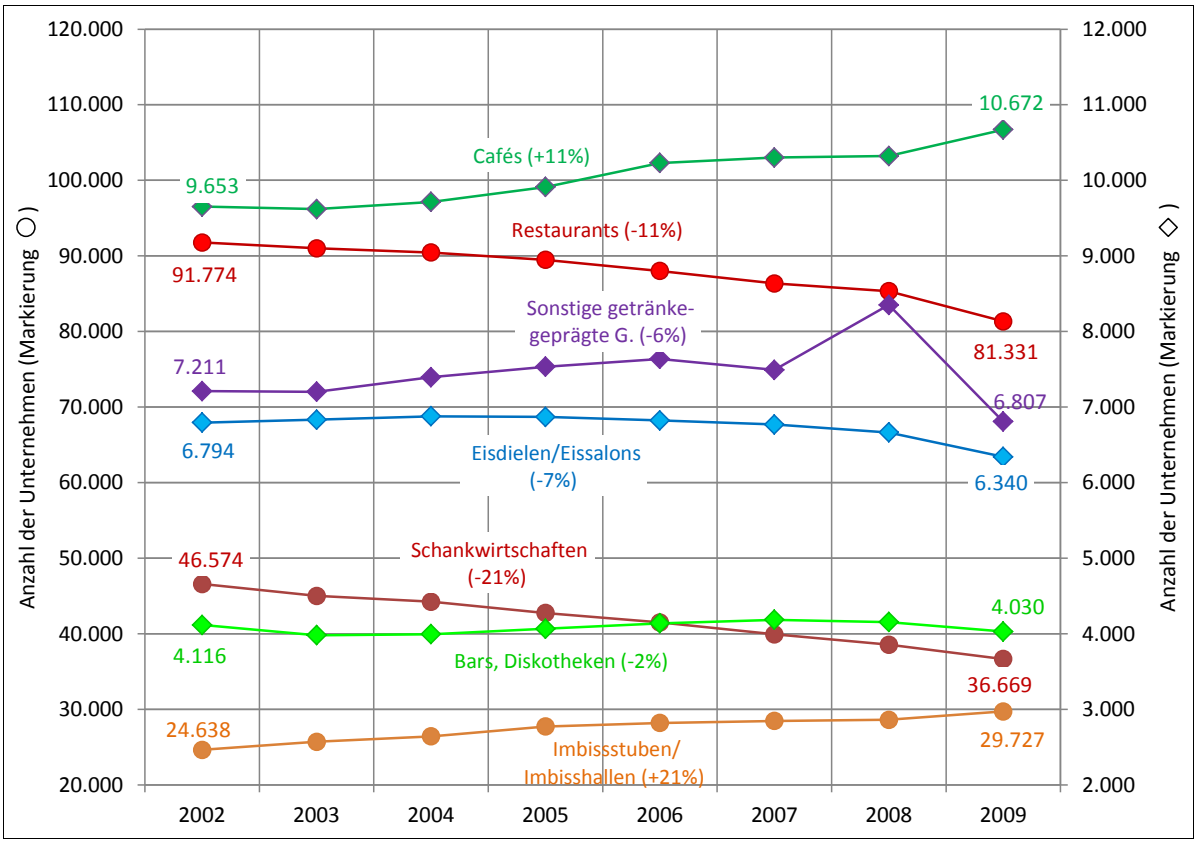

Abbildung 1: Anzahl der umsatzsteuerpflichtigen Unternehmen im Gastgewerbe 2002-2009 (Darstellung nach DEHOGA 2012)

Im Einzelhandel kann seit Jahren beobachtet werden, dass Systemkonzepte und steigende Filialisierung entscheidend zu einer sukzessiven Verdrängung der traditionellen, inhabergeführten Läden beitragen (vgl. u.a. Pätzold 2011a). Lange schien es, als würden die Parallelwelten von global und lokal ausgerichteten

[6] Inklusive der Unternehmen der Handels-, Freizeit und Verkehrsgastronomie sowie Event-, Messe- und Sport-Catering – insgesamt 54 Unternehmen mit über 6000 Betrieben.

[7] Es bestehen Zuordnungsprobleme: Die Klassifikation der Systemgastronomie der DEHOGA entspricht nicht der Klassifikation der Wirtschaftszweige des Statistischen Bundesamtes, z.B. werden unter „Fastfood, Imbiss, Home Delivery“ auch Cafés (wie Starbucks, Tchibo- und Segafredo-Coffeebars) geführt.

[8] Bekannte Formate sind u.a. Maredo, Schweinske, Wienerwald, Cafe Del Sol, Bavaria Alm oder L’Osteria.

Unternehmen in der Gastronomie nebeneinander bestehen, doch diese Balance wird zunehmend brüchig. Ursächlich ist auch hier die Verknüpfung aus wirtschaftlichen Größenvorteilen von Systemkonzepten, steigender Preissensibilität und Veränderungen in der Verteilung des frei verfügbaren Einkommens sowie anderen Nachfragepräferenzen anzusehen. Dieser Wandel ist nicht nur in Deutschland, sondern auch in vielen europäischen Ländern zu beobachten.

So wird in Großbritannien das Pub-Sterben beklagt. Befördert durch die anhaltend schlechte Wirtschaftslage schlossen 2010 allein in London sechs Pubs pro Woche. Würde man diesen Trend linear fortschreiben, wäre 2037 diese Institution gänzlich verschwunden. Die Krise betrifft allerdings inhabergeführte und Pub-Ketten gleichermaßen. Während in den Städten andere gastronomische Formate als Alternative vorhanden sind, sterben dagegen in ländlichen Regionen mit den Pubs die letzten Gemeinschaftsorte, nach den Nachversorgungs- und Dienstleistungsangeboten (BBPA 2012). Deshalb arbeitet seit 2001 die Community-Organisation „Pub ist the Hub", die auf eine Initiative von Prinz Charles zurückgeht, an Modellen zu alternativen Betreiberstrukturen (Pub 2012).

Was in Großbritannien der Pub ist, ist in Frankreich das Bistro. Im Land der Gourmets sind Fast-Food-Ketten auf dem Vormarsch und täglich müssen zwei der traditionellen Lokale schließen. Als Ursache werden die veränderten Bedingungen am Arbeitsmarkt, darunter vor allem die gesetzliche Arbeitszeitbegrenzung, in Kombination mit einer gestiegenen Preissensibilität gesehen. Die französische Küche ist zeitintensiv; das lässt sie ins Hintertreffen geraten, wenn die Mittagspause nicht auf zwei Stunden und mehr ausgedehnt wird. Hierin wird im Übrigen die vergleichsweise hohe Widerstandsfähigkeit der italienischen Traditionslokale begründet, denn die italienische Küche ist wesentlich schneller und hat in dieser Beziehung kaum Nachteile gegenüber den globalisierten Fast-Food-Formaten (o.A. 1984; Ramge 2009).

In Österreich, insbesondere in Wien, wird das Kaffeehausterben beklagt, allerdings mittlerweile die dritte Welle–Anfang des 20. Jahrhunderts waren teuren neuen Espresso-Maschinen, dann in den 1950er Jahren die Ausbreitung der italienischen Espressobars und um die Jahrtausendwende Starbucks und Co. schuld am Niedergang der Kaffeehauskultur. Bei jeder dieser Innovationswellen mussten Traditionshäuser schließen. Neben den nostalgischen Klagen, wird aber durchaus kritisch festgestellt, dass die Kaffeehäuser sich oft jeglicher Modernisierung verweigern (Holzer 2010). 2011 wurde im Rahmen des Kunstprojektes „Das große Wiener Kaffeehaus-Experiment" am MAK über die Zukunft des Kaffeehauses nachgedacht–die Ergebnisse reichten von Einrichtungsideen bis zur Integration bzw. Desintegration von neuen Medien (Wilde 2011).

Und wie sieht es in Berlin aus? Berlin war die Stadt der Eckkneipen, die zu Beginn des 20. Jahrhunderts in den überbelegten Gründerzeitquartieren das Wohnzimmer ersetzten. Im Vergleich zu Paris oder auch Wien, das Ende des 18. Jahrhunderts als der größte Gastronomiemarkt Mitteleuropas galt, war Berlin ein gastronomischer Spätentwickler. Allerdings entstand hier mit dem Unternehmen Aschinger [9], eines der ersten Systemkonzepte in der Gastronomie (vgl. Allen 2002). Die Weltkriege hinterließen tiefe Zäsuren in der gastronomischen Landschaft Berlins, die im Ostteil der Stadt durch einen gravierenden Umbau des Gastgewerbes verstärkt wurden (vgl. Abbildung 2). Noch in den 1970er Jahren hatten die Eckkneipen einen Anteil von 50 Prozent an der Westberliner Gastronomie, in den 1990er Jahren waren es nur noch 25 Prozent (Bolm 1998). Insgesamt gibt es in Berlin weniger mythische Traditionsorte als in Städten mit einer stetigen Entwicklung und es werden immer weniger. 2008 schloss z.B. das Café Adler [10], das während der Teilung das einzige Restaurant mit Blick auf die Mauer am Checkpoint Charlie war–bezeichnender Weise wird das Lokal heute von der Café-Kette Einstein bewirtschaftet.

In Summe wird das Verschwinden von Traditionslokalen–Pub, Bistro, Kaffeehaus, Eckkneipe etc.–allerorten von Melancholie begleitet. Dabei ist wie so oft ein eklatanter Bruch zwischen der „Abstimmung mit den Füßen" und den Klagen über den Identitätsverlust festzustellen. Es liegt im Wesen globalisierter Angebote, überall auf der Welt mit dem gleichen Erscheinungsbild aufzutreten. Was am Rückgang raumpräsenter Traditionen stört ist damit oft nur, dass das (Stadt-)Bild nicht mehr den Wünschen entspricht. Beklagt wird

[9] Unter dem Motto „Beste Qualität bei billigstem Preis" betrieb Aschinger (gegründet 1892) Anfang des 20. Jahrhunderts bereits 23 Bierquellen, 15 Konditoreien, acht weiteren Restaurants sowie 20 Verkaufsstellen und war damit der größte Gastronomiebetrieb Europas (Aschenbrenner 1999).

[10] In einem Blog-Eintrag war zu lesen: "It's a famous cafe from which western Berliners could have a look at the border with the East. Now it's still popular with artists, journalists and bankers, as well as tourists looking for shelter from rain." (http://members.virtualtourist.com/m/66760/12626/2/).

also vielleicht weniger der verlorene Ort, der–bei wirtschaftlichen Gründen der Geschäftsaufgabe–eben unter einem Mangel an Besuchern und respektive Einnahmen litt, sondern die Gleichschaltung der räumlichen Umgebung [11].

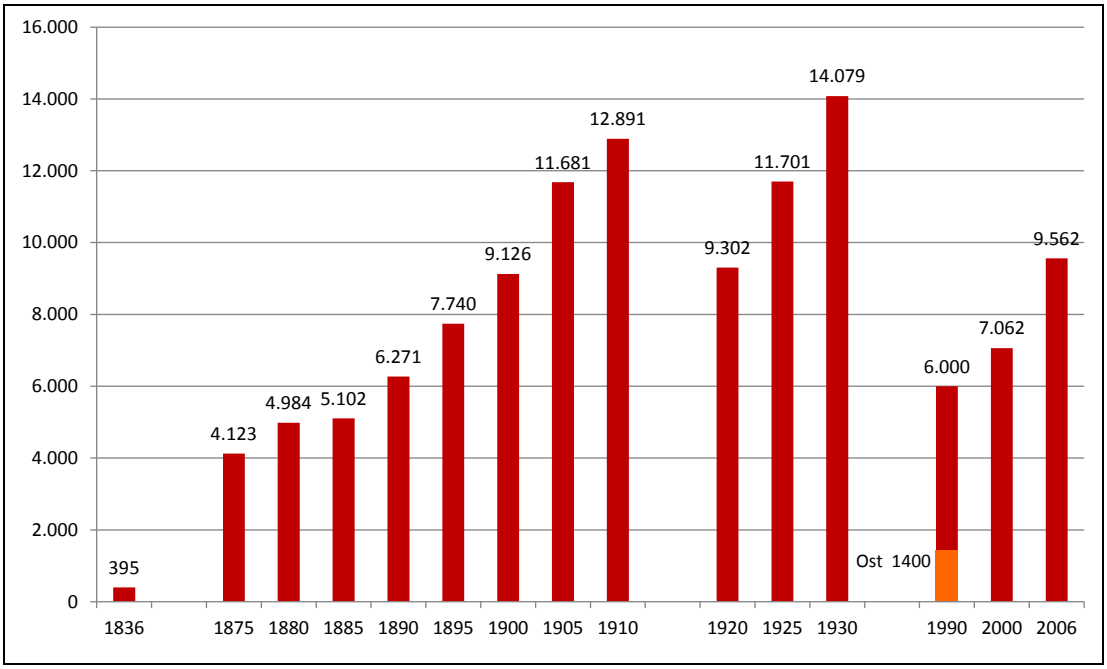

Abbildung 2: Gastronomische Betriebe in Berlin 1836-2006 (Darstellung nach Arnold 2000; Drummer 1997; Waldt 2007)

Der sukzessive Verlust von Ortstraditionen und damit gleichzeitig von Esstraditionen ist aber nur eine Seite der Medaille. Matthiesen spricht von der „Komplementarität von Globalisierungs- und Regionalisierungs¬dynamiken, die sich sowohl zwischen als auch innerhalb der kulinarischen Systeme, etwa durch das systematische Zugleich von Fast-Food- und Slow-Food-Kulturen zeigen“ (Matthiesen 2005). Je nachdrücklicher die Globalisierung in den Alltag diffundiert, desto intensiver wird scheinbar die Sehnsucht nach dem Regionalen. So wurde in der Gastronomie seit den neunziger Jahren der Zusammenhang von Raum und Geschmack neu konstruiert (Tschofen 2008). Der Ortszusatz schafft Vertrauen und macht die Welt überschaubar [12]. Flankierend wuchs in den letzten Jahren das Gewicht von Argumenten der Nachhaltigkeit, die sich unter anderem in der Forcierung von regionalen Wirtschaftskreisläufen bei Lebensmitteln in die Alltagspraxis übersetzen lassen (vgl. u.a. Stierand 2008). Die Wertschätzung der regionalen Küchen steigt parallel zum Marktwert des „Natürlichen“ und „Authentischen“; die Wertschätzung von artisanalen Produktionstechniken korreliert mit dem Symbolwert der der Nahrung beigemessen wird.

Aber sind die Huldigung des Terroir-Prinzips und der kulinarischen Identität nicht nur ein Luxusphänomen und erreichen lediglich bestimmte, quantitativ kaum relevante Bevölkerungsschichten? Der Blick in die Entwicklungen im Osten Deutschlands zeigt einerseits, dass auch unter streng nivellierenden Bedingungen eine angepasste Neuformulierung der kulinarischen Identität stattfand (Soljanka, Letscho, Goldbroiler). Andererseits hinterließ die Kappung der lokalen Traditionen eine bis heute regional wirkende kulinarische Orientierungslosigkeit. Die Neuerfindung regionaler Küchen kann als Merkmal innovativer und kreativer Regionen gesehen werden–der Blick in die regionale Verteilung der Lebensmittel mit geschützter geographischer Herkunft oder auch der Michelin-Sterne zeigt Konzentrationen im Südwesten der Republik und große weiße Flecken im Nordosten (Bröhm 2011; Ermann 2009).

In Berlins Gastronomie ist die regionale Einbettung in die brandenburgische „Steusandbüchse“ wesentlich geringer ausgeprägt als die hauptstädtische Repräsentation von Botschaften des Geschmacks aus aller Herren Länder. Man kann sich „nahezu einmal um die Welt snacken“ (Marx 2011), aber bei der Frage nach einem typisch Berlinerischen Gericht fällt die Antwort wahrscheinlich irgendwo zwischen Currywurst, Buletten,

[11] Bereits 1974 formulierte Calvino den Eindruck der zunehmenden Austauschbarkeit von Orten durch die gleichen Ausstattungsmerkmale (Läden, Hotels etc.) – „Only the name of he airport changes“ (Calvino 1974: 102).
[12] „Rund 65 Prozent der Deutschen achten beim Einkauf immer oder meist auf regionale Herkunft, denn sie wollen natürliche und authentische Lebensmittel“ PM Stiftung Warentest, 29.03.2011.

Berliner Leber und Döner aus. Die Reformulierung einer kulinarischen Tradition mit Bezug zum Terroir hat in den häuslichen Küchen über Bio-Bauern-Märkte, Gemüsekisten und urbanes Gärtnern wahrscheinlich stärker Einzug gehalten als in der Gastronomie. In letzter gilt immer noch als ambitioniertes Vorhaben, aus Steckrüben, Kohl und Kartoffeln einen heimatlichen Geschmack zu kreieren.

3 GASTRONOMIE UND STADTQUARTIERE

Die unterschiedliche Intensität der Ausprägung und die Art der gastronomischen Betriebe in Städten lassen sehr individuelle kulinarische Landschaften entstehen, die bisher im deutschsprachigen Raum nur wenig systematisch erforscht wurden [13]. Das betrifft sowohl Fragen der kulinarischen Identität als auch der Wechselbeziehung zwischen Urbanität und der ortsspezifischen Qualität von Konsumorten. Es ist unstrittig, dass die spezifische Ausprägung von Konsumorten, die lokale Lebensqualität mit bestimmt und auch als Indikator zur Beschreibung des sozio-demographischen Charakters eines Ortes herangezogen werden kann (vgl. u.a. Crewe/Lowe 1995; Mullins et al. 1999; Zukin 2004). Neal (2006) clusterte 243 US-amerikanische Städte auf Basis ihrer gastronomischen Ausstattung vgl. (Abbildung 3) in Urbane oases, McCulture oases, Urbane deserts und McCulture deserts. Die Oasen zeichnen sich durch ein hohes Angebot an gastronomischen Einrichtungen aus, die Wüsten durch ein Geringes. Sie unterscheiden sich weiterhin in der Qualität und der Vielfalt der Lokale–in den McCulture Orten ist ein dominierenden Besatz an standardisierten Gastronomieformen (McDonaldisation) zu finden. Die identifizierten urban oases weisen eine hohe Übereinstimmung mit den von Florida (2008) identifizierten Städten auf, deren ökonomische Entwicklung durch die 3 Ts (talent, technology, and tolerance) positiv beeinflusst wird.

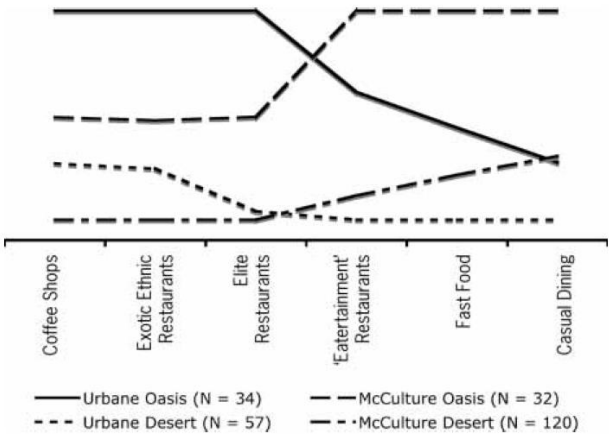

Abbildung 3: Profile von gastronomischen Clustern (Neal 2006: 11)

Die Klassifikation in gastronomische „Wüsten und Oasen“ kann auch auf den Binnenraum von Städten übertragen werden. Allerdings muss die Ausbildung von mehreren Kneipenvierteln mit unterschiedlicher Charakteristik als Spezifikum großer Städte gesehen werden, denn in kleineren Orten weist in der Regel der Marktplatz oder–sofern vorhanden–die Strandpromenade die höchste Restaurantdichte auf. In den Urbanen Oasen, also den Städten, deren Entwicklung in starkem Maße mit dem Vorhandensein der Creative Class verbunden ist, findet sich das vitalste Angebot an originellen Shopping-, Gastronomie und sonstigen Freizeitangeboten meist in den gentrifizierten oder in Gentrifizierung befindlichen Innenstadtbereichen (Gründerzeit, ehemalige Arbeiterviertel), die sich durch einen hohen soziökonomischen Status und meist auch eine ethnische Mischung auszeichnen. Die urbanen Annehmlichkeiten, wie eben eine interessante Gastronomie, sind dabei gleichzeitig Vorbedingung und Ergebnis der Anwesenheit kreativer Pioniere (u.a. Clark 2004; Florida 2008; Oldenburg 1999; Zukin 1995).

Die Dichte der gastronomischen Betriebe in den Berliner Quartieren steigt mit ihrer Zentralität–doch auch innerhalb des S-Bahnrings weisen viele Quartiere nur eine geringe gastronomische Dichte auf. Die Hot-Spots (vgl. Abbildung 4) sind in den Stadtteilen Mitte, Prenzlauer Berg, Friedrichshain, Kreuzberg, Neukölln, Schöneberg und Charlottenburg zu finden. All den ausgeprägten „Kneipenvierteln“ ist gemein,

[13] Matthiesen (2005) spricht in diesem Bezug von dem „trägeren Bereich der planungsbezogenen und sozialwissenschaftlichen Raumforschung“, Johns/Pine (2002) konstatieren aber auch für den englischsprachigen Raum, dass „the geography of dining out … seems to be a neglected area of research” (zitiert nach Neal 2006: 4).

dass die gastronomischen Betriebe zu einer Ballung neigen, d.h. dass sich innerhalb der Quartiere meist ein Knotenpunkt oder eine Hauptachse herausbildet. Das gastronomisches Gefüge in den Städten ist nur teilweise stabil: Eine hohe Kontinuität weisen oft „Touristenfallen“, hochpreisige Restaurants sowie traditionelle Quartierslokale auf; ständig im Fluss ist dagegen die „Szenegastronomie“, die oft Hand in Hand mit Akteuren aus der Kunst zur Entdeckung neuer Quartiere beiträgt.

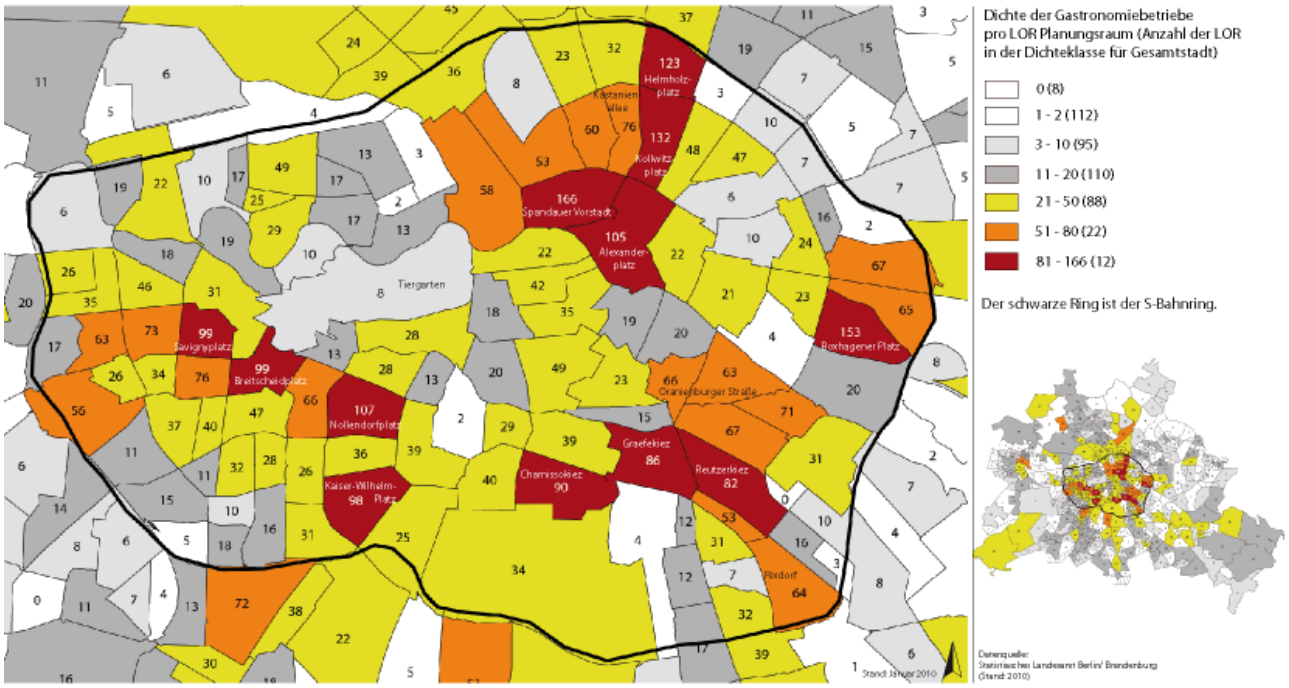

Abbildung 4: Berlins gastronomische Landschaft (Darstellung nach Berechnungen des StaLa BB 2010)

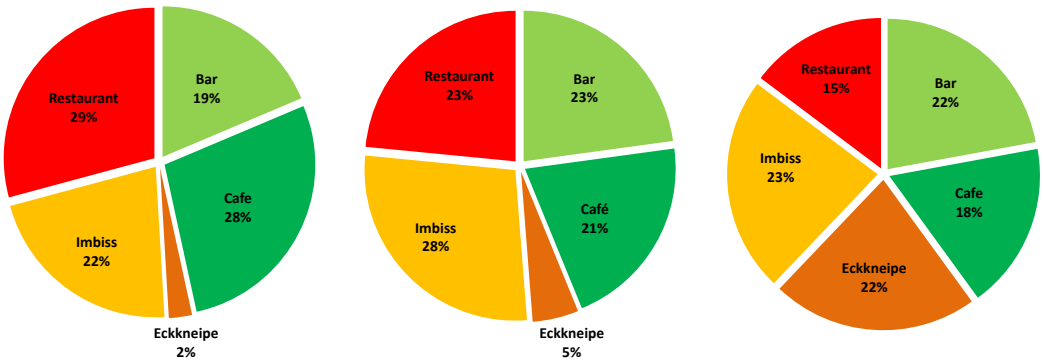
Die Wechselbeziehung zwischen Bewohnermilieus und Gastronomie kann an der inzwischen in Berlin verbreiteten symbolischen Verwendung von bestimmten Getränken zur Beschreibung einer Quartierscharakteristik verdeutlicht werden–dies hat natürlich Vorbilder in den Makro-Nationalismen, wie „Krauts“, „Frogs“, „Pommes“ und „Spaghetti-Fressern“. So stehen Bionade und Latte Macchiato stellvertretend für Gentrifizierungsprozesse und die Präsenz von urbanen Eliten. Das breit rezipierte Bild des Bionade-Biedermeier (Sußebach 2007) im Prenzlauer Berg wird unverdrossen weiter verwendet, obwohl das namensgebende Getränk seinen Independent-Status durch den Verkauf an die Radeberger-Gruppe (Oetker-Konzern) mittlerweile eingebüßt hat. Mit dem Bionade-Begriff geht die Assoziation einer neuen bürgerlichen Schicht einher, die horrende Mieten oder Kaufpreise für Gründerzeitwohnungen bezahlt, damit einkommensschwächeren Bevölkerungsschichten verdrängt, die Kindererziehung zum Lebensziel erklärt und von früh bis abends wohlgemerkt Latte Macchiato trinkt. Die Bionade selbst ist eher Symbol für ein ökologisch orientiertes Gutmenschentum.

In der medialen Aufbereitung des neuen Berliner Szenequartiers Neukölln–oder besser Nordneukölln–spielt Latte Macchiato ebenfalls eine entscheidende Rolle. Im Jahr 2006, als das Stadtviertel durch den Brandbrief der Schulleiterin der Rütli-Schule bundesweit als Problemkiez Schlagzeilen machte, erschien in der Berliner Zeitung ein Artikel mit dem Titel „Auch hier gibt es Latte Macchiato“ (Sundermeier 2006), der auf die kommenden Umwälzungen prophezeite und in dem es natürlich nicht um Espresso im Glas mit Milchschaum ging. Dem Verdruss über die Veränderungsprozesse im Quartier machte sich die Pioniergastronomie „Freies Neukölln“ mit dem Film „Offending the Clientele“ Luft. Dieser gipfelte in der Aussage „we dont have Latte … stop to life a standard live in a standard world”. Natürlich haben aber gerade die neuen Kneipen einen nicht unwesentlichen Anteil an den Veränderungsprozessen in Quartieren. Sie sind Anlaufpunkte und ihrerseits Symbole für die Gastlichkeit und Bewohnbarkeit von Quartieren. Das zeigt sich unter umgekehrten Vorzeichen im Shoppingparadies rund um den Hackeschen Markt, wo zwischen den internationalen Brand-Stores fast nur noch Filialen der To-Go-Gastronomie übrig geblieben sind.

Überhaupt unterscheiden sich die Kneipenviertel erheblich von ihrem Charakter. Beispielhaft sollen hier die Gebiete Kastanienallee (Prenzlauer Berg), Oranienstraße (Kreuzberg) und Rixdorf (Neukölln) kurz

beschrieben werden [14]. Betrachtet man die Auszählung der Gastronomietypen in den drei Gebieten (Abbildung 5), so erscheinen die Unterschiede nicht besonders gravierend–die Rixdorfer mögen eben ihre Eckkneipen. Ansonsten ist die Café-Dichte im Prenzlauer Berg etwas höher und der Anteil der Restaurants ebenfalls. Deutliche Unterschiede ergaben sich allenfalls beim Rauchverbot oder der Deklarierung des Lokals als Raucherkneipe: Im Gebiet Kastanienallee war das Verhältnis von Nichtraucher- zu Rauchergastronomie 87:13, in der Oranienstraße 79:21 und in Rixdorf 51:49. Insgesamt ist aber eine solche qualitative Betrachtung nur bedingt hilfreich, um dem gastronomischen Charakter eines Gebietes auf die Spur zu kommen. Dazu wäre Bildung von Kategorien auf Basis des visuellen Eindrucks (Einrichtung, Freisitze etc.) und der dargebotenen Speisen und Getränke notwendig. Um die Unterschiede zwischen den Gebieten zu verdeutlichen, werden im Folgenden ein paar Auszüge aus den Quartiersbeschreibungen im Projekt angeführt.



Kastanienallee Oranienstraße Rixdorf

Abbildung 5: Ausprägung der Lokale in 3 Gebieten

Kastanienallee: Das Quartier ist schon seit einiger Zeit bekannt und ist trotzdem noch nicht „festgefahren". Es hat sich seit den 1990er Jahren entwickelt, ist seitdem in Reise- oder Gastronomieführern vertreten und wird teilweise immer noch als Geheimtipp angepriesen. Die Gastronomie ist eine Mischung aus Tradition und Moderne. Aus DDR-Zeiten haben kaum Lokale überlebt, damit haben Läden den Nimbus einer Institution, wenn sie Anfang bis Mitte der 1990er Jahre eröffnet wurden. Dazu kommen zahlreiche neue kleine und originelle Läden, aber auch vermehrt Franchise-Lokale. Die Angebote im Quartier sind bisher weder ausschließlich auf die breite Masse oder Touristen ausgelegt, noch hoffnungslos überteuert.

Oranienstraße: Nach dem Bedeutungsverlust nach der Wende boomt Kreuzberg wieder. Bisher blieb aber der widerständige Geist im legendären SO36 zu Teilen erhalten. Die gastronomische Ausrichtung der Lokale ist oft nicht eindeutig festzustellen, da die Restaurants aus vielen ethnischen Richtungen etwas anbieten–Cross-Over-Gastronomie. Das Preisniveau im Gebiet schwankt stark, aber die Lokale mit sehr niedrigen Preisen überwiegen klar. Es gibt, nicht zuletzt durch die gründerzeitliche Bebauungsstruktur und die Quartiersgeschichte viele kleine, individuelle Lokale mit alternativen Konzepten und Ideen. Gerade diese Abwechslung stellt für die meisten Besucher die Attraktivität des Gebietes dar. Essen und Trinken kann man in Kreuzberg alles und das zu jeder Zeit. Frühstück um 23 Uhr abends ist genau so wenig ein Problem, wie das erste Bier morgens um 6 Uhr.

Rixdorf: Die Gastronomie ist stark durch ethnische Einflüsse geprägt. Eine touristische Prägung ist heute noch nicht wahrnehmbar und auch die Studentenszene hat keinen sichtbaren Einfluss auf die Gastronomiestruktur. Das Angebot setzt sich aus Imbissen mit überwiegend ethnischer Ausrichtung, Casinos sowie Eckkneipen zusammen, die sich alle samt im Niedrigpreissektor bewegen. Lediglich eine Hand voll Restaurants, die sich überwiegend am ehemaligen Rixdorfer Zentrum–dem Richardplatz–befinden, sorgen für Abwechslung. Durch den vermuteten Zuzug von Künstlern und Kreativen in den nächsten Jahren, werden Veränderungen in der Gastronomielandschaft erwartet.

Anhand der drei Gebiete und der weiteren Ergebnisse des Projekts kann bestätigt werden, dass das gastronomische Angebot das Bewohnermilieu deutlicher widerspiegelt, je weiter man sich von den

[14] Die Angaben beruhen auf Bestandsaufnahmen, die im Rahmen des Projekts „Kitchen Stories" durchgeführt wurden (Studienprojekt 2010/11). Ein interessanter „Nebenbefund" war, dass die offiziellen Zahlen zu den Gastronomiebetrieben (Abbildung 4) in den aktuellen Szenegebieten stark von den erhobenen Betrieben abwichen.

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

touristischen Hauptrouten entfernt. Zentralität ist damit eine wichtige, aber nicht hinreichende Bedingung, damit ein überlokal bedeutendes Ausgehviertel entsteht. Ein Blick auf die (fast) vergeblichen gastronomischen Urbanisierungsversuche am Potsdamer Platz legen die Vermutung nahe, dass die Kombination aus Genius Loci, Raumangebot (Eignung der gründerzeitlichen Ladenlokale), ausgeh-affinen Bewohnern und Standort vorhanden sein muss. Gerade in diesem Zusammenhang sollten aber auch die in den letzten Jahren zunehmend kritisch diskutierten Störungen und Einflüsse durch Touristen (o.A. 2011) differenziert betrachtet werden, denn natürlich ist diese Gruppe ein wichtiger Nachfrager [15]. Gleichwohl haben auch die Medien (Stadtmagazine etc.) einen nicht zu unterschätzenden Einfluss. Die Rolle der Gastronomie als eine zentrale Institution der Alltagskultur–Wohnzimmer, Küche, Treffpunkt, Nachrichtenzentrale etc.–scheint ebenfalls an eine gewisse Bebauungs- und Bevölkerungsdichte, aber auch an Milieus gebunden zu sein. Meist sind weder in expliziten Touristenvierteln, noch in neu entwickelten Wohnquartieren (z.B. Rummelsburger Bucht, Alter Schlachthof) Quartierslokale (im Sinne von hubs) zu finden.

4 EIN CAFÉ WÄRE SCHÖN… ABER OHNE PLASTIKSTÜHLE UND WERBUNG AUF DEM SONNENSCHIRM UND LAUT SOLLTE ES AUCH NICHT SEIN…

Die Rolle der Gastronomie in städtischen Veränderungsprozessen sollte damit nicht unterschätzt werden. Sie wird zwar oft nur als Symbol solcher Prozesse wahrgenommen, kann aber durchaus selbst Entwicklungen forcieren. Wer aber kümmert sich in Städten um die Gastronomie? Gibt es irgendeine steuernde Instanz oder auch nur eine Vorstellung von einer gewünschten Entwicklungsrichtung? Solche Fragen werden in der Regel mit einem Achselzucken beantwortet oder auch mit einem „Gott-sei-dank kümmert sich niemand“. Formal ist natürlich jeder Gaststättenbetrieb erlaubnispflichtig und der Betreiber muss Auflagen beim Ausschank von Alkohol erfüllen. Hinsichtlich der Standorte gelten die Ausführungen der BauNVO, nach der Gastronomie als Einrichtung zur Versorgung des Gebiets auch in Wohngebieten zulässig ist. Eine zentrale Bedeutung kommt damit dem Vermieter zu, der den Mietvertrag mit dem Betreiber abschließt. Da Konflikte mit den Bewohner auf Grund von Geruchs- und Lärmbelästigungen häufig auftreten und die baulichen Anpassungen an Auflagen des Gesundheitsamtes etc. nicht unerheblich sind, scheuen sich nicht wenige Vermieter vor der Neueinrichtung an gastronomische Betriebe zurück. Die erzielbaren Mieten liegen aber häufig über denen von anderen Gewerben, was wiederum ein Anreiz sein kann.

Die Formation und Qualität der gastronomischen Landschaft ist also alleiniges Resultat der Innovationsfreude der Gastronomen und Vermieter, ein Beispiel für das segensreiche Wirken der „unsichtbaren Hand“? Natürlich gibt es planerische Auflagen, aber diese betreffen fast alle den öffentlichen Raum, der sich in letzten Jahren sukzessive zum Gastraum entwickelte. Für die wachsende Zahl der Freisitze wurden in vielen Städten Auflagen erlassen bzw. Gestaltungsvorschriften entwickelt. Je nach Ambition der Stadt fallen diese mehr oder weniger detailliert aus (vgl. Pätzold 2011b). In Berlin ist die vor allem in Kreuzberg und Friedrichshain weit verbreitete Wohnzimmer-Dekoration des öffentlichen Raums mit Flohmarktmöbeln eher unerwünscht, allerdings sind die Kontroll- und Sanktionsmechanismen relativ begrenzt. Noch schwieriger als solchen überbordenden Individualismus in die Schranken zu weisen, ist es allerdings qualitativ hochwertige Gestaltungen zu forcieren und Plastestühle und Sonnenschirmwerbeträger zu verhindern.

Es gibt darüber hinaus immer wieder Vorstellungen, dass die Gastronomie zur Belebung von Quartieren betragen kann. Insbesondere auf Visualisierungen von in neuen Quartieren übernehmen Lokale die Funktion der Urbanisierung des Bildes (vgl. Abbildung 6). Wie die Fläche zu dem passenden Gastronomen kommt, oder ob sich ein solches Lokal an der Stelle wirtschaftlich trägt, steht häufig auf einem anderen Blatt.

Ein klarer Handlungsauftrag an die ordnende Hand der Stadtverwaltung erwächst meist aus Konflikten im Kontext von gastronomischen Betrieben. Von öffentlicher Seite wird allerdings erst bei Beschwerden eingegriffen, vorausschauende planerische Interventionen gibt es nicht, weil eben jeder Betrieb in der Genehmigung einzeln betrachtet wird und kein Monitoring existiert. Insbesondere aus einem raschen Zuwachs an Lokalen kann aber eine Vielzahl von Problemen entstehen. Diese können sich über das gesamte Quartier erstrecken, oder nur punktuell wirken. Nebenwirkungen des Alkoholkonsums, wie Lärm und

[15] „Food structures the tourist day“ (Richards 2002: 11), ohne die Touristen gäbe es nach Schätzungen bis zu einem Drittel Bars, Clubs etc. weniger in der Berlin.

Aggressionen, Behinderung der Gehwege durch Freisitze, Verschmutzungen und hohe Besucherfrequenzen bilden die Hauptstreitpunkte zwischen Anwohnern und Gastronomen in Wohngebieten. Diese sind allerdings häufig gar nicht die alleinigen Verursacher, denn dafür, dass das junge Publikum permanent Bierflaschen als urbanes Accessoire mit sich herumträgt, sorgen eher die Spätshops.

Abbildung 6: München–neues Wohnquartier auf dem Gebiet der ehem. Siemenswerke Obersendling. Das Nahversorgungszentrum soll ein Ort der Begegnung werden. (Quelle: o.A. 2010)

Die kulturinduzierte neue Gastronomie in Neukölln–in zurückliegenden Zyklen in der Spandauer Vorstadt oder in der Simon-Dach-Straße in Friedrichshain –, die wesentlich zur Urbanisierung und zum Attraktivitätsgewinn des Quartiers beitrug, hatte eine starke Rückbindung zumindest zu den „neuen" Bewohnern des Quartiers. Es gibt und gab jeweils für eine Zeit eine Balance, ein Nebeneinander zwischen neuen und alten Bewohnern, aus neuer und eingesessener Gastronomie. Eine ungehemmte „Goldgräberstimmung" führt meist zum Verlust dieser Einbettung in das Bewohnermilieu und damit auch oft zu einer Übernutzung des Quartiers durch das Ausgehpublikum. Daher wäre eine Art Frühwarnsystem [16], das in „trendige" Stadtteile wie z.B. aktuell im Schillerkiez angewandt werden würde, von Vorteil für die Bewohner und könnte eine frühzeitige Moderation von Konflikten ermöglichen. Meist werden planerische Instrumente–wie z.B. ein B-Plan, der die Neuansiedlung von Gastronomie verhindert–erst angewandt, wenn die Entwicklung ihren Zenit erreicht hat. Genauso sollten sich Städte aber auch mit der Frage auseinander setzen, inwiefern eine Stadt gastronomische Hot-Spots braucht, in denen dann eben weniger Ruhe herrscht. Eine Entzerrung der Probleme durch eine gleichmäßige Verteilung der Gastronomie, wie es etwa das Resultat einer Bedarfsprüfung [17] sein könnte, entspricht sicher in keinem Fall den wirtschaftlichen Funktionsprinzipien der Branche–abgesehen davon, dass es den Maximen der Gewerbefreiheit widersprechen würde.

5 SCHLUSSBEMERKUNG

Das kulinarische System einer Stadt aus Essgewohnheiten und gastronomischen Betrieben ist Teil von deren Identität. Angesichts des sukzessiven Verschwindens von Traditionsorten bei gleichzeitiger Zunahme der Systemgastronomie stellt sich die Frage nach den Perspektiven. Insbesondere Städte mit einem großen Potenzial an kreativen Menschen bringen auch immer wieder Innovationen im gastronomischen Bereich hervor. Allerdings findet nur selten eine Rückbettung zu den traditionellen Formen statt. Die hohe Zahl an Insolenzen und Geschäftsaufgaben in der Gastronomie zeigt deutlich die geringe Professionalisierung der Branche und illustriert das Bonmot: „Wer nichts wird, wird Wirt". Allerdings leistet das auch der Ausbreitung von Filialsystemen Vorschub, denn deren wirtschaftliche Konzepte sind meist stimmiger. In Summe ist eine Entwicklung hin zu den Verhältnissen im Einzelhandel denkbar, in der wenige große Player

[16] Vorstellbar als Monitoring – welche Lokale mit welchem Charakter (Ausrichtung, Größe) entsteht wo.

[17] In Wien gab es z.B. bis zur Novellierung der Gewerbeordnung 1973 eine Bedarfsprüfung, die der Regulierung der Ansiedlung von Gaststätten (und anderer Branchen) diente. Wollte ein Unternehmer ein neues Lokal eröffnen, wurde zunächst eine Prüfung vorgenommen, ob wirklich ein lokaler Bedarf bestand. Auf der anderen Seite gab es Vorgaben, dass es zwischen zwei gleichartigen Lokalitäten festgelegte Abstände geben muss. Hintergrund der Regelung war der Schutz der Betriebe vor einer existenzbedrohenden Konkurrenz (vgl. Schulev-Steindl 1996: 69).

den Markt bestimmen und wenige inhabergeführte Lokale für das Lokalkolorit zuständig sind (McCulture-Oases).

Stadtplanung oder Stadtforschung sollten sich dem Thema stärker als bisher annehmen, denn für das Verständnis der Ausprägung von Urbanität ist die Gastronomie ein wichtiger Baustein. Lokale können nicht nur vom Bild oder der gewünschten Wirkung her gedacht werden. Planerisch können natürlich die Erfahrungen im Umgang mit dem Einzelhandel genutzt werden, obwohl es sicher nicht ausreicht einfach Einzelhandel (Schrägstrich) Gastronomie in den Titel von Zentrenkonzepten zu setzen. An ausgewählten dynamischen Orten könnte eine Art lokales Gastronomiekonzept mit Ideen zur Profilierung des Standorts und Maßnahmen für die Umsetzung (Gespräche mit Immobilieneigentümern bis zu Mediationsverfahren) erprobt werden. Wichtiger als die direkte planerische Tat scheint es mir aber, zuvor mehr Wissen zu sammeln, inhaltlich tiefer in das Themenfeld einzusteigen. Welche Gastronomiestruktur hat die Stadt, wer sind die Akteure, welche Trends zeichnen sich ab? Das Wissen von Experten in dem Themenfeld, wie Gastrokritiker oder die Gastronomen selbst (Tamò 2009), liegt weitgehend brach und wird derzeit viel zu wenig genutzt. Und um all die nostalgischen Gefühle bei der Betrachtung verschwindender Orte, wie Eckkneipen, Bistros und Caféhäuser zu operationalisieren, könnte darüber nachgesonnen werden, manche zentralen Institutionen in ihrer Gestalt zu schützen und einen Modus zu finden, deren Betrieb in die Zukunft zu überführen.

1 ABSTRACT

Natural disasters are frequent treats to tourist locations, and have the potential of adversly affecting tourism industry; as one of the world's largest economic sectors. Subsequent to an disasterous event, destinations are faced with not only the daunting tasks of rebuilding infrastructure and communities, but also restoration image of desstination.The present paper aims to define the effects of the disasters, especially earthquakes, on tourism continuity plan and various ways that they affect the operations and viability of tourism in the strucken area. The study focuses on perception changes and negative impact on the "Image of the Destination" after the 2003 Bam earthquake. It also proposes mechanism to develop tourism marketing strategies tallying with internal and external environment in Bam destination.

Achieving the aim, which includes studying the effects of the 2003 Bam earthquake on behavioral intention of visitors to choose Bam destination and proposing Tourism Revival Marketing Strategies by the means of SWOT method, may contribute to the understanding of consumers' affective reactions towards a tourism destination and their influences on future visit intention. In addition, the paper provides a prescriptive list of functions that are dependent to destination or disaster characteristics that can serve as a foundation for revival policy making of Bam in post-earthquake recovery.

2 INTRODUCTION

Tourism, as one of the world's largest economic generating sectors, can affect regions' competitiveness (Wickramasinghe,?). This has made tourism destinations look for the ways to attract more tourists from all around the world. Since potential tourists are exposed to many alternative destinations similar to each other and fiercely competing to get more of the market share, then it is vital for destinations to differentiate themselves from competing ones and to occupy a favorable position in the minds of potential visitors by developing a positive and favorable image (Sahin&Baloglu, 2011). Destination image [1] can be defined as "the perception of a person or a group of people regarding a place (Sahin & Baloglu, 2011)" that can influence tourist satisfaction and their behaviors such as the choice of a destination, the subsequent evaluations, and their future "behavioral intentions [2]" (Chun-yang & Maxwell, 2010). Hence "destination image" is commonly accepted as an important aspect in successful and sustainable tourism development and destination marketing due to its impact on both supply and demand side aspects of marketing. Destination Image can be influenced by several factors including "natural disasters" that may impact on the destination marketability.

According to the World Tourism Organization (WTO, 2003), Natural disaster risk [3] like earthquake is one of the major sources of risk [4] with the potential of affecting tourism destinations (Lehto & et.al., 2008). So recreating and managing an attractive image through marketing strategies is an important key to sustainable success for tourism businesses in quake-hit areas. In this regard, the paper aims to:

[1] image is the sum of beliefs, ideas, and impressions that a person has of a destination(Tasci & Kozak,2006)
[2] The concept of behavioral intentions can be captured by a tourist's willingness to revisit a tourism destination (Andreassen & Lindestad, 1998).
[3] Natural disaster risk refers to the possibility of being involved in a natural disaster event;
[4] Risk is defined as the uncertainty that consumers face when they cannot foresee the consequences of their purchase decisions;

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

- Study of the effect of the earthquake on business continuity of tourism sector & define the various ways that it affected the operations and viability of tourism in the quake-hit areas(with emphasis on Bam);
- Propose mechanism to develop tourism marketing strategies and address feasible solutions in order to re-image destination aftermath a sudden calamity considering theoretical concepts and using analytical techniques and hence restore region competitiveness;

As a result, the paper would contribute to understanding of consumers' reactions towards a tourism destination after a natural disaster (with emphasis on earthquake) and their influences on future visit intention and serves as the foundation for policy making for revival of destinations following the earthquake.

3 THEORETICAL FRAMEWORK

Disaster refers to "situations where an enterprise (or collection of enterprises in the case of a tourist destination) is confronted with sudden unpredictable a catastrophic change over which it has little control (Lehto & et.al., 2008). Disasters that are unavoidable, since they are beyond human control, have been known to transform the reputation, desirability, and marketability of popular tourist destinations (Park & Reisinger, 2010). The occurrence of natural disasters leads to a decrease in tourists' arrivals because of perception change. Therefore, after elimination of the physical hazards associated with natural disasters, the amount of tourists is another significant issue in a tourist destination.

Perception changes can occur after natural disaster occurrences due to their devastating effects because the thought of tourism naturally evokes feelings of enjoyment, pleasure, relaxation, and safety while conversely, disasters arouse distress, fear, anxiety, trauma, and panic in individuals. This can be both serious and long-lasting because of its profound impact on the travel decision-making process (Lehto & et.al., 2008). Therefore subsequent to a disaster, destinations are faced with not only the daunting tasks of rebuilding infrastructure, facilities and communities, but also Image [5] Recovery (Travel destination image).

Where communities have considerable economic dependence on tourism related activities, their vulnerability to crisis occurrence is significantly increased and they need to maintain a positive image of attractiveness for continued success. Hence marketing strategies through business continuity plan can play a central role for economic recovery and changing potential customers' misperception.

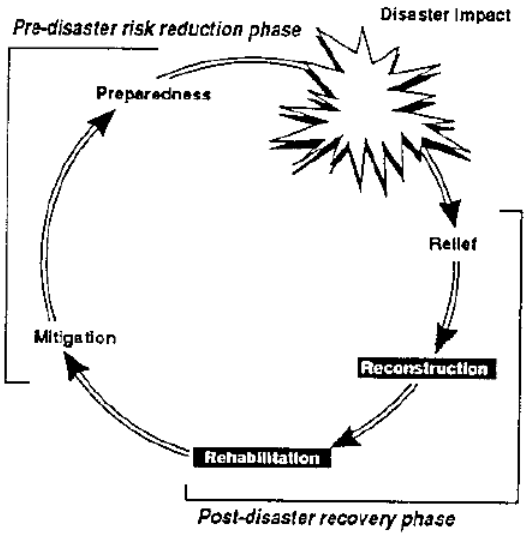

Fig. 1: Disaster management process(UNDRO,1992)

3.1 Business continuity plan concept

Disaster management for tourism has often focused on the post-disaster recovery phase. The International Strategy for Disaster Reduction (ISDR) defines "Recovery" as the "decisions and actions taken after a disaster with a view to restoring or improving the pre-disaster living conditions of the stricken community,

[5] Image is an attitudinal construct representing an individual's beliefs, feelings, and general impressions about an object or destination (Lehto, Douglas & Park, 2008).

while encouraging and facilitating necessary adjustments to reduce disaster risk". Recovery is therefore about shifting focus from saving lives to restoring livelihoods (UNDP,?).

Reconstruction and rehabilitation are considered as main steps of "disaster recovery phase" (Fig.1). These steps are focused on activities that are devoted to restoring the condition to normal. Reconstruction process is associated with the immediate post-disaster activities in order to help affected population for restoring them to normal lifestyle. On the other hand, rehabilitation is the next step after reconstruction and ongoing long-term development. This step not only helps economic revitalization, but also promotes the business continuity (UNDRO,1992).

Disaster Recovery Plan (DRP) and Business Continuity Plan (BRP) often used interchangeably in various texts. Whereas Recovery Plan is used for retrieval of systems and infrastructure components in a specific time series, Continuity Plan has more expanded scales and scopes, which is associated with determination of components and functions of recovery. Business continuity plan can be considered as an iterative process in order to determine mission of critical business function, policies, processes, plans, procedures which are needed for continuation of activities on unforeseen events (Nickolett, 2001). Instead of the focus on rebuilding of infrastructures or hotels, Business Continuity Plan emphasis on re-launching of different scale of touristic businesses and people who are the target of tourism [6] (NZIER,2011).

Proposed activities for the revitalization of long-term business continuity are (Nickolett, 2001):

- Recognize the importance of the tourism market in region and its impact on tourists in order to minimize the effects of reduced demand;
- Determination of the functions of the tourism sector should return to normal
- Preparing recovery promotional programs
- The beneficial evaluation of system through: (1) Speed of return to the former condition, (2) Rates of return to former condition, (3) Amount of increased resistance of buildings against next disasters

3.2 Destination Image concept

It is commonly recognized that destination image [7]-"the sum of beliefs, ideas, and impressions that a person has of a destination (Crompton, 1979; Kotler & et.al., 1993)"- is an important aspect in successful destination marketing; so one important aspect of destination marketing is "destination image management". Several researchers have studied destination image as an independent variable influencing several consumer behavior variables, such as destination choice, decision-making and satisfaction. Due to the importance of destination image in terms of its effects on tourist behavior, researchers have been trying to identify the determinants that define, modify, and strengthen this construct (Tasci & Gartner, 2007) in order to minimize the "gap that may be between "desired brand image [8]" and "perceived one [9]"(Lopes, 2011)" undermining the continuity of the destination business.

Promoting destination image requires knowing about image formation agents or components. Development of the image of a tourist destination is based on the consumer's rationality and emotionality, and as the result of the combination of two main components or dimensions. Beerli and Martin (2004) suggested that "affective" and "cognitive" image together leads to an overall image, resulting either in a positive or a negative image about the destination. Cognitive image is determined by beliefs and knowledge about a place,

[6] Proposed activities for capacity building in communities based on the following steps are (Nickolett,2001):

- Planning (readiness) phase including preventive activities and increase capacity;
- crisis management readiness program including evaluation of effects due to disaster preparedness management and disaster management;
- The step that response during and immediately after the accident including effective contingency plans;
- Long-term disaster recovery step;

The first three steps are outside of the subject of this study and only the final step will be considered.

[7] According to the World Tourism Organization, the image of an object or situation is defined as (Lopes, 2011) the artificial imitation of the apparent form of an object; Similarity or identity with the form (e.g.: art or design); Individual or collective ideas about the destination.

[8] Desired image is related to how the company wants to be perceived by the target segment (Lopes, 2011).

[9] Perceived image is about how the target segment sees and perceives the brand through a brand image study (Lopes, 2011).

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

whereas affective one is all about feelings towards that destination [10]. Overall tourism destination image has an indirect impact on "behavioral intentions". Also destination image literature reveals three sources of image formation factors (Table. 1):

- Supply-side or destination that refers to destination marketers engage in promotional efforts to establish a positive image or to change an existing image.
- Demand-side or image receivers that is related to their characteristics.

Disaster management literatures show a relation between "perceived influence of natural disasters" and "travel risk [11] acceptance" depending on the type of travel risk and individual tourists' characteristics(such as nationality, gender, Age, marital status, education, employment status, annual income & travel companionship). The rapid increase in natural disasters makes many tourists perceive that travelling around the world is dangerous and risky (Park & Reisinger, 2010). Park and Reisinger (2010) study about "perceived influence of earthquake on travel by demographics" shows that:

- Asian people perceived a greater influence of the earthquake on travel than other nationality group. American and the European travelers feel more comfortable about earthquake.
- Female tourists perceive a greater influence of earthquake than male tourists.
- Low-income tourists are more concerned about travel when the risk of natural disasters is high; probably because they have a relatively lower travel budget and are more concerned about the extra spending and financial losses when involved in a natural disaster accident.
- Tourists with low educational attainment perceive a greater influence of natural risk than high and middle-educated tourists perhaps because they have relatively less social skills and are less confident about their vacation choice. As a whole educated tourists perceive lower risk.
- Family and friend tourists perceptions of natural disasters are stronger than alone people.
- Independent or autonomous as intermediate factors between demand and supply side that consist of information sources such as news articles, educational materials, movies and etc.

Autonomous agents create general knowledge about a destination, and are out of a destination's immediate control (Tasci & Gartner, 2007)". Gartner and Shen (1992) assert that in the case of a disastrous event, distant countries, for which lack of knowledge exists, the autonomous agents, such as news reports, articles, and movies are able to cause a more dramatic change in image due to their high credibility and ability to reach mass crowds than destination-originated information. The intense and sometimes sensational media reporting could play a significant role influencing in consumers' cognition about a destination after natural disasters (Lehto & et.al., 2008).

image formation factor	Attribute of image factor	location	Image formation means
Supply side	dynamic/ controllable	Destination-oriented	Marketing strategies
Independent	semi-dynamic/ semi-controllable	intermediate	Information sources (educational materials, news, movies, word of mouth, user groups)
Demand side	dynamic/ uncontrollable	Perceiver Characteristics	Socio-demographics, psychologics, tourist's motivations, cultural values, experience and prior visit, attitude, needs

Table.1: Destination image formation factors(Author's analysis based on (Tasci & Gartner, 2007))

[10] Cognitive evaluation has an indirect influence on the overall image through the affective evaluation. A common agreement among researchers seems to point out that affective evaluation depends on cognitive assessment while the affective responses are formed as a function (Chun-yang & Maxwell, 2010).

[11] Travel risk is defined as the possibility of experiencing a danger while engaging in travel or the consciousness of security and knowledge of the likelihood of damage during travel (Park & Reisinger, 2010).

4 RESEARCH METHODOLOGY

This paper provides a framework for creating business continuity plan. Due to the existing definitions of business continuity plan presented in the previous section, using a strategic approach is the necessary elements to promote the business continuity plan. Strategic planning is possible in each field by answering the following four basic questions (Brewster, MTP, 2005):

- Quiddity of the current situation;
- Quiddity of probable outcome if failure to do corrective action;
- Quiddity of desirable long-term future of the community;
- How to achieve this desirable future and required actions to achieve.

Process of business continuity plan in this research would have the following steps, with focus on the final step of business continuity plan and adoption of strategic planning methodology:

- The first step: Analyzing the situation and current and future trends (identifying the opportunities, constraints and limitations) by foreseeing, if failure to do corrective action (Nickolett, 2001). Identifying the importance of tourism marketing in the region and the effects of the disaster occurred, can be done using statistical quantitative methods. The output of this step plays a major role in making the plan in next steps.
- The second step: Drawing out the desirable future through goals setting;
- The third step: Making improvement strategies and programs for regeneration; at this step, key functions would be identified and risk management prescribed. The output of this step would directly lead to business continuity plan.

There are four types of relationship between development and disaster(Fig. No. 2). Approach of this paper in making strategies is transitioning of phase (--) to phase (- +) to reduce the negative impact of disasters on development - caused by the waste of resources and as a consequence, disruption of economic growth, disruption of programs and destabilization - and to convert it into an opportunity for development.

image formation factor	Attribute of image factor	location	Image formation means
Supply side	dynamic/ controllable	Destination-oriented	Marketing strategies
Independent	semi-dynamic/ semi-controllable	intermediate	Information sources (educational materials, news, movies, word of mouth, user groups)
Demand side	dynamic/ uncontrollable	Perceiver Characteristics	Socio-demographics, psychologics, tourist's motivations, cultural values, experience and prior visit, attitude, needs

Fig. 2:The types of Relation between development and disaster (1991Stephenson,)Reference: (1991Stephenson,)

The ultimate success of a strategic business continuity plan is largely dependent on the accuracy of an effective situational assessment (Wickramasinghe,?). SWOT technique is one of the best and the simplest in situational assessment. So, Competitive strategies for tourism destinations would be offered by use of strategic assessment matrix according to internal capabilities and insufficiencies and external factors. The proposed model positions the destination's strengths and weaknesses and permits the identification of opportunities to improve Bam destination competitiveness.

The difference between this paper and other researches in this field is in making business continuity strategies, referring to the destination image concept. Accordingly, the situational assessment is done using the SWOT technique, according to the constituent elements of destination image. Demand-related and Intermediate factors will be considered as external factors, outside the system control (opportunities and threats). Also, in the supply-related factors, strengths and weaknesses of the system are considered. In the business continuity plan, strategies are following maximum use of available strengths and opportunities and confronting weaknesses and threats ahead.

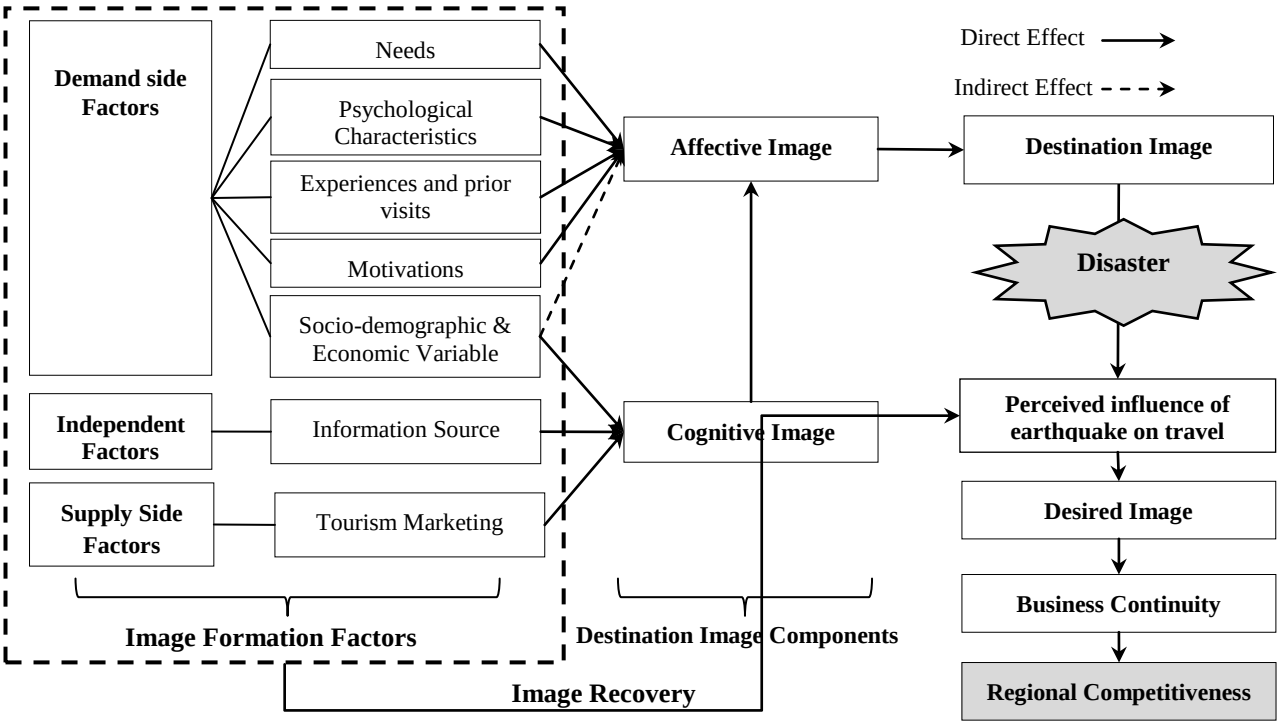

Fig. 3: Conceptual framework of the study based on destination Image concept

5 CASE STUDY

One of the ancient urban centers in Iran is located in Bam City with about two thousand five hundred years old. Due to be at the crossroads of important trade routes including Silk Road and Spice Trade Road and known for the production of silk and cotton garments, this city was of strategic importance. The cultural landscape of Bam and its Citadel, which is made entirely of mud bricks, clay, straw and the trunks of palm trees, is a significant symbol of the interaction of man and nature in a desert environment.

Bam tourism industry, a large income generating industry prior the 2003 earthquake, was an important driving force of regional economic development contributes to the employment generation and to the enrichment of many related industries.

After the earthquake, this industry was faced with a severe disorder. 90 percent Destruction in the citadel, as a showcase of Iranian architecture, due to the earthquake led to lose its place among the world's tourist attractive poles for several years; Although after the earthquake, citadel and historic perspective of Bam were simultaneously recorded on the UNESCO World Heritage List and the List of World Heritage in Danger, during the twenty-seventh session of the UNESCO World Heritage Committee, and placed in the center of international attention. Bam earthquake, despite all its' damages to the tourism sector, has made the largest international restoration workshop in this ancient city, due to the widespread absorption of foreign experts, including Japanese, German and Italian along with Iranian experts. Also, this earthquake has raised supports, credits and international attentions for restoration of the citadel.

5.1 Analysing the impact of Bam earthquake on tourism (situational analysis) and outlining the desire future

The Bam earthquake was centered approximately 10 km to the southwest of Bam. In terms of human cost, this earthquake ranks as the worst recorded disaster in Iranian history. Damage was concentrated in a relatively small area, of roughly 16km radius, around Bam-a tourist destination on the old Silk Road- famed for its 2,500 year old citadel Arg-e-Bam. The historic city center and fortress ruined. According to field reports, up to 95% of buildings collapsed within the ancient Bam citadel (Fig. 4).

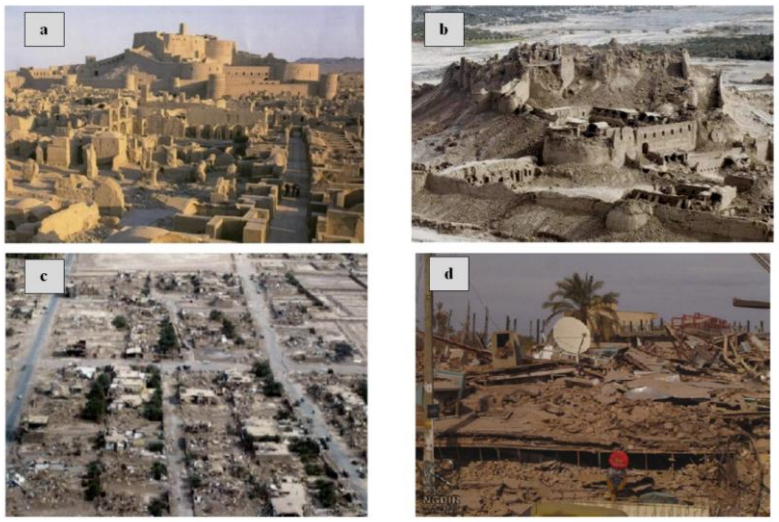

Fig. 4: Photo mosaic of the Bam Citadel and surrounding urban districts. (a) The Citadel before the earthquake struck; (b) the Citadel after the December 26, 2003 earthquake; (c) residential city blocks razed by the earthquake; (d) mud-brick houses reduced to rubble; Reference: (Adams and et.al. ?)

Also, studying the amount of active units by type and location status, based on official statistics published by the Statistical Center of Iran, shows the 88 percent destruction and 11 percent damage to the hotel and restaurant units and also 82 percent destruction and 16 percent damage to business units in Bam after the earthquake in 2003.

It is important to recognize that the impact of such a natural disaster affects not only the immediate communities, livelihood of local people, disruption of natural and built environment which are all important stakeholders at any given destination, but also the minds of the potential travelers. The later will need great attention in the recovery process.

Bam Citadel, one of the greatest monuments of Iran, was almost destroyed by the devastating earthquake on the morning of December 26, 2003. Since this year, in a period of several years, there was no registered visitor, according to official statistics published by the Cultural Heritage, Handicrafts and Tourism Organization of Kerman province.

The 2003 earthquake in Bam caused directly a 100 percent drop in tourist arrivals because of the formation of negative destination image. The ruinous Bam earthquake and the risk of another earthquake have made many tourists perceive that travelling to that region is dangerous and risky. This has caused a sharp decline in region's tourism income and has undermined the continuity of the destination business in future (Fig. 5).

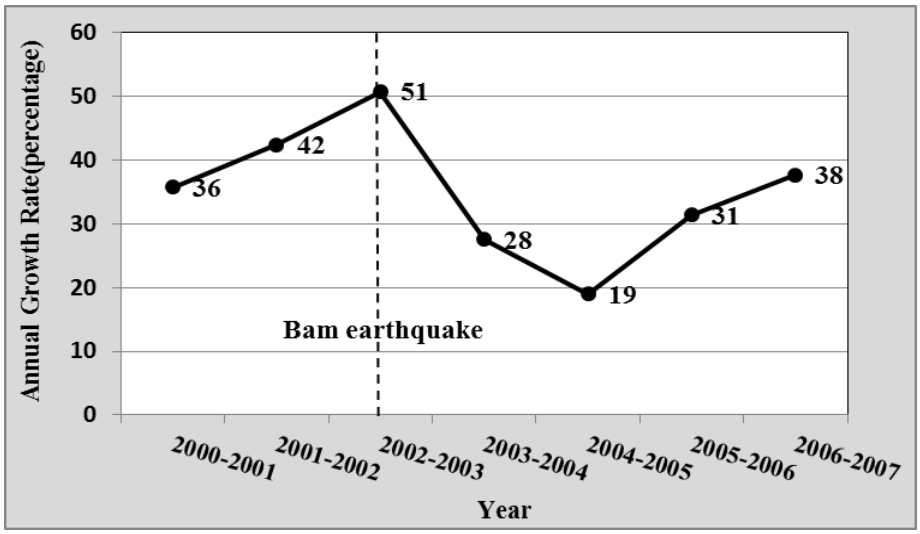

Fig. 5: Average annual growth rate of Bam tourism sector income before and after the 2003 earthquake due to authors analysis based on available official statistics (census data)

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

So due to the importance of destination image in terms of its effects on Bam's tourist behavior and with acceptance of problem solving approach, the main goal of the Bam Business continuity plan is devoted to speed up recovery of the tourism sector by restoring traveller confidence in the region so that visitor flows resume as quickly as possible.

5.2 Developing tourism revival strategies

Tourism revival marketing strategies, for establishing a positive desired image or changing the existing image, would be presented in three main parts based on paper's methodology and situational analysis as the result of confronting internal and external factors (Table. 2): Destination-oriented or supply-side revival strategies, independent or intermediate revival strategies and perceiver-oriented or demand-side revival strategies;

(1) **Destination-oriented or supply-side revival strategies**

- Ensuring the sustainability of tourism products in the form of diversification and changing nature of tourism, after the disaster.

Post-earthquake development offers the opportunity to correct the mistakes of the past and make the re-emerging destinations among the best in the world in terms of environmental conservation and community involvement in the planning process. It also offers the chance to rethink and diversify the product offer so that destinations become more competitive in the global marketplace (WTO, 2005).

- Promoting participatory approaches and decentralized planning and programming for recovery;

As one of UNDP strategies, planning, programming and execution of local level recovery initiatives does not require the complex and time consuming impact and feasibility studies and planning processes of national level long-term reconstruction planning, enabling recovery activities to begin as early as possible after the disaster. Strengthening of community groups to stimulate involvement in planning process also makes them confident.

- Increasing economic benefits and employment opportunities for the local community and hence sustainable tourism.

Recovery activities should contribute to improving the living conditions of the affected communities and sectors through the revival of production (agriculture, industry), trade and services, and the creation of income-generation/employment opportunities. The goal should go beyond the simple restoration of pre-disaster levels, but aim towards the creation of more sustainable livelihoods for the population. This could be met by improving the living conditions of the affected communities and sectors in Bam through (WTO, 2005):

- employing local staff wherever possible by retraining programmes;
- The earthquake disrupted the employment of many of people. Retraining programmes are needed to help them find new jobs or to help update their skills while waiting for their former jobs to become available again. Likewise, new employees for the tourism industry need to be trained to replace those who perished and make them more efficient and competitive in order to raise service standards. Building leadership capacity and counseling for those in the tourism sector are also needed (WTO, 2005).
- helping small tourism-related businesses and employees survive the recovery period; Small and medium-sized tourism businesses in the Bam destination, such as restaurants, handicraft producers, have less access to recovery funds than large corporations, so assistance is urgently needed. In addition, many of these enterprises are family-based and may have lost family members in the earthquake. Technical and financial support is needed to help them resume business and increase competitiveness. In this thematic area one policy could be identification and assistance to small enterprises damaged by earthquake through grants and micro-financing.
- Making coordination plan;

Coordination commands would be prepared in this strategy. In reality, multiplicity of actors, national and international, requires improving/maintaining coordination; hence, promoting and initiating recovery activities have to avoid duplications and gaps and to optimize the resources available for sustainable

recovery. This could be satisfied through conceiving recovery as an integral part of ongoing developmental process at all levels: national, regional, and local.

- Making review, refine and maintenance plan in order to update and increase the usefulness of business continuity plan. Since business continuity plan such as cyclical process of strategic planning, requires continues update;
- Making Risk Management plan

To make Bam tourism destinations safer and more secure, risk management analysis will be conducted, with special attention to clear communication channels and increase cooperation between the tourism sector and public safety authorities. Training workshops will also be offered in risk and reputation management.

(2) **Independent or intermediate revival strategies**

- Capacity building to face effectively with negative traveling propaganda for tourism destination and recovering the confidence of the marketplace;

Clear, detailed and abundant information is a key factor to recover the confidence of the marketplace. Effective communications is needed on many different levels: government; business; tour operators; travel agents; the media; and the public. Special attention needs to be paid to travel advisories. The use of special events and development of new products is also needed to help speed the recovery process. In this thematic area policies could be (WTO, 2005):

- Organizing familiarization trips for journalists and tour leaders and
- hosting "hallmark" or "mega" events, involvement with travel writers
- Provide communications expert to help look for and disseminate positive news throughout the recovery period;
- Provide financing to enhance tourism website and email newsletter;
- Ensuring a stable integrated flow of information to consumers and operators.

Prevention of the malicious rumors spread, that cause harm to destination image, requires sustainable unified information flow for users and beneficiaries and making connection between publc and private actors, national and regional organizations and other groups. This could be met tough capacity building in governmental institution for facing effectively with negative advertisements against destination by means of:

- Establishing media center responsible for correct informing;
- Provision of effective contingency plans in order to damages controlling and informing interest groups;

(3) **Perceiver-oriented or demand-side revival strategies**

From a crisis management perspective, a crisis recovery system that is built upon better understanding of consumer psychology in the face of environmental changes can be more effective than one that is built upon suppliers frame of mind. In this relation Bam demand-side revival strategies are:

- Facilitating attraction of tourists all around the world that perceive less risk and are less concerned about travel when the risk of natural disasters:
- Trying to Absorb and motivate American and European visitors that feel more comfortable about earthquake.
- Applying attractive actions for alone and high educated visitors.
- Motivating high income visitors with lower risk perception.
- Meeting these strategies require recognition of their interests in defining tourism product; furthermore improving the diversity of tourism infrastructures and the quality of tourism facilities and services that is necessary for these groups of tourists.
- Changing nature of tourism to meet short term goals and business continuity in the age of reconstruction.

In this relation, disastrous tourism seems effective. Disaster tourism is used to designate tourism to sites of natural disasters (Robbi, 2008). Pottorff and Neal (1994) in their discussion of marketing implications for post-disaster tourism destinations posited that disasters sometimes actually attract visitors that may be curious about the damage left behind. This approach to utilize visitor's mass convergence tendency could be effective to tourists who are driven by novelty, curiosity and competence.

- Persuading visitors about destination safety and restoring confidence in the minds of potential visitors. Destination marketers should therefore ensure that messages communicated after the disaster are effective at persuading visitors that the destination is safe. Additionally, marketing messages should serve to defray any misinformation prevalent in media which has the potential to significantly affect the rate of economic recovery for the destination (Lehto, Douglas & Park, 2008).
- Presenting Bam's cultural landscape and enhancing the visitor experiences. This could be done through:
- Preparing educational programs;
- Organizing cultural programs such as local festivals and exhibition for both the local domestics and international tourists;
- Developing, publishing and marketing interpretation materials preferably unified in product line and quality with Bam identity (such as souvenir guide book, brochures and information leaflets;
- Improving site presentation and interpretation;

6 CONCLUSION

As shown in this paper, after 2003 earthquake and in the post recovery phase, Bam has benn facing not only with daunting task of reconstructing, but with rehabilitation and as one of the most important parts, image restoration. Devastated Bam's destination image caused serious problems in tourist viability due to rigorous earthquake influence on behavioral intention of visitors. Bam, as a city with considerable economic dependence on tourism related activities, needs to look seriously for feasible solutions in order to re-imaging destination and hence restoring region competitiveness and it's viability; So this paper tried to promote a revival strategies framework for continuing business after earthquake by means of SWOT situational analysis in the form of three image formation factors; since linking the perception changes of the traveler to the destination is important for destinations to effectively manage image formation and change.

As a result, this paper may contribute to the understanding of consumers' affective reactions towards a tourism destination and their influences on future visit intention and by providing a prescriptive list of functions dependent to destination or disaster characteristics can serve as a foundation for revival policy making of Bam in post-earthquake recovery. It also serves as a call for active research into issues relating to the effects of natural disasters on the consumers of the tourism product in the affected areas due to the importance of managing image and image recovery after a crisis situation; Since From a crisis management perspective, a crisis recovery system that is built upon better understanding of consumer psychology in the face of environmental changes can be more effective than one that is built upon suppliers frame of mind. So cognition of differnces between feasible solutions for revival marketing strategies based on tourists with different socio-demographic background is necessary.

Internal factors		
Image factors	**Weaknesses**	**Strengths**
Supply Side Factors	• The possibility of delisting of Bam by UNESCO because of Inability to control the informal settlement; • prolonged reconstruction because of shortage of credit among other national projects; • The 15-year period in the recovery projects due to the sensitivity and complexity of the reconstruction of Bam Citadel; • Disregarding of national institutions to the issue of tourism and crisis; • Lack of the awareness of the rebuilding process and the situation in Bam after the disaster; • Lack of proper policies in order to take necessary scientific and financial assistance of UNESCO for recovery projects; • Under-developed tourism and related facilities appropriate for high income and educated national and international visitors; • Poor preparation for facing another earthquake; • Lack of Active Tourism Controlling Authority; • Inadequate Marketing promotion strategies; • Absence of systematic management of the territory and poor Coordination among local, regional, national and supranational tourism authorities; • Under-developed tourism and related facilities appropriate for high income and educated national and international visitors; • Poor preparation for facing another earthquake; • Lack of Active Tourism Controlling Authority; • Inadequate Marketing promotion strategies; • Absence of systematic management of the territory and poor coordination among local, regional, national and supranational tourism authorities;	• Existence of dependency, economic and cultural sense of belonging and interaction with residents and natives of Bam; • Attractiveness of Bam as an outstanding example of a fortified settlement and citadel in the Central Asian region, based on the use mud layer technique combined with mud bricks; • Touristic attractions of Bam Citadel as promoting economic growth; • High degree of authenticity and integrity in Arg-e-Bam in spite of the severe damage incurred during the December 2003 earthquake; • Presence of an ensemble of exceptional testimonies to the development of settlements dating back to Neolithic times; • High degree of authenticity and integrity in Arg-e-Bam(citadel) in spite of the severe damage incurred during the December 2003 earthquake; • Presence of an ensemble of exceptional testimonies to the development of settlements dating back to Neolithic times;
Independent Factors	• Lack of media coverage and Problem with inquisitive visitors;	-
Demand side Factors	-	-
	External factors	
	Opportunities	**Threats**
Supply Side Factors	• Bam registration on the UNESCO World Heritage List and the List of World Heritage in Danger after the earthquake, in 2004, as a factor to absorption of international attention; • Creating opportunities to Modernize and develop of regional economic basis; • Opportunity to correct the mistakes of the past and making fundamental changes; • Having chance to rethink and diversify the product offer so that destination becomes more competitive in the global marketplace; • Drawing the attention of the world to Bam and its cultural landscape as opportunities for economic development of the region; • The inscription of Bam and its cultural landscape on the world heritage list; • Revealing much of the archaeology in the Bam area after the 2003 earthquake; • Attraction and mobilization of international scientific, technical and financial aid and credits for renewal of historic buildings and sustainable development of tourism through UNESCO, Japan and Italy; • Bam Citadel as the largest international workshop for historic restoration experts & scholars and archaeologists from around the world; • Creation of the potential for tourism development with natural crises; • Appearance of the skills and new job opportunities related to reconstruction of the city;	• Destroying about 90 percent of the citadel and Impossibility of visiting from all parts of it; • Increase in population and social instabilities caused by migration of natives and immigration of non-native people to the city; • Reduction in safety and environmental comfort as a factor to outgoing of local capital; • Reduction in regional competitiveness ability; • Formation of negative perceived image in potential travelers regarding safety and security Instability and as a consequence sudden fall in the number of visitors; • Increase in unemployment rate with finalization of post-earthquake reconstruction; • Existence of open work sites where relatively few structures have been completed;
Independent Factors	• Increasing global attention to Bam area through the media;	• Lack of real knowledge between autonomous agents about Bam's situation that has caused a more dramatic change in image; • Negative Messages communicated after the disaster by high creditable medias have access to mass crowds;
Demand side Factors	• Less influence of the earthquake on American and European visitors' travel intention; • Less influence of earthquake on high-income tourists' intention; • Lower earthquake risk perception in educated tourists; • Lower perceptions of natural disasters in alone people; • Presence of visitors that are curious about the damage left behind the disasters;	• Perception change, specially in low-income visitors, Asian visitors and low-educated tourists; • Presence of further seismic action that contribute to a feeling of insecurity and uncertainty;

Toward Mixed-Use Communities by Transit-oriented development (TOD) in the United States

Hanieh Shamskooshki

(Hanieh Shamskooshki, Urban and Regional Planning M.A., Faculty of Architecture and Urban Planning, Sh.Beheshti University, Tehran, Iran, Hanieh.Shams@yahoo.com)

1 ABSTRACT

Increasing social and environmental damages is certainly related to current urban forms. The linkage between low-density, separated-use development and increasing travel is undeniable. In order to recent concerns about today needs of cities and their future, Transit-oriented development (TOD) has rapidly emerged as one of the popular urban planning paradigm in the world. It seeks to maximize access to mass transit and non-motorized transportation with centrally located public transportation system surrounded by relatively high-density commercial and residential development. Therefore this strategy can improve quality of life in urban areas and encourage more compact development. In essence, TOD means the creation of denser, mixed-use activity nodes connected by high quality public transportation. TOD can enhance quality of life in urban areas at the same time provide benefits for individuals, communities and developers.

Transit-oriented development in the United States has gained wide acceptance among all of the policies and strategies that the federal and local government have adopted to respond to challenge of rapid social, environmental, economic, technological and cultural changes which citis are facing. To understand more about Transit-oriented development, this study presents details about definition and typologies. It also included key actors involved in TOD projects and their goals. Current scope of TOD and implementation tools in the United States are being discussed and the following key issues are associated with the recognition of TOD benefits and barriers in the United States. In order to creat compact development and mixed-use communities according to key TOD components, some strategies about implementing TOD in the cities of the world and specially the United States follow at the end.

2 INTRODUCTION

2.1 Definition of Transit-oriented development

There is no universally accepted definition of TOD because development that would be considered dense, pedestrian-friendly, and transit-supportive in a middle-size city in the Midwest would be viewed quite differently in the heart of Manhattan or the District of Columbia. Some authors use the term TOD quite liberally, referring to any form of "transportation-oriented¬¬¬ development", including bus and rail oriented development as well as development along freeways (Lefaver,1997). This review takes a narrower definition, referring to development near or oriented to mass transit facilities.

The following represents a sample of TOD definitions found in the literature:

- "Development within a specified geographic area around a transit station with a variety of land uses and a multiplicity of landowners" (Salvensen,1996)
- "A mixed-use community that encourages people to live near transit services and to decrease their dependence on driving" (Still,2002).
- "Moderate to higher density development, located within an easy walk of a major transit stop, generally with a mix of residential, employment, and shopping opportunities designed for pedestrians without excluding the auto. TOD can be new construction or redevelopment of one or more buildings whose design and orientation facilitate transit use" (California Department of Transportation,2001).

Less universally subscribed to, though found in some definitions of TOD, are the following traits:

- Compactness
- Pedestrian- and cycle-friendly environs
- Public and civic spaces near stations
- Stations as community hubs (Cervero,2002,P5)

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

Traditional Transit-Oriented Development is designed so that residents can live, work, shop, and recreate in the same area. A TOD resembles a small, walkable neighborhood focused around a regional transit station. The transit stop (rail or bus) is the main focal point of the development and is immediately surrounded by high-level densities of commercial, office, and residential properties. The transit stop serves as the regional connection for the development as well as the connection to the urban center to which people commute. To maximize access and land-use efficiency, the transit stop is connected to vehicular, bicycle, and pedestrian traffic. As one walks further from the transit center, the building density decreases and becomes more uniformly residential. Density still remains higher than typical suburban densities to centralize the population and maximize land uses (Rappahannock Rapidan Regional Commission,2006).

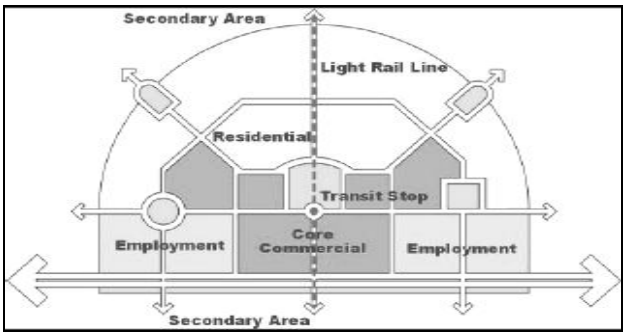

Fig. 1: Transit-oriented development Model

2.2 Transit-oriented development Typologies

City planners used a TOD typology to indicate the desired mix and intensity of development at specific transit stations and to show that not all stations will be built in identical patterns. This helped residents understand that their existing neighborhoods would change only modestly and signaled to developers where the city planned to support intensive, new TOD (An Issue Paper of the American Planning Association, 2007). The following table describes TOD typologies that should be considered in the United States:

Typology	Characteristics
Urban-Downtown	• Civic and cultural centres • Multiple transit lines and transfer points
Urban Neighbourhood	• Moderate to high density (>30 du per acre) • Extension of downtown street system • Shopping along a central street • Key crossroads • Usually more affordable housing • High pedestrian activity • Sometimes historic districts adjacent to downtown
Suburban Neighbourhood	• Opportunity for higher density and redesign • More commuter focused • Some retail and commercial in existence, but limited
Neighbourhood Transit Zone	• Mostly residential • Some shopping with limited retail or office space
Commuter Town	• Freestanding, with commuter service to downtown • Station area may be a “main street” with retail, offices, residential • Supports peak hour service but needs parking
University Centre	• Pedestrian and bike environment • Needs sidewalk and shuttle bus connectivity to student activity • centres, sports complex and libraries
Regional Town Centre	• Shopping centre, with ample auto access • Will require careful connectivity • Land use changes will likely be needed • Infill opportunities to make the area 24 hour

Table 1: Transit-oriented development Typologies

2.3 TOD Actors and Their Goals

A number of possible goals associated with each of the actors involved in TOD projects are shown in Table 2. Many of these goals-such as maintaining a high level of station parking and maximizing pedestrian access to the station-conflict with each other. Even a single actor may have goals that are incompatible, or at the very least, that require careful balancing if they are to be reconciled. Many of the incompatibilities reflect the basic tension between place and node.

Actor	Possible Goals
Transit Agency	• Maximize monetary return on land • Maximize ridership. • Capture value in the long term
Riders	• Create/maintain high level of parking • Improve transit service and station access • Increase mobility choices • Develop convenient mix of uses near station
Neighbours	• Maintain/increase property values • Minimize traffic impact • Increase mobility choices and access to transit, services and jobs • Enhance neighborhood livability • Foster redevelopment
Local Government	• Maximize tax revenues • Foster economic vitality • Redevelop underutilized land
Federal Government	• Protect “public interest” and set limits on federally-funded investments
Developer/Lender	• Maximize return on investment • Minimize risk, complexity • Ensure value in long term

Table 2: TOD actors and their goals

3 TRANSIT-ORIENTED DEVELOPMENT IN THE UNITED STATES

Transit-oriented development (TOD) has attracted interest as a tool for promoting smart growth, leveraging economic development, and catering to shifting market demands and lifestyle preferences. TOD is viewed and defined differently throughout the country, with its most common traits being compact, mixed-use development near transit facilities and high-quality walking environments. Joint development is a form of TOD that is often project specific, taking place on, above, or adjacent to transit-agency property. The results of a national survey suggest that the principal aim of TOD and joint development is to boost ridership and, thereby, boost revenue income. Community economic development and broader smart-growth agendas are secondary objectives.

A rich mix of TOD can be found across America today, and all indications are that the numbers and types of TOD will grow in years to come. Over 100 TOD projects currently exist in the United States, found overwhelmingly in and around heavy-, light-, and commuter-rail stations. While typically nodal in form, TOD corridors have taken or are beginning to take shape. In addition, over 100 joint development projects today exist on, above, or adjacent to U.S. transit-agency property. The most common joint development arrangements are ground leases and operation-cost sharing. Most often, joint development occurs at rail stations surrounded by a mix of office, commercial, and institutional land uses. However, examples of public-private joint ventures can be found among bus only systems as well, normally in the form of joint intermodal transfer and commercial-retail space at central-city bus terminals.

Many voices shape the practice of TOD in contemporary urban America. A multi-layered, sometimes complex institutional and political environment has evolved that ensures accountability and instills a degree of responsibility and fairness into the decision-making process, but this environment can also form roadblocks to implementation.

The spectrum of participatory roles transit agencies can take on are wide-ranging— from roles as modest as providing technical guidance (e.g., transitsupportive design guidelines) to those as ambitious as being the self-anointed lead developer. Most transit agencies get involved in land-use affairs (broadly defined); however, they generally limit their involvement in TOD matters to interagency coordination. Most TOD

work concentrates on public outreach and education. A common method for drawing public input into the TOD planning process is organizing design charrettes—ranging from multi-day workshops led by professional designers to facilitated community discussions (inspired by the successes at the Pleasant Hill BART station in the San Francisco Bay Area and along the Wasatch Front under the guidance of Envision Utah). Local governments wield considerable control over TOD outcomes through zoning ordinances and building codes. Some states, notably California and New Jersey, have sought to jump-start TOD through transit village initiatives that critics view as mere window-dressing since little funding support is provided.

4 TOD IMPLEMENTATION TOOLS IN THE UNITED STATES

TOD implementation ideally starts with a vision, cultivated from broad-based public input, and proceeds to strategic station-area planning backed by appropriate zoning as well as policy incentives and regulations. Around half of surveyed transit properties in the United States state that their regions have a vision, policy, or plan in place that embraces TOD principles.

Overlay zones are the most common means of controlling land uses, densities, and site designs of TOD. Overlays, often introduced on an interim basis to head off automobile-oriented uses that might compromise a TOD, usually specify desired land uses as-of-right, such as housing and convenience shops. For urban TODs, densities of 20 to 30 dwelling units per residential acre and FARs of 1.0 and above are not uncommon. Some of the more progressive TOD zoning districts also lower automobile parking requirements and sometimes even set bicycle parking mandates.

The national survey of U.S. transit agencies revealed that besides standard zoning, the tools most frequently used to leverage TOD are funding for station area planning and ancillary capital improvements; the introduction of density bonuses, sometimes used to encourage the production of affordable housing units; and relaxation of parking standards. These measures, moreover, received high marks in terms of their overall effectiveness among transit professionals who responded to the survey. Next in the order of frequency of usage have been land-based tools, like land purchases on the open market (for land-banking and potential "deal-making") and assistance with land assemblage. For the most part, redevelopment agencies have applied these tools, meaning their role in leveraging TOD has been mainly limited to economically depressed or blighted neighborhood settings. Because of the higher risk involved, redevelopment tools have often been accompanied by other funding sources, sometimes with a dozen or more participants involved in the process.

Implementation strategies that are procedural in nature, like expediting entitlement reviews and excluding TODs from concurrency requirements, have been applied less often in practice and are also viewed by public-sector interests as less effective than other measures in jump-starting TOD. This view, however, does not square with that of many TOD developers. In terms of what metropolitan planning organizations, state departments of transportation, and the federal government might do to help implement TODs, respondents from the local levels stated loudly and clearly that what is most needed is money—specifically for strategic station-area planning, infrastructure, and on-the-ground improvements. Smart-growth legislation that targets state infrastructure and urban renewal grants to transit station areas (such as that in Maryland) is also looked upon favorably by local interests. Regulations like concurrency requirements, on the other hand, generally received low grades among

survey respondents from the local level. For financing streetscape and other ancillary improvements around transit stations, monies have mostly come from federal and state grants such as the Transportation and Community System Preservation Pilot Program under the Transportation Equity Act for the 21st Century (TEA-21). The most common sources of non-grant funds used to leverage TOD are individual investor funds and nonprofit/foundation funds.

Many cities, counties and state/federal agencies across the United States are achieving TOD in their jurisdictions, using a variety of implementation tools. A number of implementation "best practices" have emerged, which are outlined below.

4.1 Provide a Vision for TOD and Keep Focused on the Long Term Vision and Interim Development

A comprehensive, strategic vision establishes TOD as a key element of a City's overall land use and mobility plan. The vision encompasses broader city-wide land use and development goals, as well as performance expectations for future development around transit stations.

Full build out of many station areas may take decades to complete. A commitment to the long term vision is necessary. However, timely plan re-assessments may be needed to facilitate small, incremental development opportunities which still contribute to long term goals.

Establish guidelines for "interim" developments that will maintain the long term vision for the station area is also necessary. Interim development can be used to provide key public infrastructure, identify future development patterns and establish quality pedestrian environments. Interim uses that prematurely fragment land or create negative external impacts that discourage TOD opportunities are avoided.

4.2 Build Community Support for Public and Private Participation

A broad understanding and acceptance of TOD is important. Community wide information and education programs should be promoted. Planning processes that involve neighbourhoods, elected officials, land owners and the development industry can create a TOD program that is supported and will be implemented.

The participation of both the private sector and local government is important in reducing project risk. Foremost, it is governments and transit authorities that will encourage supportive land use policies that facilitate TOD. Secondly, there are typically large public land holdings around transit stations. These lands can be leveraged to reduce developer risk, speed development timing and ensure other public benefits are achieved through TOD.

4.3 Identify Priority Transit Station Area Plans and Market Responsive

Wherever there is an LRT[1] station there is an opportunity for TOD. However, the market is not limitless. Identify priority stations where there is market interest, sufficient land and a reasonable opportunity for success. Focus attention at these priority stations to ensure early TOD projects are successes.

Individual stations need specific plans that recognize local market strengths, site opportunities and community interests. These plans will outline clear goals for TOD at the individual station and provide guidelines for land use, density, public systems, urban design and parking management.

TOD plans will only be implemented if they can entice the local real estate market to build. Development industry participation in preparing station area plans, land use mixes and marketing strategies is essential. Station area plans need to provide flexibility to allow the market to evolve, adapt to this new form and ultimately flourish.

4.4 Financing and Incentive Strategies and Eliminate Roadblocks

TOD and mixed use development provide financing challenges. Creative solutions have often been needed to make it happen. In many U.S. jurisdictions federal grants, tax incremental financing, public-private partnerships, joint ventures and "Location Efficient Mortgages" have been used to encourage development. Local governments also provide density bonusing, key public infrastructure and reduced approval timelines as incentives for TOD.

TOD is a unique and emerging form of urban development. It is one that many developers are not willing to risk. Often cited reasons for this uncertainty are difficulty in obtaining financing, lack of clear policy direction, lengthy approvals processes and NIMBY-ism[2]. Municipalities help reduce this risk by ensuring planning policies, zoning and approvals processes are in place to eliminate roadblocks and reduce timelines.

5 BENEFITS OF TRANSIT-ORIENTED DEVELOPMENT IN THE UNITED STATES

A recent study, "Factors for Success in California's Transit-Oriented Development", commissioned by the California Department of Transportation, identified the following 10 potential benefits of TOD. The study cites research showing that TOD can have the following benefits.

[1] Light Rail Transit

[2] NIMBY or Nimby is an acronym for the phrase "not in my back yard". The term (or the derivative Nimbyism) is used pejoratively to describe opposition by residents to a proposal for a new development close to them.

5.1 Economic Benefits

- Increase households' disposable income. Housing and transportation are the first and second largest household expenses, respectively. TOD can free-up disposable income by reducing the need for more than one car and reducing driving costs, saving $3000-$4000 per year.
- Play a role in economic development. TOD is increasingly used as a tool to revitalize aging downtowns and declining urban neighborhoods, and to enhance tax revenues for local jurisdictions.

5.2 Environmental Benefits

- Reduce rates of vehicle miles traveled (VMT). TOD can lower annual household rates of driving 20–40 percent for those living, working, and shopping within transit station areas.
- Reduce air pollution and energy consumption rates. By providing safe and easy pedestrian access to transit, TOD allows households to lower rates of air pollution and energy consumption. Also, TODs can help households reduce rates of greenhouse gas emissions by 2.5 to 3.7 tons per year.
- Conserve resource lands and open space. Because TOD consumes less land than low-density, auto-oriented growth, it reduces the need to convert farmland and open spaces to development.
- Decrease local infrastructure costs. TOD can reduce costs for water, sewage, and roads to local governments and property owners by up to 25 percent.

5.3 Social/Community Benefits

- Provide mobility choices. By creating "activity nodes" linked by transit, TOD provides important mobility options, very much needed in congested metropolitan areas. This also allows young people, the elderly, people who prefer not to drive, and those who don't own cars the ability to get around.
- Increase public safety. By creating active places that are busy through the day and evening and providing "eyes on the street", TOD helps increase safety for pedestrians, transit-users, and many others.
- Increase transit ridership. TOD improves the efficiency and effectiveness of transit service investments by increasing the use of transit near stations by 20 to 40 percent, and up to five percent overall at the regional level.
- Contribute to more affordable housing. TOD can add to the supply of affordable housing. It was recently estimated that housing costs for land and structures can be significantly reduced through more compact growth patterns (Cervero,2002).

6 BARRIERS TO TRANSIT-ORIENTED DEVELOPMENT IN THE UNITED STATES

The literature sorts barriers to TOD into three basic categories: fiscal (factors that detract from the financial feasibility of TOD projects, such as questionable market viability and lack of conventional financing); organizational (structural impediments lodged in the institutional fabric of transit agencies and other governmental entities responsible for projects); and political (land-use policies and NIMBY forces that impede multifamily housing and infill development more generally). Of course many barriers are interrelated automobile-oriented development patterns form barriers to TOD in large part because overcoming them raises costs and political flak.

6.1 Fiscal Factors

The market viability of the housing product is questionable. The market for high density housing is thought to be soft due to consumer preference for low density living. There is often a lack of conventional financing. Transit-based housing is a largely untested market. Markets fluctuate and the market demand for each element of a mix of uses seldom follows the same cycles (Bernick and Cervero,pages 139-140). For example the recession of the late 80s to early 90s hurt the office market.

6.2 Institutional Factors

The public transportation institution itself is part of the problem. The culture inside many transportation authorities is focused on operations keeping the wheels rolling. Land development in those cases is not

considered to be part of the core business. The skills required to be effective are outside of traditional transit planning expertise. The goal of using land use policies to boost ridership represents a major shift in American transportation planning. Prior to the mid- 1980s, transportation planners rarely sought to influence travel behavior by manipulating land use patterns. Furthermore, rail systems by their nature involve several stations, often in multiple jurisdictions and land use authorities. This level in intergovernmental land use policy coordination, while found in other nations, is not typical of American planning. Thus both in intellectual disposition and in the required amount of coordination, TOD is a departure for transportation planning in the United States (Boarnet and Compin,page 1). The public transit institution has been slow to adopt new policies, play new roles, and use new tools (Cervero,2002).

6.3 Political Factors

Local governments prefer retail developments at stations because of the sales tax revenue. Ironically, some governments oppose retail development at stations in order to protect other commercial areas in town such as the traditional central business district (Bernick and Cervero,page 195).

High-density housing usually increases demand for schools, city services, and public streets (Bernick and Cervero,page 140). TOD is not a priority in jurisdictions with other pressing problems such as crime and poverty (Bernick and Cervero,page 285).

There is often NIMBY political opposition. Ironically, this phenomenon can take the form of resistance to high density housing in more affluent communities where the concern is to protect against decline caused by those of a different race and class; and in less affluent communities where the concern is to protect against gentrification by those of a different race and class (Anastasia Loukaitou-Sideris, "Transit-Oriented Development in Integrating Rail Transit, Land Development And Telecommunications Mineta Transportation Institute).

7 KEY STRATEGIES FOR IMPLEMENTING TOD IN THE UNITED STATES

A review of practices from cities across the United States indicates that TOD is a unique form of urban development. How a station area is planned and developed will depend on the particular attributes of that station and surrounding community. However, the following key strategies are commonly found to be critical to the success of any transit-oriented development.

7.1 Get the Land Uses Right

- Ensure transit supportive uses: Transit supportive uses are high pedestrian generators that directly promote greater transit ridership. They also provide opportunities for multi-purpose trips that can be made as a pedestrian. Medium to high density residential, offices, high schools and colleges are significant transit supportive uses. Appropriate retail, restaurants, personal service and civic functions will support these major uses and generate activity in both peak and off-peak hours.
- Discourage non-transit supportive uses: Non-transit supportive uses generate little or no ridership. They consume large areas of land, or create bleak or unsafe environments for pedestrians. They are often dependent upon a vehicle for transporting goods, or require significant land areas for low intensity development and parking. Large format wholesale stores, warehouse storage, car dealerships, auto service centres and regional sports fields are examples of uses that are not transit supportive.
- Encourage a mix of uses: A mix of residential, office and supporting services in station areas can generate transit trips throughout the day. It provides opportunities for people to live closer to their jobs or to take advantage of reverse flow transit capacities. Workers can run daily errands within walking distance of their jobs; transit riders can access convenient services while at the station. Residents and visitors can continue a variety of activities in off-peak times.
- Locate the uses as close to the LRT station as possible: Locating a majority of transit-supportive uses within a 400 to 600 m walking distance of the LRT station makes transit the most convenient and attractive travel mode for the site.

7.2 Promote Density

- Promote density: Development densities are "as great as possible" within the context of a particular station and surrounding community. Minimum residential densities around rail stations are high enough to support higher frequency transit service and to foster lively, walkable communities. Housing forms include townhouse, walk-up apartment and high-rise buildings. Minimum employment densities are established in station areas to create a destination which generates transit trips.
- Density concentration and transition: The highest densities are ideally located closest to the station, to optimize transit rider convenience. This includes high-density housing and offices. Intensity of development can taper off away from the station, to create an appropriate transition and interface with the surrounding community.

7.3 Create Convenient Pedestrian Connections

- Walking distances are to be short: Pedestrian routes between the station and key destinations are short and direct. Key destinations are located within a 400 to 600 meter radius of the station. Circuitous routes are avoided.
- Pedestrian connections are to be continuous: Sidewalks and pathways are continuous routes that are easy to find and follow. Major connections to the station for pedestrians and bicycles are constructed at the outset. Routes are universally accessible to wheelchairs, strollers, scooters and other mobility aids.
- Accesses are to be direct: Sidewalks connect directly to the entrances of the station and buildings. Bus stops are located as close as possible to building entrances. Walking distances from the station to the nearest bus stop are generally shorter than the distance to the nearest parking space.
- People are to be at street level: Pedestrian routes are at ground level, with minimal stairs and grade changes. Adjacent buildings provide "eyes on the street" and informal security here. Pedestrian routes are located on public streets unless there are good opportunities to tie in to a safe, existing above-grade system.
- Separate vehicular and pedestrian functions: Vehicular and pedestrian ways are designed to minimize points of conflict. Sidewalk and pathway routes have as few driveway or parking lot crossings as possible.

7.4 Ensure Good Urban Design

- Create high quality streets: A pedestrian-friendly street is visually interesting and makes walking enjoyable. Trees, landscaping, wide, separate sidewalks and on-street parking protect people from vehicle traffic and create a pleasant pedestrian zone. Benches provide places for people to rest.
- Make the most of architecture: Architectural variety on the lower three to four storeys can define an interesting public realm. Articulated building facades incorporate attractive windows and varied architectural elements, and are built to the sidewalk. Upper floors of tall buildings can be set back to allow sunlight to reach the street and help reduce the sense of scale of the building.
- Relate the ground level to pedestrian uses: Foot travellers tend to relate to the ground storey of buildings. This level accommodates residential units, building entrances and retail shops oriented to the sidewalk. Surface parking lots, parkade accesses and blank exterior walls are limited along major pedestrian streets.
- All season design: Where possible, pedestrian connections and transit waiting areas provide weather protection in the form of awnings, building projections and colonnades. Ample enclosed shelters make waiting for transit more comfortable.
- Lighting, landscaping, and signs: Stations are well-lit and designed to accommodate "around-the-clock" activity. Landscaping features can define special precincts and encourage transit patrons to linger and explore the station area. Convenient and legible signs orient visitors to buildings and activities around the station.

7.5 Create Compact Development Patterns

- Compact Street Network: Frequent, interconnected streets increase the efficiency of transit circulation and offer more choices for pedestrians. Blocks of 100 to 150m in length keep walking distances short and provide alternative route options. A gridbased street pattern offers multiple accesses to the station and forms the overall development framework for long term transit supportive uses.

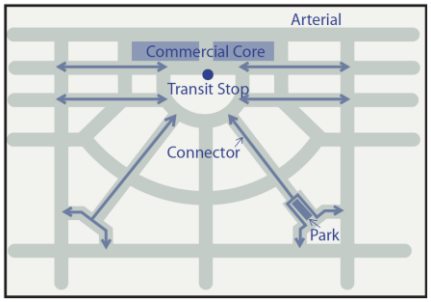

Fig. 2: Compact Street Network

- Cluster buildings: Buildings that are grouped together, or clustered, offer a "one-stop" opportunity to conveniently access a variety of destinations on foot. Clustered buildings can frame distinct character areas and create an easily navigable walking environment.
- Leave room to grow: Buildings can be thoughtfully sited on a property to accommodate future intensification. Placing buildings to one side of a parcel, instead of in the centre, leaves sufficient land that can be developed later. This will allow an initially low density area around an LRT station to intensify over time.

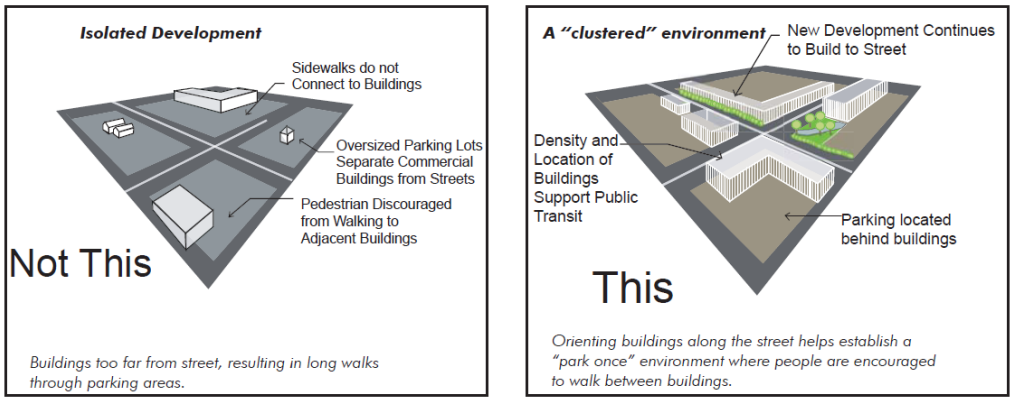

Fig. 3: Clustered Environment not Isolated Development

7.6 Manage Parking

- Accommodate the automobile: By design, TOD lessens the need for automobile use in a station area. However, accommodating vehicles is still critical to the success of a vibrant TOD district. Convenient parking and drop-off zones need to be planned for in all station area plans.
- Parking - enough, but not too much!: TOD provides an opportunity to reduce the amount of parking in the station area through increased transit riderships, reduced residential vehicle ownership and shared off-peak parking at public Park & Ride sites. Setting both minimum and maximum parking standards can help ensure the success of a station area as well as optimize transit ridership.
- Locate parking to the rear and sides of buildings: Parking lots are located at the periphery of the station area and to the rear or sides of buildings. This keeps the station and building entrances oriented to the sidewalk and to pedestrian users.
- Smaller parking lots: Surface parking areas do not overwhelm a station area. Larger parking lots can be divided into smaller lots and separated by landscaped walkways. These smaller lots also create an internal movement network and establish a framework for longer term intensification.

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

- Phased parking from surface lots to structures: Structured parking consumes less land than surface parking and allows maximum development. Station areas are designed to allow for the evolution of parking from surface lots to parking structures. If parking structures are located along key walking routes, they can enhance the public environment with pedestrian-friendly facades.
- Bicycle parking: Bicycles can extend the local commuting range beyond the typical 600 m. Ample, convenient and secured bicycle storage locations are provided at each station, close to the entrance of the transit station.

7.7 Make Each Station a "Place"

- Create a Destination: A transit station is a destination in its own right, as well as a gateway to the rest of the city. A station area with a collection of unique places will attract visitors, while also serving transit patrons and the local community.
- Make buildings landmarks: Landmarks create notable places and aid in local wayfinding. LRT stations and other significant buildings with distinctive design elements can make the area attractive and memorable.
- Sightlines and views: Sight lines to and from the station help orient pedestrians to their surroundings. Views are critical for pedestrians to find their way. Sight lines can be terminated by important features such as the station, a community building, monument or public art.
-
- Orient buildings to the street: Buildings that are adjacent to and overlook public areas create a visually interesting and safer pedestrian environment. Buildings oriented towards the street edge can enclose important vistas and shape the public realm.
- Public open spaces: Open spaces near an LRT station emphasize the station as a public place. They provide comfortable waiting and drop-off areas for users and act as central activity and gatherin points for the local community. The station area can be strategically punctuated with sm parks or plazas, which might incorporate fountains or other landmark features.

8 CONCLUSION

There is considerable evidence that interest in transit-oriented developments is on the rise in the United States. Transit Oriented-Development shifts the focus from diffuse, automobile-oriented development to denser, mixed-use neighborhoods centered around transit station. TOD can have a myriad of social, environmental and economic benefits for people and communities, from reduced costs of living, better access to jobs, and economic growth, to healthier lifestyles and, through reduced automobile use. transit-oriented development is still challenged by a lack of public and private financing and adequate policies and legislation to encourage TOD construction.

The wise use of land around LRT stations and high volume bus stops is one approach to help the United States achieve its smart growth objectives. Strategically planned station areas help promote the economic, social, and environmental well-being of a city by:

- Highlighting transportation alternatives and increasing transit ridership
- Taking advantage of non-peak direction transit capacity
- Decreasing auto dependency and exhaust emissions
- Using serviced land efficiently to help create a more compact urban form
- Making better connections between jobs and housing
- Revitalizing commercial corridors and older communities
- Providing market housing in a variety of forms and price ranges
- Creating opportunities for affordable housing
- Providing increased neighbourhood and travel options for those not owning cars
- Making identifiable and walkable neighbourhoods

- Creating more street activity and a safer station environment
- Acting as a catalyst for private investment and development
- Increasing assessment values of vacant and underused land

The desire to coordinate the planning of land use and transit investment is a growing trend across the United States. Many cities and regions are promoting better use and intensification of land around major transit facilities as a means to achieve a number of their broader planning goals.

Traffic Impact Analysis as a Tool for Planning Permiot Considewration in Lagos, Nigeria: Guidelines and Procedures

Taofiki Salau

(Taofiki Salau, Lecturer, University of Lagos, Lagos, Nigeria, salauti@gmail.com)

1 ABSTRACT

This research based paper reviews the statutory requirements of developmental projects approval process and makes a case for the preparation of Traffic Impact Analysis (TIA) as a separate and distinct study for deserving proposed projects because of the pervasive nature of traffic. Because the Environmental Impact Analysis (EIA) report as one of the requirements for planning approval is required to cover such diverse issues as the socio-economic environment and the ecological character of the project, among others, the depth of impact measurement on each is often not detailed enough. This is more germane in such areas as the impact of the proposed project on traffic and transportation which represents a major challenge in a metropolis such as Lagos, as traffic remains the most concealed component of the Impact Analysis of any new development project. This paper posits that the impact of certain project on traffic and transportation is too far reaching to be subsumed under a generalized EIA study. This paper therefore recommends the inclusion of traffic impact analysis report as a statutory inclusion in the portfolio submitted for development approval process in Lagos. The paper advocates the need for the urgent enactment of necessary legislation to make this an obligation and also spells out the procedures and guidelines for its preparation.

2 INTRODUCTION

Approval for proposed development projects in Lagos statutorily requires developers, whether private or government, to prepare and submit alongside their proposals, an EIA report while applying for a development permit (LASG 2005). An Environmental Impact Analysis (EIA) report characteristically spells out the characteristic and conditions of the proposed project environment along physical, social, cultural, economic and aesthetic dimensions with a view to providing the baseline against which to measure real and potential impacts and changes to the environment arising from the execution of the proposed project: the nature of the projects in terms of its components, services to be rendered, end-users, sources and nature of wastes and associated problems: the nature and magnitude of environmental changes attributable to project activities and appraise their impact, positive and or negative, on the totality of its environment: and suggestion on how observable anticipated impacts could be ameliorated or managed in the light of available technology and within legislative limitations in order to eliminate or reduce the potentially significant environmental consequences as a way of achieving the objectives of environmental protection and sustainability.

Broad review of available EIA reports generally has revealed the contents of most of such reports to be too broad and the depth on specific issues considerably shallow. Because EIA reports are required to cover such diverse issues as the socio-economic environment and ecological character of the project, among others, the depth of impact measurement on each is often not detailed enough. This is more germane in such areas as the impact of the proposed project on traffic and transportation which represents a major challenge in a rapidly growing metropolis such as Lagos.

Traffic remains the concealed component of the impact analysis of any new development project. Therefore the impact of certain projects on traffic and transportation is too far reaching to be subsumed under a generalized EIA study. Till date, very few proponents, if any, of development projects in Lagos including major traffic generators like major shopping centers, new terminal facilities and large scale housing development projects; conducted and prepared a traffic impact analysis in order to obtain development permit. So far, a TIA study has not been requested as part of the portfolio that a developer must summit to approving agencies before building permit for a new development project is issued. Therefore this paper advocates the need for the preparation of TIA as a separate exercise for certain specific types of development projects. The paper justifies the need for enactment of necessary legislation and also spells out the procedures and guidelines for the preparation of a Traffic Impact Analysis

TIA should by law be a separate but integral document to be delivered alongside others for granting building permits for projects and uses of specified types and sizes.

3 LITERATURE REVIEW

Public interest in issues that concern the environment and its protection and sustainability has in recent years become notable. This has come in conjunction with a number of legislation, national and international, regulating the use of national resources. An often quoted definition of EIA by Munn (1979) refers to the need "to identify and predict the impact on the environment and on man's health and wellbeing of legislative proposals, policies, programmes, projects and operational procedures and interpret and communicate information about the impacts"

GeoSystems and Technologies Inc. (2008) itemized the broad outline of an EIA to include the definition of the proposed project; description of the existing site characteristics and infrastructure including land use, water bodies, social, cultural and heritage information; assessment of public perception of the proposed development through public consultations; identification of policies, legislation and regulations relevant to the project; description of other project alternatives; description of possible short, medium and long term impacts, indirect and cumulative impacts; identification of any mitigation action to be taken to minimize predicted adverse impacts, with associated costs where applicable and practical; and development of an Environmental Monitoring Plan (EMP) to ensure that mitigation measures are adopted during the implementation stage.

On the other hand, the process of EIA preparation can be summarized as characterization (qualitative and quantitative) of the baseline environmental conditions of the study area, prior to the start of the project activities; identification and assessment of potential impacts of the proposed project; recommendation of practical and cost effective mitigation plans to limit plans to or completely eliminate negative impacts; recommendation of practical and cost effective post-developmental environmental management programme; preparation of a detailed EIA report, which will form the basis for the issuance of an EIA and the final clearance by the approving authority.

TNL (1999), in a report identified the objectives of an EIA study to include;

- Identifying negative and positive impacts that are likely to result from the implementation of a proposed project
- Generating mitigation options that can be used to reduce or completely eliminating the negative impacts of the projects during construction and those associated with the operation of the project after construction;
- Generating technical schemes which must be added to the design of the project, to ensure environmental benignness and;
- Developing an environmental management plan that must be in place to ensure continuous environmental soundness throughout the project lifetime (Thermosteel Nigeria Limited 1999).

The Nigerian Constitution in its environmental and directives of state policy on the environmental states that "the state will protect and improve the environment and safe guard the water, air and land, forest and wildlife of Nigeria" (Nigerian Constitution, Chapter 2 and Article 28).

The legislation that made the preparation of the impact analysis mandatory for development projects in Nigeria were focused mainly on assessing the impacts of projects on the broad environment. For instance, the National Environmental Impact Assessment Decree No 86 of 1992, Nigerian Urban and Regional Planning Law Decree No 88 of 1992, Environmental Impact Assessment Decree No 59 of 1992 and several states (including Lagos) enacted urban and regional planning and development laws. All these laws stipulated that before any person, corporate body or agency takes a decision to undertake or authorize the undertaking of any activity that may likely or significantly affect the environment, prior consideration of its environmental effects should first be taken; hence the need for the preparation of an EIA report.

Lagos State government recognizes the need to protect its territorial environment and has affirmed its commitment to the preservation of same. Hence … specifically, the Lagos State Urban and Regional Planning and Development Law of 2005 stressed that "where the application submitted (to planning authorities for approval) is in respect of any development of land area of four hectares and above, and other institutional, commercial, industrial complexes, such application shall be accompanied with an Environmental Impact Analysis Report giving the details of effects of the processed development on socio-

economic environment, traffic, ecology and communication network duly prepared by a Town Planner registered to practice in Nigeria".

This existing administrative and legal framework which has ensured that the impacts of development projects are subjected to pre-construction evaluation before a go-ahead is given to construct does not however include the preparation of TIA, specifically as a precondition.

A Traffic Impact Analysis (TIA) is a study carried out to predict the magnitude and effects that a proposed development project generated traffic will have on the transportation network. TIA is an important document in helping planning authorities in making decisions on land and its use. TIAs can also be used to evaluate whether the proposed developmental project is appropriate and what type of transportation facility improvements would be necessary. Traffic impacts could be direct or cumulative. A direct impact would result solely from the implementation of the proposed project while cumulative impact is based on list of past, present and probable future projects in the area. This means that a cumulative impact would occur as a result of traffic growth both the project and from other projects in the area.

Specifically, according to Edwards (2000), Traffic Impact studies help to

- Forecast additional traffic associated with new development;
- Determine the improvement that are necessary to accommodation the new development's anticipated traffic;
- Identity potential problems with the proposed development which may influence the developer's decision to build;
- Help to ensure safe and reasonable traffic conditions (volume, flow, etc) on streets after the development is completed;
- Reduce negative impacts created by developments by helping to ensure that the transportation network can accommodate the development; and
- Provide direction to decision makers and the developer of expected impacts
- TIS is to be prepared and submitted, if one of the following criteria applies to the project.
- The site to be developed for a residential use is to generate more than 100 vehicles per peak hour,
- The site to be developed for a use other than residential is to generate 250 vehicles per peak hour, or more than 2,500 per day, or
- The site to be developed for a residential use, is located on a low volume road, and generates 200 vehicles per day or more and at least doubles the existing volume of the road (Edwards 2000).

4 TRAFFIC IMPACT MEASUREMENTS

A traffic impact is an effect, either positive or negative, on the traffic of the adjoining roads and other transportation infrastructures that may be associated with a proposed project activity. The assessment of the proposed project may be based on a synthesis of such criteria as, the nature of the impact, directness of the impacts, spatial extent, duration, intensive or magnitude and determination of significance.

The study of the nature of impact is an evaluation of the type of effect the proposed activity would have on the affected roads and other transport facilities and traffic attributes or components. Its description should include, what is being affected and how. A direct impact refers to an immediate impact appearing because of the project activity while a secondary level. Spatial extent analysis is a description of the scale of potential impact, using the following parameters.

- Local, where the impact could affect the extended area adjacent to the site such as a neighourhood or town, probably affecting traffic up to 10km outside the immediate environment.
- Regional, where the impact could affect traffic in areas which include outlying parts of the city, transportation route, adjoining towns, etc; and
- National, where the impact could be as far reaching as national boundaries.

The duration criterion refers to the expected lifespan of the proposed project's traffic impact. This can be defined as;

- Short term, if the traffic impact will disappear with mitigation, or will be reduced in a span shorter than the construction phase; impacts that are predicted to last only for a limited period.
- Medium term, if the traffic impact will last for only the construction phase; thereafter, it may completely terminate; and
- Long term, if the traffic impact will continue or last for the entire operational period of the project, however, it will be mitigated by direct engineering or traffic control solution afterwards.
- Permanent, if the traffic impact is considered non-transitory. That is mitigation by engineering or human processes will not occur is such a way or in such a time span that the impact can be considered transitory.

Impact intensity or magnitude analysis refers to a description of whether or not the intensity or magnitude of the impact would be high, medium (moderate), low or negligible (no impact). Evaluation of potential traffic impacts on traffic components may be qualitative or quantitative. The factors used to describe intensity or magnitude include;

- Low, if the impact will not have significant influence on the adjoining traffic, hence it will not require significant accommodation in the project design or implementation. The impact may alter the affected transport environment in such a way that traffic processes or functions are not affected in any significant way, i.e., the existing road networks are not overburdened, or existing traffic patterns and flows are not altered or affected).
- Moderate, if the impact could have an adverse influence on the existing level and flow of traffic, requiring a modification of the project design or alternative implementation schedules. The affected traffic and transportation environment is altered, but the functions and processes will continue, albeit in a modified way.
- High, if the impact could have significant influence on the traffic environment, but cannot be mitigated or accommodated by the project design, but introducing alternative mitigation measures, such as road re-alignment at a particular stretch, construction of new parking facilities, widening of existing adjoining roadways, etc. Functions or process of the existing traffic environment is distributed to the extent where it may be affected temporarily or permanently.

Determination of significance criteria is an indication of the potential impact in terms of physical extent, intensity and time scale. It is an indication of the required level of mitigation, and is determined through a synthesis of impact characteristics or combination of effects. The various classes of significance are defined as follows;

- Negligible, if the impact is considered to be insignificant and does not require any mitigation efforts;
- Low, if the impact of the little importance, but may require limited mitigation;
- Moderate, if the impact is of importance and considered to have mitigation. Mitigation is required to reduce the negative impacts to acceptable levels or to maximize positive impacts; and
- High, if the impact is of great importance. Hence, failure to mitigate and reduce impact to acceptable levels could potentially negate development, or make entire project unacceptable.

5 METROPOLITAN LAGOS: CASE STUDY

Lying approximately between Longitudes 20 42’ E and 30 22’ E and Latitude 60 22 ‘N and 60 2’ N in the southwestern part of Nigeria, Lagos, the nation’s most populous city, Nigeria, with an estimated population of 18.5 million (2009 projections), is located south of Ogun State and 800km southwest of the nation’s capital, Abuja. The metropolitan area, an estimated 300 square kilometers, comprises 88.7% of Lagos State, a total of 19.87 square kilometers is centrally located within the coastal frontage of Lagos state, comprising of 17 local government areas (LGAs).

Lagos with its 29 industrial estates and 4 CBDs, is the commercial and industrial hub of Nigeria, is home to 70% of the country’s total industrial investment and 65% of its commercial activities and accounts for approximately 50% of the country’s manufacturing sector (Ehingbeti 2002, NEPAD City Lagos Profile, 2003 and Badejo 2009).

6 NEED FOR TRAFFIC IMPACT ANALYSIS STUDIES IN NIGERIA AND LAGOS

Given the high population density of Lagos metropolitan area (estimated 18.5 million people, on 3,577 square kilometers of land) with over 85% of this population on an area that is 37% of the land area in Lagos, the amount of pressure that the existing transport infrastructure system bears can be envisioned, especially in an urban environment with no efficient transit system. Lagos population is growing ten times faster than the population of New York and Los Angeles (in US), and more that the population of 32 African countries combined (Badejo 2009). This growth rate plus the chaotic character of the urban transport system has manifested a number of outcomes. Some of these, according to Badejo (2009), include long travel times on the road, poor road condition largely due to overuse and lack of maintenance, high level of emission and pollution from vehicles, deplorable road system, traffic congestion along major corridors of the state, among others.

According to Edwards (2000), "understanding the demands placed on the community's transportation network by development". Every development is a generator of traffic and some development projects can generate large enough traffic and so as to create congestion, leading to more public investment in the transportation network (construction of new roads, expansion or improvement of existing routes, new traffic control mechanisms, new terminal facilities etc.). Traffic congestion leads to economic costs as a result of longer travel times, air and noise pollution and accidents. As a road becomes more congested, drivers tend to turn to other roads not necessarily intended for thorough traffic (Edwards 2000).

The purpose of TIA study is to maximize traffic related impacts on the existing land use in the immediate vicinity of the proposed development, on the proposed development itself and on traffic conditions and traffic control devices that are not within the vicinity of the proposed development but are expected to be affected by increased traffic volumes.

7 METHODOLOGY

The methodology employed in this research is largely secondary dat. The secondary data for this research were sourced from various published and unpublished documented sources, such as urban and regional mater plans, policy documents published texts, journal articles, etc. a number of transportation and planning reports were studied and relevant information extracted

8 GUIDELINES AND METHODOLOGY FOR TIA

Traffic Impact Analysis (TIA) is developed to estimate the impact of new development on adjoining area's roadways and identify improvement necessary to mitigate that impact. For the purpose of determining what level of study must be completed for a proposed development, the following thresholds have been established. For project generating fewer than 100 net new peak hour trips, a Traffic Impact Statement is required, while for those generating 100 or more net new peak hour traffic, a Traffic Study has to be prepared.

A Traffic Statement includes a review of a site access, circulation and access management, and also provides driveway volume, distribution, site trips and roadway information; while a traffic study includes the review of site access, circulation, access management, safety, roadway links analysis and intersection analysis that will be significantly imposed by the development.

At the minimum, the TIS shall include site access review the circulation and access management components to be considered complete. On the other hand the Traffic Impact Study shall include at a minimum an introductory note which typically includes the description of the type, size, location and the expected construction duration of the project development. This is followed by an analysis of the existing condition which is usually presented in a tabular format and presents a review of the current conditions in the study area without the trips generated by the proposed development.

Intersection and Segment Analysis table, which presents an analysis of all road intersections and segments within the study area and the project analysis based upon the results from traffic volume estimates (trip generation), directional distribution (trip distribution), and total traffic projections are presented. The study area segments, intersections and the site access are evaluated for capacity constraints and operating conditions.

A complete future conditions analysis is also included in the study. This analysis includes all roadway links and intersection analysed in the existing condition section of the study and also includes a peak hour/peak direction Level of Service (LOS) analysis showing the future roadway conditions after applying the base traffic, the proposed project traffic, any other improvements.

As an additional inclusion, future conditions table and a future turning movement illustration are also to be included in all traffic studies. The future conditions table shall be consistent with the existing conditions table, for easy comparison; and provision has to be made for the analysis for roadway segments and intersections within the study area. The table, at a minimum should provide information such as, functional classification, Generalized LOS Tables classification, LOS capacity future projected traffic volumes, and the projected LOS (peak hour/peak direction for two weekdays). In some cases, a Saturday or Sunday analysis may be required. Segment identified in the future conditions table shall be consistent with those identified in the existing LOS table. The analysis for all intersections and segments within the study area shall be performed and the existing intersections peak hour segments with the projected intersection peak hour segments shall be compared; calculating the estimate LOS and volume-to-capacity ratios.

A future turning movement illustration shall be prepared as part of the analysis, showing the individual movements for the project traffic, projected background traffic and total traffic. A mitigation analysis section summarizes the overall impact of the proposed development on the study area and identify specific improvements required, timing for construction of those improvements, and the agency responsible for those improvements. All supporting documentations are to be included in the appendix.

9 CONCLUSION

Development projects, depending on their intended use and intensity of development, have varying level of traffic attraction, causing imposition of new traffic on the existing traffic on adjoining roads. As traffic increases, delays and convenience to commuters becomes increasingly costly and ultimately unacceptable to both the public and the decision makers. As developments become larger and more complex, their effects on local traffic conditions become more pronounced.

For a city like Lagos, when traffic flow and management is a major challenge and given the rate of its urban expansion, especially with its megacity status with its attendant attraction of mega projects, it has become imperative that proposed development projects are subjected to TIA so as to predict and mitigate its impact on traffic and transportation. This paper is therefore recommending the inclusion of traffic impact analysis report as a statutory inclusion in the portfolio submitted for approval process. The paper advocates the need for the urgent enactment of necessary legislation to make this an obligation and also spells out the procedure and guidelines for its preparation.

1 ABSTRACT

Following the examples of the United States and Western Europe, from around 2000 Japan has adopted a neo-liberal urban policy with the deregulation of downtown and a consequent encouragement of investment to this area. In April 2002, the Act on Special Measures Concerning Urban Reconstruction was enacted, and since then, intensions of landuse and land prices have drastically changed. This study refers to the first decade of the 2000's and analyzes the transitions of the CBD (Central Business District) of Nagoya, Japan as an example. Nagoya CBD locates on the center of the third largest metropolitan area in Japan with over 5 million people as well as Nagoya City with a population of 2.15 million.

In this article, we firstly give an overview of actual landuse trends between December 2001 and December 2006. Next, we deal with a comparative analysis of the especially retail agglomeration of the Meieki and Sakae cores within the Nagoya CBD in the 2000s, then show the actual state and changes of land prices in 2001 and 2006. Finally, we analyze of landuse change factors in the 2000s by analyzing and comparing data of landuse and land prices.

2 RESEARCH BACKGROUND, RESEARCH OBJECTIVES AND ITS COMPOSITION

Following the example of the United States and Western Europe, from around 2000 Japan has adopted a neo-liberal urban center policy with the deregulation of downtown and a consequent encouragement of investment to this area (Allmendinger, 2002). This study refers to this time as the "Urban Regeneration Period" and analyzes the transitions to the structure in the Nagoya CBD (Central Business District) as an example case; it is the 3rd largest metropolitan area in Japan with over 5 million people, and contains Nagoya City with a population of 2.15 million.

Fig. 1: Precincts (cho-me) in Nagoya CBD

The Nagoya CBD has two main retail and office cores: an area around Nagoya Station (hereinafter referred to as Meieki); and an area around Sakae Station (hereinafter referred to as Sakae). In particular, the Sakae core has historically been considered the center of the CBD, but in 1999, the completion of a giant bulding complex above Nagoya Station, named the JR Central Towers, consisting of retail, office and hotel floors with 200,000 sq. meters had been a turning point for the city, and the development at the Meieki core

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

attracted many investments. In April 2002, the Act on Special Measures Concerning Urban Reconstruction was enacted, and since then, a variety of landuses and their land prices have increased in the both cores. As a result, Meieki enjoyed a period of strong growth and mass-media reported that Meieki would pull ahead of Sakae during the 2000's. Such kinds of a boom with the drastic transition had been going on until they were finally depressed by the world financial crisis of 2007, as well as Tokyo.

In accordance with the divisions made by a office marketing report into the Nagoya CBD, the survey target area was defined as the 51 chome or precincts with a total area of approximately 560 ha (Fig. 1). They include around Meieki, Sakae, and Kanayama where is far a few kilometers south from the two cores, and also include the Designated Area of the Masterplan of City Center Vitalization, and the High-Priority Development Area in the Urban Regeneration Zone and so on.

The components of this paper is as follows. Section 3 gives an overview of actual landuse transitions between December 2001 and December 2006. Section 4 is a comparative analysis of the retail structure of Meieki and Sakae during the 2000's. Section 5 analyses the changes and the actual state of the land prices in 2001 and 2006, and Section 6 explores the characteristics of landuse changes in the Nagoya CBD in the decade of deregulation by comparing and analyzing data of landuse and land prices.

3 ANALYSIS OF LANDUSE IN THE NAGOYA CBD

3.1 Employed for Analysis on Floor Use

To aggregate floor areas amounts for each use in 2001 and 2006, the following three types of data were taken from the "Present Status: Building Use Survey" in Urban Planning Basic Survey published by Nagoya City: 1) building area; 2) the number of stories (excluding basement floors); and 3) building use category. Concerning the mixed use buildings, the floor area was calculated proportionally taking into consideration the relation of the widest and others; in this regard, for buildings with a total floor area exceeding 10,000 sq. meters, the aggregated results were verified by using the Zenrin Residential Map. Floor areas were calculated 61 subcategories of use and then classified into 7 categories: retail, office, residential, culture and welfare, industrial, hotel, and others.

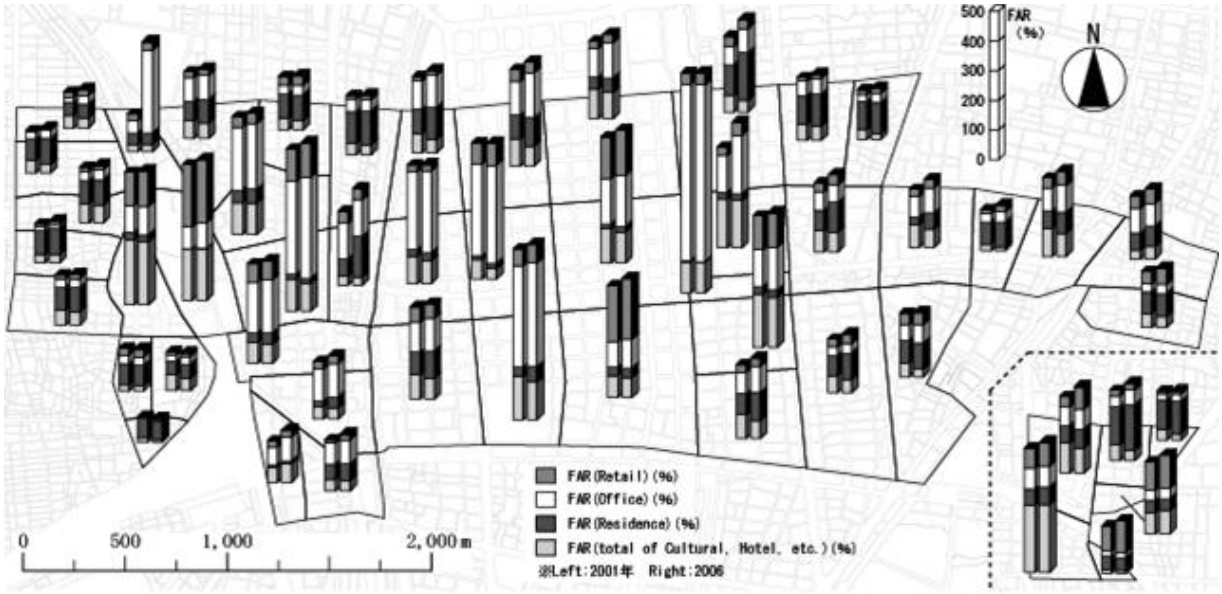

Fig. 2: Comparison between floor area ratios (FARs) in Nagoya CBD from 2001 to 2006

3.2 Transitions of Landuse from 2001 to 2006

Floor-area ratio (FAR) for each use category in each precinct is obtained by dividing the floor area amount of each use category in a precinct by the total area amount of the precinct, in other words, the total sum of blocks within the precinct, excluding Shirakawa Park and all of the roads. The FAR of the whole CBD in 2001 was 287% and in 2006 was 308%, giving a 21% increase (Fig. 2).

When spatial patterns around Meieki and Sakae were examined, the FARs of most precincts were 400% to 500%, and most along the Meieki-Sakae axis were 300% to 400%. However, to the west side of Tsubaki

Town, and the east side of Higashi-Sakura 1-chome, when compared to the Meieki-Sakae axis, many more precincts with FAR of less than 200% were found. The precinct with the highest increase, which was due to redevelopment, was Ushijima Town (245.0%). The next highest increases were found in Higashi-Sakura 1-chome (85.5%), and Meieki 5-chome (77.6%), and in the precincts with FAR of 300% or so, an increase in density was noticeable. The precincts with FAR of 400% or more also showed a 10% to 20% increase, which shows an ongoing rise in the density of the CBD. In contrast, decreasing densities were found in the following three precincts with FAR of 200% or less: Nakono 1-chome, Taiko 1-chome, and Taiko 2-chome.

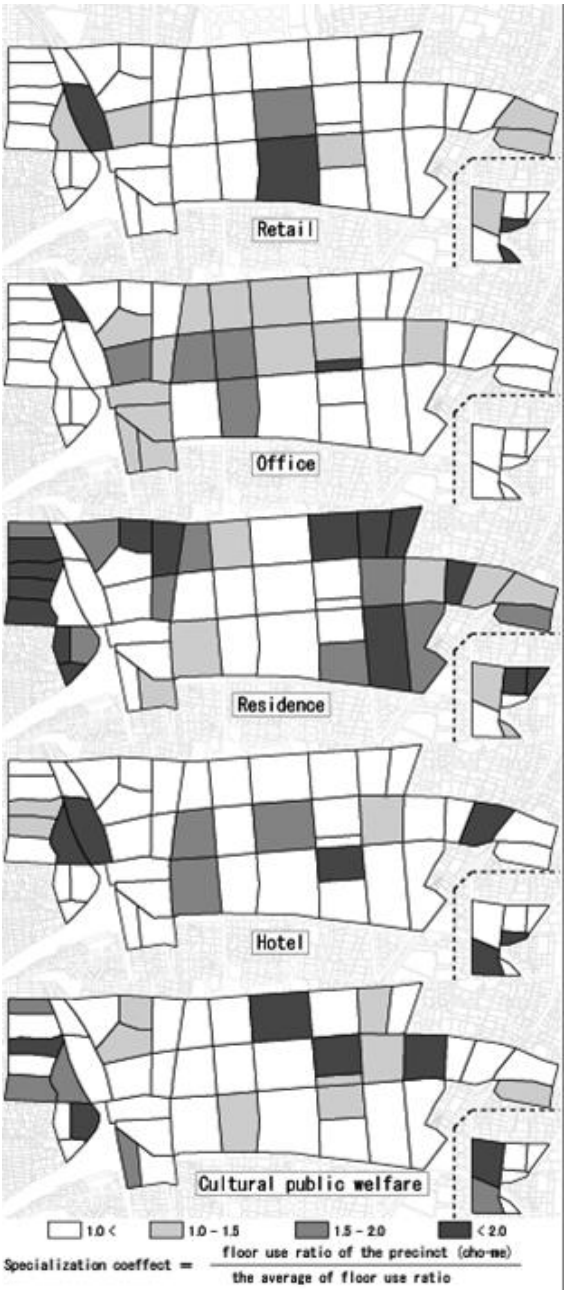

Fig. 3: Spatial patterns of the specialization coefficients in 2006

When examined according to the use category, a 4.4% increase in the retail FAR was found throughout the CBD. Increases in the Kanayama district stand out as seen in the following figures: Kanayama 1-chome (43.3%), Kanayama Town 2-chome (24.7%), and Kanayama 4-chome (17.1%). The increase in the office FAR was 14.7% throughout the CBD, which was larger than retail. When examined by precinct, increases were found in Ushijima Town (240.9%), which was affected by the redevelopment project, Higashi-Sakura 1-chome (74.0%), and Marunouchi 2-chome (36.3%). The office category also showed the tendency to increase in precincts with a high FAR in 2001. Concerning the increase of residential FAR, as seen in Meieki 5-chome (81.6%), Izumi 1-chome (59.5%), and Higashi-Sakura 2-chome (30.4%), many increases were found in precincts with FAR of 100% to 300%.

3.3 Analysis on Specialization of Landuse within Nagoya CBD

To examine the specialization of landuse in each precinct, focus was given to floor use percentages; the result obtained by dividing the floor use percentage of each area by the floor use percentage throughout the CBD was defined as a specialization coefficient, and this value was used (Fig. 3). When the specialization coefficient exceeds 1, this indicates that the land is specialized in the relevant use category. Next, with regard to each use category, areas with a coefficient exceeding 1.0 in 2006 were reviewed.

[Retail] Large values were found in the precincts around Nagoya, Sakae, and Kanayama Stations. Although the coefficient of Meieki 1-chome dropped from 2.44 to 2.37, and that of Sakae 4-chome dropped from 1.39 to 1.36, those of the other 9 areas generally showed an increasing trend of specialization. Particularly, the effect of the commercial complex in Kanayama 1-chome can be seen, where specialization was significantly developed with a coefficient of 1.43, up from 0.73.

[Office] The value was high around the Meieki-Sakae axis. Many with a coefficient of between 1.0 and 2.0 were found, and these form one specialized cluster.

[Residential] In many precincts other than the Meieki-Sakae axis, the value exceeded 2.0, and the pattern shows a reversal of the office trend. However, as seen in Marunouchi 1-chome, areas specialized in both office and residential can be found.

[Hotel] There was the same trend as retail, and high values were found in the precincts around Meieki, but unlike retail, large values are also seen around the precincts specialized in offices, such as Nishiki 1-chome and Sakae 1-chome.

[Cultural and Welfare] It was difficult to find any clear trends; however, high values were found in the precincts specialized in residential, and also in locations that provide easy access, especially around a station.

3.4 Comparison of Landuse Transitions between the Meieki and Sakae Blocks

The Meieki and Sakae blocks were aggregated and the totals were used (Fig. 1) to compare their landuse transitions (Fig. 4). It was found that over this period, offices increased in both blocks, but residential increased mainly in the Meieki block, while retail increased in the Sakae block. However, after the sum total of each block was aggregated, and compared to the grand total of both blocks, no dramatic change was seen in the ratio of Meieki to Sakae, and it was found that the amounts of major landuses had occurred equally in both blocks.

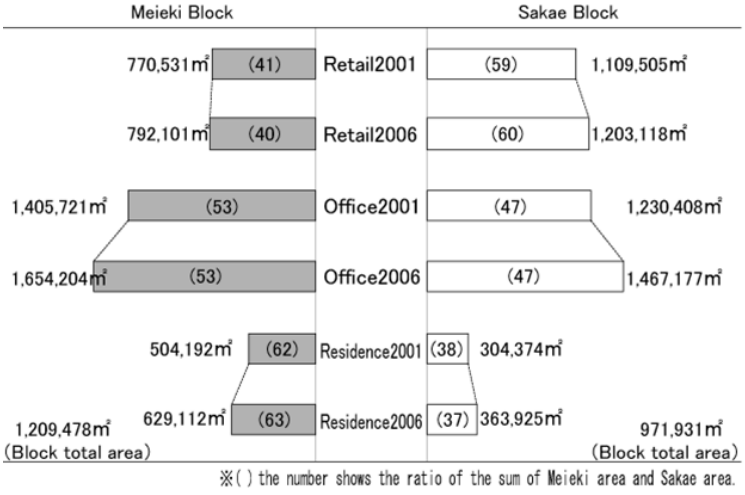

Fig. 4: Comparison of floor amounts between Meieki and Sakae block

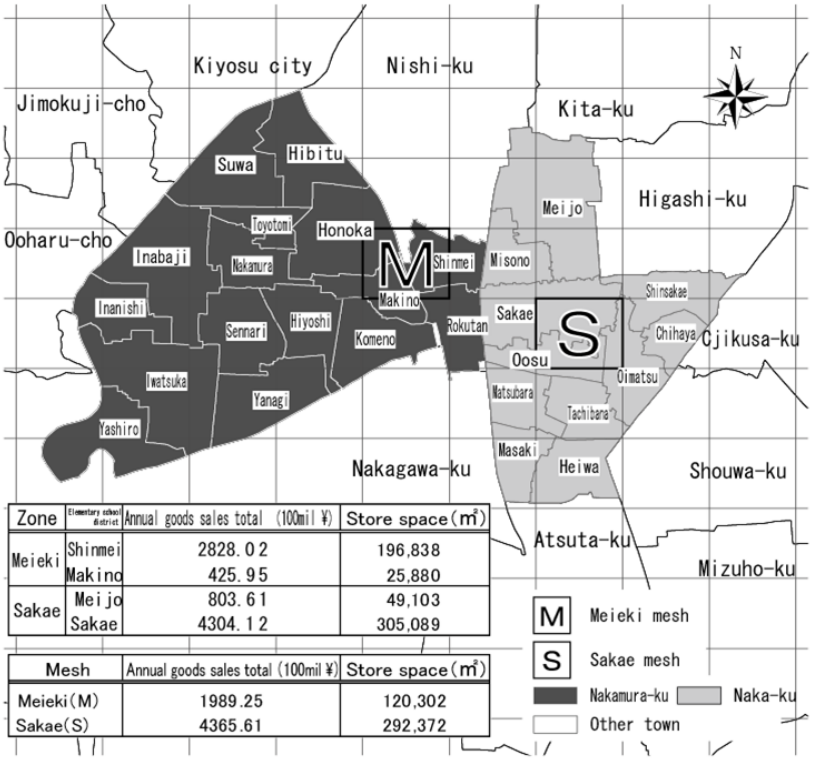
4 COMPARISON OF CHANGES BETWEEN THE RETAIL STRUCTURE AOUND MEIEKI AND SAKAE

4.1 Data Employed for Analysis

Regarding changes in the 2000s to the two major retail cores, Meieki and Sakae, a comparative analysis was conducted (Kojima, 2010). The main data used was the Official Commercial Survey of 1997, 2002, and 2009, the National Census of 2005, and the Nationwide General Report of Large-Scale Retail Stores of 2000,

and 2008. In the Official Commercial Survey the Shinmei and Makino elementary school districts in Nakamura Ward were regarded as the Meieki zone, and the Meijo and Sakae elementary school districts were regarded as the Sakae zone, and the combined totals were aggregated (Fig. 5).



Zone	Elementary school district	Annual goods sales total (100mil ¥)	Store space (m²)
Meieki	Shinmei	2828.02	196,838
	Makino	425.95	25,880
Sakae	Meijo	803.61	49,103
	Sakae	4304.12	305,089

Mesh	Annual goods sales total (100mil ¥)	Store space (m²)
Meieki(M)	1989.25	120,302
Sakae(S)	4365.61	292,372

Fig. 5: Outline analysis of retail structure in Nagoya CBD

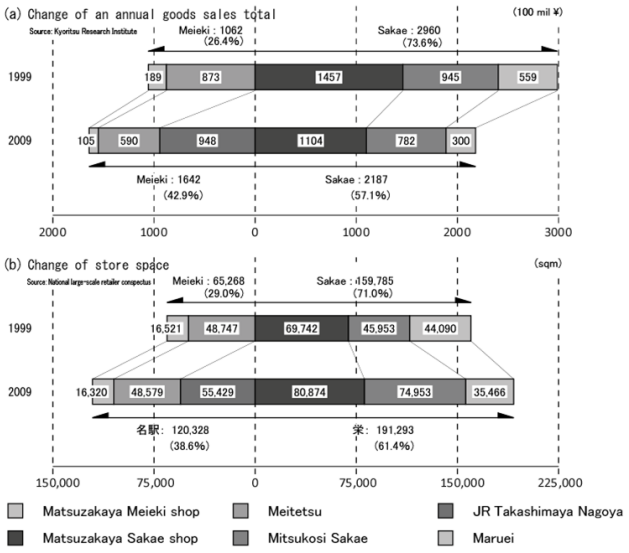


Fig. 6: Transition of the retail structure in the Meieki and Sakae zones

4.2 Transition Analysis on the Retail Structure in the Meieki and Sakae Zones

From 1997 to 2007, the fluctuating increase of retail floor area in both zones resembled a seesaw. Fig. 6 shows changes to the retail over this time, and indicates that the proportion of Meieki had become larger. Concerning the sales amounts, Meieki showed a significant increase, whereas Sakae was stagnant, and in 2007 the share changed to 4 : 6. In these ten years, the floor efficiency value decreased in both zones, which indicates the intensifying competition of this time. Fig. 7 gives data with a focus on large department stores, and the same tendency of significant growth in Meieki and a decrease in sales in Sakae can be found. We can also see that the superiority in the floor efficiency value was reversed silghtly.

5 ANALYSIS ON RELATION BETWEEN LANDUSE AND LAND PRICES

5.1 Land Price Indexes as the Data and Their Spatial Patterns

In this analysis Inheritance Tax Street Value Indexes of 2001, 2006 published by the National Tax Agency were used. The street value indexes were classified according to areas, and the CBD there are four categories: advanced commercial, busy shopping street, ordinary combined commercial and residential, and ordinary residential. From among them, street value indexes of both of the advanced commercial and the busy shopping street were composed as a commercial street value index (thousand yen/sq. meters). In addition, as an index to compare land prices in an areal scale, a land price (thousand yen/sq. meters) created based on a arthmetic average of the street links was used. Fig. 8 shows both of the spatial patterns of the above-mentioned retail street value indexes and land prices.

Firstly, high values of the retail street value indexes in 2006 concentrated on major streets such as Meieki Avenue and Otsu Avenue, and their surroundings. Closer to Meieki and Sakae, land prices rise, and in particular, in Meieki Avenue the price rose substantially from 3,240 to 4,600. The highest street value index in the CBD in 2001 was the 3,590 of Otsu Avenue and this value increased to 4,360 in 2006, resulting in Meieki overtaking Sakae for the highest street value index. However, in other streets in the CBD, such as Sakura, Nishiki, Fushimi, and Hirokoji Avenues the retail street value index decreased.

Dummy variable: "1" Meieki(or Sakae) and adjoining town area(is A), "1/2" The town which adjoins A(is B), "1/3" The town which adjoins B.

Table 1: Variable list for factor analyses.

Next, focus is given to the patterns of land prices in 2006. Sakae 3-chome had the highest land price with 1,401, followed by Meieki 1-chome with 1,349. These results are the reverse of the street value indexes, and this is because the high land price streets in the Meieki zone is distributed along a few specific street lines, and the pattern in the Sakae zone is broader with a grid shape. Concerning the increase ratio, however, Sakae 3-chome recorded 13.6%, and Meieki 1-chome showed a substantial increase with 23.8%. Moreover, Nishiki 3-chome and Meieki 4-chome, each of which is adjacent to the respective precinct, showed a similar tendency. On the other hand, in other 40 precincts – nearly 80% of the whole – showed a decrease of 10% or more. The land prices of the Nayabashi and Fushimi precincts located along the Meieki-Sakae axis also decreased; bipolarization in land prices was observed.

Furthermore, the relationship between the land prices and the specialization coefficients of 2001 and 2006 were examined based on the data in Fig. 9. The graph for 2001 shows the following trends: areas with a land price exceeding 1,000 specialize in retail; areas with a price exceeding 400 up to 1,000 specialize in offices; and areas with a price of 400 or lower specialize in residential. The graph for 2006 shows similar trends; however, a threshold was seen around 800 and a growing gap was seen between those areas with increasing and decreasing land prices.

5.2 Factor Analysis by Stepwise Multiple Regression Method

Analysis was carried out to examine the factors of the floor-area ratio (FAR) in 2006 and the percentage increase/decrease from 2001 in the FAR. For analysis of the explained variables, the FAR in 2006 and its increase/decrease were prepared; and 15 candidate factor variables were prepared and classified under precinct (chome) situations, characteristics, land prices and accessibility (Table 1). Prior to analysis, a correlation matrix was found, and the following variables in 2001 were suspected of having multicollinearity and eliminated: FAR (X1), commercial FAR (X2), office FAR (X3), and residential specialization coefficient (X11). Then, by using the stepwise multiple regression method, the standard partial regression and multiple correlation coefficients were found. Table 2 shows the results obtained through analysis. For analyzing the FARs, the multiple correlation coefficients were over 0.9 or more for all, and highly persuasive factors were obtained. On the other hand, the FAR increase/decrease (Y5) and the office FAR increase/decrease (Y7) gave relatively low multiple correlation coefficient values.

	Y1	Y2	Y3	Y4	Y5	Y6	Y7	Y8
X1								
X2								
X3								
X4	0.285			1.030				0.624
X5	0.266	0.176						
X6	0.325		0.168			0.356		
X7		0.103	−0.100					
X8					−0.492		−0.323	
X9	0.159	0.576				0.561		
X10	0.610	−0.091	0.748	0.179				0.448
X11								
X12	0.379	0.509	0.214		−0.267			
X13								
X14						−0.462		
X15		−0.068				−0.270		
Multiple correlation coefficient	0.953	0.981	0.908	0.940	0.396	0.713	0.323	0.522

Table 2: Extracted candidate variables with standardized partial regression coefficient values (by stepwise multiple regression method)

Next, the selected factor variables were considered. With regard to the 2006 FAR (Y1), the values of the office specialization coefficient (X10, 0.610), and land price (X12, 0.379) were high. Similarly, for the 2006 office FAR (Y3), the office specialization coefficient (X10, 0.748) and land price (X12, 0.214) were chosen; office specialization and land prices contributed as factors. For the 2006 retail FAR (Y2), the retail specialization coefficient (X9, 0.576) and land price (X12, 0.509) were selected, and for the retail FAR increase/decrease (Y6), retail specialization coefficient (X9, 0.561) and a accessibility variable to the Nagoya Station (X14, -0.462) were the main factors. The period between 2001 and 2006 saw a rise of the seesaw in favor of the Sakae zone, which experienced an increase in retail floor area.

For 2006 residential FAR (Y4), 2001 residential FAR (X4, 1.030), and office specialization coefficient (X10, 0.179) were selected. In the residential FAR increase/decrease (Y8) as well, the same factors were at play, and it was found that the residential specialization areas became even more specialized. In addition, residential FAR (X4) in standardized coefficient exceeded 1.0, and it can be considered that this was because of a slight multicollinearity effect. Regarding the FAR increase/decrease (Y5) and the office FAR increase/decrease (Y7), the multiple correlation coefficients had a low value of less than 0.4, resulting in a difficulty in finding any contributory factors.

	Group Ⅰ	Group Ⅱ	Group Ⅲ
Category	<0%(minus)	0%–10%	<10%

X9	0.996	−0.066	−0.310	1.771		
X11	−0.002	0.406	−0.424	1.425		
X13	−1.725	−0.004	0.662	5.448		
constant term	−2.274	−0.137	−0.712			

Table 4: The factor of the FAR(Office) change by discriminal coefficient

5.3 Factor Analysis of the Office FAR Increase/Decrease by Employing Discrimination Analysis

In the foregoing section there were two variables for which it was not possible to gain a clear understanding, and one of them, the office FAR increase/decrease (Y7), was selected for discrimination analysis. Firstly the office FAR increase/decrease (Y7) was classified into three ranges: less than 0% (Group I); 0% to less than 10% (Group II); and 10% or more (Group III) as shown in Table 3. These three groups were defined as group variables, and by using the same candidate factor variables, linear discrimination analysis was carried out for the three groups. As a result, with the four variables listed in Table 4, a good discriminant was obtained with the F value of 7.153, and an accuracy rate of 68.6%.

When the standardized discriminal coefficients were examined, the following was found: in the areas with a decrease, 2001 industrial FAR (X7) and the land price increase/decrease (X13) acted as strong negative factors; in the areas with a less than 10% increase, residential specialization coefficient (X11) acted as a strong positive factor; and in the areas with a 10% or more increase, 2001 industrial FAR (X7) and the land price increase/decrease (X13) acted as strong positive factors. It can be interpreted that this is because the shift from industrial use to offices caused a rise in land prices.

6 CONCLUSION

The results of this research are summarized below:

From 2001 to 2006, in each precinct of the Nagoya CBD, an increase of floor-area ratio(FAR) in each use was seen and a variety of floor uses was developed. Floor areas of both the Meieki and Sakae blocks kept increasing equally, and in this period, no significant decline in the position of the Sakae block was seen.

From 1997 to 2007, the retail floor amounts substantially increased, but the floor efficiency value greatly decreased; this was in accord with a general trend seen throughout Japan. Meieki and Sakae as two major retail cores with department stores as the main players were no exception to this phenomena; however, in this period, the increased floor area amount was noticeable in Meieki, and the share of sales also increased to 4 : 6.

Land prices in 2006, when compared to 2001, showed a broadening gap in the whole CBD with high prices and low prices. In relationship to each floor use, the specialization threshold was high led by retail specialization, and followed by office and residential specialization. Land prices were still high in Sakae, but Meieki had overtaken its rival to win the competition for the highest land price.

With regard to the 2006 floor-area ratio (FAR) and its fluctuations, the factors were analyzed, and for each use category FAR in 2006, its use category specialization coefficients in 2001 were major contributory factors, and a tendency on specialization or aggllomeration was recognized. In addition, analysis was conducted by classifying the office FAR increase/decrease into three groups; as a result, it was found that particularly 2001 industrial FAR and land price increase/decrease played key role factors. It can be interpreted that this was because the shift from industrial use to offices caused a rise in land prices.

1 ABSTRACT

The compatibility of, and conflict between, resilience and sustainability has received increasing attention in recent years, most notably in relation to the design, construction and operation of urban spaces. Considering that urban spaces can be fixed in time scales that range from several years to several decades and beyond, as well as the heightened influence of fiscal concerns at present and in the future, there is a need to understand and consider such interconnectivities at the earliest possible opportunity. Drawing upon ongoing research into the design of safer urban spaces, the relationship between resilience and sustainability was analysed through the exploration of whether emergency planning and the design of space could further both agendas. A state of the art literature review was conducted, as were eleven interviews with key stakeholders in the fields of emergency planning and resilience in the United Kingdom (UK).

Analysis of the above provided results indicating that a range of promising practice has been occuring in the UK, practice that not only increases the resilience of urban spaces to a range of hazards, threats and major accidents, but that is integral to the sustainability of the built environment itself. However, also apparent is the impact of the current fiscal situation, including the Government's extensive public sector spending cuts that are threatening the progress that has been made in relation to resilience and emergency planning; impacts which emphasise the need to identify long-term incentives and cost-effective solutions to the protection of the built environment. Conclusions drawn purport that whilst resilience is integral to sustainability and not merely compatible or conducive to it, a framework is required to further understand the integrated nature of urban space and how its users are made safer, built assets can be made less vulnerable to damage, and its natural environments are more protected.

2 INTRODUCTION

This paper is based on preparatory work for the development of an integrated security and resilience design assessment framework, as part of the Designing Safer Urban Spaces (DESURBS) project, which is funded under the EU Framework Programme 7 Security Programme. DESURBS explores urban space security issues, looking at how the involvement of local stakeholders in integrated security and resilience can improve urban security. The geographic focus of DESURBS is international, but concentrated research is being conducted in the cities of Nottingham (UK), Jerusalem (Israel), and Barcelona (Spain). Outputs of the project will include urban resilient design guidelines and a web-based decision support portal. The DESURBS project is a consortium of eight partners from five countries. This paper is produced by consortium partners at Loughborough University, with a particular focus on the Nottinghamshire region and the City of Nottingham itself.

2.1 Aim

The aim of the paper is to examine the relationship between resilience and sustainability, through the exploration of emergency planning and urban and building design, within the UK. This is being conducted in order to further understand the integrated nature of the built environment and how its users and assets can be better protected from the range of hazards, threats and major accidents that pose a risk to them.

2.2 Methodology

The methodology for this activity comprises a review of literature, together with semi-structured interviews with eleven key stakeholders involved in emergency planning and resilience in Nottingham and Nottinghamshire. The review used a web-based search of documentation, legislation and organisational information, most of which is readily available online, through local authority and government websites.

Several databases were also interrogated such as the Construction Information Service (CIS), Web of Science, ICE Virtual Library, and Health and Safety Science Abstracts. The key informants were sourced from member organisations of the Nottingham and Nottinghamshire Local Resilience Forum (LRF), which exists to "establish and maintain effective multi-agency arrangements to respond to major emergencies, to minimise the impact of those emergencies on the public, property and environment of Nottingham and Nottinghamshire" (Nottingham City Council, 2009).

2.3 Nottingham and its LRF

Nottinghamshire is a county in the East Midlands region of England with an estimated population of just over one million, about 350,000 of whom live in the city (Nottingham and Nottinghamshire Local Resilience Forum, 2011). Nottingham has main railway links to London (in the South) and Sheffield (in the North). The M1 motorway runs through the county, as does the A1 main trunk road. East Midlands International Airport is about 15 miles from the city. Nottingham has a vibrant city centre, renowned for shopping and entertainment. It is also home to several sporting facilities, namely the Nottingham Forest and Notts County football clubs, Nottinghamshire County Cricket Club and the National Water Sports Centre.

The LRF has several levels of involvement in emergency planning and resilience. The strategic (Gold) level consists of the Chief Constable, the Deputy Chief Executive of the Council, the local director of the Environment Agency, chief executives from the emergency services, and a representative from Nottingham University Hospital Trust. The tactical (Silver) level comprises middle management personnel, but includes the head of the County Council, and senior emergency planners. The operational (Bronze) level is made up of people who work on the ground responding to emergency situations and incidents. The Nottingham and Nottinghamshire LRF meets three times a year. A number of sub groups with specific areas of responsibility such as chemical, biological, radiological and nuclear (CBRN), pandemic influenza, and flood response meet six times a year and report to the LRF. The process they adhere to in terms of risk assessment and how that influences emergency planned is shown in Figure 1 below.

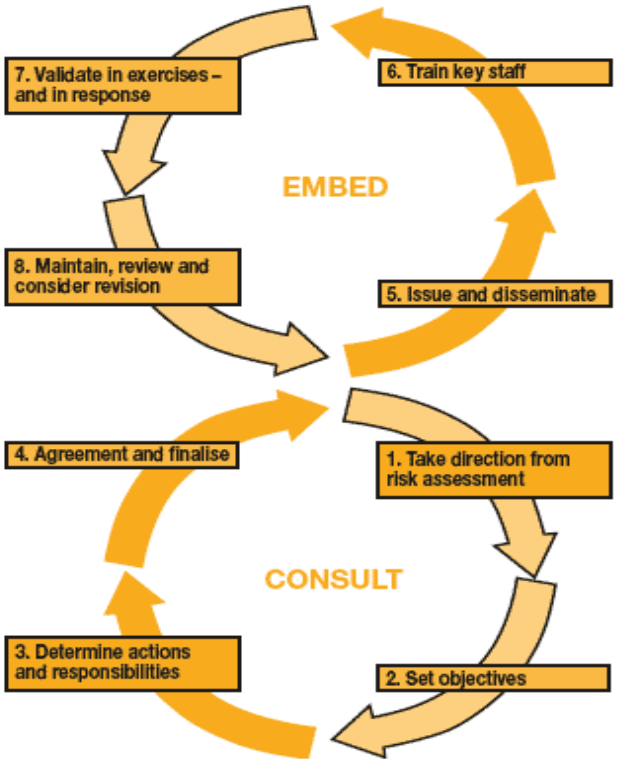

Fig. 1: Cycle of Risk Assessment and Emergency Planning (Nottingham and Nottinghamshire Local Resilience Forum, 2011)

3 RESILIENCE AND THE UK

Geis (2000, p.154) states that the 'built environment' encompasses the substantive physical framework in which society can function in its social, economic, political and institutional aspects. However, not only does the built environment facilitate the functioning of society, it also represents the majority of national savings and investment (Little, 2002; Ofori, 2008). Yet the built environment itself is not designed purely to accommodate these functions alone, as a vast array of legislated considerations and other options and pressures influence the design, construction and operation of the built environment. Pertinent to this paper is the array of hazards, threats and major accidents that can pose risks to urban space and those who use it, as the consequences of those risks manifesting themselves can be so profound as to nullify years of development and investment (Dainty and Bosher, 2008, p.358). Urban space must therefore be planned, designed, built, managed and operated so that it is, and supporting systems are, 'resilient'.

3.1 The Concept of Resilience

In order to understand what constitutes a resilient built environment, and what the term 'resilient' means, the origins of the term must first be explored. Sapountzaki (2007, p.298) and Klein et al. (2003, p.35) highlight that the Latin root of the word is 'resilio', which means to 'jump back'; what could be considered as returning to a previous state. Bosher & Dainty (2011) suggest that the concept of resilience primarily emerged in research concerned with how ecological systems cope with stresses or disturbances caused by external factors (see Errington, 1953; Blum, 1968), but has more recently been applied to human social systems (Manyena, 2006), economic recovery (Rose, 2004), engineering (Hollnagel et al., 2006) and urban planning and recovery after calamitous events (Vale and Campanella, 2005).

Holling (1973, p.14) asserted that resilience is the "measure of the persistence of systems and their ability to absorb change and disturbance and still maintain the same relationships between populations or state variables". However, as asserted by Bosher (2008, p.13), such definitions are evolving to capture that it is not sufficient for systems to simply 'bounce back' or return to a previous state, as the system needs to be a more robust version of this. Resilience can therefore be seen as the ability of an asset to cope with disruption, maintain essential operations, return to normal operations after the disruption has ended, and elevate to a more-informed state. Determining an asset's resilience will, therefore, always result in the question 'resilience of what, to what?' (Carpenter et al., 2001, p.779).

3.2 Within the UK

Within the UK, the resilience of the built environment has been given increasing attention over the past decade, with a range of obligations and incentives to aid in reducing the vulnerability of the built environment to the plethora of hazards, threats and major accidents that pose a risk to it (Harre-Young, 2012). Advancements have occurred particularly in relation to the two areas of emergency planning, and urban and building design, each of which will now be explored.

Emergency Planning

The UK has a well established formal system for emergency planning, namely the Civil Contingencies Act (CCA) 2004 (Civil Contingencies Secretariat, 2004). Prior to this, civil protection legislation dated back to 1948 with the notion of hostile attack from a foreign power. The year 2000 is known as 'the year of the 4 F's', as fuel shortages, severe flooding, foot and mouth disease, and Fire Service strikes highlighted the need to re-think emergency planning nationally, regionally, and locally, and that new legislative measures were needed to ensure that there was an adequate framework for such arrangements. The CCA has two parts: local arrangements for civil protection, and emergency powers, and it redefined the concept of 'emergency' to cover threats from international terrorism, the loss of communication systems, as well as such risks as biological or chemical contamination of the environment.

The CCA stipulates two categories of front line responders (category one and category two responders) and identifies their duties and responsibilities relating to 'localised incidents through to catastrophic events' (Civil Contingencies Secretariat, 2004, p.2). Category one responders, or 'core responders', are the emergency services, all principal local authorities, National Health Service bodies and key government agencies. Category two responders comprise 'co-operating responders', such as utility companies, transport operators, strategic health authorities, the Health and Safety Executive, and voluntary agencies. The CCA

also describes the duty of these agencies to cooperate in a Local Resilience Forum (LRF), based on each police area (HM Government, 2004), although in many instances, such forums (co-ordinated groups of category one and two responders who undertake risk assessments and carry out mitigative activities accordingly) existed in other forms prior to the Act coming into force.

Urban and Building Design

Urban and building design has also been used to advance resilience, and has arguably been seen as a 'universal remedy' to an ever-increasing array of socio-economic problems, policy priorities, and risks and threats that contemporary society faces (Bretherton and Coaffee, 2009, p.35). The use of such design has traditionally been associated with territorial control in the face of terrorist threats, through the regulation, restriction and control of access, and ensuring surveillance coverage (Coaffee et al., 2009, p.489). Rogers and Coaffee (2005, p.323) assert that government policy has been concerned with making the environment of cities more attractive as a whole, whilst also improving safety and security. HM Government (2010, p.5) states that the incorporation of counter terrorism into the built environment is to be achieved within the overall aim of creating high quality public places. Whilst Harre-Young (2012) highlights that the protection of places can occur through the use of organisational measures such as business continuity management, concern regarding the modification of the built environment remains a constant presence, as highlighted by Coaffee (2010, p.940): "we need to consider the 'physical' changes brought about through counterterrorism measures being embedded in the urban landscape as a result of heightened terror threat levels". Harre-Young (2012), however, highlighted that urban and building design that leads to increased resilience can have a number of advantages, including the ability of measures for specific risks (e.g. counter terrorism or flood risk management measures) being able to do more than their intended outcome, and that commerical and fiscal gains can be accrued by doing so, all of which furthers the resilience of the built environment and its longevity.

4 PROMISING PRACTICE

Evident above are the ways in which emergency planning and the use of urban and building design can increase the resilience of the built environment and those who use it to a vast array of hazards, threats and major accidents. Further still, analysis of literature and of the data collected from the interviews with key stakeholders involved in emergency planning and resilience shows that there is not only promising practice occurring that needs to be highlighted as such, but that increases in resilience can be an integral part of the sustainability of the built environment.

4.1 Resilience in its own Right

Feedback from respondents strongly suggested that the Nottingham and Nottinghamshire LRF is an effective mechanism which facilitates an integrated multi-agency response. A number of reasons were suggested for this, which included debriefing practices, the testing and exercising of plans, business continuity planning, communicating with the public, the engagement with and role of voluntary services, and the extent to which community resilience has been encouraged and developed. Three of the most important aspects that were evident were the relationships between stakeholders, emergency response, and the input of stakeholders into urban design itself.

Relationships

At an organisational level, it was raised that the success of the Nottingham and Nottinghamshire LRF is due to: "the fact that they look at every single department, every single group that should be there, not just it's Police, Fire, council" [Interview(I)11. Senior Manager, Voluntary Service]. This inclusive approach allows a wide range of sub-groups to be created, which are generally seen to be an effective way of working: "If you want to produce some meaningful work which is done with cooperation, which is a requirement of the Act, then you really need those sub-groups in place" [I8. Senior Manager - Planning Organisation]. Good governance and management of those involved was stated as being essential to the effective working of the LRF [I5. Emergency Planner - Planning Organisation]. Noted was the Secretariat to the LRF and that it alternates every two years between the City and County Councils, which results in a slight competitive aspect that typically has positive impacts [I7. Emergency Planner - Fire and Rescue Service].

Individual personalities were emphasised as being an important factor in the effective working of the LRF: "I think the partners work well as a group. I think it is personality. And the chairs of most of the standing groups all work well together" [I4. Manager - Care Trust]. The fact that key stakeholders know each other and their ways of working together strengthens the resilience of relationships within the group and ultimately, their effectiveness in planning for and responding to emergencies.

Response

All LRF partners can activate command and control procedures when a situation that cannot be managed using normal management structures occurs [I6. Manager - Health Trust]. When this occurs, a Gold (strategic) Commander is identified from the lead agency, followed by lower levels of Silver (tactical) and Bronze (operational). These roles can be subject to change, as for example, a fire might result in the Fire Service leading Gold, yet the site could become a crime scene, which would result in the Police taking over. The protocols for response are well known and rehearsed among the stakeholders and can be operationalised extremely quickly. Therefore, in a major incident, everyone is familiar with the different roles and who to communicate with: "a big factory going up in smoke, they [the Fire Service] would let us know… So then we would deploy people to site, we'd open our incident room up at our Nottingham office, that's our area incident room, and we've got a hierarchy of roles that we would send out and they're trained to go to the right place at the rendezvous point and speak to the right people and respond in a professional way" [I8. Senior Manager - Planning Organisation]. In situations which exceed the capacities of the local agencies, mutual aid is invoked with agencies from other regions, with those arrangements also going through periodical testing and exercising.

Input into Urban Design

The Police, the Fire Service and the Environment Agency have input into the design and planning of urban buildings and environments. Specifically in relation to counter terrorism, domestic extremism, and hazardous sites and substances, the National Counter Terrorism Security Office (NaCTSO) co-ordinates trained Counter Terrorism Security Advisers (CTSAs), who are Police staff embedded within each Police Force to undertake threat and risk assessments and provide advice to a range of stakeholders. The Police also have a number of Architectural Liaison Officers (ALOs), who provide advice to those planning new builds on matters relating to 'lesser crime' than terrorism. As there is no legal obligation for organisations to adhere to any advice given, this is therefore couched in terms of developing and increasing business continuity, which is evident in literature (Harre-Young, 2012). Fire regulations exist for all new buildings and the Fire and Rescue Service has legal responsibility for their enforcement. However, the Fire and Rescue service only has statutory rights over enforcement of legislation from "the point at which the building is finished and then occupied" [I7. Emergency Planner - Fire and Rescue Service].

4.2 Contributions to Sustainability

The relationship between resilience and sustainability has been evident in literature for a number of years, with notions of 'turquoise design theories' to denote the typical associations of resilience/security with the colour blue, and sustainability/environmental with the colour green (Perelman, 2008). The developments in resilience, emergency planning, and urban and building design, as previously outlined (Bosher and Dainty, 2011; Coaffee, 2009), have arisen most notably through the emergence of resilience as the key discourse in relation to security, and being an objective of society through to individual buildings. Perelman (2008) states that this is the very essence of 'turquoise design' and the true meaning of resilience; resilience is the merging of security and safety concerns with the broader goals of sustainability and sustainable development.

Coaffee (2008, p.4636) states that "in future decades it is most likely that the sustainability agenda will provide the most appropriate policy vehicle for the achievement of resilience, with security seen as an essential element of corporate and organisational responsibility alongside economic, environmental and social concerns". Such assertions are also evident in a range of governmental and non-governmental literature (Fussey et al., 2011; Coaffee and Bosher, 2008; Zimmerman, 2008). However, how such practices are carried out and incorporated is unclear, although a number of synergies have been identified. For example, Harre-Young (2012) identified that the incorporation of counter terrorism measures mitigated the impacts of a range of other threats, hazards and major accidents, prolonging the longevity of buildings and urban space, and also highlighted a range of environmental benefits.

Integrating Resilience and Sustainability Approaches

Coaffee and Bosher (2008) provide examples of how the potential synergies between resilience (specifically security aspects of resilience) and sustainability might include developing landscaping systems that are both 'green' and can conform to Crime Prevention Through Environmental Design (CPTED) principles. For example, ponds and strategically planted trees can be used as physical barriers against vehicle-borne crime such as 'car bombs' and 'ram-raiders', instead of using expanses of concrete and rows of steel bollards. It is also possible that such ponds and landscaping features could be used as part of sustainable urban drainage systems (SUDS) that are designed to reduce the occurrence and impact of flooding in urban areas (Coaffee and Bosher, 2008).

It is also suggested that integrating security systems with other built systems at the design stage (whole building design) can reduce energy use, as can the use of thick thermal walls or window film, which better insulates a building while providing additional blast resistance or fire protection (Coaffee and Bosher 2008). Arguably, in the future a more inclusive and joined-up approach to integrating resilience and environmental sustainability should be advanced through the greater collaboration between a wide range of stakeholders - architects, engineers, planners, the police, insurers, surveyors importantly, the public, who are, or should be, involved with the planning, design, construction, operation and management of urban spaces. However, while the respondents in Nottingham were generally open to these types of integrated approaches, where resilience and sustainability could be coalesced, a number of barriers were identified that would undoubtably impede the transition from theory to practice; these barriers are discussed in the next section.

5 BARRIERS TO PROMISING PRACTICE

Despite the promising approaches that have been identified within Nottingham and beyond, barriers to such practice being further developed and incorporated are evident, most notably the fragmented nature of the construction industry itself (Bosher and Dainty, 2011). However, other factors were also identified through the key informant interviews, those being fiscal constraints, strategic sign-up, communicating with the public, and the use of tools and hardware, all of which impact the potential of emergency planning and the design or urban space and buildings.

5.1 Fiscal Constraints

The LRF is not a legal entity and there is no budget for its activities; associated costs are met by the relevant agency or sector involved. All respondents expressed concerns about the current fiscal situation, and in particular, the impact of the UK Government's spending cutbacks to public services such as emergency planning. This has resulted in prioritising resources to the groups that have the 'biggest impact' [I7. Emergency Planner - Fire and Rescue Service] and staff cut-backs resulting in some issues being left until a later date [I1. Emergency Plannger - Local Authority], which ultimately affects resilience [I4. Manager - Primary Care Trust]. The full impact of budget cuts is yet to be quantified or qualified, but the fear is it will result in a lack of insurance against incidents, "because if you want that insurance policy, you need that resilience" [I9. Emergency Planner - Police Force]; without it, progress that has been made in relation to resilience and emergency planning could be lost. Within these constraints, there is a need to identify long-term incentives and cost-effective solutions for the protection of the built environment.

Harre-Young (2012) has identified such incentives and solutions in the context of counter terrorism design features, which can include reductions in risk and injuries, competitive gains for engaged stakeholders, revenue generation, increases in reputation, increases in property and area values, and potential insurance incentives. As an example, Harre-Young (ibid.) highlights that exclusion of traffic from a given area (measures that can be used to do so are presented in Figure 2) can be a costly approach to incorporate, depending on the size and context of the space being protected, yet there are numerous benefits, apart from the mitigation of not just vehicle-borne terrorism, but: the mitigation of other forms of crime (such as ram-raiding), reductions in noise and air pollution, less soiling of buildings, increased safety of pedestrians within, and increased footfall that has resulted in increased turnover for retail outlets within the protected zone. It is therefore argued that the incorporation of resiliency measures are a fundamental aspect of sustainability, due to the measures being able to protect and sustain the life of urban spaces that they protect. The aforementioned incentives, therefore, could be suitable for making the costs of some resilience measures more viable or acceptable in both financial and aesthetic terms, and therefore aid in supporting business

cases for incorporating what could be costly resiliency measures, as well as the overcoming of the other constraints that are outlined in the rest of this section.

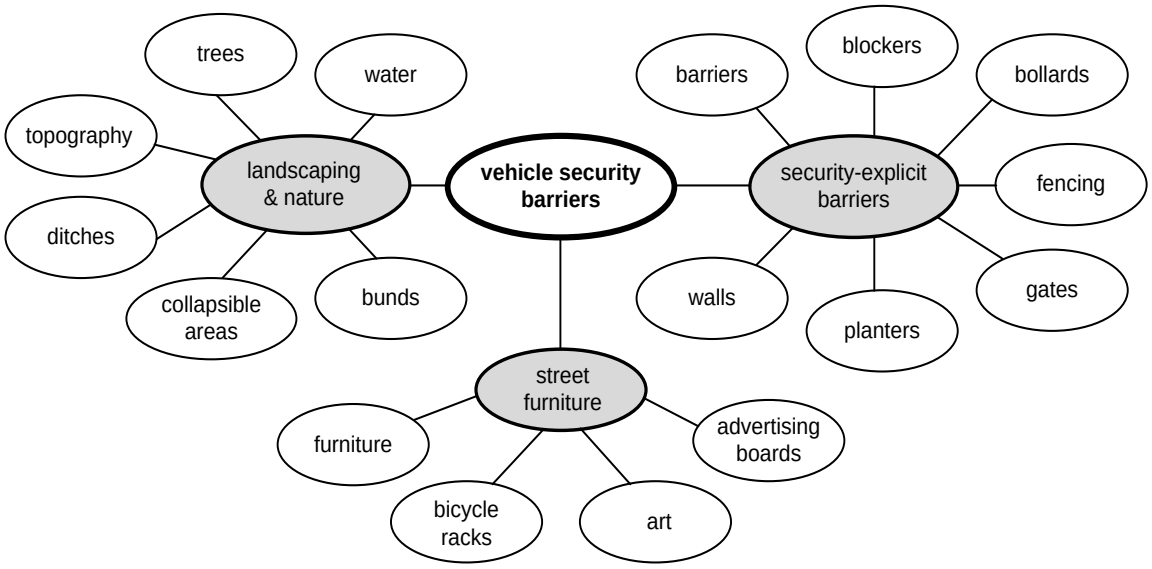

Fig. 2: Measures that can be used to exclude vehicles from a given area (Harre-Young, 2012)

5.2 Strategic Sign-Up

Getting senior management to engage with the LRF process was noted as being difficult, as those in senior positions prioritised issues as they saw fit, rather than according to those defined by the LRF. An example is the need for key decision makers to attend meetings: "you need people there who have got the authority to make decisions, that could spend millions if they needed to" [I10. Manager - Ambulance Service]. There were also concerns about the quality of the multi agency plans as these are difficult to achieve without high level support; "it's about getting people's buy-in for something that you might perceive as important but actually they think it's somebody else's job to do" [I5. Emergency Planner - Planning Organisation]. Authorising the mainstreaming of resilience issues within organisations is an area for improvement, and a lack of awareness of agency involvement in the LRF prevents personnel from engaging with the process, with an example being given of a community safety department not being involved in a 'warning and informing' sub-group, despite the potential benefit of their involvement.

5.3 Communicating with the Public

The UK Government's Community Resilience Programme (HM Government, 2011, p.5) aims to "increase individual, family and community resilience against all threats and hazards". An important aspect of this aim is the requirement to facilitate discussion between all stakeholders, including central government, emergency services, the voluntary sector and communities on good practice. Giving the general public, and specifically local communities, this shared responsibility in ensuring community resilience is arguably a sub-text to the UK Government's strategy to devolve resilience decision-making to the regional and local levels so that interventions are more likely to be self-sustaining.

Central to the Communitry Resilience Framework is effective risk communication at local level to increase awareness and enhance public response. Although there are advances in this area, some interventions that would increase resilience require legislation, in order to, for example, allow mobile phone broadcasts to be made "and just blast everybody's mobile phone to say there's been an incident in Nottingham city centre, please make your way to wherever, and that technology exists" [I9. Emergency Planner - Police Force]. A flood warning system used by the Environment Agency to warn the public of flood risk exists, however take up of this is low, as homeowners "don't want to know because it potentially affects their insurance" [I8. Senior Manager - Planning Organisation]. Consequently, the Environment Agency is considering how to make membership of this list the default position.

5.4 Use of Tools and Hardware

While different agencies use various tools and hardware, there is no common information management system subscribed to by all, although all stakeholders can subscribe to the secure National Resilience Extranet (NRE) which was developed by the Civil Contingencies Secretariat to provide access to restricted documents. Although agencies have been encouraged to do this, not all have done so, with one reason being that it can cost between £15-20,000 per organisation. Atlas Incident Management System (AIMS) is used by several responders however, including the Ambulance service, the Police, the Fire and Rescue Service, and the County and City Councils. The system works through the logging of information and the actions that are required, the allocation of someone to achieve those actions, and whether this has been completed or not [I7. Emergency Planner - Fire and Rescue Service]. The above challenges of strategy, finance and communication are areas that underpin all aspects of resilience; without addressing these broader issues, the success and long-term sustainability of the multi-agency response enshrined in the LRF cannot be guaranteed, despite the skills and efforts of the individuals and organisations involved.

6 CONCLUSION

This paper has explored the interconnectiviites between resilience and sustainability in relation to emergency planning and urban design within the UK. Ideally, the design, construction and operation of urban space should be based on principles that are both sustainable and resilient. With this as a starting point, ensuring resilient management and operation of these spaces naturally follows. However, a further challenge is to manage the existing urban built environment to ensure that effective emergency planning is in place and resilience is maximised. The Nottingham case study highlights a range of promising practice in the UK that increases the resilience of urban space to a range of hazards, threats and major accidents. Central to such successful practice has been the effective individual and organisational relationships, familiar structures for command and control, and level of input into the design of urban space. These examples demonstrate that resilience is actually an integral part of the sustainability of urban space, and not simply compatible with it.

However, such progress is threatened by the potential impact of fiscal constraints and in particular the public sector spending cuts, the difficulty in securing senior management engagement with the LRF, and communication and engagement with the public and local communities. These factors are inevitably linked as increased prioritisation is demanded by restricted budgets. Research has already shown that incorporating resiliency measures can also lead to environmental benefits and increased sustainability, so there is a need to identify such cost-effective solutions for stakeholders so that they continue to prioritise the protection of urban space. However, further investigation is needed to better understand the integrated nature of urban space, how its users are made safer, how its natural environments are better protected, and how urban space can be made less vulnerable to the vast array of hazards, threats and major accidents that pose risks to it.

Urban Development 2050: Resource Efficiency as Guiding Principle for Rebuilding European Cities

1 ABSTRACT

Results from the FP 7 project SUME (Sustainable Urban Metabolism for Europe) show the long term im¬pacts of urban form and alternative spatial development paths of European metropoles on resource flows such as land consumption and energy consumption (until 2050).

For the first time, the concept of urban metabolism has been used in a spatially explicit way, demonstrating the effects of transformation of urban form on resource flows. By analysing the current and future spatial dis¬tribution of population and jobs, the transport system and urban building technology, impacts have been mo¬delled. The potential effects or resource-oriented urban planning are substantial: the expansion of the agglo¬merations analysed can be reduced altogether, especially in dynamic cities. The fastest growing agglomera¬tions in the group are Munich, Stockholm and Vienna, where the expansion to 2050 can be greatly reduced by -68 %, -57 % and -75 % respectively. This differentiated spatial development pattern has a great impact on the potential to provide and use attractive public transport.

In order to follow these strategic recommendations, it will be essential to develop a cross-sectoral approach in urban development, integrating urban planning, housing policies, energy policies, infrastructure provision and transport policies. Such integrated, coherent approaches for the development of new and existing urban quarters, however, are hardly being found nowadays. This disjunct, sectorial policy approach is presenting the greatest challenge in bringing about a sustainable, resource-oriented restructuring of European cities.

2 SUME APPROACHES

Results from the FP 7 project SUME (Sustainable Urban Metabolism for Europe) show the long term im¬pacts of urban form and alternative spatial development paths of European metropoles on resource flows such as land consumption and energy consumption (until 2050).

For the first time, the concept of urban metabolism has been used in a spatially explicit way. By analysing urban form and transformation pathways and depicting current and future spatial distribution of population and jobs, the transport system and urban building technology, impacts have been modelled. This has been done in four integrated approaches:

(1) Approach 1: In a long-term scenario approach 2050, alternative urban development perspectives (a trend-type versus a resource-minded development path) have been applied in a consistent way for seven case studies (agglomerations of Vienna, Stockholm, Oporto, Newcastle, Athens, Marseille and Munich), providing with the spatial distribution of population and workplaces in 2050. Demographic and economic development dynamics, of course, are the main parameters influencing the potential to change given urban form.

Results from urban develop¬ment scenarios and metabolism models (below) have been integrated. While the scenarios provide the spatial allocation of population and workplaces and estimate the future use of urbanised land, the metabolism models' focus is lying on estimating building- and transport-related energy flows.

The potential effects or resource-oriented urban planning are substantial: the expansion of the agglomerations analysed can be reduced altogether, especially in dynamic cities. The fastest growing agglomerations in the group are Munich, Stockholm and Vienna, where the expansion to 2050 can be greatly reduced by -68 %, -57 % and -75 % respectively. This differentiated spatial development pattern has a great impact on the potential to provide and use attractive public transport.

In four case studies (agglomerations of Vienna, Stockholm, Oporto, Newcastle), a comprehensive application of all four SUME approaches (see below) was performed.

(2) Approach 2: The spatially explicit urban metabolism model allows for systematic simulations of the functional relations between socio-economic developments and their consequences on the urban metabolism. Based on the scenarios´ spatial allocation of population and workplaces, the metabolism models' focus is on estimating building- and transport-related energy flows (for four key case study agglomerations, Vienna, Stockholm, Oporto, Newcastle). The model can be extended to include greenhouse gas (GHG) emissions and other resource and waste flows. The model was designed in a modular, incremental and flexible way in order to be applicable at different levels of spatial and functional aggregation, ranging from the low spatial resolution applied in the SUME cross-city com¬parisons to relatively detailed and data-rich analyses of selected areas within a city.

(3) Approach 3: Since cities are built in a step-by-step way, with larger or smaller development projects changing the existing structures, it is important to understand the projects' individual contributions to the improvement of the overall performance of a city/agglomeration. The Metabolic Impact As¬sessment (MIA) is a novel methodology to evaluate the effect of proposed urban development pro¬jects on the metabolism of a city. It is a decision-support tool geared to analysing and understanding the complex metabolic consequences of new urban projects or urban plans, e. g. in terms of energy flows associated with the project, for heating, cooling and transport.

MIA addresses a common problem found in many cities throughout Europe and elsewhere: Seen in isolation, a project may look quite attractive and contributing to a sustainable performance regarding energy, land use and material use. However, when plugged into the existing urban fabric of buildings and infrastructure, the impact analysis may show a contribution to a worsening of the metabolic performance. Thus, only projects in the right location and with good infrastructure can provide a positive contribution to the overall metabolic performance of a particular city. This is shown in the four case study projects in four cities.

(4) Approach 4: Urban agglomerations' development processes are very complex. Many factors inter¬sect to generate the spatial pattern that we see in the built environment today. Hence also the proces¬ses, actors and their respective rationales were under scrutiny in the SUME project: 'producers' of the urban fabric, such as landowners, developers and investors, are important players, but they are not the only actors who matter: 'consumers' are also crucial. This group includes individuals and companies who use buildings and spaces in cities, not just the inhabitants of homes and offices, but also visitors to the city, whether for work, shopping or recreation. Sustainable, re¬source-oriented ur¬ban development policies need to understand these complex interactions of pro¬ducers and con¬sumers, and will have to be integrated urban policy packages, addressing both sides and – as has been shown in the analyses of the four case study cities – will have to be coherent over different policy sectors and municipal boundaries.

3 SPATIALLY EXPLICIT METABOLISM MODELLING

Urban metabolism encompasses all flows of energy and material resources of a city or agglomeration; in SUME the relationship between urban form and urban metabolism has been analysed in a long-term development perspective to 2050. It is about the contribution of urban development and reconstruction towards more resource-efficient cities. With the majority of the global population living in urban areas, the question of how existing cities can be rebuilt in more resource-efficient and climate protecting way, is key to our common future. If global efforts to address climate change are to be successful, they will need to integrate city requirements and environmental management capacities (UNEP/UN Habitat 2009).

The urban metabolism concept investigates the biophysical interaction between a society and its environment, by accounting for resource use (energy, materials, land, etc.) and outputs to the environment, and linking these with social, economic and technical parameters. Here, the concept of urban metabolism for the first time is being used in a spatially explicit way, demonstra¬ting the impact of urban form on resource flows, by analysing the spatial distribution of population and jobs, the transport system and urban building technology. This is performed in a long-term scenario approach, projecting the urban development perspectives of seven European urban agglomerations. For four of these agglomerations, a spatially explicit metabolism model has been developed and applied.

Urban forms have been developing over periods throughout history, and can be changed substantially only over longer periods and/or through dynamic restructuring. In search for the potential to reduce urban resour¬ce consumption, the SUME project estimates the potential to transform urban building and spatial

structures to 2050 by applying alternative spatial development policies for a given demographic and economic develop¬ment path. Urban agglomerations in Europe show extremely different spatial dimensions: some are compact and confined; many are fragmented and spread out spatially. Urban transport systems are of very different qualities: some with attractive, well integrated public transport provision; some with reliance on individual transport. Technical building standards – often related to the period of construction – also vary widely, adding to the impact of greatly different climatic conditions. All these differentiations are included in the term 'urban form' as it is used here.

BASE and SUME scenarios – the space for action in seven agglomerations

In the SUME project two different storylines are at the core of two urban development scenarios elaborated for seven cities: a BASE scenario, understood as a continuation of urban develop¬ment policies supporting past spatial development trends; and a SUME scenario, defined as a path of sustainable spatial development. The 'space for action', as referred to in this project, is the choice between these two scenarios, meaning whether or not the SUME principles are being applied in urban development over an extended period. The SUME scenarios – geared to improve urban resource efficiency – are guided by the so-called 'four SUME principles'* for future urban development:

- Principle 1: Spatially focused densification: Promoting a minimum density standard for any new quarter and redevelopment of existing low-density quarters in areas with attractive, high-level public transport
- Principle 2: High-density development only with access to high-quality public transport: Focusing new high-density developments exclusively in areas close to public transport networks (especially those with job and service functions)
- Principle 3: Functional mix in urban quarters: Providing a mix of functions (i. e. residential, jobs and services) in close proximity to each other at the local level, allowing for short-distance access
- Principle 4: Combine urban development and building (object) reconstruction: Improving the thermal quality of buildings and using the opportunity to improve the spatial qualities of urban quarters[1]

* To increase the impact, these principles should be applied in combination with each other.

It seems clear that the importance and potential impact of each of the four principles depends on the current urban form of the respective city. The varying range of potential future improve¬ments in terms of land use and energy consumption is analysed in the subsequent case study cities presented below.

4 RESULTS FROM URBAN DEVELOPMENT SCENARIOS AND METABOLIC MODELLING

4.1 Urban development scenarios in 2050

Urban development scenarios have been elaborated for the so called Urban Morphological Zones (UMZs[2]) of different cities. Comparing the urban development scenarios shows that there is a great potential to impact urban form over time if a consistent set of policies is being applied, as assumed in the SUME scenarios, and if there is some growth. It is important to note that growing cities have a great¬er opportunity to improve existing spatial structures than stagnating agglom¬erations (comparing BASE and SUME scenarios). Therefore, the case study cities with substantial growth perspectives (especially Stockholm UMZ and Vienna UMZ, but also Marseille UMZ and Munich UMZ) show the greatest differences between the alternative scenario futures – there, spatial planning decisions will have a major impact on future metabolic performance.

Comparing BASE and SUME scenarios also shows that the differential between the policy sets add up and become resource-relevant over time: There is significant room for improve¬ments, if past spatial development has not been consistently sustainable (as in the case of Vienna: filling up spatial gaps near major lines of transport and moderate densification in underused but well serviced areas can have a major

[1] Likewise, these efforts should be seen in combination with Smart City initiatives, improving the production of renew¬able energy and the intelligent distribution of energy flows.

[2] The continuously built-up area of an agglomeration, as defined by UN-Habitat (200 m max. distance between buildings, based on the CORINE land cover data).

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

impact). On the other hand, the case of Athens also shows the limits to a strategy of further densification: here, densities are already high enough to provide attractive urban transport systems; expanding and improving the transport system is a key for more sustainable transport in this agglomeration.

The BASE scenarios show a substantial expansion of the UMZs for the fast growing cities, ranging from a growth by 24 % in Athens UMZ to 30 % in Marseille UMZ, 41 % and 47 % in Munich UMZ and Stockholm UMZ to 54 % in Vienna UMZ. These results are due to population increase, a pro¬por¬tional growth of jobs and a continuing increase of the per capita floor space consumption.[3] It has been assu¬med here – based on the empirical evi¬dence of the past – that the historic trend of floor space increase will con¬tinue in a stable eco¬nomic development, but the per capita growth will slow down compared to past decades.

From this 'baseline' of expected development, the so-called SUME scenarios demonstrate a develop¬ment path which should provide for lower resource consumption (land use, energy, materials) and can be reasonably achieved through concerted urban development policy packages. SUME scenarios focus on inner-city development, high-level public transport axes and more compact development on the fringes of the existing UMZ.

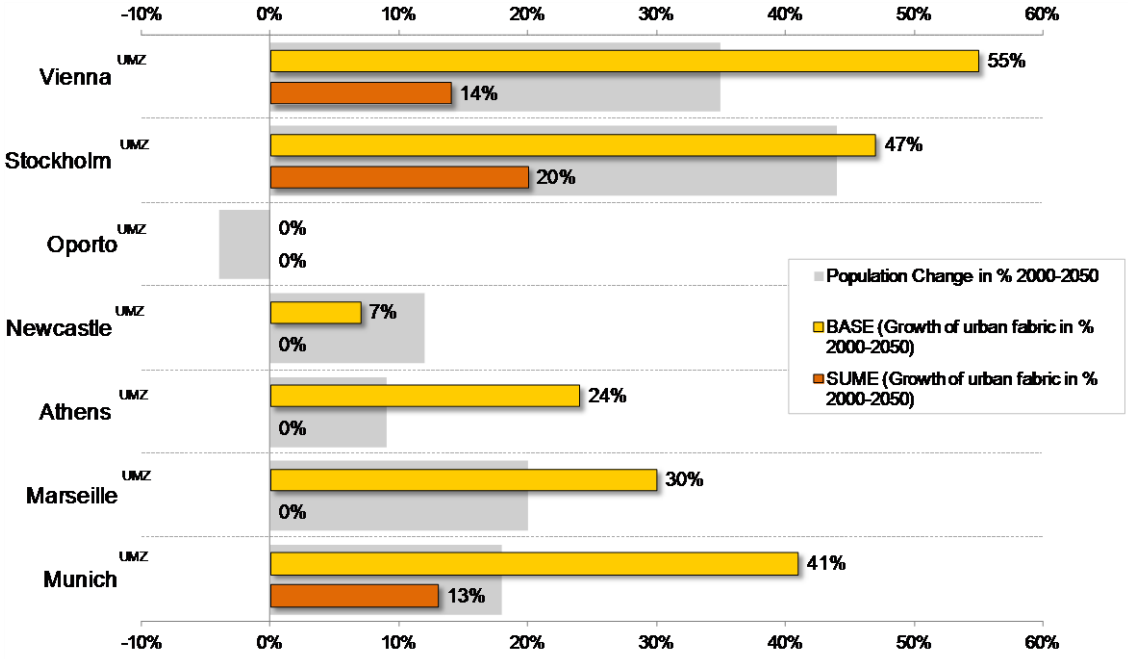

Fig. 1: Spatial development scenarios: Population growth and expansion of the Urban Morphological Zones (UMZs), comparing BASE and SUME scenario. Source: SUME Working Paper 1.2 (2011).

The potential effects – the results of the search for an 'action space' – are substantial: the expan¬sion of the agglomerations analysed can be avoided altogether in Oporto UMZ and Newcastle UMZ, mainly due to their small demographic development, but also in dynamic cities such as Athens UMZ and Marseille UMZ. The fastest growing agglomerations in the group are Munich UMZ, Stockholm UMZ and Vienna UMZ, where the expansion to 2050 can be greatly reduced to 13 %, 20 % and 14 % respectively. This differentiated spatial development pattern has a great impact on transport, with a direct ef¬fect on the potential to provide and use attractive public transport. This effect has been ana¬lysed through a combined transport and diversity-pattern indicator, which shows a considerable de¬terioration in all BASE scenarios and the need for concerted policy measures – as in the SUME scenarios – in order to maintain or slightly improve the existing level of public transport provision.

4.2 Overview results from metabolic modelling for the four main case study cities

The individual case study city results for the two spatial development scenarios, with their spatial distribu¬tion of jobs and residents, localisation of services and central functions and fast lines of public transport, were used as input for the spatially disaggregated modelling of energy flows in the four cities (Vienna, Stockholm, Oporto, Newcastle).

[3] Defined as average per capita residential floor space in m².

The table below, an overview of the main results for the agglomeration aggregates is given for both, the building and the transport model results. It shows the final state of development in 2050, comparing the per capita energy demand figures for heating and transport in the BASE and SUME scenarios. The main results show that today's energy demand can be reduced by 60 % to 80 %, varying between cities and scenarios. In general, a SUME-scenario-type agglomeration development will reduce energy consumption between 10 % and 40 % by the year 2050 compared to the BASE scenario.

	Vienna UMZ	Stockholm UMZ	Oporto UMZ	Newcastle UMZ
Per capita energy demand for space heating in 2050 (GJ p. a.)				
2001	**42,8**	**57,0**	**22,8**	**50,6**
BASE scenario	**16,1**	**18,0**	**9,9**	**18,3**
SUME scenario	**9,2**	**11,1**	**8,8**	**9,8**
SUME vs. BASE (abs.)	**-6,9**	**-6,9**	**-1,1**	**-8,6**
SUME vs. BASE (%)	-42,7 %	-38,1 %	-11,1 %	-46,8 %
Per capita energy demand for transport in 2050 (GJ p. a.)				
2001	**11,2**	**15,3**	**17,8**	**13,3**
BASE scenario	**5,6**	**7,3**	**5,1**	**4,0**
SUME scenario	**3,9**	**5,7**	**4,9**	**3,5**
SUME vs. BASE (abs.)	**-1,7**	**-1,6**	**-0,2**	**-0,4**
SUME vs. BASE (%)	-30,0 %	-21,8 %	-4,9 %	-10,7 %

Fig. 2: Metabolic modelling results: Per capita energy demand for heating and transport 2050 in four cities (UMZs). Source: SUME Working Paper 2.3 (2011).

The following figures show the modelled development of energy demand in the periode 2001-2050 and the space for action between BASE and SUME scenarios for the examples of Vienna and Oporto – the two UMZs with the highest respectively the lowest action space in terms of energy demand.

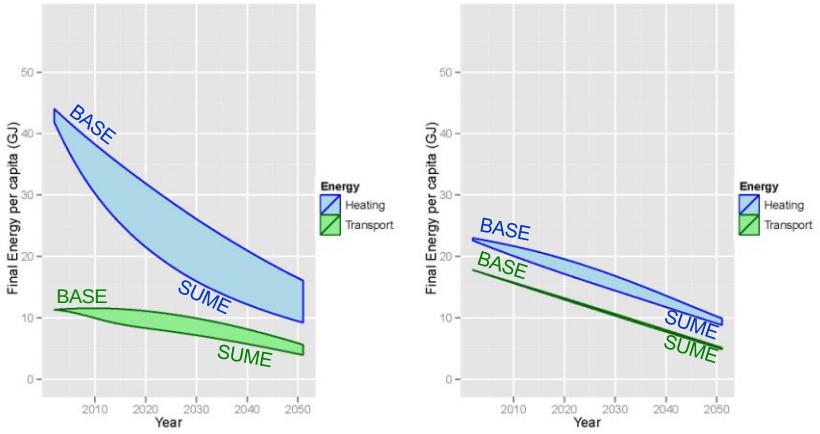

Fig. 3: Metabolic modelling results: Per capita energy demand for heating and transport 2001-2050 in Vienna (left) and Oporto (right) UMZs. Source: SUME Working Paper 2.3 (2011).

The results demonstrate that, even in a future agglomeration development which will use all available tech¬nological improvements, there is a great differential between a BASE- and a SUME-type development: A higher replacement or renovation rate of buildings and a better spatial focus of new developments with respect to public transport accessibility will reduce energy con¬sumption by 30 to 40 %. Only in special situ¬ations like in Oporto, where relatively small changes are anticipated for both components – buildings and transport – will the differential between the BASE and SUME scenarios be less than 10 %.

5 METABOLIC IMPACT ASSESSMENT (MIA) FOR URBAN DEVELOPMENT PROJECTS

In principle, Metabolic Impact Assessment (MIA) can be applied to different types of planning proposals – policies, programmes, plans and projects. However, within the scope of the SUME project, it was applied to detailed plans of large urban development projects. It has been recognised that at strategic levels, MIA's application will be complex and demanding. At a local level, data is more easily identified and the analysis becomes more objective.

Within the general objective of SUME, to analyse the impacts of urban form on resource use, the application of MIA has focused on specific components of urban metabolism, namely energy, land use, water and materials. Moreover, in each case study some limitations of data have caused further restrictions.

The four case studies in the European cities of Vienna, Stockholm, Oporto and Newcastle have demonstrated the application of this new method. The case studies show the impact of projects, compare them with the performance of alternative projects and of the relevant districts within the agglomeration. Applying MIA can lay the ground¬work for improving planning proposals in key aspects of urban metabolism and also contri¬bute to a necessary assessment of alternative locations for such projects within the urban fa¬bric. MIA shows that it is essential to include the impacts of urban development projects regar¬ding infrastructure needs and transport in the agglomeration context, because a) unexpected effects in other sections of the complex transport network can be detected; and b) underuse of existing infrastructure in certain districts can be determined. Both of these potentially lead to substantial project modifications.

6 METABOLISM-ORIENTED, SUSTAINABLE URBAN DEVELOPMENT STRATEGIES

To improve the metabolic performance of a city or agglomeration, urban spatial development strategies should focus on the application of the four SUME principles for developing new settlements and for rebuilding existing quarters. This would be an ongoing process with a clear strategic orienta¬tion:

- Containment at the level of agglomerations: reduce urbanisation expansion to a min¬imum, keep travel distances low, provide for good spatial access to public transport routes and attractive service there. Currently most growth happens in the spaces be¬tween transport axes in areas out of reach of attractive public transport.
- Spatially focused densification in low-density urban outskirts: key strategy in growing cities to avoid expansion and improve transport service quality.
- Locate services and offices at transport nodes and allow for a mix of functions at neighbour¬hood level: the busiest nodes of agglomerations' public transport systems are attractive for office and service space, and most advantageous for the location of jobs with excellent access to public transport. At a neighbourhood scale, it is also important to have a functional mix within each of the urban regions' neighbourhoods to provide for services and access to daily supplies at short distances.
- Improve agglomerations' public transport systems: some urban regions have comparatively high densities, but do not provide well developed public transport systems – there exists a great potential for improvements, particularly at agglomeration level (reaching out from the core city into the surrounding urbanized area).

Urban development policy packages (see below) need to be oriented towards the following:

- All urban growth and the life-cycle turnover of built structures should be used as potential to improve the existing urban form, both in terms of spatial structures and object qualities – urban growth in this sense is not an enemy to sustainable development but can be a partner in getting there.
- Large urban development projects can be located and serviced with infrastructure in such a way that they improve the overall performance of a whole area of a city/agglomeration (see MIA).
- At the level of users/developers, all ongoing relocation and renovation activities have the potential to improve urban form qualities, if continuously directed regarding location, building standards and functional distribution (residential, services, jobs).

Renovation and building rehabilitation programmes for urban quarters should reach beyond solely improving thermal qualities, but include raising inner-city attractiveness (green spaces, pedestrian/bicycle mobility, services) and putting metabolism-relevant technology in place (this means connecting this spatial strategy with smart city initiatives, e. g. including energy networks, storage and production of renewable energy).

In order to follow these strategic recommendations, it will be essential to develop a cross-sectoral approach in urban development, integrating urban planning, housing policies, energy policies, infrastructure provision and transport policies. Such integrated, coherent approaches for the development of new and existing urban quarters, however, are hardly being found nowadays, presenting the greatest challenge in bringing about the sustainable, resource-oriented restructuring of European cities (see policy recommendations below).

When following these general recommendations, it is important to note how different the starting conditions and development perspectives in European city regions are: urban form, density and fragmentation and the quality of existing transportation networks demonstrate tremendous differences. Adding to this complexity,

the outlook for future population and economic development ranges from fast growth to stagnation or even decline and out-migration.

As a result, fast growing urban agglomerations have a greater potential to improve their exis¬ting urban form overall – stagnating agglomerations need to focus on strategic use of their turnover potential and improve¬ments to existing urban quarters.

The second challenge for those urban regions, however, comes from the fiscal side, since stagnating cities usually have only very limited financial resources with which to improve public transport systems and support an aggressive renovation strategy. Those city regions will need most attention and support from the national and/or EU levels of government.

A portion of these recommendations have been applied in the SUME case study cities; still, in most cities and their respective urbanised regions, it seems to be a long way from a coherent and complete implemen¬tation of the recommended development strategies.

7 METABOLISM-ORIENTED, INTEGRATED POLICY PACKAGES

Based on the SUME findings, we recommend that at the EU, national and municipal levels, the metabolism-oriented spatial development strategies as described above should be incorporated into urban policies, strate¬gies, and plans. At all levels, these policies may be encouraged through:

- using an urban agglomeration perspective (e. g. UMZ) as the basis for information gathering and comparison, as well as coordinated policy development and implementation;
- introducing metabolic standards for urban areas as a way of raising awareness and policy development;
- using comparative, long-term metabolic scenarios for information, coordination and action;
- encouraging Metabolic Impact Assessment (MIA) as an additional method of evaluating new developments and improving the conditions of existing areas.

A coherent, integrated policy approach for sustainable, long-term urban development should encompass five key elements, addressing both sides of urban development, producers and consumers:

Governance, planning and building regulations; incentives; education and raising awareness; direct pro¬vision; and promoting behavioural change.

Governance, planning and building regulations

Planning processes need to be integrated in governance structures that allow for cross-sectoral strategy and decision-making. Anchored in such a comprehensive governance structure, plan¬ning processes should be designed and equipped in a way that they can proactively elicit the participation and contribution of non-governmental actors (both private and public). It is increasingly important to strategically bundle public and private resources together. Commit¬ment of stakeholders and strategic leadership through the municipalities become the crucial characteristic of future sustainable urban development.

Urban redevelopment of existing quarters, smart city initiatives or agglomeration-wide transport systems are examples where such a cross-sectoral approach – also reaching beyond adminis¬trative boundaries – is nee¬ded. Judging from the four case study agglomerations, implementing the four SUME principles will be chal¬lenging for policymakers, requiring much more effective governance structures.

Incentives

Understanding the market mechanisms and the dynamics of property values and property development is a starting point for the design of effective incentives, by which cities can give targeted stimulus and guidance to actors in urban development processes. Effective sets of incentives need to be wide-ranging (crossing administrative boundaries), precise (in relation to development patterns) and long-term. Intervention is necessary to alter development patterns, foster specific built forms and behaviours, and discourage others.

Tax breaks, subsidies and grants in various combinations have been common incentives; in financially less buoyant times, differentiated tax increases and pricing related to behaviour patterns, etc., may be introduced as effective measures. Again, as the experience from the case cities has proven, both targeting and a compre¬hensive approach will be key to success.

Direct provision

Direct intervention by public authorities can steer development towards more sustainable patterns of urban form as described by the SUME principles. Where municipalities have played a direct role in urban develop¬ment, their effectiveness in delivering SUME principles has been noticeable. In the case studies, Vienna, where over half of the households live in either subsidised or municipally-owned housing, may stand out as an example of a municipality's strong, direct role in urban development. Innovative housing competitions are used for large subsidised housing projects, combined with direct provision of infrastructure projects.

In this approach, the active acquisition of building land at reasonable prices is crucial, as in Sweden, where municipalities have the power to acquire land and set up construction and housing management companies. However, these approaches are more geared to greenfield development – a complementary instrument for the redevelopment and densification of existing urban quarters is still lacking.

Education and raising awareness

It is crucial that both the producers and users of the built environment have a high level of awareness of the issues, whether through promotion of standards, codes of practice or under¬standing of the social, cultural and psychological aspects of sustainable development which are key to changing behaviour. Combining this with (and promoting) financial incentives, to stimulate sustainable urban develop¬ment and to reduce CO2 emis¬sions, will increase the effectiveness of awareness-raising initiatives greatly. According to a Stockholm prac¬titioner, the 'pricing of unsustainable solutions could generate better knowledge on sustainable solutions'.

Promoting behavioural change

'Social practices' in relation to individual behaviour play a key role in implementing sustainable urban development strategies. All the case study cities need to do more in this area: the mismatch between the po¬licies' intentions and their actual – visible – implementation often contributes to the reluctance on the part of consumers to adopt more sustainable lifestyles.

Positive examples – encouraging mixed-use developments, thermal improvement, shopping street redevelop¬ment, pilot projects such as large, innovative passive house development (e. g. over 700 flats in Vienna's Aspanggründe) – have had a number of positive impacts, such as improving the thermal quality of existing and new buildings. Encouraging wider involvement and participation at every stage of policymaking can help build broader community support for policies.

8 GOVERNANCE, INSTITUTIONAL CAPACITY AND STRATEGIC EU SUPPORT

Given the complexity of contemporary urban systems, the capacity to design and implement effective urban development strategies depends on the quality and capacity to coordinate interdependent actors within and beyond the formal governance structure.

Working 'in between' the legal system, development processes, the political system and community concerns to achieve public realm benefits is difficult – requiring organisational structures, platforms and pro¬cesses capable of developing, guiding and implementing sustainable strategies. These (new) organisational forms and activities also need personnel skilled in grasping urban dynamics and understanding legal issues, often in relation to complex technical and/or political issues.

Commitment to adopt the four SUME urban development principles is the first step; to bring the relevant actors together into a workable organisation and an effective governance structure is a major challenge. Only then will coherent strategies and policy packages be drawn up, equipp¬ed with resources for implementation and guided through the implementation process. It is clear that work will be required to ensure that the institutional framework necessary for policy implementation is in place.

The lessons from cities which have been more successful in implementing policies to shape urban form in more sustainable ways include:

- Open planning processes with broad participation, so that citizens are fully aware of the factors being considered. If the reasons for the four SUME principles being adopted are made clear, along¬side the targeting of consumers discussed above, this increases the likelihood of building consensus and should increase the level of acceptance.

- Governance structures to maximise plan effectiveness: fundamentally, if the governing bodies in an agglomeration lack the capacity to act collectively, it will be impossible to adopt the four princi¬ples. Proactive organisational development strategies are essential to improve governance capacities.
- Cross-sectoral policy coherence: this also reflects the conclusion that policy context is vital. Inte¬grating land-use planning with transport, legal structures and incentive patterns, energy planning and other policy areas is essential, needing political support and coherence across tiers of governance.

Institutions and policies at EU level

Urban planning is not a formal competence of the EU. Nevertheless, various EU policies and programmes can have substantial impacts on the nature of development in urban areas (e. g. Structural Funds, the Com¬mon Transport Policy, the Air Quality Directive, Birds and Habitat Directives and procurement regulations). These European policies can also exert various indirect influences on urbanisation patterns, some of which can be supportive to sustainable urban development, but others may be obstructive. Promoting sustainable urban development has been at the heart of the EU's regional policy since its inception in 1989.

At the European level, greater attention needs to be given to issues of resource efficiency and urban development in allocating research money (Horizon) and also in the use of structural fund money. Programming, ex ante evaluations, project selection and assessments need to prove that the EU-co-financed project will have a positive net effect in terms of the resource efficiency and the application of advanced technical standards, not a contribution to an ill-defined "economic competitiveness".

However, European cohesion policy will only be effective in supporting sustainable urban development when supported by legal systems within member states that affect land-use planning and development, such as incentives and taxation – particularly taxation related to property – and zoning. Decisions on these policy areas remain the preserve of national, regional or local authorities.

The common challenges to the quality of life in towns and cities are frequently beyond the control of local agents alone. Since the EU has no direct mandate for urban affairs, its involvement in urban affairs must always be sensitive to the subsidiarity principle. However, the performance and development of cities and towns clearly has a European dimension, which must be addressed with supportive action at the EU level. SET-PLAN and Smart City Initiatives, as well as the Research Framework programmes (Horizon 2020), already do have a major impact and will increasingly do so in the future.

It is important, however, that the governance of complex spatial urban development strategies is understood as an essential key for success. Therefore, research and pilot actions, awareness and knowledge exchange will be extremely important in improving urban governance. EU support here will be most valuable, if urban redevelopment is not to be lost within discussions of purely technological 'solutions'. The design and implementation of effective governance structures for agglomeration development also require innovative encouragement on the part of the EU.

The review of actors and institutions involved in urban development has illustrated that the management of urban issues is complex, and is influenced by a multitude of issues and stakeholder interests. These need to be considered and reflected in any policy response. At the European level, policy requires consistency in its urban approach, based on an audit of the impacts of EU policy in terms of the implications for the urban level, and by developing supportive cross-sectoral policies for the urban area. To achieve this, closer partner¬ship with the local level of governance is key, while respecting the multi-level nature of governance in Europe and the specific local division of roles and responsibilities.

Urban Governance and Contribution of Climate Change Consideration and Energy Efficiency: Case Study of Hashtgerd New Town, Iran

Ghazaleh Jasbi

(PhD student Ghazaleh Jasbi, Technical University of Berlin, Leibnizstraße 29, 10625 Berlin, ghazalehcivil2001@yahoo.com)

1 ABSTRACT

Local government, as subset of national state and an organizational framework of city development have a great impact on efficiency and function of the city towards reaching sustainability and energy productivity; and determine interactive of urban management with the main subject of this paper, meaning climate change and energy efficiency. This paper is about best actions and policies that could change the local government of Hashtgerd new town in Iran,[1] to a key and effective elements to develop and optimum execution of urban energy consumption and decrease of CO2 gases. Main efforts were on conformity of environmental conditions and making approaches and actions native, extracted from successful experiences of leading countries. The research approach to encounter with this issue is a combination of applying a multidisciplinary view, urban planning strategies, integrity of urban management and organizational capacity making. Finally, an action plan has been produced, which is a new plan for integrated and coordinated local management in Hashtgerd new town that have a specific look on energy consumption optimization, decreasing of CO2 and sustainability.

In current situation, municipalities, as key elements of local government system in Iran, are responsible mostly in execution of urban development plans and have limited rights in preparing, approval, review and amendment of it. They encounter with several problems such as multiplicity of decision making institutions, implementation of parallel managements, ambiguity of authorization and responsibilities and power, absence of coordination, lack of institutional capacity and urban disintegration (including functional, political, planning, benefits (beneficiary and influential), spatial and structural disintegration). In addition, separation of urban planning and its execution section, resulted in abundant problems and challenges and is one of the main factors of non-fulfillment of comprehensive and detailed plans in urban areas.

New towns, unlike the existing towns have the potential to be energy efficient from the start of their construction. Sustainable urban development and efficient management system at local level are the two essential factors in this context. On the contrary, for new towns in Iran (such as Hashtgerd new town) no special local government system is defined and its position is not clear. This is resulted urban fragmentation, dual management because of interference of authority and responsibilities of New Town Development Corporation and municipality. Thus, due to mentioned insufficiencies, related actions about decreasing climate change, energy efficiency and sustainability, which are in planning and urban designing stages are left from the scope of authorities and responsibilities of urban management and adequate capacity and preconditions for taking any action are missing.

As a result, establishment of an intra-section institutions as an interactive point and homogeneity of organizations and institutions in Hashtgerd new town is necessary. Actually, this institution besides the city council that is a public and elected institution could help to increase the horizontal co-operation across multiple sectors at local and municipal level and the vertical co-operation between central, regional and local level. Also may provide more linkages and interaction among peoples, private sector and non-governmental stakeholders. The aim for establishment of this institution is to provide a multi-level governance framework for the management and planning of the city, to effectively tackle climate change and increase energy efficient urban development.

2 INTRODUCTION

Climate protection is an urban issue. Urban areas produced a high proportion of Greenhouse Gas (GHG) emissions, especially in high income countries. Also, cities are vulnerable to the impacts of climate change, particularly in developing countries. In addition, there are strong argues which support the relevance of the

[1] New town of Hashtgerd is located 80 km west of Tehran. This new town is the case study of Young Cities project that is a German-Iranian research and development project set up for five years until 2013. The young cities project belongs to a worldwide ‘‘family’’ of ten research project that are funded by the Federal Ministry of Education and Research of Germany and dedicated to the question of energy efficient urban development in future megacities.

city level and climate protection. While, cities are places of aggregation of knowledge and wealth, they result in political matters. City levels are an effective scale for political interferences that have fewer obstacles than national and international levels. Also, local political and governance structures could be effective in policy making scopes such as transportation planning, urban planning, urban design and land-use planning and conduct them towards adaptation policies. The said scopes have significant influence on decrease of climatic change and energy consumption because they determine spatial and physical structures and affect energy consumption, directly or indirectly, and therefore diffusion of GHG. Thus, effective solutions need application of the most proper factors and actions in different spatial, physical, institutional, managerial and planning levels, which is resulted in improving of climate change adaptation and mitigation actions in various spatial levels.

This paper is about best actions and policies that could change the local government of Hashtgerd new town in Iran, to a key and effective element to develop and optimum execution of urban energy consumption and decrease of CO2 gases. Main efforts were on conformity of environmental conditions and making approaches and actions native, extracted from successful experiences of leading countries. This aim achieved through exploring good case studies on urban governance of climate change in pioneer and leading countries so that how climate protection is being addressed within local government and engaged with the different forms that through which governing take shape . In fact the processes and power through which governing is arranged is the matter of interest. However, the competencies and powers of municipal governments in these leading countries and Iran differ significantly. What can be achieved at the local level depends critically on the nature of central-local relations, and local competencies for climate protection. I begin by identifying the essential factors behind the growth of local climate governance. I then explore the current situation of urban governance system in Iranian cities (new towns in particular), and the role that local government can play in area of climate change policy and energy conservation . This leads to the formulation of potential, challenges and a model which shows the preconditions and reforms need the current urban governance system in new towns in Iran. The paper concludes by providing a local climate action plan through a multi-sector network approach. Thus, this research has examined both the character and capacity of local authorities particularly municipality and emergence of new forms of governance.

2.1 Local governance and climate change protection

Key determinates for governing climate change in cities

Review of literature shows in order to understand how climate change mitigation is being governed locally it is important to consider: actions across the different modes of governing, potential for local authority action on urban policy sectors, local governance capacity and multi-level governance. Bulkeley and kern (2006, p2243) have identified four modes of climate governance for a local authority. Table 1 outlined the key determinates for governing climate change in cities.

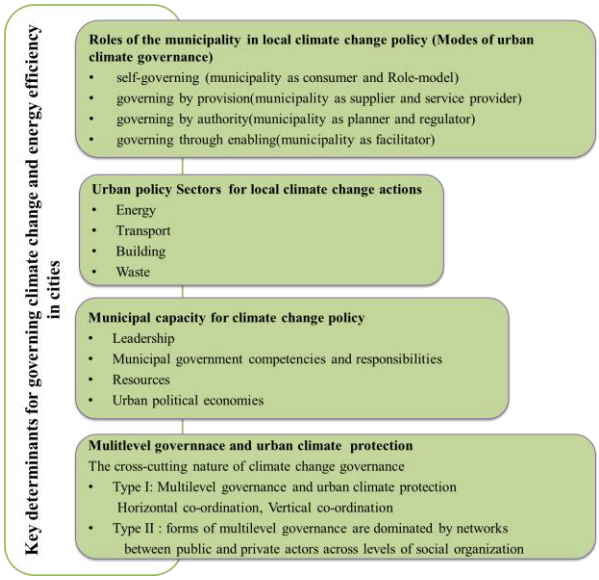

Fig.1: Key determinates for governing climate change in cities. Source: Author

Local governance capacity

A range of authors such as: Alber and Kern 2003; Betsill and Bulkeley 2007; Collier 1997; Schreurs 2008; Bulkeley and Betsill 2003; Bulkeley and Kern 2006; Qi et al 2008 identified crucial factors that shape local capacity to address climate change. The most frequently pointed factors are: leadership; municipal competencies; resources; and urban political economies. Table 1 shows these factors and their importance.

Key factors	Characteristics
Leadership (committed individuals)	In terms of the role of individuals as leaders within a municipality. The degree of institutionalization of climate change agenda by policy entrepreneurs and political champions is critical to local governance capacity.
	Available opportunities for municipalities to perform leadership roles with respect to their peer communities. E.g. the ability of London to position itself at the forefront of the movement of 'global' cities to address climate change through the formation of the C40 network gave strength to internal policy commitments to address climate change.
Municipal government competencies and responsibilities	Competencies, power and duties of municipal government in the key sectors of energy, transport, planning and waste are critical in shaping the capacity for local climate change policy and action. National policy and central-local relationship play very important roles. However, The capacity challenges facing municipalities with respect to their competencies and responsibilities are only partially derived from their relation with national government, but also dependent on their relation with other partners, and on the ability for local governments to create an enabling environment for local civil-society action. It demonstrates that municipalities have competencies both to shape their own emissions profiles, and through the use of different modes of governance (see 2.1) can affect the emissions generated at the local level by a range of actors and activities. Research shows that when competencies for regulation, provision and enabling modes coincide, capacity to act on climate change can be achieved at higher levels.
Resources	Local authorities' financial and human resources can deploy in relation to address climate change. Limited human resources can make a significant difference to the extent and efficacy of measures to address climate change. While lack of finance for basic service provision is acute in many cities, this is also a key issue in relation to the mitigation of climate change for investment in low carbon energy and transport infrastructures. Both, external and internal source of funding are critical. Significant difference in the local capacity to address climate change can happen through secure funding from external sources like national governments. Presence and ability of individual political champions or policy entrepreneurs are the key factors for securing internal funding. Innovative financial mechanisms within municipalities such as energy performance contracting can overcome their inflexible budgetary structures.
Urban political economies	Climate protection is a political issue, where different actors and groups have their own understanding of the problem and responding upon. A key aspect in this regard relates to the priority which is accepted locally. Often climate change responses considered as a negative connotation that slow economic growth and hinder development of basic needs. However, reframing or linking climate change problem to other pertinent local issue such as air quality can mobilize local action on climate change effectively.

Table 1: Local governance capacity for urban climate change mitigation. Source: adopted from Bulkeley et al. (2009)

Multi-level governance

Vertical and horizontal co-ordination (multi-level governance) is another key factor regarding capacities of local governance for climate action. According to Betsill and Bulkeley 2007; Abler and Kern 2008 evidence to date presents that municipal climate change mitigation policy remains concentrated in environmental departments, fragmented, and often isolated from national and regional climate change policy. This is due to dispersed nature of climate change governance which caused a highly fragmented strategies and actions. Therefore, a multi-level approach has increasingly been highlighted and demanded by different authors and expertise in the context of cross-cutting nature of governance (see Betsill and Bulkeley, 2007:448; DeAngelo and Harvey 1998; Bai 2007:24; Crass, 2008:7; Alber and Kern 2008:6). Regardless of the constitutional form of government, multi-level governance calls for a narrowing or closing of the policy gaps among levels of government. It also provides a flexible framework to understand relationships between different actors

horizontally across and vertically between different levels of government. The integration of climate change policies with other policy sectors such as transport, planning, economic development and etc. call for a greater co-ordination between different agencies and policy division within municipalities which calls horizontal co-ordination. On other hand, the vertical relation of different levels of government can enable or constrain municipal responses towards climate change mitigation. According to literature co-ordination of competencies and resources and national level commitment and political will play important roles regarding vertical co-ordination.

2.2 Urban governance and climate change in Iran

In case of Iran, energy consumption and climate change consideration in urban areas is more significant due to its rapid population growth, young population and massive uncontrolled urbanization. One of best example in this regard, which is research area of this study, is the city of Tehran and its surrounding new towns which forming the Urban Growth Center, has a considerable impact on climate change and energy consumptions. Nevertheless, climate change in Iran is not high on the agenda and has low priority. Iranian cities are vulnerable to climate change and have potentially significant contribution to global GHG in the medium to long term, but their responses represents hitherto mostly neglected area for research. However, in recent years, the Iranian government has started to realize the importance of energy efficiency, the use of renewable energies, and is trying to apply them in developing different energy policies and strategies. At the national level, government has implemented the main national policy on energy-efficiency within its Five-Year- Development-Plans (FYDP). Several sectorial policies have also been ratified and several energy-related organizations have been established in governmental institutions. But results have not been very successful due to institutional problems such as parallel institutional structures and a lack of effective coordination. On the local level, which stands in the center of this research study, existing sectorial and national policies for energy efficiency and climate change mitigation have not been very successful yet. Local actors due to highly centralized and sectorial political structures have comparably low influence for these matters. In the case of municipalities, there is a lack of recognition and knowledge concerning the municipal role in improving energy efficiency and climate change mitigation. Also, there is an absence of a well-defined autonomy for municipalities regarding energy issues at the local level. In addition, municipalities are hindered by limitations associated with the power and competencies of municipal authorities and financial resources to implement energy efficient activities. On the other hand, organizations responsible for the planning and management of new towns such as the New Town Development Corporation, the city council, etc. are currently not sufficiently aware and have not performed adequately in this regard up till now (which is also the case in Hashtgerd new town). The importance of energy conservation and CO2 reduction becomes readily apparent if one considers first the growing trend of new town construction in Iran, and second that these new towns, unlike existing ones, have the potential to be energy efficient from the start of their construction. Here, I review each of these factors in turn. This problem is also obvious in new towns of the country.

Macro administrative- executive system in Iran

Studies and assessments about current situation of urban governance system in Iran demonstrated different problems. A large part of these problems are the result of inappropriate macro administrative-executive system of the country. The main features of this system are expressed in detail below.

Political- social history of Iran demonstrates that regarding political development level and its social-economical structures, it is classified in centralized systems. Factors such as long record of absolute governments and severe political and administrative centralization resulted in non-acceptance of innovation in creation of policy making and legitimacy (Ghavam, 1993). This is resulted in the fact that the current organizational structures were under dominance of dative and formal elements and there was less space for informal and selective elements. The mentioned general conditions caused tendency of managers and managerial systems towards absolute power and dominant of formal authorities and did not permit participation of management systems to informal and public participation. This problem is tangible especially in urban governance system that inherently needs more active participation of peoples and informal groups and had wide consequences. On the other hand, dominance and partial priority and/or absoluteness of the authorities on formal rules and regulations resulted in the fact that top managers have significant effects on their organizations and to fulfill organizational objectives and sometimes personal

benefits, ignore rules and regulations. Moreover to centralization and shortage of general participation mechanisms in the records of society's political culture, weakness and defects of management system and its supervisory mechanisms, gaps and defects in regulations, and inconformity of them with managerial realities and necessities caused more difficulties. The state's administrative organizations were generally established based on sector classification and have sectorial function with vertical relationships in all around of the country, while macro administrative- executive system of the country needs existence of organizations with spatial and multi- section functions. Current relationships are vertical and unilaterally top-down; in a way that decision making is done on top and execution is done on the bottom and there is no significant possibility for interference and participation of the lower levels in decision making process (Hamin, 1992). This macro system includes Iranian urban governance as well . In fact urban governance has been shaped in the framework of this macro system and act based on it. Consequently, these shortages and difficulties have a dominant impact on urban governance system as well.

Urban governance structure: related organizations and their relationships with urban management

Urban governance structure in Iran could be classified in three levels of macro (national), regional and local levels. In macro level, ministries or organizations are placed that their working scope is all around of the country and are capable of decision making about local government. Main units of political division in Iran are: country, province, county, district, city and village. The political division system sets out the spatial framework in which different organizations operate. Usually, all administrative organizations in Iran follow the levels set out by political divisions. Thus, the government system has a hierarchical order. There is no independent local government organizations in regional level, but available organizations are accounted as province branches of the ministries and state organizations that could be act in the province level and effect on urban management in that levels. In local or urban levels, except from municipality, which is the main element of local government in Iranian cities, other organizations, including official or unofficial ones are running the city. Official elements include municipality, city council, governor, county planning council and organizations related to infrastructure and urban services like water, electricity and gas departments.

Current objectives and policies in Iranian local government system are classified based on three resources: 1- Five-year economic, social and cultural development plan of the country; 2- Urban development plans and; 3- Regulations of municipalities. One of the main resources for determination of local government objectives that involves in macro targeting, is the five-year development plans. These objectives and policies are called urban development chapter that have a significant relationship with local government (Taheri, 1992). Knowing objectives and determining resources of the objectives and policies is essential. Objectives give meaning to management and determine what is necessary and why. So, by study and analysis of current objectives in Iranian urban government system we understand importance of decreasing CO2 and optimization of energy in cities and their managerial systems, and necessity felt by the authorities, planners and national, regional and local policy makers. Study and analysis of the objectives and policies demonstrate the following problems and weaknesses: Lack of codified specific and specialized objectives and policies: objectives are implicitly propounded in the scope of local government in the framework of urban development discussions and have not a special part in official documents of the country's managerial and planning sections. This reflects the lack of legal recognition and enforcement of local government and urban management scope in policy making, planning, legislating, and executing as a principal. This marginalized local government and its objectives. Lack of an integrated and comprehended view: Interest and benefit Interference of influential organization and institutions in developing urban policies and objectives, frequent change of top managers and immoderation in basic principles related to local government caused dispersed sectorial approaches which often proved to be expensive, inefficient or even a total failure. Lack of a long term view and approach and no appropriate relationship between objectives and policies: One of the reasons for not fulfillment of the objectives and policies is shortage of specific relationships between macro and micro urban development objectives and the provided policies. It is as a result of excess consideration of micro urban management level, particularly municipalities and not regarding the role and responsibilities of other interfering organizations (at national, regional and local levels) in local government system.

Urban development plans, integrated urban management system and institutional capacity

In current situation, municipalities, as key elements of current local government in Iran, are responsible mostly in execution of urban development plans and have low rights in: decision-making, preparing plans,

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

supervision on plan preparation, approval, review and amendment. This problem originates in the fact that planning and executing system of urban development in Iran is defined basically in separated rules, indeed of one hand, urban development planning system is ruled by Ministry of Housing and Urban Development that includes wide expertise, which relates directly with urban development planning in all around the country under the supervision of Supreme Council of Urban Development and Architecture. On the other hand, implementation system of the approved plans is defined variously and a executive system is provided to the municipalities (Kazemian, 1995). This matter results in a severe distance and separation what is propounded in the plans and what is done by the municipalities. This is also one of the factors of non-fulfillment of comprehensive and detailed plans in urban areas. Also, in this planning and implementing cycle, no specific position is accounted for public participation in the planning. Actually, submitting planning to the Ministry of Housing and Urban Development is decreased participation in planning to the minimum. On the other hand, municipality has not established an appropriate position for public participation, or if it does exist, it is in the primary levels. In execution section, municipalities encounter with several problems, of which the most important are: the multiplicity of decision-making organizations, duties and responsibilities overlapping and parallel managements in different urban scopes, ambiguity of authorization and responsibilities of organizations and lack of coordination between other influential organizations in execution part of the plans . This matter emphasized on the current urban disintegration in Iranian cities. The disintegration include functional, political- planning, benefits (beneficiary and influential), spatial and structural disintegration. Another important aspect, is capacity and effectiveness of municipality organizational structure, their human and financial resources (Barakpur, 2010). However, in some cases, establishing working groups, agreements are concluded between these organizations, because of several reasons, including changing of managers, violation in benefits, inflexible nature of the organizational structure and no tendency towards participation for solving the common and complex problems, cooperation is not continued. Thus, two key factors, meaning integrity and cooperation between organizations and related institutes are established less. As a result, resources wasted, current situation became unorganized, cities are not appropriate and balanced, unfair and violation of Citizen's public benefits. So, necessity of intra-section institution as an interactive point and homogeneity of organizations and institutions is observable. Next part discuss this matter in detail (see 3.2).

3 A LOCAL CLIMATE ACTION PLAN IN THE NEW TOWN OF HASHTGERD

3.1 Current situation in Hashtgerd new town

New towns in Iran like other old cities, encountering all problems and challenges that mentioned above, affected by inappropriate process of management and urban development plans; a process that was encountering with different problems and could not fulfill expectations and development perspectives. Based on my research, in new towns no special urban management system is defined and its position is not clear. Even, the New Town Development Corporation (NTDC) that is specifically responsible for new towns, has not fulfilled any research on this matter and relies on other problems of the new towns and believes that this issue is included in other discussions.This is resulted in various problems, of which the most important is urban differences, dual management because of interference of authority and responsibilities of NTDC and municipality. At present Hashtgerd NTDC and the municipality possess equal authority, since the town is developed enough to have a municipality, but not completely to dissolve the NTDC. This fact, quite often brings the two organizations into conflict, which is unhealthy for the development of new strategies and action plans and may cause delays and problems. Thus, lack of a distinguished and integrated system, we could not be involved in the research synthetic issue, which is the relationship of urban governance with optimization of energy and decrease of CO2 gas. Therefore, the primary weakness shall be removed partially and then the combined issue can be involved. The research approach to encounter with these issues is combination of applying interdisciplinary view, urban planning strategies, integrity of urban management and organizational capacity making. My attempt was to find out the expert opinion, definition and understanding of the local climate protection actions and policies according to the functions and powers of local actors and municipality. Also, the preconditions needed for an effective implementation of local climate protection action plan. Following this, Stakeholder analysis approach was undertaken using a qualitative research method. Different levels of stakeholders, including city policy-makers, expert's member from municipality and city council, energy providers and community members were interviewed as either

individuals or focus groups. Interviews with actors within the municipality and NTDC revealed that not much is done regarding climate protection and energy efficiency and that these officials are little concerned about the climate change consideration, energy consumption pattern and efficient use. It seems that the critical role that energy plays in economic development, social welfare, and environmental sustainability is underestimated. This stems from the lack of awareness and information and the absence of an ethical consumerism culture, but could also be due to an optimistic dependency on fossil fuels (in which Iran is quite rich). Another obstacle is the absence of a dedicated budget for an energy efficiency program. However, to maintain a sustainable development which is the target of new towns, energy management in a sustainable manner is essential. Communication with the Technical Committee of Urban Development Studies and the Center for Cooperative Affairs of Hashtgerd NTDC, revealed that the scope of work of NTDC is mostly in infrastructure and urban development and their activities in the field of construction of residential units is done by participating in cooperative projects by transferring the land to public and private investors and developers. Therefore NTDC as a client and also as an executive organization must have a proper control on the construction and execution of projects. Hence one of its responsibilities is controlling the implementation of code19.[2] But since necessary measures and actions for energy conservation in buildings are costly and developers have to spend more money, the overall cost of the project will increase and consequently NTDC's share of the profit will decrease. Another important deficiency and objection which is directed to the City Council as legislator and decision-maker is the absence of policies and regulations regarding energy and climate protection (Jasbi, 2008). The City Council has to define a program, allocate staff and funds and institute policies to achieve continuous improvement in energy conservation and climate. Implementation of code19 of the National Building Code in Hashtgerd New Town is negligible. Energy auditing has not been carried out on any of the existing buildings. Since March 2007, the Municipality made the implementation of code 19 compulsory for all new constructions. This is clearly stated in building licenses issued by the local government. Issuance of the building license, depends on the provision of energy efficient concepts (e.g. envelop insulation, double-glazed windows, etc.) in the detailed design. But corruption, bribery, carelessness and lack of cooperation between responsible organizations and also lack of proper supervision hinders proper implementation. The fundamental reason behind this is that officials, residents and developers do not realize the importance of implementing this regulation and hence do not consider it seriously. In their opinion it is more of a theoretical concept and a farfetched ideal. Interviewing municipality officials revealed that the municipality is not actively involved in cultural training and awareness rising with respect to energy efficiency and use of renewable energy sources at organizational or community level. Without proper education through adequate programming, changing the attitude of the citizens will be very difficult. Community participation in matters and decisions, concerning the city is negligible. And as mentioned before the key issue is the absence of a well-defined energy management-climate mitigation sector within the municipality.

3.2 Formation and evolution of the intra-section institution

In this part of the paper, the actions taken against the problems and recommended approaches are provided. Based on the mentioned aspects, final part of the paper is about establishment of a coordinating institution for urban development planning and management system in Hashtgerd new town. Finally, I have provided an action plan that has a specific look on energy consumption optimization and decreasing of CO2. The aim for establishment of this institution is management and planning for city development, which is as a homogeneous point and unity for decision making in intra-section levels and particularly, between central and local governments. This institution should be established based on an interaction and homogeneous relationship to conduct towards more sustainable development of city. This institution, aside from interrelationship between effective organizations, could facilitate the fulfillment of development plans. In

[2] The Iranian National Building Code consists of common and consistent mandatory elements and applies to all activities related to construction of buildings, including demolishing of existing buildings, construction, change of purpose of a building, expansion of an existing building, and reinforcement of structures (NCEDO, 2003).According to code33 of the National Construction Engineering Disciplinary Organization (NCEDO), the Ministry of Housing and Urban Development is responsible for supervision on the implementation of national buildings regulation and codes in the design and construction of all buildings. Based on this code, the Ministry of Housing and Urban Development has made an effort to publish national regulations consisting of 20 codes, of which code 19 deals with energy conservation in buildings.

fact, this intra-section institution, away from any sectorial and organizational approach, could result in closeness of the government, municipality, city council and people, urban planning system and executive system. To establish the intra-institution, there is a need to take specific actions. Preparation of legal fields as the primary necessity for taking actions, establishing appropriate administrative fields according to institution's policies and objectives and designing the process and completeness of the institution are the most important things. In the first stage, which is creation of the institution, relates to institutional establishment idea based on specific aim. This stage that is based on mutual understanding and agreement builds initial ideas and aims. Here, regarding special problems in urban planning and development, several special approaches are considered. First, urban development plans are prepared by this institution. Since urban development plans (both comprehensive and detailed) define different policy sectors, regulation and guidelines, intersectional relationships and integrated decision making in conformity with organizational objectives, from one hand, and in conformity with fulfillment of appropriate development aim, on the other hand, can be achieved through integrated approach of this institution . In this period, organizational nature of the institution is not independent, but relates to central authorities such as Ministry of Housing and Urban Development of its related organizations and the most activities shall be established based on agreements (Andalib, 2011). Another important approach, which should be included in the organization's programs is involving energy consumption optimization and decreasing climate change in different urban scopes. Actually, in this stage, we only rely on the agreed titles and points and use already existed administrative and financial supports; because the institution has not independent identity and managerial body. The next stage is called institutional stabilizing stage. Here, which is in fact a new period of cooperation, moreover to the Ministry of Housing and Urban Development and municipality, the city council is also entered. Actually, an agreement shall be concluded by and between these three organizations as the main founders of the institution in order to facilitate the establishment of the institution. City council as an elected organization plays a significant role to stabilize this institution. Then, by defining of budget for the institution and approval of annual plan and budget, it will have stable identity and found legal status. But, it should be mentioned that to change an institution from a temporary and agreement stage to legal and formal one, and enters urban management and development planning, needs the parliament approval. At this point the institution enters a stable situation with persistent and permanent identity. As a result, considering problems establishment of an intra-institution in Hashtgerd new town is necessary. Actually, this institution besides the city council that is a public and elected institution could help more relationship of the peoples and government. The following diagram shows stages of establishment and evolution of the institution.

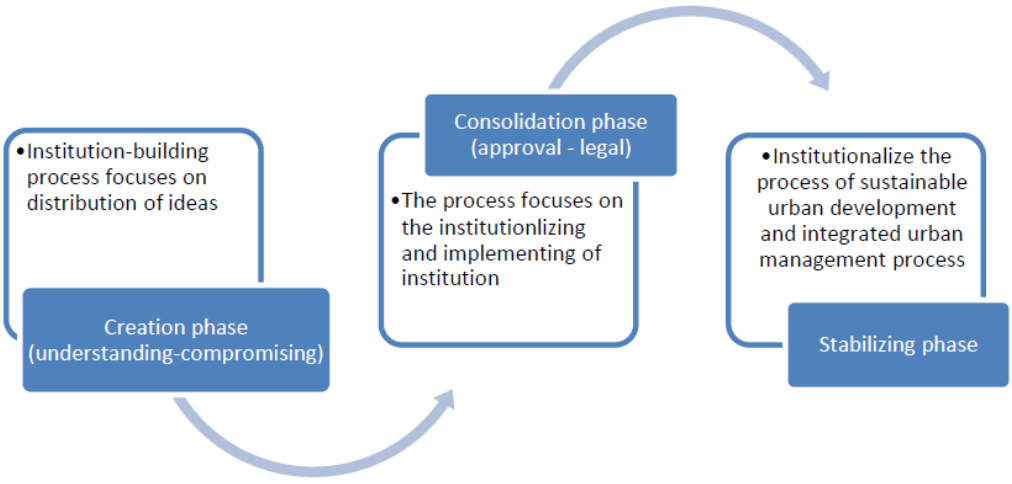

Fig. 2: Stages of formation for coordinating intra-institution. Source: Author

3.3 Development of action plan through a multi-sector network

The intra-institution not only integrates the urban management and planning in Hashtgerd new town, but also helps the local government in providing the action plan to combats climate change. The overall objective of the action plan is to enable local government to sustainability increase energy efficiency and reduce GHG emissions in their own operations and communities. This action plan which will be formed after stabilizing stage of intra-section institution operates through a network governance approach. So that, a multi-sector

network in an open dialogue has to be build inside the intra-institution. In this network participants are a diverse group of actors and organizations from public, private and non-profit sectors. This is because success in the institutionalization of a network as described by Milward and Provan 2006 can only be achieved when the goal formulation and the decision of participation are not dependent of one party or some parties. In this network all participants would strive for a common goal next to their own mission. The starting point is to determine and exchange initial views, their specific view on climate change and what to do about it. Therefore, the first attempt is to make the climate change and energy optimization as a topic of broad interest. After that groups will be formed according to their interests. Themes around climate change topics will agree upon and workshops will be held and fundamentals of the future structure of the network identify. According to output of workshops of each group, different alliances in relevance to their urban policy sector will be set up. The best way to organize such network is to set up a separate administrative unit (here called central board) to support the network, its alliance and activities. This unit plays a key role in coordinating and sustaining the network. Therefore the structure the network consists of the central board and its alliances. The central board is under the direction of intra-section institution.

4 CONCLUSION

In summary, this paper reviews the factors that are important in influencing the development and implementation of urban governance and planning for climate change mitigation. Also the specific local competencies and powers for climate protection and how climate change policies are institutionalized at the local level have been discussed. In Iran, lack of desirable inter- sectorial coordination mechanism as well as integrated urban Management (as part of an integrated spatial management system in the whole country), and lack of policy integration is one of the most basic constraints in implementation of urban development programs including urban energy efficiency and climate protection programs. On the other hand, the study also showed that there are several organizations responsible for some dimension of planning of the city, but not one of them is designed to take the city's unique needs into account. None are enough empowered to bargain the priorities of citizens and municipality as central core of local government. Communication between different agencies, utilities and the city administration are fragmented. Strategies and action for energy conservation and climate change mitigation like improving air quality are often deployed in a highly fragmented manner. Municipality and its affiliated agencies and departments are frequently marginalized within administrative system so that they lack the power and authority needed to co-ordinate policy across a municipality. Therefore they are not able to implement the policies that are required. Climate change mitigation cuts across many sectors such as energy, transport, planning, finance, education and etc. Hence, the current local government system is increasingly calling for greater co-ordination within municipalities and demanding mainstreaming, coordination, and cooperation across government agencies.

Most of the cities that are active in optimization of urban energy consumption and decreasing or conforming actions in climatic changes have an effective and strong local governmental and managerial system. In these cities, discussions about climatic changes, energy efficiency and sustainability in local government system are constituted, and using potentials in the cities, governmental and managerial system could promote and develop these matters. Efficiency of urban governance, results in more sustainable and greater effectiveness of urbanism, have correlation to factors, including political stability, managerial and social integration, economical rise, skill, policy makers and appliers motives. In this condition, framework and organizational characteristics of urban governance, particularly role of execution of governmental, public and private sectors, have significantly essential effects on its success. We also need to consider the Iranian cities and off course new towns don not have a long history on climate change climate protection policies. A systematic climate protection strategies and action plans were not adopted in Iranian local government. Neither found that in municipalities. This very new and unknown subject is intangible for local authorities which makes changes and reactions more difficult in this situation. In addition, integration of climate change policies with other policy issues, the required capacity within the internal organizational structure of municipality is essential. Therefore it is clear that where there is a lack of capacity which is also in the case of Iran the potential of local climate change strategies and policies will be limited.

1 ABSTRACT

This paper takes a close look at the interrelated phenomena of international business migrants and rural migrant workers in Shanghai, China. Through separate case studies of each group's role in the construction process in this rapidly developing world city, we observe them in parallel and shed light on the spatial implications of both groups' migrant status. In doing so, we determine that both groups live in "cocoon worlds", albeit in different ways. We recognize that both groups live in a state of permanent temporariness in Shanghai, and, drawing on work by Lefebvre (1974) and others, we assert their temporary "right to the city" and thus call them "Urban Nomads".

Our uncovering of the stark inequalities and harshly inadequate living and working conditions affecting rural migrant workers in the construction industry in Shanghai leads to our development of a concept of "Fair Building", a socially conscious architecture that calls for accountability in ensuring that rural migrant workers' needs are taken into account so that their living and working circumstances can improve. We address several central arguments for a socially just and sustainable form of urbanization by offering possible strategies for future construction. We propose scenarios wherein urban planners, designers, and architects could include fair building processes in their concepts and builders, contractors, and construction managers could support the fair realization of projects. The arguments for Fair Building ultimately form the framework for our concluding section – the project Lüxing Laoshi, a mobile vocational school for migrant construction workers. This educational program works toward a solution by addressing all participants in construction to support a building process that goes beyond the traditional audience and contributes to a socially conscious architecture.

2 INTERACTING WITH URBAN CHINA – AN INTRODUCTION

"Looking through the window of the little kiosk, the xiaomaibu, one is confronted with a framed view of a typical scene of Shanghai street life: people passing by on bicycles with huge loads on their bike trailers, school children in their uniforms stopping to buy snacks, motor bikes honking. The street is particularly vibrant and busy in the morning. People rush by on their way to work while eating their breakfast, while elderly men and women sit all day at the lane's entrance, children play with toys, near the gate guard and the residential committee's leaders.

This scene is displayed as a movie inside of the original kiosk where it was shot – now located now inside the ddmwarehouse gallery at the Red Town, Shanghai Sculpture Space. For the exhibition "Double Act" 2010 the young Chinese artist Xu Zhifeng aka Shaw worked together with the German artist Petra Johnson to record this spontaneous and authentic Shanghai street culture that is slowly being erased through rapid urbanization. Localized kiosks in Cologne, Liverpool, and Shanghai have been connected with video feeds over the internet, so local residents can communicate across great distances.

The intention is to transform the kiosk from a provider of products for daily use for those in its immediate surroundings into a cultural space connected to the world. The art project gives a small glimpse of recent urban transformations and their environmental effects, as well as China's shift towards the West. The removal of the kiosk also stands as an example of the reckless urban development taking place in China that often doesn't consider local communities. Now this xiaomaibu has disappeared from the streets of Shanghai and has been replaced by one of the shiny new large-scale apartment compounds" (Clarissa & Ulrike's Research Notes, November 2010).

The example of the xiaomaibu (小卖部 , the little kiosk) shows the importance of mapping the social transformation of Shanghai. Here we are employing critical urban studies as a way of reading between the lines of urban space and adding new perspectives to it. To understand the "dichotomous organization of space and society" and how society organizes itself, contextualization is needed that includes local specificities as well as globalized patterns (Madanipour, 2003, p.102).

The development of megacities is a global phenomenon that is particularly visible in contemporary China (and especially Shanghai). In no other country is the process of urbanization occurring at such a large scale and with such speed. In the familiar debate about the quality of buildings that are erected at such speed in China, it is often forgotten that construction is more than the materialized end result. Following arguments from critical urban studies, space is not just a (material) object, nor is it a pure idea; it is also a societal process of production (Lefebvre, 2009 [1974]). It is crucial to understand production of space as a social phenomenon. Thus the main focus of our analysis lies in the relationships between the production of the built environment and the people who are involved in the construction process.

2.1 Construction – a Process

Construction processes are highly depended on capitalism and urbanization processes and are also influenced by the changing balance of social forces, power relations, socio-spatial inequalities, and political-institutional arrangements (Brenner, Marcuse, Mayer, 2009). In the context of this paper, when dealing with marginalization, exclusion, and injustice during the construction process we refer to the need for a profound engagement in the planning phase to achieve greater social and environmental equity by critically examining how space is produced in China. Therefore when considering processes in construction it is important to understand the overall linkages between the involved, their role, their position in the process, and their dependencies.

According to project management principles a stakeholder is a person, group or organization, who has a direct or indirect stake in a process. They can affect or be affected by the process action, objectives, and policies (Wiegand, 2008). Successful project realization implies that particular attention needs to be paid to an efficient project organization structure and to the involvement of qualified experts. Thus a building process can be broken down into a concrete timeline beginning with the project idea and concluding with the actual use of the building. Based on internationally approved models such as HOAI[1] a construction process can be divided in project phases and scopes of action for various disciplines and areas of expertise that are required to deliver the contractually agreed-upon end results.

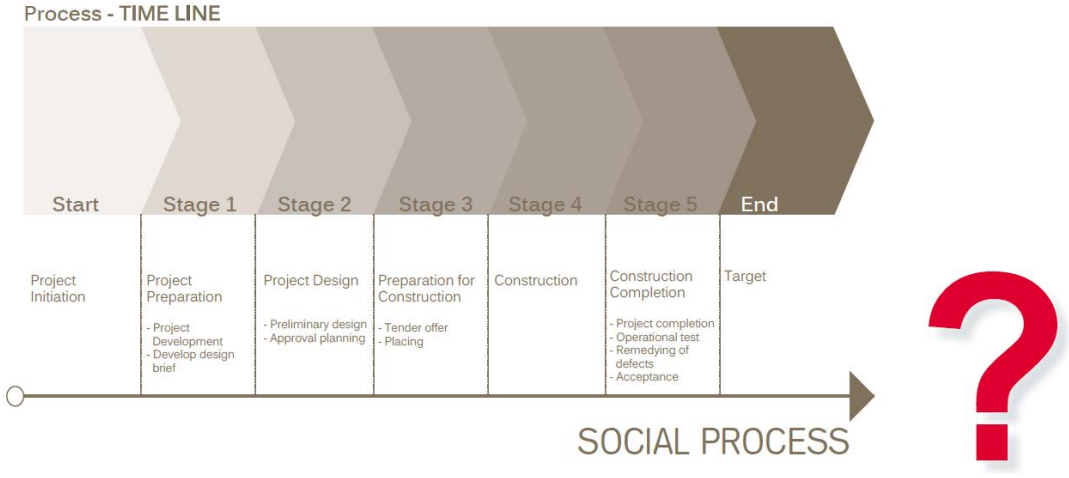

Fig. 1: Stages of the construction process according to the HOAI

While project management studies have analyzed in detail the organization of construction processes, they have not yet considered sufficiently the social processes imbedded therein, nor have they considered that some people involved change their residence according to the building project they are currently working on. The discipline of project management describes the production of material space as a process driven by the three key variables of time, cost, and quality, and has defined the positions of participants involved in the process. The focus is usually on a smooth progression of work on the site and on important interfaces between different disciplines.

However, on the construction site more than just material space is produced. The process of construction needs to be linked to the much larger process of the production of social space, including perceived,

[1] HOAI (deutsche Honorarordnung für Architekten und Ingenieure, German Fee Structure for Architects and Engineers)

conceived, and lived space as defined by Lefebvre. In China, construction workers actually live on site, which makes the building site a 'lived space', adding a whole new layer to the traditional operations at a site.

2.2 Urban Nomads – a Different Concept of Mobility

This paper is an examination of a very specific group of people: individuals who are involved in various construction processes over time. The ongoing building boom in China has caused them to following their work without settling permanently due to the temporary nature of building projects. Among the people involved in the construction process in China, two groups must be emphasized: internal/rural working migrants and international/global working migrants.

Despite the many obvious differences between rural and global migrants, upon closer examination there are a surprising number of similarities that characterize these two social groups. They are part of the so-called immigration society at the same time as being part of the emigration society. Migrating individuals have effects on the society of origin and simultaneously on the receiving society. One of these measurable effects is the transfer of money by foreign workers to the home country – the remittances.

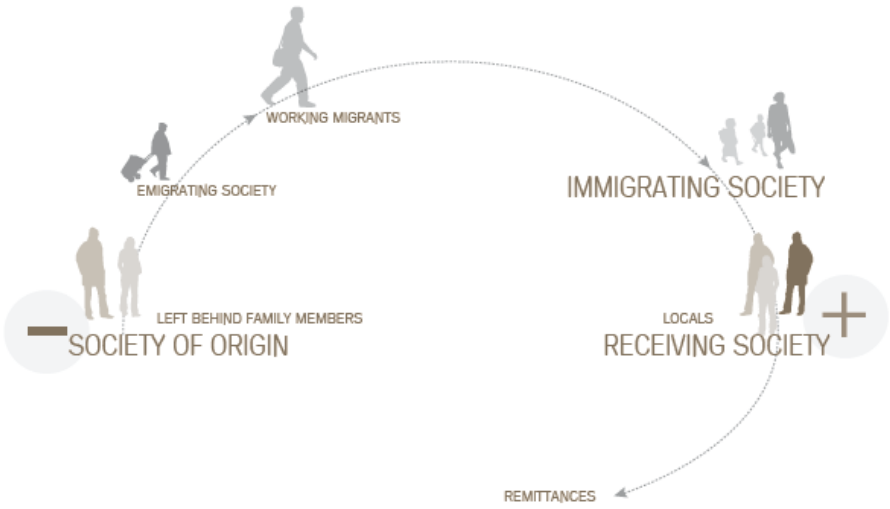

Fig. 2: Societies influenced by migration

Within the vast field of migration we are particularly interested in working migration within the construction industry. Explicitly, this means that we are focusing on peasant migrants who come to the city to work on construction sites as construction workers on the one hand, and on the other hand we are observing Western business migrants who come to Shanghai to work in the construction business mainly as planners, designers, managers, and builders. Both groups are involved in the construction process, but at quite different stages of the process – whereas the construction workers are executers, responsible for manually erecting the buildings, the global migrants are in most cases active in preparation and control.

This juxtaposition is of course a simplification of the much more complex realm of urban production but what makes this observation so relevant in the discourse on migration – they are permanently temporary urban citizens with unique explicit and implicit spatial needs. They repeatedly change their habitat according to their work as they move from place to place. And in this continuous life phase of moving, rural and global migrants constantly seek to connect to emerging opportunities and change their circumstances accordingly. While most migration studies focus on social circumstances, our observations emphasize the social and spatial nature of migration.

By trying to highlight this potential we will call them URBAN NOMADS. Urban, because the phenomenon is particular to the urban environment and nomads, to make a clear distinction between people who have made one or many major moves which are complete and those who are in recurrent temporary living situations caused by their work, for example by the unsteady nature of construction projects. While migration is usually a topic discussed by sociologists, anthropologists, politicians, and other social scientists, the discussions on nomadism are in many cases related to the spatial aspects involved in such mobile lives.

Explicitly, we want to highlight and further observe how urban nomads interact with space, as well as how social issues are implicated in this interaction.

3 SHANGHAI – HEAD OF THE "CONCRETE DRAGON"

The title refers to the call by Deng Xiaoping in 1982 to make Shanghai a role model for Chinese development, merged with the book "The Concrete Dragon" by Campanella (2008), which describes the rapid urbanization of China. The scale of China's economic transition and social transformation is evident in its economic growth rates, which average nearly 10 percent per annum over the last 30 years (HDR China, 2008). Rapid urbanization can be seen as one of the key characteristics of contemporary China. This urbanization has fundamentally altered the image of today's Shanghai with its consumer-driven attitude (Davis, 2000). Hence, the changes in urban space are manifested not only in a "flood of new construction", but also in the change of urban culture and the lifestyle of residents, including their attitude towards life, consumption behavior, and political outlook (Schein, 2006).

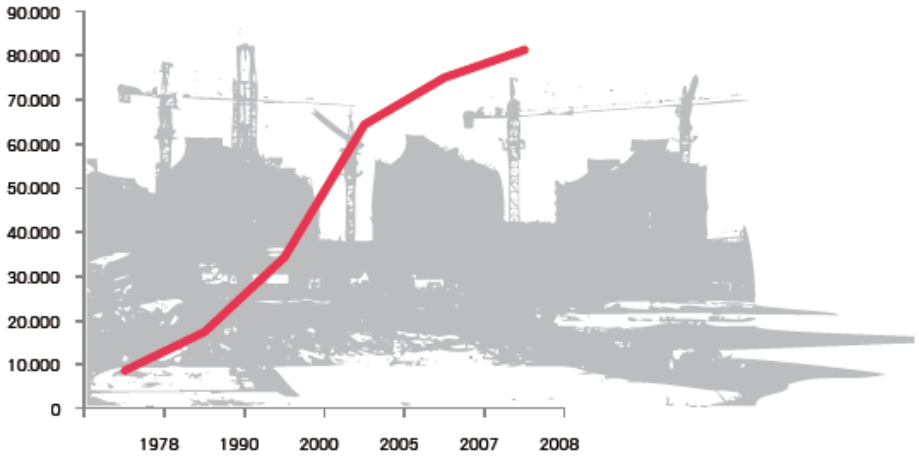

Fig. 3: m² total floor area Shanghai by year - including various functions: staff dwellings, stores, offices, plants, schools, villas, warehouses. Source: Shanghai Statistical Yearbook 2009

According to the results of the 2010 census (National Bureau of Statistics, 2011) Shanghai's population has reached over 23 million with 14 million registered and nine million floating inhabitants without a proper registration. As one of the megacities of the twenty-first-century Shanghai plays back and forth between what it means to be modern and what it means to be Chinese (Keith, 2010). As a result of the continuously growing population new buildings are rising everywhere and are usually in the form of high-rise buildings due to limited land supply in the inner-city. At the moment Shanghai has 988 skyscrapers, with another 158 planned or under construction (Shanghai Urban Planning Exhibition Center, 2010). This number changes constantly, as do the people involved in the process of construction by changing their place of residence.

Fig. 4: Construction Site near Shanghai

3.1 Construction Sites as Research Field

When looking in greater detail at the field of our research – construction sites in and around Shanghai – some special features become apparent. Construction sites are situated in the setting of existing urban development; they dominate the changing urban landscape and at the same time are themselves rapidly

transforming these spaces. Further, similar to the observed groups who are in a permanent state of temporariness, construction sites as a research field are also constantly changing. Thus, like transitory people, the place itself is impermanent.

4 CASE STUDIES

Within the framework of labor migration in the research field of Shanghai, we have taken a dialectic-discursive approach: on the one hand we examine local internal working migration, and on the other hand we look at the phenomenon of global migration within the Chinese construction industry. The results are not directly compared, but rather give an understanding of their circumstances.

4.1 Global Urban Nomads

The word migrant is nearly always used in reference to the working class and is therefore associated with a subaltern status. But there is another flow of migrants who are typically neither victimized nor spoken of as migrants. Their key driver for migration is also work, but the circumstances are completely different. They are international migrants, better known as expats, who move around the world from one working place to another. Expat is short for expatriate, and the word expatriate comes from Latin and means being outside the native country. The word is used to create a distinction along socio-economic lines between the aforementioned group and manual labourers who also move from one country to another. The usage varies depending on context and individual preferences and prejudices.

Expatriates have the ability to remain mobile, to make the most of their opportunities, and to follow the flows of global commerce. They are flexible executives– or "flexecutives" (Pico Iyer, 2001 in Herbstreuth, 2005). Due to their high level of education and professional skills they have both economic and social capital (Beynon, 2008).They quickly adapt to new urban environments; but do the new urban environments respond to their needs?

Research Approach

As European researchers we first asked ourselves how we could best approach this provocative topic of working migration within the construction industry in a different cultural setting like China. On the one hand we have the advantage of discovering China and its construction industry through the eyes of outsiders - as two architects. That gives us the chance to recognize difficulties that those involved do not realize or see anymore because they are surrounded by them every day. On the other hand we were part of the observed group as expatriates. Among other things this allowed us to gain greater insight into the challenging situation of being a "global nomad" living in a foreign culture. In ethnography these methods can be described as a participatory micro-approach, which is based on the personal experiences of action researchers. "Action researchers, however, are insiders' researchers. They see themselves as part of the situation" (Tornaghi, 2010, p.35).

Social Networks

A network of internationally connected people living in Shanghai has organized an infrastructure tailored to suit arriving foreigners; thus, when expats come to Shanghai they are greeted with numerous offers upon arrival including survival packages and support services. These support services on arrival are manifold but also have their cost; the more extensive the offer, the more expensive it is. In a similar manner, the Chinese media have adapted to the needs of foreigners, and expats have accordingly been recognized as consumers in the media sector. Nevertheless, expats usually rely on information from familiar media sources from their home country. Expats have been recognized as a target group with strong purchasing power, and their new demands have strongly influenced supply.

Spatial Conditions

The reasons why foreigners have been recognized as a consumer group in Shanghai are largely tied to historic events. Regulated by law, they have been concentrated in communities within Special Economic Zones. With demand being closely linked to capital, they have also influenced the supply of space in the city, which has led to a transformation of the residential landscape. The foreign housing market is characterized by an apartment design imported from the West and adapted to the new requirements of living in Shanghai, but as a result this cocooned living has led to further segregation between local residents and the expatriate

communities. This can be seen in the city wherever foreigners have been defined as a consumer group, influencing commercial retail spaces and other commercialized open spaces.

Fig. 5: Scale model of Rainbow city compound

Working Challenges

Also historically determined was the need for modernization in China's cities after Mao had prevented city development for three decades. The current building boom in China's cities that has attracted such great numbers of foreign architects has resulted in an extremely rapid pace of development. The example of the Dutch Co-Working space shows how quickly the market has adapted to the new needs of foreign temporary residents; this example can also be seen as a spatial reaction to the latest type of nomadic lifestyle. In spite of this spatial development, Western architects are often not up to the challenges they face, due to unfamiliar aspects of the foreign culture and a completely new scale and context of architectural production. We have observed that, in the course of adapting to the new working environment, architects often remain silent or uninterested when dealing with situations where working and living conditions of other participants in the construction process clearly do not meet international standards of safety and decency.

4.2 Rural Urban Nomads

In China the term dagong is used to describe the phenomenon of labour migration quite accurately – literally "being employed" – and stands especially for rural people seeking work elsewhere and for people working in temporary or casual jobs. Rural migrant workers are a special group resulting from China's economic transition and are called nongmingong (农民工) – peasants who have become migrant workers.

Migration in China, with all its possibilities and obstacles, is inevitably connected to the national household registration system – the hukou (户口) system. This system determines the movement of individuals by dividing China's population into rural and urban citizens and thereby creating a two-class system.

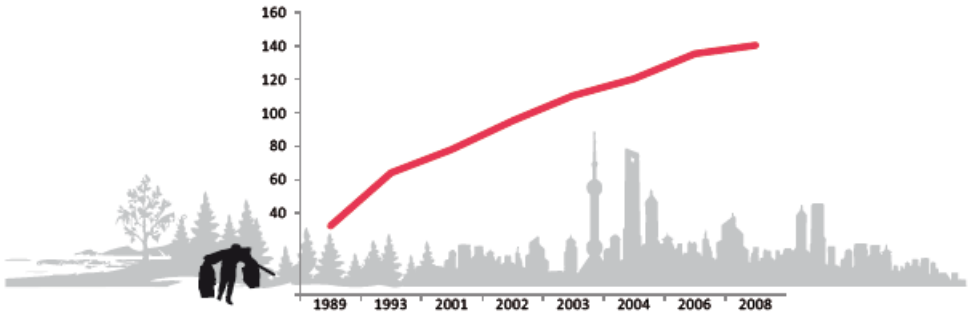

Fig. 6: The number of rural migrant workers in various years; Source: Chinese National Bureau of Statistics, 2009

In order to understand the various causes that led to rural working migrants' living and working conditions, it is helpful to take a closer look at their present situation.

Research Approach

The use of different approaches was essential in order for us to come to a better understanding of the group under investigation – rural urban nomads. The following description is based largely on interviews, debates,

and construction site visits that were part of our empirical research in fall 2010. The research took place at several construction sites in and around Shanghai.

While we were part of the research group in the case study of global urban nomads, our research on rural urban nomads was conducted from the "outside". We pursued an approach that combines bottom-up research methods and personal narratives as a powerful means to link migrants to qualitative survey field data and the literature. We have used pseudonyms to protect the privacy of interview participants, but our intent is to try to give voice to marginalized individuals in society.

Working Conditions

The situation faced by rural migrant workers arriving in Shanghai stands in stark contrast to that of international migrants, as no comparable welcoming services are provided for the rural migrants. Becoming oriented and settled in the vast city happens mainly with the help of relatives already in town, or through fellow workers from the same place of origin. The job search and employment contracts work in the same way, which results in complex dependencies among family members and people from the same village that are based on trust.

Generally, migrant workers endure extremely lengthy working hours that do not allow for sufficient rest overnight. The lack of mechanisms to ensure that labour rights are upheld leads to job exploitation on several levels: often workers are not paid the agreed-upon wages, have to work unpaid hours of overtime at night, and are subject to considerable uncertainty with regard to future work. They often have little savings left after sending remittances home to their families. Due to hukou regulations, migrant workers are excluded from the social benefits provided by the state, and regional differences in social insurance prevent highly mobile migrant workers from effectively insuring themselves. In conclusion, it is obvious that minimum standards of human rights and labour regulations are consistently violated by the existing working conditions on construction sites in and around Shanghai.

Living Conditions

The living conditions of migrant construction workers, like their working conditions, do not meet housing standards as defined by Article 25 of the Universal Human Rights. The prefabricated dormitories on site, where construction workers tend to live, usually have no insulation and are far from meeting standards of decent living. They have one water source, which is usually outside, and no access to hot water. The shelters offer no privacy with up to six people living in one small room; additionally, living on site exposes them to enforcement (e.g., of working hours) by the employer. Precarious circumstances for construction workers can be found worldwide and while at first glance in Chinese cities there do not seem to be whole districts with substandard housing such as slums, there are huge numbers of people affected by these low living standards. Just as construction sites are scattered throughout the city, substandard dwellings for workers are decentralized and not always immediately visible.

Fig. 7: Taicang construction site visit

Social Situation

Given the situation of a rapidly growing construction sector enabled by over 40 million construction workers in China, it is incomprehensible that they still don't get social recognition for being the motor of the economic miracle. Since about 80% of urban growth in China is caused by rural-urban migration (Fan, 2008). The integration of these migrants into urban life seems long overdue if the objective is ensuring the

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

existence of a humane urban environment. An analyze of the "degree of intermingling" in urban spaces of rural construction workers is rather redundant, as the reasons for their isolated life within the city and for their non-use of public (open) space in Shanghai have been shown in detail in the previous chapters.

While the hukou system is being reformed by the government, it hasn't had a positive impact for the migrant workers yet. However, the national framework for working and living conditions can't be changed by the employer, but of course other layers can. The intensification and extension of the urbanization process with all its side effects for the people involved has led to various survival strategies and support programs, but the turning point where public opinion – including temporary residents – is actually changing the ways in which the urban environment is currently managed, has yet to come.

4.3 Reflecting on Both Case Studies

Reflecting on the two case studies and our research methods, we are aware that we have provided insight into only a small number of the many aspects of the urban phenomena occurring in China's cities. Social reality can be approached from many different ways and from different angles, thus we had to make the difficult decision of which scientific approach to take to best illuminate the urban phenomenon of migrants within the construction process in Shanghai. As described in the research methods of both case studies, we chose different approaches for the two social groups, including participant observation, ethnographic research, and action research.

5 SYNTHESIS OF RESEARCH FINDINGS

Chinese urbanism in general and in Shanghai in particular is extremely rapid. It is not only economic and political changes that have led to this rapid urban development, but structural changes in society have also made the ongoing transformation of urban China possible. Post-reform urban development has been driven by increasingly opening policy, as well as the progression of the market economy on the one hand, and rising consumerism and individualism on the other (Davis, 2000). In 1984 real estate enterprises began dealing with the urban housing market, which was previously regulated by the Chinese state. With the implementation of new reforms different income groups emerged and led to the rapid development of urban housing in the 1990s. The Chinese urban housing market began to integrate the needs and demands of consumers and paid more attention to comfort and higher living standards. At the same time the freedom of choice in housing led to the differentiation, reconfiguration, and segregation of urban space (Li Xiangning and Zhang Xiaochun, 2008).

This dynamic urbanization can be seen not only in physically perceivable urban space, but also in the fast-paced working and living conditions to which the inhabitants are subjected. (Ribbeck, 2000). While society adapts quickly to new circumstances (for example, working migrants and specialists from abroad recognize and take advantage of opportunities), architecture does not seem to take the resulting new requirements of temporary life into account during the process of architectural production. As city planning in Shanghai does not succeed in meeting the quantitative requirements of the latest developments in migration flows, it is clear that "planners of Shanghai's municipal development often ignore [migrant workers] as if they did not exist" (Wang Xiaoming in Bridge and Waston, 2011, p.401).

When conducting research on temporary residents of Shanghai, no matter which circumstances led them to being temporary, it becomes obvious that they are disadvantaged when compared to local urban citizens. Excluded street communities are not considered part of the public by politicians, architects, and planners. They are not viewed as communities of their own. They lack legal and political power in China and therefore these groups are excluded from city planning and architectural practice. The basic human rights of decent living and working conditions are not regulated for them by the formal system and, while global urban nomads are often able to compensate for the lack of state benefits at their own cost, rural urban nomads cannot afford this kind of support on their own. They have the social status of being guests or aliens in the city and therefore have no political voice in decisions. There is a trend in Chinese real estate business to du shen da zao (度身打造), a term literally meaning "measuring your body to make it just for you". But these purpose-built and tailor-made areas are only for selected consumer groups. Although migrant workers are building the city, they have not managed to create a visible and empowered urban nomadic society; the migrants are usually invisible and marginalized in architectural culture and discourse as well as in practice.

Expats have been discovered as consumers of support services, media, and residential compounds and other enclosed spaces, but their needs as temporary citizens within the urban realm are not sufficiently taken into account by designers and decision-makers. Depending on the planning systems in question – public or private – foreigners only influence projects where affluent consumers are the target group. Beyond this, we believe that expats are more than a consumer group reliant upon capital; they are permanently temporary urban citizens, and this status calls for their further sustained social, political, economic, and spatial engagement. In this paper we argue in support of urban nomads' contributions to city life. The human potential of cities is determined by users of the city; these users are intimately implicated in the potential of these cities to provide the benefits of better urban and social infrastructure to their residents. In a city where certain areas are home to more "aliens" than local residents, it is imperative that city planning take the needs of these residents into account, ideally through a participatory planning process.

6 CONCLUSION

6.1 Situating Our Work within the Research Landscape

In terms of the position of our paper among other scientific work, the multilayered approach we have taken has engaged with several areas of research within the interdisciplinary field of critical urban studies. Our research bridges the disciplines of urban studies, project management, business studies, and migration research, as we have engaged with existing concepts of urban nomads in architecture. By doing so our intent was to forge a link between existing investigations and the present work.

Much work in migration studies has described in detail the divergent circumstances of migrant workers worldwide and within China. In an approach that differs from typical research on migrants, we have emphasised two aspects of these workers' mobility: a survival-based decision of people with no alternative combined with a strategic choice made by individuals actively realizing their identities. Further, we have highlighted the exceptional nature of the observed social groups, who are both not only migrants but also permanently temporary residents.

The rapid transformation of the urban environment is often described in the economics and business studies literature. This work highlights the ongoing building boom as representative of constant growth and as attractive to consumers. Although very precise in providing statistical data, these surveys are often quite one-sided as they do not consider the social and cultural aspects of this urban development. Similarly, the discipline of project management focuses on the construction phases and mechanisms to control them rather than on the actors involved in the process. We are left wondering: what are the mechanisms to supervise a fair and ethical construction process?

However, there are two reasons why we might have come to different conclusions than other scientific researchers. On the one hand we have taken an approach that combines scholarship from the above-mentioned disciplines, which has helped us to grasp the complex urban development occurring in Shanghai and has enabled us to make these observations a critical urban study. On the other hand, we had special access to the research field by approaching it from two sides at the same time. Various perspectives on two such different – but also similar – groups of working migrants gave us the opportunity to look at them through different eyes and thus not victimize them but rather search for possibilities for improvement of their circumstances. Although it directly addresses planners and architects, this paper is relevant to anyone working in the field of construction in China or planning on working there. To us, a critical discussion and consideration by architects and planners of the social circumstances in the construction industry in China is urgently needed; our analysis intends to be a beginning to just such a critical look at present circumstances. This paper illuminates particular areas within the production of space in Chinese cities where basic human rights and international labour rights are compromised and where change is urgently necessary.

6.2 Outlook and Prospects

Dealing with the topics of labour migration, multiculturalism, and the diversity of local and transnational identities will be a challenging issue in Shanghai over the next few years. Hence it remains necessary to further encourage intercultural exchange in planning as well as long-term project implementation. Based on the needs of Shanghai residents – even if they are just temporary like the observed groups – the aim should be to create liveable and unique environments. Increasing awareness of cultural and social issues among

architects, urban planners, and designers could lead to cities being shaped not only by economic and political decisions but by a greater focus on the inhabitants' needs. We strongly advocate and support such an approach and emphasize this through the call for "Cities for People, not for Profit". We call for an urbanism that responds to human needs rather than to the capitalist imperative of profit-making (Brenner, Marcus, Mayer, 2009), although of course both concerns are a part of urban development and must coexist.

In the age of globalization, and particularly in China, buildings are becoming bigger, higher, and increasingly complex. And while additional technology and greater numbers of people are involved in the building process, it seems as if the profession of architecture has hardly changed. Successful architects still see themselves as creators, as master builders and designers of the built environment, where success, reputation, and image usually count more than shared social responsibility. Here we wish to add a social layer to the ongoing green building debate and promote the transfer of concepts like "Fair Wear" and "Fair Trade" to the construction industry. While a trend toward sustainable urban development has become measurable through certifications like LEED, this is a call for "FAIR BUILDING", which entails the need for an ability to track building processes and building transactions on a social level.

Throughout our research we have contemplated how we, who at the time were not directly involved in any construction processes, could go a step beyond simply describing the present circumstances. Following the approach of Social Entrepreneurship we found a way to position ourselves with our concept "Lüxing Laoshi," which aims to improve the social consequences of the production of space.

Our idea is to establish a training program for migrant construction workers in order to strengthen their working skills. We propose to do this by setting up a part-time education centre in a vocational school that focuses on building trades and handcrafting skills. The training program aims to provide adequate education for rural migrant workers and encourages improved cultural understanding of global migrant workers. As there are so many different stakeholders in the construction process, it is now more important than ever that those involved have the skills necessary to understand and communicate with one another. By providing the needed infrastructure in the city, by intensifying existing networks, and by providing the opportunity for regular and spontaneous interaction, Lüxing Laoshi supports migrant workers involved in the construction process and helps them to determine the course of their own lives.

Urban Safety of the Public Spaces in Belgrade, Serbia

Nataša Danilović Hristić

(Nataša Danilović Hristić, PhD in Architecture and Urban Planning, Urban Planning Institute of Belgrade, Palmotićeva 30, Belgrade, Serbia, natasa.danilovic@urbel.com)

1 ABSTRACT

This topic deals with the field of urban planning and design and it is closely associated with the social context and theory of safety. Researching the elements of fear of physical urban environment and population inhabiting it, the focus is on the prevention, in the social and technical fields, which can reduce or eliminate negative perceptions of the users. Determining the standards for furnishing classified urban public spaces, which will contribute to their safer use, has been implemented by defining the conditions, reasons and patterns of the occurrence of personal feeling of (un)safety and by analysis of preventive measures that can contribute to higher quality and more intensive use of public spaces in Belgrade.

Previously conducted researches in Belgrade were within the domain of social studies (feeling of safety of a specified group of residents within limited space), or their starting point was in the concrete institutional or technical measures (surveillance and CCTV). By analyzing the theoretical hypothesis, case studies and by sublimation of all available information for specific space, with numerous comparative evaluations, the general image of the level of safety in public urban spaces of Belgrade has been created. By this method, the social, physical, economical and environmental aspects, as the inputs for planning alternatives, preferences and decision making have been gathered in one place.

This paper incorporates the information provided by the relevant institutions and the poll of the citizens, as well as analysis of spatial urban elements, typology of their use and their condition from the aspect of safety. Finally, it provides recommendations for urban planning measures and architectural design elements for implementation that will contribute to better public spaces use and higher level of safety and security.

The practical application of the results relates to creation of information base, upgrading of cognitive aspect and opening the possibility for new researches, recognition of the process, monitoring of changes, elimination of consequences, promotion of urban planning and architectural design profession, realization and maintenance of public places and creating the legal framework.

2 SPATIAL, SOCIAL AND ECONOMIC ASPECTS OF RESEARCH OF SAFETY IN BELGRADE

The relation between the planned and implemented in the urban planning practice in Belgrade has been debatable for quite some time. Although it is considered that urban planning on the territory of Belgrade has a tradition and that it has shown results, the discontinuity and inconsistency in the implementation of planning documents is apparent, their lack of respect and the fact that due to poor perception of priorities and interests the plans "do not produce" fast enough and in advance. Chaotic social system, followed by constant political and economic instability has certainly been translated to the spatial level of the city, which naturally must not be an excuse. On the other hand, the plans of previous epochs have been criticized for its determination, which did not correspond to real conditions, needs and abilities, and have therefore remained unimplemented. Modern urban plans are based on more extensive research, after the European models, through studies and analyzes prepared that should clearly indicate the existing space deficiencies and potentials, and in further phases verify the solutions proposed and provide creative development. If urban safety has been set as a goal, it is necessary to define the current condition and specify the factors that affect the reduction of a feeling of security by associating them with specific spaces. In order to prepare a strategic plan that covers the territory of Belgrade, a series of researches and analyses of available data at disposal to the numerous city institutions have been conducted, the evaluation of the existing situation has been made and targets provided for future development, which are of great importance for this study since they provide a range of information on average condition and further expectations. These data, related to the current situation and planned spatial and socio-economic development of the city, are important for considering the possibilities of setting another development goal - a safe environment for living.

In order to better perceive the socio-economic context of Belgrade, the Master Plan of Belgrade provides the overview of the social development, which partly explains also the attitude of the present citizens to urban

Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

life: "In the development of society in terms of urbanization, in the past, one may differentiate rural, industrial and urban characteristics of the society and the city. By degree of urbanization our society is still at the bottom of the list of Central and Eastern European countries. The share of urban population in total population, only in the early 1990s exceeded the half (53 %), where, from demographic viewpoint, we became predominantly an urban society."[1] Demographic data provide a clear image of the rapid growth of urban population as a result of immigration, but also of mortality and drain of the young people, which classifies our society in the category of old populations. It can be concluded that Belgrade is on the way of becoming a metropolis in terms of the regional center, owing to its size, importance and numerous functions and activities, although, from historical viewpoint, this development has encountered many obstacles which have slowed it down significantly. Aspiring to take a prominent position on the map of Europe, the city must find a way to leave the" provincial" habits and style behind, while at the same time preserving its unique identity and charm. According to the Tourist Organization of Belgrade in the first five months of 2009. the number of foreign tourists was greater by nine percent than in the same period last year.[2] The visit to Belgrade is on the upscale, and generally stated reasons are good amusement and entertainment, cultural and sports events and conference tourism.

3 LEGAL AND PLANNING REGULATIONS AND EVALUATION OF ITS APPLICABILITY FROM THE VIEWPOINT OF SAFETY IN URBAN PUBLIC SPACES

Pursuant to the Constitution of the Republic of Serbia of 2006,[3] being the supreme legal document of a state, the rights of citizens were defined, especially the right to life, dignity and free development of personality, human and minority rights and freedoms, inviolability of the physical and mental integrity, the right to freedom and safety, freedom of movement, non-discrimination, prohibition of racial, ethnic and religious hatred and regulated status of the foreigners. The Law on Planning and Construction of 2009 as a legal act related to the topic of urban planning, does not address the topic of safety in urban public spaces, except that it addresses the requirements for equal accessibility. This field has also been directly and indirectly affected by implementation of: the Law on Amendments to the Criminal Code of 2005, the Anti-Discrimination Act of 2009, the Law on Prohibition of Manifestations of Neo-Nazi or Fascist Organizations and Associations and the prohibition of use of Neo-Nazi or Fascist symbols and hallmarks of 2009, the Law on the Amendment of the Law on Prevention of Violence and Misbehavior at sports events of 2003, the Police Act of 2005, the Law on Offences of 2005 and the Act on Communal Police of 2009. The current By-law which specifies the standards and norms related to the accessibility is the Regulation on conditions for planning and design of the buildings related to unobstructed movement of children, the elderly, the handicapped and disabled dating 1997.

In conclusion, it could be pointed out that the existing legal framework provides a general possibility for the application of preventive measures and increase of the level of safety of the citizens in times when using the public spaces, because there are no legal obstacles and contradictions in the viewpoints. On the other hand, there is no legal obligation to implement these measures, especially not from the aspect of urban planning and design, except for measures related to the principle of accessibility. Until the eventual creation of the legal framework in the form of ordinances or regulations, it is possible to work on education of both the professional sector, and also the citizens and the decision makers, and to propagate this principle and advocate in public, to cooperate with police but also with the non-government organizations and in accordance with the possibilities, introduce applicable rules and standards in urban document by own professional authority, especially in the segments related to regulation of the public areas and spaces.

The current Master Plan of Belgrade dating 2003, covers the territory of 12 urban municipalities,[4] i. e. about 80 % area of administrative boundaries of the municipalities or 77602 ha. They are included as per the character of different space units, from the central urban zones to peripheral rural areas (the central zone – 3206 ha, the middle zone – 8532 ha, the external zone – 21962 ha and the peripheral zone – 43902 ha),

[1] Master Plan of Belgrade 2021, Chapter 1.2. Society
[2] http://www.tob.co.rs
[3] http://www.parlament.sr.gov.rs
[4] According to the By-law of the City of Belgrade from 2008 and pursuant to the Law on Capital City. The higher-order plan which includes the overall area is the Regional spatial plan of the administrative areas of the city of Belgrade from 2004 for the "metropolitan" zone of Belgrade with the projected population of 1,65 million.

which comprise a variety of topographic, morphological, typological, economic and social characteristics and components. The planned population is 1.4 million, with time projection of the plan until 2021.

On the territory of the City of Belgrade there are about 500 current detailed urban plans. This type of plans is adopted for settlements or parts of settlements and as per the spatial coverage, i. e. per the area, it can be rather diverse, which on the example of Belgrade ranges from 1 ha to 750 ha. The minimum coverage is one city block with appertaining traffic routes. In the total summary, the detailed urban plans cover about 65 % of the urban space intended for construction. Substantially, these plans closely determine the use of space, the routes and corridors of roads and infrastructure, horizontal and vertical regulation, capacities and building codes, rules of parceling out, special conditions associated with the preservation of cultural-historical heritage and environment and the manner of further implementation. In preparing them particular care has been taken of the application of urban standards for public spaces and uses. Legally defined procedure of plan preparation involves also the cooperation with all relevant institutions, organizations and utility services, comprising also obtaining adequate conditions and approvals to the planned solution. Also, except for the expert controls, the plans are presented for the public hearing as well, where citizens can provide their comments to the solutions proposed. Since the existing detailed urban plans date from different periods of their preparation, on several occasions they were re-examined in terms of their compatibility with the new legislation, compliance with the plans of a higher order that are relatively recently dated , the condition in the field i. e. degree of implementation, new requirements and the like.

4 GENERAL CHARACTERISTICS OF URBAN PUBLIC SPACE IN BELGRADE

The emergence and historical development of the public spaces in Belgrade is best to be freely studied in the area of the historical core of the city, i. e. in the part of the central area. The need for reconstruction of oriental Belgrade presented itself after 1862, at the same time when in many European cities (Paris, Barcelona, Berlin, London, Vienna and Rome) comprehensive and radical reconstructions were under preparation or in progress being the consequence of the industrialization process. The complete transformation of Belgrade borough had a different cause, goal and symbolic, however, it was implemented after the European model. The plan of Emilijan Joksimovic was radical, it set the whole new orthogonal traffic network which would permanently determine physiognomy of the central zone of Belgrade, by forming regular urban blocks and defining the public spaces.

Urban public spaces of Belgrade today are fundamentally no different from the same ones in other cities, even for their diversity, location and interaction they have great potential for further development and improvement. According to generally accepted opinion, one of the greatest qualities of Belgrade public spaces is made by their users, the citizens who in different ways, whenever weather conditions permit, visit the open urban spaces, socialize and enjoy in that which they have to offer. Belgrade squares, street cafes gardens, pedestrian zones, parks, urban forests and picnic sites, rivers and coastal zones, the beach of the artificial lake of Ada Ciganlija and biking trails are only some of traditionally visited and gladly used urban spaces. The Belgraders are accustomed to mutually sharing good and bad in the urban spaces environment, to celebrate victories (e. g. welcoming winning athletes), the New Years, running the marathons, roller skating, listening to concerts but also to protest and express their disapproval. In a survey conducted in Belgrade by the Bureau team of the architect Jan Gehl 2008,[5] it was concluded that the city possessed the culture of frequent use of public space, adjusted to the climatic region, and that attention should be paid to their development, so as not to lose the valuable habits and a positive effect of their use and have the vitality of the city redirected over to the enclosed malls and similar places. In Belgrade circumstances, compared to the budgetary resources of other cities, the investment in furnishing and maintenance of the public urban spaces is rather modest. Besides, if retrofitting of public spaces has been proposed in order to increase the level of safety, one should bear in mind the diversified organizational structure, shared responsibilities and a lengthy process of decision making and execution. For this reason it is necessary to consider the minimum level of equipment that will provide optimal results.

[5] GEHL Architects, 2009.

5 RESULTS OF THE STUDIES CONDUCTED ON THE TERITORY OF BELGRADE FROM THE ASPECT OF SAFETY

On the territory of Belgrade until recently there were no specific studies on the subject of safety of the users of urban public space, especially in terms of urban planning and design. For many years, Belgrade has been considered a safe and secure city, with an average crime rate for the capital of one million inhabitants, a successful organizer of the international conferences, open and warm to the tourists. The events during the 1990s, the difficult political and economic situation, life in a war environment and degradation of social norms and standards, have introduced some changes. It was not until the middle of the last decade that studies were conducted on this topic from the viewpoint of sociology and criminology.

The Institute for Sociological Researches of the Faculty of Philosophy in Belgrade[6] prepared a study in the period 2003-2004 on the theme of safety and risk sources in the neighborhood from the perspective of children and their parents. From the spatial aspect, the survey was conducted in three parts of the city; through a survey the results were obtained which testify of a high degree of coinciding perceptions of the children and the parents in identifying the issue of the reduced safety level. The most frequent risk sources are the presence of drug addiction in the spaces planned for the stay and play of children, unilluminated space and disorder in the space, suspicious unknown individuals and bullying. On three occasions, in 2004, 2007 and 2008 the Institute for Political Studies, Center for Security Studies and Terrorism Research studied the attitude of the citizens when it concerned the feeling of safety in the capital. Certain publications of the Institute for Criminological and Sociological Researches can be consulted in terms of understanding the topic and its importance. In addition to the above researches the topic of safety in a broader sense, is dealt with by a number of non-governmental organizations - OSCE Mission to Serbia and UN-HABITAT.[7]

6 ANALYSIS OF THE USERS PERCEPTION OF SPACE BASED ON THE RESULTS OF THE SURVEY AND THE OFFICIAL DATA

Based on the data and information available to the Ministry of Interior of the Republic of Serbia – Secretariat of Belgrade and non-government organizations (SOS telephones, legal aid, trauma center, safe houses, etc.), an impression can be obtained on the cases of violence in urban public spaces. Narrowing down the analysis of the data to one specific society group - women, the image was obtained of vulnerability, according to the traditional understanding as a sensitive and easily vulnerable population groups, which at the same time is rather active and mobile, and in Belgrade makes a significant proportion of the population (according to the census from 2011. about 53 % of the capital population are women).[8] Based on data obtained from the MIA RS – Secretariat of Belgrade, a review of criminal acts against women on the territory of ten city municipalities of Belgrade was created and which were committed exclusively in public areas, in the period from 2000 to 2005, when 2135 cases of robbery of women were recorded and also the declining trend of this type of crime was observed.

The information about the attitude of the citizens of Serbia towards safety is a result of the public opinion poll on police reform in Serbia which was conducted by OSCE and IPSOS Strategic Marketing. The survey was conducted in two phases (in November 2008 and October 2009); on the total of 2990 respondents, aged over 18 and by "face to face" method. The question asked " Which problems do you think present the greatest threat to the security of the citizens in Serbia ?"; resulted with violence in public places as an answer taking the fifth place, with an increase of concerned citizens from 3 % in 2008 to 9 % in 2009. Responses like: drug abuse (in the first place), crime (generally speaking, elsewhere), violence (in the fourth place) and minor offenses (in the sixth) are not negligible either, since they are all in some way associated with the level of safety in public places.

The research conducted in 2007-2008 by the team of Urban Planning Institute of Belgrade involved the analysis of users' perception of space and its safety based on the survey of the citizens. This is a common way of information gathering, and the form, i. e. survey contents and the method of analysis and interpretations of the responses obtained were carried out in accordance with the similar surveys conducted

[6] TOMANOVIĆ S., 2006.

[7] http://www.transconflict.com, http://www.ccmr-bg.org, http://www.bezbednost.org, http://www.osce.org/serbia, http://www.unhabitat.org.rs, http://www.skmbalcani.cooperazione.esteri.it

[8] DANILOVIĆ Hristić N., 2008.

in other European cities. The main aim of survey was determination of the personal feeling of safety of the citizens in public spaces, i. e. consideration of their personal perceptions associated with this issue as well as information gathering about which spaces in Belgrade are deemed less safe by the citizens, i. e. where they feel more vulnerable or exposed to danger. In order to obtain as clear indicators as possible, the survey was anonymous and was distributed to various categories of population, i. e. it was ensured to include the participation of both sexes, various generations, certain threatened and minority groups, as well as foreign citizens currently living and working in Belgrade. Essentially, the survey's parameters were defined after the similar surveys conducted in the cities worldwide, and the questions asked could be classified in three groups:

- questions related to personal information on the respondents as well as their daily habits - sex, age group, part of the city they live in, work and spend their leisure time, whether they belong to some of the specified social groups, what time of the day or night and which way they mostly move around the city.
- questions related to personal perceptions, feelings and experience - whether they do not feel safe enough in certain parts of the city, whether they avoid leaving the place of residence for fear and whether for that or some other reason their mobility has been endangered, whether they feel more secure when they are in company, whether they have personally experienced something unpleasant in public urban spaces, or someone close to them experienced the same and how they react when they witness an incident.
- suggestions about which way safety in public spaces can be improved – level of trust in law-enforcement, selection of some of the proposed measures and space for providing suggestions and proposals.

This way data were obtained that the majority of citizens stay in the public spaces in the afternoon, between 12 and 19, and during the "active" part of the day, from 8-24 hours, there is 88 % of stays outside the place of residence. It is interesting to note that most of the respondents take mobility in the public space to mean stay in the public space and leisure activities, like for instance walking the dog in the early morning, going to market or window-shopping on weekend mornings, stay in the park in the afternoon, walking downtown in the afternoon and evening, meeting with friends, going to an outdoor event (concert or other event), but not going to work or college.

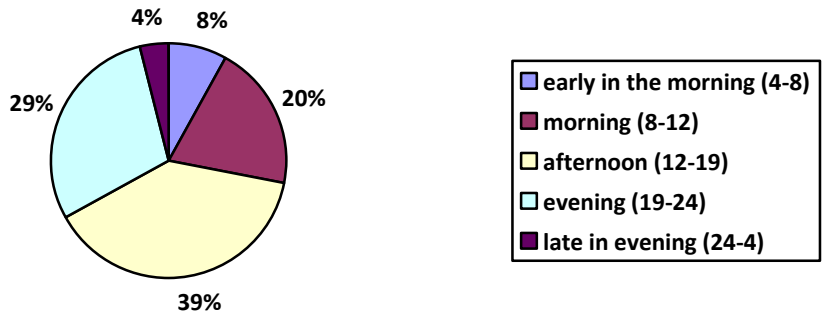

Fig. 1: The most frequent period of mobility in the open public spaces

Most of the respondents move in Belgrade on foot (35 %) or by some sort of public transportation (36 %), whereas about 24 % use their own vehicle or taxi service. The smallest number of respondents ride a bicycle which can be attributed also both to unfavorable morphology of the terrain and the lack of adequate bike trails in greater number.

When answering the question whether the respondents avoided certain parts of the city, some settlements or parts of the space in fear for their own safety, half of the respondents opted for positive reply. In the explanation the parts of the city or type of space were stated. Generally, it primarily concerned vast park spaces in which citizens did not feel comfortable when it got dark, then the areas primarily intended for traffic (highway loops around highways, the area around the railway and bus stations, bridges, underground

passages, public transportation stops etc.) and peripheral settlements that by their typology belong to the open block, and also the areas with a great circulation of pedestrians were mentioned where due to crowds there came to decreased concentrations related to safety which may present mitigating circumstances for minor criminal acts, such as theft. It is quite interesting that approximately the same number of respondents stated spatial and social problems as crucial for avoiding certain parts of the city. The relation between these two aspects is obvious, i. e. dark and unarranged spaces, according to the understanding of the citizens, automatically attract the individuals of deviant behavior (according to the survey's quotes: „homeless persons, alcoholics, junkies, skinses, bullies") and present potential danger for all the rest.

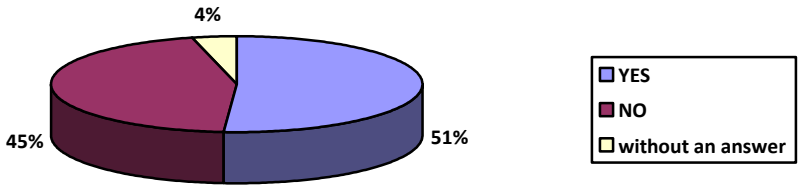

Fig. 2: Answers to the question: "Do you avoid some parts of the city because of fear?"

The mobility of the citizens, i. e. the undisturbed feeling of freedom and security in using urban public spaces is of great importance. To the question whether they avoided leaving the house (being the synonym of safe space) at certain time of the day, most respondents (59 %) answered that they did not, but close to one-half of them said that they avoided going out in the late hours at night. As regards the question what the citizens were afraid of, i. e. what prevented or restrained them to stay in certain urban public spaces during certain period of day and night, mostly quoted answers indicated to the combination of spatial and social problems, such as insufficiently illuminated spaces, desertedness i. e. absence of other users, or presence of persons who one can expect offences and violent attacks from. The feeling of greater security when in group compared to when the individuals find themselves in urban public spaces does not significantly differ, 53 % versus 45 %.

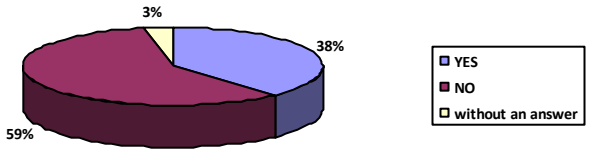

Fig. 3: Answers to a question "Do you avoid going out at certain time of the day?"

Fig. 4: Answer to the question "Do you feel safer in public space as an individual or when in a group?"

The next group of questions related to the personal negative experiences which occurred in urban public spaces, and 69 % of the respondents considered that they personally had had or had the knowledge that somebody close to them had had some sort of an unpleasant experience, from verbal attacks, insults and comments to physical attacks, thefts and other criminal acts. To the question how the citizens reacted when they happened to witness some sort of attack on the other person in the public space, the respondents even provided several variants of answers, having in view different situations they had found themselves in, as

well as hypothetical standpoints on how they would act in those situations. Basically about 50 % of citizens do not react, about 29 % react actively, independently or with the help of the people present, while 21 % of the respondents call police.

The third part of the survey was devoted to the proposals for safety increase, where the overwhelming majority of respondents, 98 % of them, believed it was possible to implement the measures which would lead to better public security in the urban areas. The greatest number of respondents, from 22 to 30 %, marked better lighting and more frequent patrols of law enforcement officials as key measures. A large number opted for a different mode of public transportation, even also for video surveillance (12-13 %), which often is considered an unpopular measure because it is often associated with compromising the intimacy and privacy of the citizens. A smaller percentage, between 7 and 9 % recognized problem in buildings orientation and arrangement of green areas, while the smallest number (3-4 %) chose the response offered related to the space good layout and fencing.

On the basis of the official data obtained, the research and surveys conducted and interviews with the citizens a conclusion may be reached that certain areas of Belgrade, namely the types of space and spatial elements and certain users of the mentioned spaces cause the feelings of fear and worry for personal safety. Based on these data the criteria for identifying potentially dangerous areas and their spotting on the map can be created. Thus marked "black spots" or stretches, as opposed to a network of spaces that have been evaluated as safe, provide the signal at which place it is necessary to implement any of the technical measures of prevention or to reinforce police supervision. The general conclusion is that the residents of Belgrade and the visitors to Belgrade still feel relatively safe in urban public spaces. They feel the safest in the areas that are "alive", frequented and well illuminated at night, or in some manner monitored, and they feel insecure near the areas with a large circulation of people or the presence of "risky groups" or in the spacious park spaces where there is not enough visitors. The feeling of insecurity is equally caused both by spatial elements and by the presence of "unwanted persons", and the majority of citizens believe that there is interdependence, i. e. the spaces that are under-equipped and used to attract offenders or other persons who inspire fear (listed as: homeless, alcoholics, drug addicts, etc), which makes the space dangerous and undesirable, i. e. leads to the fact that it causes fear and people avoid it whenever possible.

At the time of conducting this research the majority of the respondents who participated did not know much about the topic of safety, i. e. they were not informed about the importance of this topic and its impact on the quality of urban life. Also, preventive measures are not known to our citizens and are mostly identified with a greater presence of law enforcement with better night lighting and space surveillance. At the same time almost half of the respondents were not prone to react to the observed criminal act or violence, and nearly half also have no confidence in law enforcement. For this reason it is necessary to work on the education of the citizens on their being informed, active participation in planning and spatial development and building of trust in law enforcement.

7 RECOMMENDATIONS OF URBAN-ARCHITECTUAL ELEMENTS AND GUIDELINES FOR PROVIDING HIGHER LEVEL OF SAFETY IN URBAN PUBLIC SPACES

As already mentioned above, safety is one of the aspects of quality of life in the society, where people, individually or collectively, and to a sufficient degree are spared from criminal acts and associated forms of behavior, and reassured about myths and well-informed about real risks related to criminal and prepared to bear with the consequences. The feeling of the citizens that they are completely safe and carefree in urban public spaces has a positive and beneficial impact on the daily cultural, social and economic life of the city. The crime suppression is considered to be any single action or set of actions that have an impact on reducing the frequency and severity of criminal acts, and it is believed that the best results are achieved by application of measures of prevention, which act directly on the causes. It should be emphasized that prevention measures do not involve great investment and can be implemented already in the planning and design phase. In the next phase, it is important to estimate what the priorities for implementation are, what is viable to be carried out through mutual cooperation between citizens and experts in charge of safety. The practice has been to compare the wishes and perceptions of the citizens to the information at disposal to the authorities, and then, on the basis of that to form a very clear image of which measures, at which locations and in what order should be applied. In order to enable the citizens to have an opportunity to participate and express their perceptions and fears, provide their opinions and ideas, it is recommended to the local government to

conduct surveys or organize public forums. In addition to diagnosing problems in space and make the identification of needs, which has never been easy, the next step that requires special attention is the implementation and monitoring of measures, since following the decision on a set of appropriate measures after their implementation often remains a problem of maintaining the elements of urban design at a satisfactory level and its possible improvements based on shortcomings identified. Therefore, achieving good results requires long-term and ongoing site management and maintenance of physical outcomes of the project. Regular maintenance of vegetation, lawns, paths and grounds, waste removal and graffiti cleaning, replacement of street furniture and lighting, is within the competence of the existing system of public communal services, but it is necessary to coordinate their work and pay more attention to safety aspect which in fact can be easily achieved by regular maintenance of the spaces.

Urban planning can directly contribute to the prevention of crime through the application of tools such as development plans, supplementary planning guidelines, discussions and negotiations prior to their adoption, making decisions that control the development, planning conditions and obligations, working in partnership with the police and non-government organizations.[9] The suggested attributes can contribute to the sustainability of the community in terms of its safety through crime prevention: access and mobility, are associated with areas of well-defined routes, which allow communication, mobility, transit and stay without compromising safety, buildings spatial layout that prevent and minimize conflicts, spontaneous and uninterrupted natural monitoring of publicly accessible spaces, a sense of ownership and possession as well as belonging, togetherness, mutual respect and appreciation and territorial responsibility, physical protection, which in addition to safety features also possesses characteristics of a good design, the level of everyday human activities appropriate to the location, which reduces risk of crime and creates a feeling of safety in all situations and effective spaces management and maintenance. In an environment that is well planned, attractive, clearly defined and well maintained, people will feel proud of their environment, they will mostly feel comfortable and have a sense of shared possession and responsibility. Poorly planned environment provides a sense of alienation and fear, and unlike it, a well-planned environment contributes to the cohesion of the community and meets all planned functions in an efficient and harmoniously coordinated way.

The use of space makes one of the most important aspects which affect the activities in space and therefore the security level as well. As mentioned before, the ideal is a city which is 24 hours alive i. e. which consists of the combination of diverse uses (dwelling, business, commercial, public uses), of moderate density, clearly defined relation between the private and the public, well-planned and projected directions of movement, which provide constant and equal circulation of the inhabitants and reduce the risk of the space being deserted at some point. Also, compactly developed spaces without uninhabited areas and voids, are by far more favorable. It is desirable to orientate the buildings in such way so that the rooms where the most time is spent provide an easy-to-survey street or other public spaces view; fencing the land for better visual survey should be of less height or if high to provide satisfactory level of transparency. In order to be considered a safe space it has to be easily accessible, easy-to-survey, provided with alternate directions for movement and well-marked signalization, well illuminated and surveilled, as needed. In that respect, the starting point is planning and designing, having in mind activities and functions, identifiable benchmarks and views, unique image of settlements or certain buildings, clearly visible and moderately long directions of movement, but also the elements of urban furniture. The quality and well-designed furniture is by itself an obstacle to vandalism. Likable and authentic design makes citizens feel proud and intensify the feeling of identity with their own city while disdain to bad design reflects mostly on the elements themselves (benches, garbage baskets, sculptures or public transportation stops).

In the recent years, Belgrade has ensured to take care of this aspect and in accordance with its financial means to keep up with the trends. The recommendation for the city of Belgrade is certainly to pay more attention to design, placement and maintenance of urban furniture as well as to re-investigate public lighting in some areas i. e. to adjust it to comply with safety terms and conditions. In respect to video surveillance which is associated with controversial standpoints, maybe it would be the most appropriate to restrict it to a necessary minimum i. e. to those spaces where it is not possible to gain desired results with other measures or which present the constant neurological points. If the citizens would feel safer and would be free of fear of the potential unpleasantness and violence, and cameras would not cause in them some other sort of resistance

[9] OFFICE of the Deputy Prime Minister & Home Office, 2004.

to space or feeling of compromised privacy and freedom, then it can be considered a justified measure and positive solution.

The principle of accessibility is based on the same humanistic concepts and legal provisions guaranteeing equal rights for all citizens to freedom and which prohibit discrimination and exclusion on any grounds. The freedom of movement, the feeling of comfort include also the feeling of security and safety, and most of the measures, including also the technical ones, contribute to a different appearance, understanding, acceptance and manner of space usage. The concern about the public spaces, but also the concerns about all members of society, providing equal opportunities to all through the measures of adjustment, sharing space and enjoying life together, communication and a sense of belonging are the basis for creating a secure and safe environment. If the needs of the most vulnerable sections of society have been met (e. g. people with disabilities, the elderly, children or women), then the needs of all those who do not feel vulnerable or endangered will also be met, but they can easily become the same (vulnerable and endangered) if they are exposed to the inconvenience of a neglected and hostile environment.

8 CONCLUSION

The measures of prevention applied in the phase of urban planning could contribute to more comfortable and freer space usage and the fear of urban structure could be reduced to fear of possible risky activities and incidents and the possibility for such events to happen exactly where the environment provides them the opportunity by its nature (e. g. neglected, isolated, badly laid, dark and similar spaces). The measures of prevention could be applied both to already built spaces through their reconstruction and adjustment to the influential factors, and also in the phase of planning new urban spaces, by application of the standards and spatial normative for its arrangement. In this way, with small additional investment, huge benefit can be achieved which registers in the more intensive use of urban public spaces but the surrounding functions as well, and resulting in the pleasure of the users, increased mobility, feeling of a higher level of security and belonging to the society and economic profit. These measures are less "imposing" and by far more agreeable than institutional controls of the space by surveillance of law-enforcements (uniformed officers, video cameras and so like).

An important characteristic of the public spaces is their integration and incorporation in the network system that allows for unrestricted movement and use. If any element of this network is considered by the users to be inadequate, unsafe or undesirable, it would result in its avoidance, i. e. exclusion from the matrix. In line of identification and diagnosis of problems, it is important to identify whether it concerned just a poor spatial organization, neglect and failure to maintain the space, the more profound sociological problem of settlements or a combination of all these problems. Depending on that measures are to be selected which are possible or necessary to implement. Since public spaces should present the priority in the process of urban planning, in terms of protecting the public interest and promotion of the overall quality of life, it is necessary to include more actively the segment relating to measures for safety and security into urban practice.

Analyzing the condition in Belgrade, based on the information gathered, including also the opinions of direct users it have been concluded that Belgrade is still a relatively safe city but also that measures should be taken which would contribute to the feeling of safety to still remain. The recommendations for further actions were certainly creation of the unique data base in GIS technology which could provide process monitoring in space, mapping of events and actions, registering of changes, making comparative analyses and analyzing the results of the application of positive measures of prevention. Education and specialization of experts in these topics is preferable equally as general awareness of the citizens and their elected leaders. Considering that legal framework provides the possibility of application of urban-architectural measures of prevention, it is necessary to work on their standardization and creating by-laws or running professional publications.

Urban Structure as a Repository of Social Content – the Case Study of the Lodz 'Jewish District'

Małgorzata Hanzl

(dr inż. arch. Małgorzata Hanzl, Institute of Architecture and Town Planning, Technical University of Lodz, mhanzl@p.lodz.pl)

1 ABSTRACT

The spatial structure of the city rests at the confluence of the human nature and the artefact of the era. Cultural factors are among important determinants of the shape of structures and of the construction process. Each community has its own distinctive social characteristics. An analysis of the spatial record of community functioning preserved in the physiognomy of a city allows for the comparison of features of different groups of city users. Lodz is said to be the city of four cultures. Its construction is attributed to Poles, Russians, Jews and Germans. The spatial distribution of different nations in the city downtown was not even, although the whole area was inhabited by the mixed population. The downtown part of the current Bałuty district was among the regions where Jewish nationality prevailed. The paper analyses the spatial features of the area, with emphasis on morphological characteristics of buildings and public spaces.

2 INTRODUCTION

2.1 General assumptions

Cities, understood as concentrations of large groups of people in a limited area, are places where civilisation occurs (Xenakis 1965: 336-337). Similar conclusions from empirical investigations, with regard to the large concentration of people in cities, are provided by Florida (2008). It should be noticed here that the city space is the only possible place of contacts for people belonging to various milieus. The lack of spatial relations between the location of different social groups - which Sachs (2006) defines as belonging to different periods of civilisation development: information, industry, agriculture - and the place, which they occupy remains characteristic for contemporary *'urban regions'*[1]. Such situation – usually of positive connotation, as mixing contributes to the equalisation of differences – is the result of many years of evolution and spontaneous transformation of social structure. This is an antithesis to the Chicago school approach[2], which defined the city social structure as a juxtaposition of areas occupied by people belonging to various groups, seeing in the situation of change the transformation period between the following phases of succession. While mixture and variety create fortuity and are a source of richness of the urban environment. Carmona et al. (2009) and Gehl (2009) also underline the need for integration of different groups within an area and point at enabling direct contacts between inhabitants as the primary challenge for today's urban design.

Studies of former cities, which successfully developed as multiethnic communities provide important guidelines, when looking for solutions for problems of contemporary multicultural cities. Thus this case study, which concerns Lodz – a 19th century, textile industry centre, the development of which was a common oeuvre of four cultures: Polish, German, Jewish and Russian. Their activities left durable traces in the city structure in the form of important edifices: factories and palaces of factory owners, and common structures: tenements and social housing, serving for factory workers and other employees. Architectural forms expressed the differences in religious habits: there are catholic and orthodox churches, whereas most of the synagogues were demolished. The analyses of urban structures, including social spaces of squares and markets, streets, passages and nooks provide an important perspective. The patterns differed throughout the city - their overlay with the distribution of communities representing various cultures indicates the correlation. Their concentrations and mixing up provided occasions for both: isolation and mutual relations.

2.2 Thesis

When regarding the development of physical structures in relation to culture, the built form constitutes an important repository of cultural information, an artefact of cultures and societies that created them in a given time (Lawrence, Low 1990, Dubos 1972, Alexander 1977). Studies of the physical form of the city allow to reveal the activities of former citizens. The physical urban structure constitutes part of the material culture,

[1] The term proposed by Zuziak (2008, 28) to describe a city and its surrounding areas.

[2] R. Park et al. after Jałowiecki, Szczepański (2006, 18). An exemplary thesis of Otmar Spengler, used as reference by the creators of Chicago School *„a city is the same for civilised man as a cottage for a peasant"* stops making sense in the description of the contemporary reality.

which, as Mead states, remains a series of *"collapsed acts, the signs of what would happen if the acts were carried to completion"* (cited in Richardson 2009: 75). Material culture becomes an expression of the defined situation (as described by social scientists, e.g. Perinbanayagam (1974)), when an unity is brought about between the situation itself and the material settings. Then the situation may be described as placed as it has achieved its material existence (Richardson 2009: 75).

Hillier and Hanson (2003) underline the relation of patterns of people movements and physical environment introducing the concept of spatial logic of space. Thus, the analyses of existing and former urban structures provide an important tool for the creation of new structures, which not only follow the site's genius loci and local tradition but also stay in compliance with the integral cultural patterns of social groups. More contemporary research on the social production of space seeks to place the understanding of built form in the larger context of the society's institutions and history: Lefebvre (2003), Lawrence, Low (1990) and their followers. Proxemics relates the human environment with behavioural patterns proper for distinguished cultures (Hall 1966, 2009). The above factors remain important, when considering the constant displacement of people in an era of globalisation and the requirement to provide an environment, which suits their needs while at the same time reducing the problems of social adaptation.

The present case study discusses the settings, which were created by Jews, who lived in Lodz in the 19th and 20th centuries, addressing the relation between the level of mixing up and assimilation and presence of features specific for this culture in the city structure.

3 HISTORICAL BACKGROUND

3.1 The definition of the area under consideration

The delimitation of the area may raise some controversy. The common perception of the Jewish district in Lodz refers to the area of the Old Town and the adjacent part of the former Nowe Bałuty settlement, and is enclosed by Pomorska and Legionów Streets, including the former Factory of I.K. Poznański and its closest surroundings. Citizens with higher level of historical consciousness consider the area extending to Zielona and Narutowicza Streets, aware of the presence of more assimilated Jewish population in the direct neighbourhood of the pre-war edifice of the reform synagogue (*Dajcze szil*), which was erected on the corner parcel of Zielona Street and Aleja Kościuszki (former Zachodnia Street). The consistent concentration of Jews was located in the Old Town along with the most urbanised part of the former Nowe Bałuty settlement – this area is referred to in literature as the one of essentially Jewish character. In the South part the area lines up with the extent defined by analyses of statistical data of the beginning of the period between the World Wars (Grabowski 1922), shown in Fig. 1. The spatial extent of the contemporary administrative Bałuty unit differs from the common understanding of the name, and from its historical meaning. The tragic events associated with the functioning of the Litzmanstadt ghetto in Bałuty overlap on this in the public consciousness.

Basing on the Municipal Register of 1918-1920 (Grabowski 1922) the population of Moses' faith occurred in the area limited by Św. Andrzeja and Przejazd Streets (current names: Andrzeja Struga and Tuwima Streets). The greatest number of Jews lived in the Old Town (statistical unit III – 89%), in the neighbourhood of Pomorska Street (unit V – 78%), in the neighbourhood of Zielona Street (unit VII – 62%) and Dzielna Street (current name Narutowicza Street, unit VIII – 68%), in the North-East part of Bałuty (XVIII - 43%) and in the neighbourhood of Konstantynowska Street (unit IV – ca 50%). Certain percentage lived in Górna district, in the neighbourhood of the market place. The extent of the occurrence of Jewish population for units VII, VIII, XVIII and IV did not match the borders of the statistical units, thus the aggregation to bigger units did not allow to show the effective concentrations of this group within the whole unit (Spodenkiewicz 1999).

The analysis of the spatial development of the Old Town in Lodz and of the Bałuty district, thus of the areas, the final spatial shape of which was mostly the artefact of the Jewish community, indicates the presence of a set of morphological features proper for this culture. German authorities of Litzmanstadt extensively redeveloped the area during the World War II, further redevelopment was conducted in the post-war period by Polish authorities. However, even the later alteration, which diluted most of the former character, did not utterly destroy the general character of these places, which remains present and allows for reading of the former citizens' activities and habits.

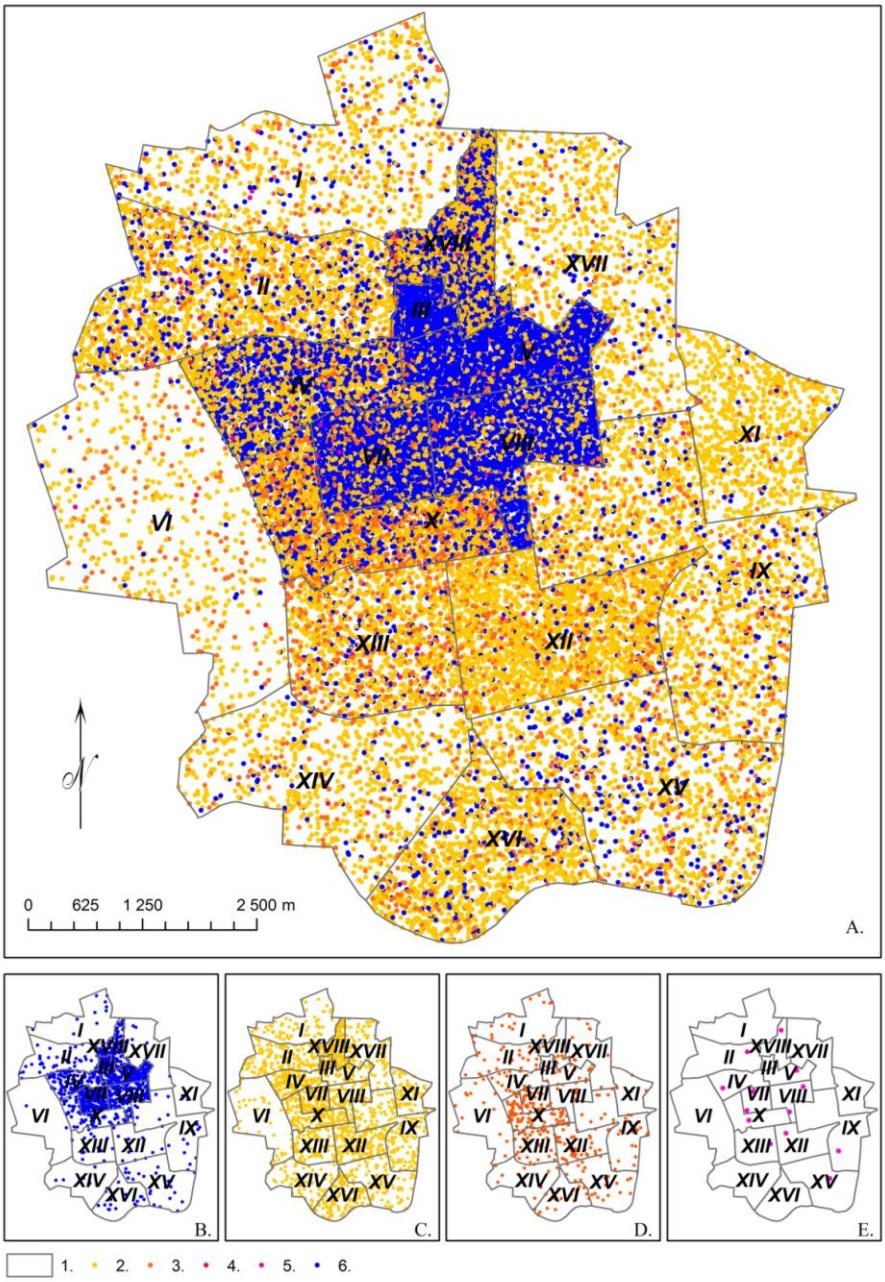

Fig. 1: Sociotopography of Lodz in the beginning of the 20th century, data source: Grabowski (1922).

3.2 History of the Jewish settlement in Lodz

The initial low influx of the Jewish population to Lodz before the end of the 18th century was the effect of the economic stagnation of the city (Puś 2003: 11). The lack of interest continued despite the fact that Lodz, which remained the property of Wroclaw bishops did not have the privilege *"de non tolerandis Judaeis"*, that is there were no legal limitations for Jews' settling (Friedman 1935: 22). The economic development of the city under the initially Prussian (to 1806 r.) and then in the period of the Duchy of Warsaw – Polish government administration, contributed to the considerable growth of the population - in the years 1793-1808 it was above twofold: from 191 to 434 persons. In this time, the number of Jews in Lodz grew up five times: from 11 to 58 persons (Puś 2003: 11). The conclusion about the economic development of city as the main factor inducing the Jewish population to settle in Lodz is important for further considerations (Baranowski 1988: 12).

The regulations of the Constitution of the Duchy of Warsaw, setting up the equality of all citizens *"before the face of law"* did not refer to the Jewish population. Moreover, their law to move freely was limited and the successive policy of the government aiming to transfer Jews living so far in the country (above 30% of the entire Jewish population at the Duchy of Warsaw) to cities was introduced. This was one of the factors,

which fostered the growth of immigration to cities, among others to Lodz. The treatment of the Jewish population did not change in the Kingdom of Poland (in the period between the Congress of Vienna in 1815 and 1862), however it did not reduce Jewish immigration to Lodz. The number of Jewish inhabitants of Lodz grew up from 98 persons in 1809 to 259 in 1820.

The decision of the authorities issued on the 7th May 1822, concerning the establishing of Jewish districts in cities, belonging to the government, was introduced in Lodz on the initiative of the authorities of the Mazovian Province, as part of the regulation on constructions, accompanying the location of the factory settlements (first of Nowe Miasto, and then of Łódka). The decision of the governor of Congress Poland of 27th September 1825 established in Lodz the district for the inhabitants of Moses' faith and obliged all local Jews to move to the appointed zone of the city before the 1st of July 1827. Exception was made for these, who showed high income, spoke Polish and French or German fluently, were sending children to public schools and did not use *"superficial signs, which so far distinguished the Jewish nation from other citizens"*. The privilege to choose the place of residence was also granted to persons of high material status, scientists, artists and wealthy merchants (Rynkowska 1960, Nr 152). Economic development was the factor attracting subsequent immigrants: in the years 1825-1841, the Jewish population grew up four times from 342 to 1359 persons. It resulted in the growth of the inhabitants' density in the zone and, as a consequence, its enlargement. The first informal enlargement, took place in 1841, when the Government Committee annotated the project presented by the Mazovian Governor Franciszek hr. Potocki, stating that the Committee *„confirms that, building intended and already begun by the Jewish population in the part of the city of Lodz proposed for spreading of their district, should not stopped".* The district was then enlarged, including the whole of the Old Town market and the northern part of Podrzeczna and Wolborska Streets as shown on the plan from 1841[3].

Nobody decided to settle outside the zone, despite the regulations allowing for this. It was partly a result of the hostile attitude of artisans, mostly German, who referred to the regulations of Zgierz, where Jewish people were forbidden to settle. The first Jewish investment outside the zone was the yarn store erected by Ludwik Mamroth from Kalisz only in 1833. Until 1848, there were only eight Jewish families living outside the zone. From 1848 to 1860, further 40 families got their permissions, there were also 312 Jews living in Nowe Miasto without permission (Friedman 1935: 82-85). The next enlargement of the zone took place in 1859, confirmed by the Decree of the Administrative Council of the Kingdom of Poland on 12 May 1861. It covered the territories to the East from the Old Market, where four new streets were marked out, as well as parts of the streets: Zgierska, Kościelna and Piotrkowska (currently part of Nowomiejska) and the North side of Północna Street. A year later, on 5 June 1962, tsar Alexander II signed an ukase defining the rights of the Jewish population, which, along with equalising the Jews' rights in access to merchant and artisan corporations, liquidated the Jewish zones and cancelled the former discrimination of Jews in the civil and penal law.

Concurrently, in 1853, merchants from Lodz: Szlomo Icchac Bławat and Icchat Birenzweig signed a lease contract with August Zawisza, the owner of Bałuty estate. The allotment of the New Bałuty settlement began in 1857. According to Orłowski (1984) *"its objective was the foundation of a new, industrial settlement which, neighbouring with the Jewish district, would have in it a constant source of cheap and professional labour force"*. One could argue with the term 'industrial settlement'. Especially that the same author quotes the statement of the then president of Lodz Franciszek Traeger, describing houses, *"the structure, layout and size of which are conceived as convenient places for craftsmen and merchants*" (Rynkowska 1960, Nr 130), thus confirming the commercial character of the new settlement and pointing at the perfection of adopted solutions from the point of view of commerce. In the report for the gubernial government Traeger stressed the satellite character of the new settlement in relation to Lodz, being rather a prolongation of the city than an independent organism, the spontaneity of the new development and its possible competition for Lodz. The Nowe Bałuty settlement was inhabited mainly by poor people, both Jewish and Polish, who earned their living from small trade, home industry and domestic service in Lodz (Puś 2006: 95). The land properties belonged to all three groups (German, Jewish and Polish), though Germans seldom settled in the neighbourhood.

3 *"Plan rozszerzenia rewiru żydowskiego w r. 1841 (ze zbiorów Archiwum Akt Dawnych Miasta Łodzi)"* Map 2 in Friedman (1935)

The Jewish district in Lodz, initially restricted to 'the zone' was enlarged with time covering a big part of Bałuty and the North part of the downtown. Richer and better-assimilated citizens lived rather in Nowe Miasto, poorer groups in Bałuty. The main reason of Jewish immigration was the economic development of the city as textile industry centre (Puś 2006: 47). After 1890 there were about 10 000 Jewish immigrants from Russia, who arrived in Lodz – so called Litvaks (Puś 2006: 47), what fostered the development of commercial contacts with Russia and facilitated export of products to the East. This by turn indirectly influenced the wealth of this ethnical group, its position in the city and allowed to enlarge their properties outside the zone.

3.3 Spatial distribution of nationalities in the pre-war Lodz

The spatial distribution of nationalities in pre-war Lodz was not even and changed in time. In the period just before the beginning of the World War II Jews counted ca 231,000 people - 34,4% of the total population of the city (Baranowski 2009, 85). The Old Town, the central part of Nowe Bałuty and the North part of Nowe Miasto were inhabited mostly by Jewish population, though the social characteristics of this group, mainly its level of assimilation were varied. Most descriptions of the life in Lodz of these times, referring to the areas in question, mention Polish, Jewish or German owners of tenements, Polish janitors and mainly Jewish inhabitants. The spatial distribution of different levels of income was clear: the poorest – proletariat, small artisans, outsource workers lived in Nowe Bałuty, traders and small producers inhabited the Old Town and larger merchants and bankers resided in Nowe Miasto. Obviously, the above-described distribution is very schematic, as the mixing of professions, nations and countries of origin and the differences of the degree of assimilation was huge and not equal.

The spatial distribution of nationalities influenced also the perceived safety. The districts: Widzew, Chojny and the neighbourhoods of the garrison at Konstantynowska Street or of the Hallera Square seemed dangerous for the Jewish citizens. Parks Sienkiewicza or Poniatowskiego – safe on weekdays, could occur dangerous on Sundays or during holidays, especially on Corpus Christi or on 3rd of May – the anniversary of the adoption of the Constitution of 1791.

4 METHODOLOGY OF ANALYSES OF URBAN STRUCTURE

4.1 Conzenian tradition

Polish tradition of analyses of urban morphology, derived initially from the German and Austrian research and enriched by Polish scientists[4] drew further on from the methodology of MGR. Conzen[5]. Works of M.R.G. Conzen (resumed 2004), developed further by, e.g., Whitehand et al. (2000a), Whitehand (2001), concentrated on examination of urban structure in the morphological approach, against the economic and social background, looking for relations between the city, its inhabitants and the dynamics of city construction (Vernaz Moudon A. 1997: 4). Studies on morphology of plans of small towns and villages of medieval provenience, conducted since the early 60s, aimed at proving the Polish roots of the so-called Regained Territories[6]. Similar studies on different morphological units distinguishable in the urban structure of Lodz[7] also based on the Conzenian methodology of parcellation analyses. The above studies belonged to

[4] Koter, Kulesza (2010: 112) refer to the work of Dziewoński K.: Zagadnienie typologii morfologicznej miast w Polsce, Czasopismo Geograficzne 33/ 1962, 441-56

the historical geography. They were based on the analyses of the plans of cities, including their visible elements like street network, layout and characteristics of parcels, etc.

4.2 Other methodologies

Bandini M. (2000, p.133) points at the lack of methodology for analyses of the physical form of the city in the field of humanistic and social sciences and presents the review of the main analytical threats in the field of analysis of the city architecture. A similar review of analytical threats is presented in the work by Panarai, Depaule and Demorgon (2009). The development of modernism as an international style set back the tradition of morphological analyses, which were in opposition to its basic assumptions (Rykwert 2000: 4-6). In the area of the British culture the continuation of the English *Picturesque* style became one of the threads recalling earlier traditions of development of urban structures, indicating the need of paying attention to the features of urban landscape including: diversity, semantics, intimacy and contrast[8]. This tradition is represented by the oeuvre of Cullen (2008, 1961), which assumes analyses of elements such as series of views, the way of experiencing of a site by examination of physical relations between the human body and its environment (proximity, scale in relation to human dimensions, the presence of defined, enclosed spaces). The essential features of urban environment included local colour, textures, scale, character, etc. Lynch (1960, 1994) developed the theory of perception of the urban landscape based on five elementary features: nodes, landmarks, paths, regions, and edges. Further studies on urban form (Lynch 1994, Lynch, Rodwin 1991) concentrated on the development of the notional apparatus allowing for description both of the elements of *"adopted spaces"* as well as of the system of space of *flows* – in other words of the network of open spaces: streets, squares and pedestrian passages. Attempts to conceive the notional apparatus were also made in order to describe relations between objectives and functions fulfilled by specific elements of the system and their physical properties, with the special emphasis on the concept of habit (Kropf 2009).

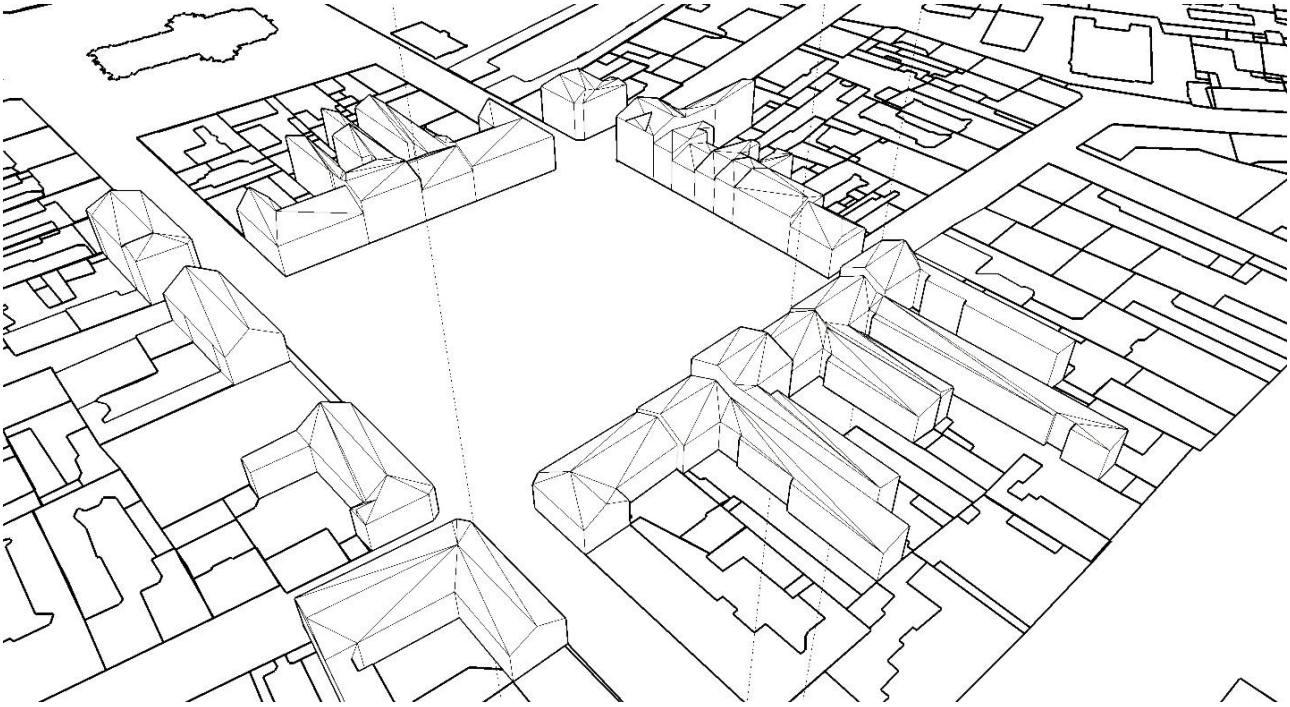

Fig. 2: Hypothetical reconstruction of the model of the Old Marker direct neighbourhood basing on archive photographs and postcards.

Traditional, morphological way of perceiving urban structures, present in the postmodern architecture and urbanism (Rossi 1984) inscribes into the general trend towards the contestation of modernism as an international style. The analyses of former structures, addressing the genius loci and the research to revert to

[8] Bandini (2000: 139) refers to the works: Hussey Christopher: The picturesque: studies in a point of view, G.P. Putnam's Sons London 1927 and Watkin David: The English Vision: The Picturesque in Architecture, Landscape and Garden Design, Murray, London 1982

a concretisation of the genius loci are among the key challenges. Typology of public spaces and more architectural considerations, concerning scale and form of constructions, constitute one of the basic areas of interest of the New Urbanism movement (compare Krier 1975). The comprehensive set of features allowing for the characteristics of physical structures, including the culture related features was developed, among others, by Rapoport (1990: 106-107).

5 CHARACTERISTICS OF URBAN STRUCTURE

5.1 The Lodz 'Jewish District' – an example of 'shtetl[9] culture'

The different character of the Jewish settlements in the countries of Western and Eastern Europe was the result of initially larger spatial isolation of the Jewish population in Western Europe, followed by their more essential assimilation than it had place, among others, on the terrain of Poland (Wirth 1962). Here the initial privileges, allowing for the development of Jewish communities not only in large cities, but also in small towns as well as the permission to undertake many occupations, and further isolation and restrictions concerning the available locations for settlement, caused that this ethnic group settled in small towns, villages or districts of similar character (Wirth 1962).

A huge number of historical, demographic and social studies provide an exhaustive picture of Jewish presence both in Poland and in Lodz. Numerous monographs and collective works, popular science works as well as fiction describe in a comprehensive way the habits of the nation and the issues of coexistence between Poles and Jews, in particular problems concerning World War II and Holocaust. The numerous studies concerning the culture of Jewish emigrants from the areas of Eastern Europe deal with the characteristic features of the life in small towns, villages and districts of bigger cities defining them under the same notion 'the shtetl' (Zborowski, Herzog 1962, Ertel 2011).

The proxemics approach, presented by Hall (2009) and his successors, examines the relation of spatial patterns of usage of space in different cultures with the material environment. The differences between morphological structures representing various cultures are particularly apparent in cities, which like Lodz had become a melting pot of many cultures. Hall (2009) identifies direct relationships between interpersonal distances and other characteristics specific to individuals and communities and the way they shape their own physical environment.

In nomadic tribes, the members of which are accustomed to residing in small spaces, social distances are usually smaller than in other groups. Assessment based on the descriptions of the crowd in literature, e.g.: Singer (2010) or photos of the Ashkenazi Jewish population (those of Eastern European descent, e.g. Bonisławski, Keller 2002), which once used to live in Lodz, correspond to that characteristic. Hillier and Hanson (2003: 27) also refer to the usage of space, the patterns of behaviour appropriate for different communities as the determinants of the final shape of urban structures: *"Throughout the social grouping, a similar family of characteristic spatial themes is reproduced and through its repetition we recognise ethnicity in space. (...) Different types of social formation, it would appear, require a characteristic spatial order, just as different types of spatial order require a particular social formation to sustain them."*

Much has been written about the Jewish architectural heritage in Lodz (Wesołowski 2009, Walicki 2000, Stefański, Szrajber 2009), but there is probably no description referring to the urban structure of the areas inhabited by Jewish citizens. These settings were commonly described as possessing a special 'Jewish' character, e.g. in Bonisławski (1998), though referring this attribution to urban structure only would be, in this case, an oversimplification. The descriptions, frequent in the literature, indicate at the presence of narrow, "circulating" back- streets of the downtown part of Bałuty district and of the Old City as at an example of spontaneous development, realised without any previous conception: *"The still curved and tight back-streets... are sad witnesses of the unusual history of origins of Bałuty"*(Friedman 1935: 94).

An attempt has been made to define a certain set of features proper to the area, describing its morphological structure, which is repeated in most Polish towns and neighbourhoods populated by Jews (Dylewski 2003, Hanzl 2011, 2011a, Hanzl *in press*). The characteristics of the physical form was significantly altered during their stay in Lodz. In this context, it seems clear that the considerations about the relation between the presence of this nation and the appearance of the area are justified.

[9] Yiddish: שטעטל

The characteristic of urban spaces presented below refers mainly to the areas of the Old Town and of the central part of Nowe Bałuty. The Nowe Miasto settlement, established in 1821-1823 by Rajmund Rembieliński, with the main octagonal square and rectangular, regular network of large blocks (average 230m by 190m in the proximity of Wolności Square) belongs to a different era of urban development than the areas described. Some features proper for Jewish concentration in the discussed districts concerned also the area of Nowe Miasto, which is indicated below – though the level of assimilation processes of the society living there, the mixing of different groups and the character of spaces represented different stages of urbanisation processes (Wirth 1938).

5.2 The ubiquity of commerce

The basic character of the area of concern may be defined as the ubiquity of commerce. In 1913 there were 4050 shops and trade companies in Lodz. Basing on the singular registry data in the *"Czas"* calendar of 1913, completed with the list of enterprises in the publication *"Przemysł i handel Królestwa Polskiego"*, the Jews owned ca 80% of transport and freight companies, including branch offices engaged in businesses in Russia, which in 74% belonged to Jewish entrepreneurs. In other branches Jews owned about 60% of shops and warehouses with textiles and 50% of warehouses with stationary and technical products (Puś 2006: 58). In the description of the Old Market, which used to fulfil the functions of a marketplace, one reads: *"The small, poky space was heaped high with piles of merchandise... the intensive movement, most of all on fair days, both residents of the city of several thousand, local peasants and merchants from other cities were huddling together, buying and selling."*(Friedman 2006: 57-58) The space of commerce was not restricted to the main square or main squares only. This function of public space was present everywhere: in nooks, alleys, in the smaller squares and in the streets neighbouring the main square. The assortment of goods was very rich; one could buy or sell nearly everything.

5.2.1 The presence of edifices proper to the Jewish culture

Most of the studies on the Jewish cultural heritage (Rykała, Kulesza 2009: 209-210, Wesołowski 2009, Bergman 1991, 2009) point at the presence of characteristic edifices belonging to this culture, including synagogues, prayer houses, mikves and religious cemeteries. The proximity of religious buildings was indispensable, as on the Sabbath day they had to be accessible within a walking distance. The concentration of orthodox Jews around religious edifices remains a characteristic feature of this religion, though it is not as imperative as it used to be before (Diamond 2008). The specific form of these buildings was defined by religious regulations.

Among secular buildings, which are listed as traces of the presence of Jews, there are schools and buildings of educational societies, premises of different public institutions, manufacturers' residences, and factories. Tenements seldom attract attention, though the basic city structure consisted mainly of this type of buildings. The general layout of medieval streets as well as the former allotment was preserved to a big extent but the structures were replaced, following the 19th century modes of construction. Many buildings erected in this period are still preserved, comprising a general character of this part of the city, significantly different from other areas. *"Directly next to the synagogue, on the left, there was a gate and entrance to the bes medresz płac – a vast interior yard of the synagogue, which extended until Żydowska Street; there was another entrance there. Next to this square there was bes medresz (hebr. beth midrasz) - "the house of science" sponsored by the community. The large, close yards with different buildings were quite typical for Jewish districts in Poland. The most famous one was Szulhof in Vilnius"* (Spodenkiewicz 1999: 30)

Fig. 3: Nonexistent appearance of the central part of the old Jewish district: 1. frontages, 2. distant landmarks, 3. landmarks, 4. special places, 5. buildings in 1939, 6. parcellation in 1939

5.3 Parcellation and street network

5.3.1 Parcellation

The parcellation in the Old Town was of medieval provenience and dated from the period when the charter was granted to the city by the King Władysław Jagiełło (Koter 1984). Main streets, their directions and tracing were on one hand an effect of the pursuit to connect in one straight line the main settlement units characteristic for the Kingdom of Poland and on the other - the response to their inscribing into the preceding structure of settlements, property divisions and former terrain configuration. Koter (1984) writes about using of the passage on the Łódka river and of the formerly existing bridge on the Jasień river, when laying out the road to Piotrków and about taking into consideration the central part of the former village with the market and the church (Koter 1984: 55). At the occasion of the second enlargement of 'the zone', further streets were traced: Aleksandryjska, Św. Jakuba, Jerozolimska and Franciszkańska (Rynkowska 1960, Nr154).

Describing the allotment of grounds of Nowe Bałuty undertaken by Bławat and Birenzweyg the then president of Lodz Traeger stated *"they laid* out *the squares and markets preserving the directions and shape of former ones, according to the character of the city"* (Rynkowska 1960, Nr154). The assumption may be done that laying out the main streets in the central part around the Bałucki Market and Bazarowy Square, and also the initial scheme of the parcellation was the work of the two merchants. The streets in the remaining grounds and further parcellation in the central part of the settlement were spontaneous, devoid of any control. An example of this is Ciesielska Street traced by its owners for servicing the properties, which were located along (Sygulski 2006).

5.3.2 Street network

The physical structures, in the Jewish period, due to the breaks in the lines of frontages surrounding most of the blocks, allowed for enriching of the initial network of streets with numerous passages, small squares, hooks, completing the official sociometric layout with the possibility of informal circulation in the area. The actual network of passages was thus richer than the layout of streets, laid out as part of the initial parcellation. Hillier and Hanson (2003: 53-66) indicate at the relation between the characteristic of a given society and the sociometric layout, which is created by the group.

The dense network of curvy streets, alleys, nooks, passages and pedestrian ways, including informal passages through private properties is a characteristic feature for the whole of the discussed area – also in the part of Nowe Miasto inhabited by Jews the quantity of such junctions is higher than elsewhere. The density of the street network is a feature, which Jacobs (1992) qualifies as facilitating the development of all kinds of

services, especially commerce in the ground floor of buildings, as it stimulates pedestrian movement. Most of the connections remained mostly pedestrian, which fostered the presentation of goods and making deals.

5.4 Public spaces

The essential features of the outdoor space, characteristic for the given area refer to the issues of scale and dimensions. The narrowness of streets and presence of numerous slight turns and directional differentiation, providing the notion of concavity, thus closing the views' perspective and assuring perceived and felt closure, are factors favouring direct physical interaction. The irregularity of enclosures of streets, their broken line, the apparent lack of precise form, which enlarged the amount of border space, where people stop more willingly than in the centre of an open space, facilitates transactions, presentations of goods, etc. The abundance of such spaces enabled the location of numerous outdoor, commercial furniture: stalls, kiosks, stands and presentations encouraging buying. Furthermore, purchase was encouraged by the merchants' activity; by the way, not all methods were upright[10]. The aforementioned behaviours are also the most successful in narrow and intimate places; compare the narrowness of pavements in the street cross-section, even in the comparably wide streets such as Zgierska or Łagiewnicka. The analysis of old photographs shows that their shape remained unaltered, except for the former open gutters, which were removed.

Whyte (2009) defines the set of features of outdoor space favouring contacts and fostering relations pointing at the location inside of the human flow. Gehl (2009) indicates at small dimensions of spaces as favourable for establishing relations. In his further considerations he underlines the role of the corrugation of the edge of space (through the presence of elements of urban equipment and the shape of walls themselves) as a feature important for enhancing communal life (Gehl 2009: 150). In the case of the discussed area the tightness of some places, the complication of wall shapes, the apparent chaos could hinder concentration and easiness of perception by persons from outside, which could by turn facilitate transactions profitable for sellers (not necessarily for buyers). Attracting passersby, their stopping was fostered by the presence of numerous small size elements in the outdoor space, providing even sham shelter – Cullen (2008: 103-105) describes this phenomena using the example of a street „cross", the main function of which was to stop pedestrians. Here such role, less formal, was fulfilled by outhouses and stalls. Whyte (2009) confirms the observation concerning attractiveness of elements freely distributed in the outdoor space.

6 CONCLUSIONS

Recent research (Ladányi 2001) proves that concentration of ethnically distinguished groups favours social exclusion. As Wirth (1938) stated *"the larger, the more densely populated, and the more heterogeneous a community, the more accentuated the characteristics associated with urbanism will be."* The lack of an intermediate, socially mixed zone fosters separation, thus belonging to the 'folk society', following Redfield's terms (1947), rather than introducing urban, more heterogeneous culture. Ethnic and cultural groups distribution had been subject of many studies since the research by Park, as described by Gottdiener and Hutchison (2006: 155-180). The latest research on allocation of distinguished social groups in cities (Rankin 2010, 2011) confirms Wirth's (1938) and Redfield's (1947) theses, concerning the presence of heterogeneous, urban specific transition zones between ethnic groups, instead of distinct borders as proper for urban communities of high level of stability. The case study of Jewish presence in Lodz confirms all of the above observations: the core part covering the *shtetl*-like development of the Old Town and central part of Nowe Bałuty settlement presented features of distinct, socially isolated population of folk features. The social equilibrium and more accentuated city-like characteristics of development were achieved thanks to the presence of an intermediate, socially heterogeneous community, which as far as Jews were concerned was apparent along with the increased level of assimilation and the dilution of traditional religious orthodox practices and habits resulting from it.

Contemporary studies on segregation and integration processes in the globalising world confirm the presence of different social patterns and the ethnical heterogeneity as the feature proper to a contemporary, urban society (Schnell, Benjamini 2005). Spatial distribution of ethnic groups in Lodz in the beginning of the 20th century tended towards this model. The co-presence is understood in categories of social situations as Goffman (1963) defines it. The community of *shtetl*, with its specific and closed character and defined

[10] The interview with Don Goren in Spodenkiewicz (1999: 33).

culture along with the transition zone of assimilation provided the environment, which remained balanced and did not generated conflicts for long period of time, which may still serve as an example to follow in cases of co-presence of many different cultural groups.

Lévi-Strauss describes the city as "*the most complex of human inventions, (…) at the confluence of nature and artefact"*[11]. The recognition of an area as belonging to a specific culture is an issue addressed by anthropologists, cultural geographers[12] and urban morphologists – starting from Geddes (1904). The subject of investigations are the tangible results of social and economic forces, the outcomes of ideas and intentions expressed in actions, which are themselves governed by cultural traditions (Vernez-Moudon 1997: 3). Experiencing of culture may be effectuated via examination of its influence on the physical form of the city: spaces of flows and built-up places. A number of features confirm the influence of the presence of the Jewish community over the physical form of spatial structure. Referring the methodological remarks presented in the paper to the attempt to analyse the spatial structure of the part of Lodz, inhabited by Jews and in its important part erected by them in the second half of the 19th century and in the beginning of the 20th century (Hanzl 2011, 2011a), the following features may be distinguished:

1. Adjustment of public space to the needs of commerce: various scale of public spaces, important quantity and density of passages, nooks, alleys, also within private properties, irregularity of border line of public spaces and thus lengthening of the edge – increased comfort of stay in public spaces,

2. Variety of building forms, diversity of styles, materials, lack of homogeneity – as an answer to the requirements of current needs only – a feature considered characteristic for Jewish communities as representative of Diaspora lifestyle (Zborowski, Herzog 1962),

3. Adjustment of the plan of medieval village to the needs of 19th century reality without significant changes in the former state, only through replacement of buildings,

4. The presence of edifices, both public and private, belonging to Jewish culture.

5. The core location of Jews constitutes the most densely populated part of the city.

Panerai et al (2009) propose a concept of habitus, which seams significant for the present considerations, and which assumes that urban structure, as reflecting the repetitions of social practices of everyday life, becomes the form of record of these practices. With time the recorded layout may become the contribution to the further continuation of the former way of use of space. Such situation happens also in Lodz, where in spite of important changes resulting from the new usage of the Old Town Market, despite the widening of some streets, demolitions and destructions of war and post-war periods, and the intensive car transit through the former Jewish district, the use of social spaces still remains to a large extent commercial, thus compliant with the one produced once by the presence of their former inhabitants.

1 ABSTRACT

The temporal map of a city – its fast and slow speeds, working and opening hours, the location of its businesses and its mobility infrastructure – is of major importance for the quality of life in a city. Several policy measures such as changing public transport intervals, transition to flexible working times, changing opening hours of public services, and spatial planning have changed and will change urban patterns of time use and have an effect on both the economic performance (synergies, production and consumption patterns, income, etc.) and the natural environment (energy flows). Time-use structure of household members (phenomena such as "time squeeze" and synchronization of activities of different persons), the energy demand of households and the spatial organisation of cities entail each other. In the 1970s first concepts appeared to integrate time aspects in regional sciences (Hägerstrand 1970). The demand for equal opportunities for men and women and for a better work-life balance marks the beginning of time policy in the 1980s, a young interdisciplinary field aiming to integrate time aspects in urban development planning and decision-making processes. Spatial planning plays a significant role in the design of time structures. The currently starting project UTE (urban time and energy) aims to gain a better insight into the drivers of time-use patterns and energy use by focusing on time-policy measures that consequently impact on energy and material consuming activities of urban households and on the necessary urban infrastructure. The project will base its assumptions on the case study of Vienna. An integrated socioecological simulation model will be developed to study the inter-linkages between time-use patterns in differently structured areas of the city of Vienna. Time-space-energy scenarios will highlight the potential of time-use structures for energy-use reduction.

2 INTRODUCTION

Several policy measures such as changing public transport intervals, transition to flexible working times, changing opening hours of public services and spatial planning have changed and will change urban patterns of time use and have an effect on both the economic performance (synergies, production and consumption patterns, income, etc.) and the natural environment (energy flows). Time-use structure of household members (phenomena such as "time squeeze" and synchronization of activities of different persons), the energy demand of households and the spatial organisation of cities entail each other. Reaching the goal of an activity faster requires more energy for the same achievement. Similarly, larger distances between locations of activities require either more time or more energy or both. "Time sovereignty", which is some freedom of choice over one's time use, is considered a key feature of quality of life. Available time – as much as available money – governs everyday decision making of household members concerning living space, consumption patterns and means of transportation. All of these activities are energy consuming (transport energy, heating/cooling energy, etc.). Consequently, lack of time often translates into spending more money and more energy, severely constraining individual and household choices.

The UTE project aims to gain a better insight into the drivers of time-use patterns and energy use by focusing on time-policy measures that consequently impact on energy and material consuming activities of urban households and on the necessary urban infrastructure. An integrated socio¬ecological simulation model will

be developed to study the inter-linkages between time-use patterns in differently structured areas of the city of Vienna and urban energy consumption by addressing the following questions:

- Is there a link between time-use patterns in a city and urban energy flows?

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

- How can time-policy measures in a city change quality of life, i. e. work-life balance, time-affluence, time-pressure, family life, educational situation, recreational situation and how do they affect energy consumption?
- Could an awareness of these interrelations help to improve spatial settings and infrastructures in cities, as a win-win connection between quality of life and energy savings?
- How can a socio-ecological model further our understanding of the interplay of socioeconomic and natural drivers (time-use patterns) influencing urban energy use?
- What is the potential of the developed simulation model to serve as decision support tool for municipalities, urban planners and traffic management?

Time-space-energy scenarios will highlight the potential of time-use structures for energy-use reduction. Model results concerning emission reduction potential will be critically challenged in order to take rebound effects into account. The project will elaborate basic principles for integrated systematic solutions in practice. This entails the following innovative conceptual as well as methodological development:

- Furthering our understanding of time-use patterns as drivers for energy use of urban households.
- Developing an integrated causal toy model capable of simulating changes in household energy use based on different time-use scenarios.
- Testing the applicability of the integrated model for one case study region in Vienna as a decision support tool time, space and energy.

3 TIME, SPACE AND ENERGY

3.1 Time-policy and Time-use research

Time policy and its research is a young interdisciplinary field aiming to integrate time aspects in urban development planning and decision-making processes. Beginning in the 1980s in Italy largely as a result of linking gender issues to urban planning and transport (Bonfiglioli, 2005; Bonfiglioli et al., 2000; Stadtgemeinde Bozen, 2006; Mairhuber, 2001), it also has a tradition in Germany (Henckel , 2000; Deutsche Gesellschaft für Zeitpolitik, 2003; Eberling and Henckel, 2001) and France (Boulin and Mückenberger, 2000). These studies address the question of how major changes in western industrialized societies over the past 50 years – i. e. the increase in female employment, the shift to a knowledge society and changes in production and consumption patterns (Post-Fordism, precarious work, internationalisation of labour) – lead to new patterns of time use, and how arising issues of time pressure and time conflicts can be addressed in terms of political measures concerning the times of a city (Läpple et al., 2010). A city's time map – its fast and slow speeds, working and opening hours, the locations of its businesses and its mobility infrastructure, which together set the pace for how its inhabitants move about in it – is of major importance for the temporal quality of city life and work (Mückenberger and Boulin, 2005; Kramer, 2005).

The project will draw on the international preliminary work and experiences gained from time-policy projects in Italy, Germany, France and the Netherlands. Vienna has recently launched an assessment of the potentials of communal time policy in a feasibility study (Mairhuber and Atzmüller, 2008). Similar to other international model projects, this study aimed at optimizing time issues in order to improve citizens' quality of life and their "time affluence". The relevance of such communal time policy for energy and resource consumption has not yet been researched.

In sustainability sciences, it is important to find indicators to assess quality of life and changes therein. Time-use is an integrative aspect of many facets of quality of life and is seen as helpful in its monitoring (Carlstein, 1981; Fischer-Kowalski and Schaffartzik, 2008; Mückenberger and Boulin, 2005; Moe, 1998; Garhammer, 2001; Garhammer, 2008; Mischau and Oechsle (eds.), 2005; Schaffer, 2007). The terms 'time scarcity' and 'time affluence' (Rinderspacher, 2002; Heitkötter, 2007; Kränzl Nagel and Beham, 2007; Schor, 2010a) are used to link economic and social factors and to find alternatives to a solely economic notion of growth and development (Sanne, 2002; Kasser and Sheldon, 2010; Graaf, 2003). Eurofound, the European Foundation for the Improvement of Living and Working Conditions, examines in its European Quality of Life Survey a range of issues, such as employment, income, education, housing, family, health, work-life balance, life satisfaction and perceived quality of society. "Having sufficient time to fulfil both professional and personal

goals – raising children, caring for older relatives, maintaining social and family contacts – is a crucial element in determining a good quality of life. However, findings from the European Quality of Life Survey 2007 indicate that work–life balance remains an elusive goal for many working Europeans." (Eurofound, 2010, p. 3, see also Boulin, 2003).

A number of European nations conduct time-use surveys on a regular basis. These data are widely used to analyse changes in gender relations (Eurostat, 2003; Statistisches Bundesamt, 2004; Döge, 2006; Sellach et al., 2005; Bundesministerin für Frauen, 2010) and socioeconomic changes like family and household structures, working hours, recreational behaviour and consumption patterns (Schor, 2010b; Hartard et al., 2006; Stahmer and Schaffer, 2004; Gershuny, 2000). Statistics Austria finalized a new time-use survey for Austria in 2009 (Statistik Austria, 2009).

Linking sustainability research with time-use research is attaining some importance in socio-economic national accounting, in non-monetary input-output approaches (Stahmer et al., 2003; Schaffer, 2006; Minx and Baiocchi, 2010) and in other new attempts to strengthen socioeconomic features within sustainability discourse (Chiou, 2009; Vinz, 2005; Jalas, 2002; Jalas, 2008; Hayden and Shandra, 2009).

3.2 Time Structures and Urban Planning

First approaches to integrate time aspects in regional and geographical studies already appeared at the beginning of the 1970's. A central model was the space-time aquarium of Hägerstrand (1970). The movement of humans is demonstrated in a three-dimensional model, whereby the area is represented as two-dimensional map and the temporal dimension in the vertical Z-axis is supplemented. Range of movement and speed depend on outside factors and are subject to certain restrictions. Hägerstrand divides these restrictions in three categories: capability constraints, coupling constraints and authority constraints (Hägerstrand 1970, 12).

Contemporary models of urban architecture and spatial planning aim to align themselves again with the historical city. Knoflacher (2007) states a "space-time dimension on the human scale" in the historical city whereas the "new city" is oriented along a "space-time dimension for machines". Concepts of the "compact city" or the "city of short distances" are favoured in contrast to the inflexible, divided and homogenous use of spaces. In opposition to these efforts to counter large-scale expansion in area terms, land-use is constantly growing. A study by the University of Natural Resources and Life Sciences, Vienna, shows that in Austria 15 hectares of land are swallowed daily by construction and transport development (Weber, 2008). Along with the loss of land as an important future CO2 sink and source of energy and raw materials, the high ensuing costs (infrastructure costs for construction, maintenance, repair and renewal) and all further climate-related consequences of urbanisation (increase in individual motorised transport, expansion of additional traffic routes, great use of fossil energy sources, etc) are alarming.

3.3 Urban Energy Use

Departing from energy metabolism as crucial concept in assessing society-nature interaction and sustainable development (Haberl, 2001a; Haberl, 2001b) we focus on energy use. Urban energy use can best be understood from a demand perspective, not just for final energy forms, such as electricity or transportation

fuels, but for energy services (Lovins, 1976; Jochem et al., 2000). Each household and economic activity in urban areas can be interpreted as a demand for energy services, such as mobility (physical access to certain destinations and certain goods), ambient temperature (hotter or colder than the local climate), or working appliances (for home, office and industry, communications, etc). These urban energy services are common to most urban areas, but the energy consumed to provide them varies greatly. Household demand for energy services changes depending on several factors, which can be categorized as economic, demographic and behavioural.

The positive correlation of income and energy use has been long established in the traditional energy literature, especially in national level analyses. Energy use correlation with income has been measured for households in the Netherlands (Vringer and Blok, 1995), India (Pachauri and Spreng, 2002), Brazilian cities (Cohen et al., 2005), Denmark (Wier et al., 2001) and Japan (Lenzen et al., 2006), with similar results for GHG emissions in Australia (Dey et al., 2007) and CO2 emissions in the USA (Weber and Matthews, 2008). Urban dwellers consume energy directly, in their homes and vehicles, and indirectly, through the goods and

services they purchase. Since urban incomes are often higher than the national average, by this metric alone, urban populations can be expected to consume more energy than non-urban populations.

Demographic factors such as population growth, household size, average household age and migration influence urban energy usage. Household size plays an important role in energy use: above 2 persons per household, economies of scale can reduce the energy consumed per capita. Urban populations may have significantly smaller household sizes than rural populations, due to smaller family sizes and a larger generation gap as well as smaller dwellings, and are thus less likely to shelter extended families or many generations under the same roof. The evidence for the influence of age is mixed. In Sydney, increasing age was correlated with higher residential energy consumption but lower transportation use (Lenzen et al., 2004). The most important effect of age may be through resulting changes in household sizes.

Behavioural or cultural factors clearly influence energy use: e. g. using a car, especially a big car or SUV, as a social status symbol, compared to using the bus or a bicycle. Individual behaviour and household decisions on dietary patterns, eating habits, preferred ways to spend leisure time and many others are surveyed in research on sustainable consumption and possible rebound effects (Kletzan et al., 2006; Duchin, 2005; Hertwich, 2005; Jackson, 2005; Bruckner, 2008; Binswanger, 2002; Sorrell and Dimitropoulos, 2008). Recent research on energy consumption and gender aspects (Räty and Carlsson-Kanyama, 2010; Carlsson-Kanyama and Linden, 2007), on household behaviour according to energy use (Linden et al., 2006; Duchin, 2003) and studies on individual mobility types (INFAS, 2002) and sustainable lifestyles (Graham et al., 2009; Sutcliffe et al., 2008) will supply valuable guidance for potential time-use and energy scenarios.

3.4 Urban Time and Energy Scenarios

UTE aims to explore the options for future development which depend on internal choices (of households) as well as on changes in the framework conditions, such as time-policy measures. Using the "magic triangle of sustainability" (Fischer-Kowalski et al., 1997) as the model concept and guide for this innovative approach, we try to link concepts and knowledge from different scientific disciplines and data from different accounting systems. The model analyses the decision-finding process of households according to their energy use (mostly transport and heating energy) using a 'sustainability triangle' (see Figure 1) in which each corner represents one of the core sustainability dimensions (social / ecological / economic dimension).

To apply this so-called 'magic triangle of sustainability' to households, the three dimensions are:

- Household energy consumption (ecological dimension)
- Income of household members and working situation (economic dimension)
- Household time-use pattern (social dimension)

Figure 1 shows these dimensions in their interdependencies on household level (Smetschka et al., 2009).

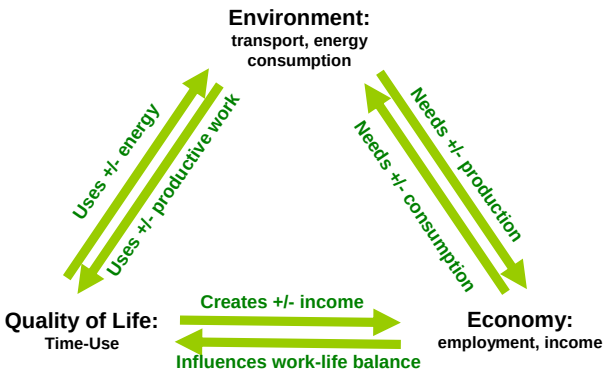

Fig. 1: Zooming in on the models' "Magic triangle of sustainability"

In analysing changes in the use of energy in the city it is important to take into account that these changes are based on human decision making, occurring at a very local scale on a day-to-day basis. Recent developments in computational science allow for the application of numerical models for the systematic analysis and

simulation of human decision making and its direct and indirect effects. Modelling such as agent-based modelling can be applied as a means for testing hypotheses about interrelations in complex human-environment systems (van der Leeuw, 2004, Lawrence et al., 2007, Liu et al., 2007) in cases where approaches limited to the analysis of social or biophysical parameters alone are insufficient. Moreover, model development provides a transdisciplinary platform for stakeholders and experts to communicate on an equal footing throughout the research process. Participation of this kind is described as key to enabling social actors or social systems to learn from, or be stimulated by, a research process (e. g., Hare and Pahl-Wostl, 2002, Pahl-Wostl, 2002), and represents a core methodology of sustainability science (Kates et al., 2001).

4 UTE APPROACH

4.1 Linking Time-use and Energy-use

UTE aims at studying the full cycle of time-use patterns in selected urban areas in the city of Vienna and energy use of households by focusing on decision-making processes of households in relation to their time-use strategies. The interlinkages between time use and energy use will be modelled for different household types (distinguished by socio-demographic and employment status) according to the actual data of the urban model area.

Existing scientific models mostly reflect theories and concepts developed within single disciplines and usually focus on ecological, social or economic aspects. Thus, to analyse socioecological systems and impacts of external drivers on these systems, the approaches of different disciplines are needed. Integrated modelling in terms of integrating different modelling approaches (agent-based, stock-flow, etc.) makes it possible to integrate social-science based approaches with concepts from the natural sciences (van der Leeuw 2004). The model presented here belongs to this new model type that can deal with local situations and aim to integrate biophysical issues (e. g., built infrastructure, energy supply) with socioeconomic factors (e. g., Time-use patterns, energy consumption).

4.2 Case Studies

Participatory modelling

An initial goal of UTE is to design an accompanying process throughout the whole project duration with iterative methodological elements such as qualitative partially structured interviews, workshops, explorative focus groups and national & international co-operations on the one hand. By using qualitative interviews with representatives of important stakeholder groups, UTE aims to generate first assumptions about time-use patterns and energy use. On the other hand, the collected qualitative information will be implemented in a simulation model. Consequently, those interviewed will gain systematic understanding of the time-policy relevant questions in their respective area of competence and work in correlation with energy use.

The study brings together insights from a range of diverse subjects, combining them to develop an interdisciplinary approach to analysing links between time-space and energy use such as:

- Local times and infrastructure (opening hours of municipal offices, public/private services and shops, hours of school and childcare facilities, etc.)
- Urban planning and development, urban renewal (distancedependent times, i. e. mixing of residential areas with social infrastructure, etc.)
- Transport and mobility (working hours, time schedules of public transportation, etc.)
- Buildings (energy services, household preferences)

It is in the interplay of these areas that the study will investigate in how far time-policy measures can result in added energy efficiency and altered energy consumption.

The developed model will build upon the first version of a residential location decision model developed for Vienna in the FP 7 project SUME (Sustainable Urban Metabolism in European cities, http://www.sume.at/). This model focuses on households and their residential location decisions in relation to their economic and demographic situation. Based on assumptions according to their internal structure (more or less family members, age, income situation) and external urban planning decisions changing infrastructure access in different areas in Vienna, households need or want to move to another place of residence. This provides an

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

excellent starting point for our proposed model, as it already delivers a spatially explicit distribution of households in Vienna according to their socioeconomic situation. UTE will use this spatial model of Vienna and extend it with assumptions about time-use requirements of households and time-affecting services in urban areas. In order to structure and implement the decision-making process of each single household, the magic sustainability triangle will be applied (see Figure 2).

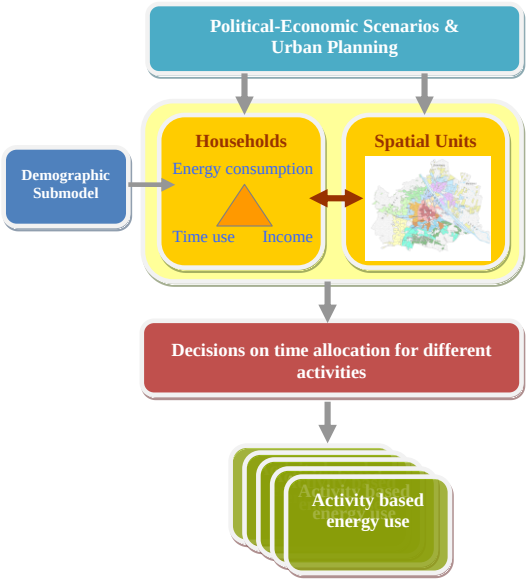

Fig. 2: Overview of the model concept

Implementation in different types of urban areas

An overall model concept will be adapted to different types of urban areas, such as urban renewal area, new urban residential area and urban development area (see Table 1).

	Urban renewal areas	New urban residential areas	Urban development areas
Urban Development structure	densely built-up area, traditional block perimeter development with narrow courtyards	five to seven-storey buildings, ribbon or block perimeter development	moderate building density, mixed structural types
Age of the buildings	up to 50 % built before 1918 (promoterism), numerous buildings from the inter- or post-war period	up to 60 % built after 1990	future planning
Location	inner city, centrally located, directly adjacent or close to the historic centre	periphery, suburban location	suburb
Land use types	small scale residential and commercial use	uniformly residential area	residential buildings, offices, commercial and educational institutions
Transport and mobility infrastructure	good public transport accessibility, restricted accessibility for private vehicles (narrow traffic lanes, restricted parking areas, congestions)	restricted access to public transport (limited number, intervals and directions), good accessibility for private vehicles	high-level public transport system, good accessibility for private vehicles but with restricted areas (pedestrian zones)
Social infrastructure and services	well-established infrastructure, short distances (walking distance)	limited social infrastructure and services (choice, long distances)	good infrastructure for everyday necessities (shops, restaurants, libraries...), moderate offer of educational and public institutions
Green and open space structure	barely parks and open spaces	parks or wide-open green spaces and wilderness areas in the immediate surroundings	parks or wide-open green spaces and wilderness areas in the immediate surroundings

Table 1: Description of the typical characteristics of the three urban areas for the toy models

After implementing the model and using the model results, future scenarios and policy measures developed in our case study, we will design a transfer process enabling us to learn more about the model. This will primarily enhance cooperation with stakeholders and people interested in applying the model.

5 RESULTS

The principal outcome of the project is a model-based integrated understanding of the interrelation between time use and energy use in a city. Time-space-energy scenarios will highlight the potential of time-use structures for energy-use reduction. The project's potential for successful application is to develop a decision support tool which can be used by stakeholders of communal administration, urban development and planning bodies in politics and civil society. This tool can trigger and guide time-policy measures of the city's administration and planning processes which integrate time policy, participatory processes and energy saving. One feature of the planned agent-based model is that it can easily be handled by users not belonging to the scientific community through an user-friendly interface. Given a participatory process, its graphic design will show the most interesting influencing factors for these actors as interactively changeable sliders. The realization of a commercially or politically useable model should be envisaged with industrial partners in a subsequent project.

Urban Types and Transformation of the City

Mohammed Qasim Abdul Ghafoor Al Ani

(Dr Mohammed Qasim Abdul Ghafoor Al Ani, Al Nahrain University, College of Engineering, Architecture Department, Baghdad, Iraq, PhD Consulting Architect & Urban Designer, mohammedkassim66@yahoo.com, 00964 7901 398763)

1 ABSTRACT

This research deals with the subject of Urban Types, for what it represents, as an element dealing with the conscious and the unconscious, in the process of thinking of the city future, in order to build a continuous civilization. The urban types were established historical cities in the middle age in the Christian civilization in Europe land, and in the middle age of Islamic civilization in Arabic land. To determine important urban design intervention, which take part in development plans of cities, and make there to conserve the basic types which established on its.

The continuity process is the main concern of the research, and it will not be achieved without taking the Urban Transformation, as well as studying their effects on the historical city centers, where the interest in the process of continuity will come to its peak.

Therefore the research aim is to mention the transformation meaning of the Type and Typology concepts; and clarify specific definitions for each of them; which considered challenge due to the conception transformation for them and their wide uses in the other fields. So, the research aims to examine type and typology importance in architecture and urban design of the city.

The research procedure has dealing with the past & present experiments of historical cities in the fields of architecture & urban planning, represented by the historical city center through the age. So it takes many study case of cities like (Rome, Paris, Baghdad, Damascus) to study their architecture and urban types, before and after urban development plans to determine useful or affect factors, with four different city types there are some types are more useful from others in the developing design of the city. These developing designs are decided by theory of type or by providing new types to meet the needs of the community. focusing on the important conclusion about continuity types or urban transformation happened on it, to determine which types could have the ability to be adapted with these changing and transformation, and which one haven't this ability. So the research choose these historical cities with different types from different places in the continuous civilizations.

The research explain how cities transform by introducing the idea of urban morphology through an examination of more than a century of transformations in downtown of experimental cities including (vitality, alienation livability, and un belonging). Considered the main aim of the research to reach the conclusions of city future, so we can have a clear vision of the coming future, what is the future of the historical center of the cities, in terms of its policies, and the development projects?

Furthermore, the research is looking for the transformation of urban types, and which one can be adapted of twenty one century requirements. To make the process of the continuation of civilization sail strong, safe and sound, through urban academy and practical institute.

2 INTRODUCTION – WE SHAPE OUR BUILDINGS AND THAN OUR BUILDINGS SHAPE US (CHURCHILL)

Urban environment reflect in architecture and urban design for the way in which buildings are formed by the elements and gather with neighbors. This indicates a problem in the urban environment today by losing much of its characters and their basic components that maintain the cohesion and harmony bound thereby to further disintegration, ruptures and fragmentation, these components include (human, spatial dimensions, timing dimensions), which generally represent the basis for establishing and achieving the concept of belonging of the urban environment, and research on the concept of the built environment and the factors affecting them and their basic components with an indication of what we are suffering from the problem of erasure, removal and insertion, and others that carry implicit notions of separation of spatial and temporal for the general context of the total, this separation in the built environment today marks the beginning of the disintegration of the urban fabric in, and go to separate the building solo on the overall context of the existing in, and thus the embodiment of the phenomenon of alienation of civilization and cultural heritage, which represents the most prominent manifestations of fragmentation in configurations major decay of urban spaces, and the

appearance of duplication between the (old and new, heritage and modernity, past and future, natural and artificial), which was reflected in the duplication of personal humanity. Therefore, the environment can be divided into two parts (Hillier, 1996, p.89):

2.1 Natural environment

Represent data that surround the human being and has no income in its presence, which vary from region to region depending on the data component.

2.2 Man-made environment

The physical material products made by human being in order to adapt laws to serve the purposes of natural rights and the achievement of its objectives, and work to achieve the protection and safety and the establishment of social relations in the modern sophisticated societies.

Any ruptures or discontinuity between the human and the natural environment will lead to create of urban environment does not meet the requirements of the psychological, social and even health, and the emergence of a number of problems like incoherence, the lack of identity and personal characteristics of the built environment. The confusion of psychological disturbance and alienation because of lack specific solutions to the development of environment construction.

Urban design of the city is a prior thought behind design process; which could got from Forms; sketches or images and even verbally; and all summarizes through the concepts of Type and Typology in Architecture by its time transformations. So how do cities transform over time? And why do some cities change for the better while others deteriorate? In articulating new ways of viewing urban areas and how they develop over time?

3 THE CITY SHOULD BE A LIVABLE PLACES

A city is the characteristic physical and social unit of civilization, with it possesses size, density, grain, outline and pattern. The people who live in it shape these properties and are shaped by them. The old cities usually were roughly circular or rectangular in outline, with a sharp boundary commonly marked by a wall. Such is the medieval cities in Europe and Arab land.

Every city has its intimate inner pattern: the streets, squares and other openings that make buildings accessible and livable. In ancient cities and those of traditional European cities and in the Arab land today the pattern is highly irregular (organic fabric). Buildings or high-walled private gardens are dominant: the public way is simply the land left over. This complex composed mass may be perforated occasionally by design larger open spaces for gatherings, exchange or ceremonials.

The city is the most explicit index of power relationships. Walls, squares and streets are not only meant to support the functioning of the city, but they also form an extensive governmental instrument. Without proposing a cause-and-effect relationship between form and politics, the intention here is to trace the political origin of quintessential city projects within the history of the modern city. The aim is to test the political instrumentality of architectural types and reflective forms. For this reason, instead of focusing on the city at large, the focus will be on paradigmatic architectural archetypes. The category of archetype that will be advocated here will not be the way Carl G Jung defined it, as a universal content less form, nor as innate pattern of behavior. The category of archetype is advanced here as an alternative to the idea of type. If type traditionally indicates the idea that regulates the development of a group of forms (and for this reason is irreducible to any particular form), and contribute to make the city as livable place. Archetype offers the possibility of addressing a found singular form as a definition for a possible group of forms. In architecture, an archetype is thus a paradigmatic form through which it is possible to illuminate a particular critical passage in the development of the city. (Aureli, 2011)

4 TRADITIONAL CITIES AND MODERN CITIES

Christopher Alexander put in his studies compare the structure of the city of traditional and modern cities through the concept (structure inclusive), as shows the urban fabric of cities, the traditional integrated holistic result of cumulative growth and gradual compared to modern cities, and confirmed (Alexander) in a book (The Nature of Order-2001) the importance of the positive space in the structure of the urban fabric through the continuity of urban space and the surfaces of buildings constant that defines the space, he define positive space: that the space gets defined surfaces surrounding it and its association with direct building and

confirmed the ability of the city to rebuild and repair itself, detect city (urban pattern) has a dynamic of its own, and the goal of urban designer in the search for the city in the mechanical support and develop itself constantly (Salingaros, 2002, p4). And so a city had several models:

4.1 Natural Models

Since cities were founded in these things, it is hardly surprising that cities ever since have been permeated by them or their equivalents. As for their physical design, (Broadbent, 1990, p5), cities and part of cities, have grown in tow types:

- Many towns owe their foundation and underlying plan to specific event, a 'big-bang' origin. Such towns were the result of a self-conscious design decision and existed as concepts before materializing in fact.
- Type of beginning has no such precise definition. For such towns, it is no more profitable to pin down the moment of birth than to define that of the culture to which they belong. These 'steady-state' settlements seem to have grown organically with that culture and even where we can be fairly clear about the period of their beginnings. (Gosling, 1984, p25). As with the many medieval towns of Europe and traditional Arabic-Islamic cities which sprang up during the population expansion of the twelfth and thirteenth centuries.

The first is described by Alexander (1964) as a natural way in which people simply start buildings, as they still do in the shanty towns of the emerging world. There is the artificial way in which a master plan is prepared; streets laid out, squares and urban blocks on to which buildings are then placed according to some planners' sense of order.

This contrast will recur many times in the book. So wills another contrast: between formality and informality. The "natural" city tends towards informality, not mention an apparent disorder whilst the planners will want their conscious decisions to show. Most planners aim for regularities of a kind which shoe that human minds have been at work; but some aim for a self-conscious irregularity of the kind we call Picturesque (Broadbent, 1990, p5). Natural Cities express the needs of the same set of design decisions over an extended period of time, and take in its message multiple variables, and a special system in the format might suggest chaos, but it carries the spirit of the system (Gosling, 1984, p27).

4.2 Utopian Ideal Models

In this, it contrast sharply with another powerful tradition -the utopian or ideal- in which town design is closely allied to the design of society itself. And whereas the organic town can exist only in fact, as the physical result of a multitude of small forces and actions, the ideal town can exist only in theory, as one designer's formulation of possible complete solution to the design problem 'town', Such as utopian ideas of Bacon, Fourier, Le Corbusier, Wright and Howard. (Gosling, 1984, p32)

So the research see that idealists architects - including (Aldo Rossi) – searching for permanent fixed formal types by trying to re-study and research in the concept of Typology and Ideals with the same sense, inspired by the early idealists, such as Plato, Descartes and others.

4.3 Models Derived from Arts & Sciences

This model given the complexity and intractability of urban problems, it is not surprising that designers have found it helpful to borrow ides from other fields in order to gain fresh insight. These references have taken two forms; analogy and translation, which together have constituted an important further source of urban design theory. These theories derived from (walking city in archigram's projects, mathematical theory of Alexander, psychological studies in Gestalt theory, psychoanalyses studies of Piaget, anthropological studies like Defensible space of Oscar Newman and Territorial Behavior of Jane Jacobs). (Gosling, 1984, p40)

Alexander discussed the structure of the urban fabric of the city through the analysis of urban structure of cities through a wide range of studies. And discussed in his article (A City Is Not A Tree) the difference between the natural cities and modern cities which are designed according to the ideas of specific criteria, did not grow naturally, point the importance of not analyze the cities according to their forms as far as research on the basic principles in the organization and the importance of testing those abstract relationships also.

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

Having thus defined his terms, Alexander goes on to analyze a number of city plans in tree' semi-lattice terms, including Abercrombie's Greater London, Tange's Tokyo, Soleri's Mesa City, Le Corbusier's Chandigarh, Costa's Brazilia, and so on taking as the most extreme example of a tree- like plan that described by Hilbersheimer in the Nature of Cities (1964). And in the second part of his paper, Alexander goes on to show that whenever a city thought out by planners it is bound to have a tree- like structure. National cities grow over time but they are the most appropriate containers for the complex, semi-lattice forms of our complex social relationships. (Broadbent, 1990, p145)

With this concept Alexander submit (A city is not a tree), where he distinguished between the different structures of the cities into two groups:

- Semi-lattice forms: includes traditional areas of organic-oriented design and grow over time. Seems that the physical fabric of urban in any traditional Arabic city or any other traditionally European city came like a spontaneous planning a network of winding streets and roads graduated from expanding to the narrower end of the col-de-sac roads, and the entry of other factors in the production of the city like (social, cultural, religious and economic).
- Lattice forms: which is mostly newly designed cities. (Broadbent, 1990, p.143) that modern cities affected by the modern growth of new types and functions, and by searching for positive space and confirm the centrality of urban growth through the five essential components in the structure of the urban fabric; (buildings, the axes of pedestrians movement, open spaces "parks" , the streets of movement, parking) by dealing with the basic elements in the structure of the urban fabric of the city as a dynamic overlapping stages, and its emphasis on physical factors and neutralize other factors.

Alexander in the definition of the structure of the urban fabric by defining axes of infantry, as the axes of pedestrian links to know the urban fabric, while the adoption of the principle modern cities with career progression in zoning and in the relations between the parts of the city and the isolation of the various events led to the fragmentation of the fabric of the city. The research also stressed the idea of the urban center that overlap the events for the gradient space as shown in the holistic integration of traditional city centers (the adoption of the principle of deduction), while the modern city built according to topical parts shall be the sum of all parts of the local entity and has no special distinctive (adopting the principle of induction) (Alexander, 1987, p93).

In this system, the news rack, the traffic light and sidewalk are all fixed parts of the system; product, as it were, of design, whilst the people, their money, the newspaper and the impulses which drive the traffic light are all things over which the designer has much less control. So to start with two categories; the fixed parts of his system and the changing parts, each part can be numbered. So clearly a city which is zoned, into working, residential and service areas forms a tree in Alexander's sense whilst a mélange of houses, shops and so on of the kind which Jane Jacobs describes is, in his terms a semi-lattice. (Broadbent, 1990, p144)

5 THE ORIGIN OF EVERY THINGS WITH DYNAMIC NOT WITH CONSTANT

All the strength of the Stability and changing are essential for the sustainability of any society, the decline in the power of the Stability may lead to a decline of culture, but the lack of change or decline may lead to death or the end of that society.

Since the Stability and change the status of all living systems, including the system of the city, so we find that many of the thinkers adapted constant for many centuries ago, while dynamic anomaly and a rare exception, and even the mid-eighteenth century emerge the idea of dynamic - especially living ones - take place gradually to the stable constant, especially after the detection James Watt to use steam power, then the Einstein theory of relativity, put forward the idea of relative movement and constancy.

Heraclitus adapted Changing and says: "Without change there is nothing" because in his opinion the stability is death and lack of, and he belief, this change must happen by a certain act. If things were static and fixed on one case does not change, the human couldn't originated the idea of causality, because this idea is the result of what occurs to change things. What ever-one thing we do know with our senses, changing is immediately transformed after the event?

So Emerged theories put forward (Genius Loci of Space) as spirit of the place, the Romanian idea with existence of the spirit of all the assets of independent and serve as a spirit Guardian and specify the nature of

these things, and what it wanted to be, in essence fixed things (Schulz, 1980, p6), If this essence constant, how can discrimination "spirit of place" in the cities of Britain in place of the difference between ancient and modern cities, or Genius Loci of Rome (Fig.4). And highlights the important question is: If the change is inevitable, how can we find the balance that preserves the survival of the system?

6 URBAN TYPES REPRESENT CONSTANT IN THE CITY DISCIPLINE

As Vitruvius, the type is trying to standardize the changing, and may be done by quantitative approximation. The type is mentality attempt; try to find a common objective vision of the objects or the relations among them, to get the kind of understanding, control and prediction.

"Aldo Rossi" Said: "The fixed type arises from necessary, is linked to the mind and feelings and values of a social iconic, and linked to the community and human innate." Chomsky called this mental ability the term Competence and defined as: "a set of mental rules, one can by the results make an unspecified number of sentences." With this ability we can produce results for the specific language. While "Carl Jung" defined by that represents the "mental forms cannot explain its presence, which seems to form a primitive, innate, or a tendency instinctive, as generated by the human is always the tendency towards the formation of these representations." It is a "factors governing the elements of a mental or psychological specific developments are described as types, but know the effect produced by such as the concept of religion, guess and likely to constitute the dominant structure of the same in general, and perhaps compare the crystals are not visible in the liquid as prior factors" (Jung, 1981, pp. 86-100).

Therefore Type represents constant in thought, it is preceding forms. And the image of this type is conceptual thought, which is termed (Archetype), shows "the internal structure of the form, which is the principle has the potential to generate infinity different forms." From this sense, we find the conceptual Archetype network or neutrons, through its ability to (willingness, tendency, respectively), which starts from the moment given the evolution of the human mind. "Type does not present so much an image of something to be copied or imitated exactly as the idea of an element which should itself serve as a rule for the model…" (De Quincy, 1998, P. 618(.

6.1 Autonomy of the City

The City is case of (Institution Form), this would be through the formation of any selection of the appropriate Shape, and this does not mean that, the chosen form is linked to the images, forms reflect Types in the first, and second images. In other words, the image is brought through the selection of an appropriate type, this type on the level of conscious, not at the level of physical verification. Type does not require re-use the old within the particular level attributes, but it helps in understanding the Old, with this perspective the type had the possible interaction and generate forms which had the prospects appear.

Rossi was interested in how research is produced architecture, how it works and then gradually building to create the city. The establishment of the city means rational foundations for the birth of a city over time, so look for analysis of the concept of style (or the intellectual ideals), as Plato and Quatremere. Any timeless elements that give the city the archaeological dimensions and urban types are the physical objects that make up the city through time. So type had a range of intellectual relations that remain fixed behind a set of physical models (Broadbent, 1990, pp.181-187). After these steps are detected on the laws that produce these types, then the lines in recent research on the laws that combine these types to form the baseline to the image of the city and the urban sectors.

6.2 Type in the urban design of the Neo Rationalism

Rationalists work on the new abstract geometric architecture since the eighteenth century in France such as: Laugier, Ledoux, and Boullee (Fig.3). Most of the neo-rationalists they belong to the group (Tendenza) affected by the ideas of Marx. Continuation of the develop rules and principles addressed in the architecture, Are treated with it at the level of relations, as abstract that are connected by these elements, on the level of (Types), which count their existence previously to the presence of architecture or any other historical period, and these types interact with the functions and tasks that arise in the building at any stage to form the overall system, but keep the relationship between type and any model is a random relationship depends on the designer intuition. There are some of the proposals of the most prominent theorists' current new rationality about the relationship between architecture and types: (Broadbent, 1990, p157)

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

Manfredo Tafuri (Ideology and Utopia) - 1976

For Tafuri, the very existence of multi-nationals makes socially responsible planning impossible. And whilst in previous centuries, architects and other visionaries had imagined Utopias; Capitalism has destroyed the very concept. If they cannot even conceive of Utopias, They have no hope of achieving anything like them. Nor will them ever again whilst Capitalism retains its grip on human affairs. (Broadbent, 1990, p158)

Aldo Rossi (The architecture of the city) - 1966

Focused in its arguments to deal with the facts as urban facts objects list is working on the composition of the city over time. It highlights the facts on the products of the city, buildings and urban spaces. So he focused on the Types as descriptive elements that make up the city and grow it over time, defined them like constant of relational despite changes in specific examples of buildings of heading to read the facts within the architectural methods reveal implicit infrastructure within buildings (Broadbent, 1990, p.325).

The Krier Brothers (Architecture and Urbanism) - 1977

Rob Krier located his studies in urban design to look at the types of the urban spaces, which has represented the intellectual relations which make Essential form, and join its. Essential Pure forms in the formation of interference types create for the design of the building at the beginning of the formal types of presence within the Urban Context and autonomic architecture, and components of the architectural details. Naturally enough whilst most internal space is rectangular, he finds examples which match his three major Urban Types: square, circular and triangular with equivalent combining and distortions. (Broadbent, 1990, p328)

Either Leo Krier believes that the basis on which the lesson can be inspired from the basic types of the archetypes lies in the understanding and analysis of urban components which are streets, squares and different configurations. A good city is made of streets and squares and squares provide natural settings for people to meet. But the square also provides the "choice location of all things public". It is, in other words, the proper location for monumental buildings. (Broadbent, 1990, p333)

Antonio Vidler (The Third Typology) - 2000

Vidler Submit a group of urban design, which calls for a return to the morphology of the traditional city's development, deduction types of space and processors in the traditional urban structure. The Third Typology of the city consider as the main source of proposals for urban design, The first Typology depend on function, and The second Typology depend on machine, the third came to return to the morphology of the city and the promise of types that are derived from design trends in the work of neo rationalist of the earliest models to morphological design (Vidler, 2000, p292).

"Columns, houses, and urban spaces, while linked in an unbreakable chain of continuity, refer only to their own nature as architectural elements, and their geometries are neither naturalistic nor technical but essentially architectural" (Vidler, 2000, P291). The third revolve in Architecture led to emerge the importance of the Type and Typology Concepts in practice; for discussing great cases in architecture like first architecture origin.

Although the bid difference between the rationalism and empiricism; they agreed that the type is the origin in first architecture; and it's extrude all the architectural splendor of luxury. The Type Theory used in understands and analysis all architectural and urban design projects.

6.3 Urban types and the form of the city

Type and Typology are effective tools in the process of analysis form of the city, as well as a tool classification and tabulation of history and understood by the gradient historical, and make it in the form of successive types, draw accurately the characteristics and features of the times its own; it is also the classification and tabulation types of city planning, which can't be counted as a result the emergence of new types in every age since the analysis the city and the extent of its success depending on the typical practice, and upon them if they are drawing the attribute and the general character to its; to solve all problems in the city planning. The planning of the city is located within several types depending on the shape of space and formal composition such as:

Centralized Type

A central organization is stable, concentrated composition that consists of a number of secondary spaces grouped around a large, dominant, central space. Such as the circular type in Baghdad rounded city (Fig.1).

Linear Type

A liner organization consists essentially of a series of spaces. These spaces can either be directly related to one another or be linked through a separate and distinct linear space. (Ching, 1996, p198) An example of this type proposed by Soria de Mata (linear city), and Leon Krier (Stuttgart-Leinfelden). (Krier, 1979, P.166)

Radial Type

A radial organization of space combines elements of both centralized and linear organizations. It consists of a dominant central space from which a number of linear organizations extend in a radial manner. Whereas a centralized is an introverted scheme that focuses inward on its central space, a radial organization is an extroverted plan that reaches out to its context (Ching, 1996, p208). The Re-planning of Paris by Haussmann (Fig.3), and re-planning of Damascus by Ecoshar (Fig.2), examples of this type.

Clustered Type

A clustered organization relies on physical proximity to relate its spaces to one another. It often consists of repetitive, cellular spaces that have similar functions and share a common visual trait such as shape orientation. A clustered organization can also accept within its composition spaces that are dissimilar in size, form, and function, but related to one another by proximity or visual ordering device such as symmetry or an axis. Because its pattern dose not originates from a grid geometrical concept, the form of a clustered organization is flexible and can accept growth and changing readily without affecting its character (Ching, 1996, p214). This type is evident in the traditional environment in the old city of Baghdad (Fig.1), Damascus and other traditional Arabic cities (Fig.2), as well as the city of ancient Rome (Fig.4), Paris and other traditional European cities (Fig.3), which is known as the traditional fabric.

Grid Type

A grid organization consists of forms and spaces whose positions in space and relationships with one another are regulated by three-dimensional grid pattern or field (Ching, 1996, p220). For example, New York City, new districts of greater Baghdad plans (Fig.1).

In order to analysis the form of city, the research need to analysis of the following open space types, usually associated with city development:

- Forecort: an open space between the public sidewalk and the main entrance of the building.
- Walkway: an exterior public pedestrian way at street level, usually providing connection through the block.
- Urban garden: a landscaped open space, usually of intimate scale, located and oriented to provide maximum sunlight during midday.
- Plaza: an animated gathering place with landscape features flanking a public street.
- Courtyard: a landscaped open space, located in the centre of a single or consolidated block with no direct street frontage.
- Street: path or axis for vehicles, cars, bicycles, pedestrians, etc.

The archetype of the closed monumental courtyard clearly separated from the city but fully accessible by the community of workers that inhabited each superblock introduced a type of space that is neither public nor private (Aureli, 2011). The urban archetype of the isolated block can be interpreted as the product of an urban ethos in which the growth of the city requires a certain openness of the city space.

7 TRANSFORMATION REPRESENTS CHANGING IN THE CITY DISCIPLINE

The process of urban transformation in the context of cities changes in the modern economy and society, and it's deriving from the post industrialization of the urban economy and from the modifications deriving from the processes of the knowledge, information and new technology society, as well as from the new social

forms of consumption and social relationship make the transformations of European cities a topical issue. Urban transformation is a habitual process in the evolution of cities. It is based on a constant tension in the relations between the cities' physical and social elements.The changes in social and economic processes always involve an almost permanent urban need to update or modernize or simply to transform cities. (Maria, 2007)

We live today in a conflicted time of both accelerated change and business-as-usual, a time of both transformation and stagnation. Those who want to change the conceptual direction of architecture and forge a larger cultural change. Of course it would be silly, after so much twentieth-century evidence to the contrary, to think that architects could change society. They are relatively powerless compared to politicians, developers, journalists, and businessmen. They can only tinker with ecological and population problems set by others. They do, however, have one power that no other profession enjoys: they have some control of the architectural language and the messages sent. A single building can celebrate a better world or signify a change in direction. It has the power to engage the imagination and symbolize the basic truths of the universe. Man is not the measure of all things - the emergent cosmos is. We are beginning to know some of her predispositions, but the question is: can we build a shared culture on them (Jencks, 1997, p21).

Transformation is a positive option in the face of changes in urban and regional structures. Transformation processes are essential to the city's existence and comprise part of urbanism itself. The physical, architecture and urban planning dimensions, and social, economic and cultural dimensions, are always connected in a transversal way. And we should point out that this is more of a process than a structure. Therefore the situation of going from one initial position to another - which is the outcome of a transformation process - generates a certain transitory position. This characteristic is essential at the conceptual level of the more theoretical reflections on the subject. But it does not modify either the characteristic of the requirement, of the processes of urban transformation in study case cities, or the almost deliberate or conscious sense of modifying the urban environment to introduce factors of a new urban vitality. (Maria, 2007)

Nevertheless the issue of urban policies should not be reduced to the most dramatic aspects of urban issues. It is necessary to return to the reflection that the conditions of the urban environment are a key to the competitiveness of the cities themselves. And this brings us to recall the planning aspects which constitute basic factors in the attractiveness of cities. This dimension is a key to cities in particular - since they depend, to a greater degree than large cities, on their own characteristics, conditions and elements of potential transformation. (Maria, 2007)

8 NEW URBAN TYPES AND CHARACTERISTICS OF THE CITIES IN THE TWENTY ONE CENTURY

Le Corbusier write: "If we eliminate from our hearts and mind all dead concepts in regard to house and look at the question from a critical and objective point of view, we shall arrive at the 'House Machine', the mass production house, healthy (and morally so too) and beautiful in the same way that the working tools and instruments which accompany our existence are beautiful." (Frampton, 1980, P. 153 (

These new ideas were emerged in the end of twentieth century was attempt a short and brief outline of a political history of the modern city, and the way its ethos, made of urban management on the one hand and conflict on the other, was embodied and represented by the use of certain architectural forms.

While the changes of the city in the twenty one century can be thought of as the evolution of urban types, its realization can only happen within a political 'state of exceptions', in which the exemplarity of specific and singular forms plays a leading role in resetting the urban condition.

So new types emerge in the contemporary city: like Entering mega structure and taller buildings to small contexts of historical fabric, Emerge new disciplines with information revolution of twenty one century like (digital city, cybernetic, cyborg, etc). As a result of significant changes which began to appear in some of the literature different expressions and new words such as: (Networked territories, Electronic Spaces, Post modern hyper – Space, Cyberspace, Virtual space, Virtual Communities, New social Space, Electronic agora, Net world). These terms show how the relationship between Information & Communication Technology (ICT) and their effects in space, city and the community.

With Cyberspace we built non-geographic land in electronic - information networks without distance limitations, and time plays a central role here instead of the distance which can influence the world in Real

Time. But the gap here is the explanation for the mechanism of behavioral change of the city parts within a type of network, and then to influence of city system and regional system. This helped the emergence of new concepts for future cities affected by the massive developments in modern science.

8.1 Intelligent City

"All this plastic machinery is realized in marble with the rigor that we have learnt to apply in the machine. The impression is of naked, polished steel" (Frampton, 1980, P. 153 (. The idea of the Intelligent City depend on identify the idea of housing and smart buildings in the type, which calls to mind the relationship of telecommunication systems and computerized urban network management, but under the guise of a more comprehensive perspective of thinking. It looks smart cities and closely related to the emergence of new relationships based on the flow of physical and metaphysical exchanges condensate for telecommunication systems in resolving the central problems of access to the best means to improve the urban environment.

The telecommunication rule depend on dissolution of the need for physicist rapprochement between people, services, and this makes it easier to imagine the beginning of the dissolution of cities and the formation of a new life status of the house. But other anti rule of telecommunication networks that increase the central urban centers control flow of information and thereby increase the dominance of global cities not as largest cities, but as the Smartest. It is clear that intelligent cities be node within the telecommunication network which fellow multinational companies and provide a new political tool for urban management and strengthen the urban face of cities and support the economic interdependence between local and global levels (Graham & Marvin, 1996, P 383). The application of these ideas emerge in Silicon Valley in America, and the European Union countries, and Southeast Asia countries.

8.2 Globalization instead of local culture

The cultural sector as a factor in the development conditions for the transformation of society. Today the world are witnessing the phase of historical changing, described in a aspects of the emergence of the information revolution that will take physical place in the maintained frame by the existing cities. There is no doubt that the power to influence the ancient urban types would be great effect and leave their signals on the urban morphological system of the city.

These urban policy models and criteria to improve the factors of cities' attractiveness are a base or framework for the processes of urban transformation, which can be detailed; so the research going to do this in the following points, based on the local and global conditions of cities, and based on their reflections online.

We couldn't understand the city parts and their behavioral changes in full partial contexts unless the city is considering node within the integrated network. This network contain several cities together constitute the Global City Region. The characteristics of global cities and territories different from the characteristics of individual cities in (economic, social, cultural and political) without being beyond the concepts of behavioral changes in terms of public order as a part of the city or sub-system of a larger system (salingaros, 2008).

The idea of the Global Village puts cities in the relationship joint between local and global levels, where the information disturbed boundaries between it and became the look of both the two together (Both / And) interpreted the entities are not monolithic in seeing what is universal and what is local and this so-called interaction scale. In order to treated with the global cities system in the interpretation of their behavior within the levels of economic, social, cultural and political relations with the type of the information network to gain access to understanding the behavioral changes to these parts in the level of space / time, and its effects on urban structure, in particular the experience of cities that were raised the idea of world city.

In this new type the Factors and dimensions in the transformation of cities are (Maria, 2007):

- The changes in the modern economy and in the social model linked to it, as well as the regional system, which places the urban centers in a new network tension, are at the base of the process which the processes of urban transformation originate.
- Cultural and social transformations resulting from the impact across society of the so-called "weightless" economy arising from the internationalization or globalization process. Technological transformations, of systems of production and distribution and the knowledge economies. As well as the new uses and techniques of communication.

Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

Social transformations and in economic relations deriving from the changes in role of every individual and of social groups and networks, resulting from the impact of the new financial flows of globalization (On markets, on industries) but above all on the relationship between global and local, Including the basic aspect in all this of democracy and liberties.

8.3 New metropolitan cities

Global cities known today as a base of integrated infrastructure that is assist transformation toward high density urban networks which contain group of hubs, Spokes and Tunnel Effects which connect urban economies together in real time and reshape the production of border space / time, including and between (Graham & Marvin, 1996, p384).

As result of the economic and social developments in the era of information revolution is the reorganization of cities, so that they are both integrated by grouping the units that operate as nodes in global networks. Dematteis focuses on the emergence of Planetary Metropolitan System, cities does not show equal within these broad changes. Batten was named these cities as Network City. The complex interactions between these cities as places of constant and intensive transition between networks (telecommunications, Multinational Corporation's network, the flow of the center, etc.) form of urban life and urban development (Graham & Marvin, 1996, P.71).

9 FOUR DIFFERENT TYPES OF CITIES

The political form of the modern city will be defined by addressing four archetypes (Rome, Paris, Baghdad, and Damascus). The sequence of these four archetypes attempts to synthetically describe the emergence of modern urban types that embodied specific power relationships within the ancient types of the historical city, especially those related to entering new urban types such as Information & Communication Technology, social relationships, the rise of economic accumulation and management as a response to particular conflicts in the city.

The research counters the current millstone of evolutionary and empirical development projects on the city that portrays urban space as an evolutionary and self-organizing organism. Against this idea, the city emerges as a locus of a permanent political conflict of which architectural types are one of the most extreme and radical manifestations (like genius loci of Rome) (Fig.4).

	City form types					Open space types				
	Clustered Type	Grid Type	Circular Type	Linear Type	Radial Type	forecourt	walkway	urban garden	plaza	Courtyard
Baghdad	*	*				*				*
Damascus	*				*		*	*		
Paris			*		*		*	*		*
Rome	*				*		*		*	*

Table 1: Table of comparative between four cities including types and transformation of the city (Author, 2012).

Transformations of cities' urban systems, the work arising from the study and types the description summarized in the specific case studies. Where the issues which are considered key to the transformation process are:

- The emerge stage which established Urban types.
- The growth stage when types conserve with its characters.
- Changes in the nuclear character of cities by another broad or diffuse dimension.
- New social and demographic systems transform the use of the urban space.
- Less rigid cities in less hierarchical societies.
- Technological innovations which are key to the type changes in forms of productivity.

- Urban transformation, from this period of "renewal" to urban regeneration.
- Transformations in diversification and restructuring of urban forms.

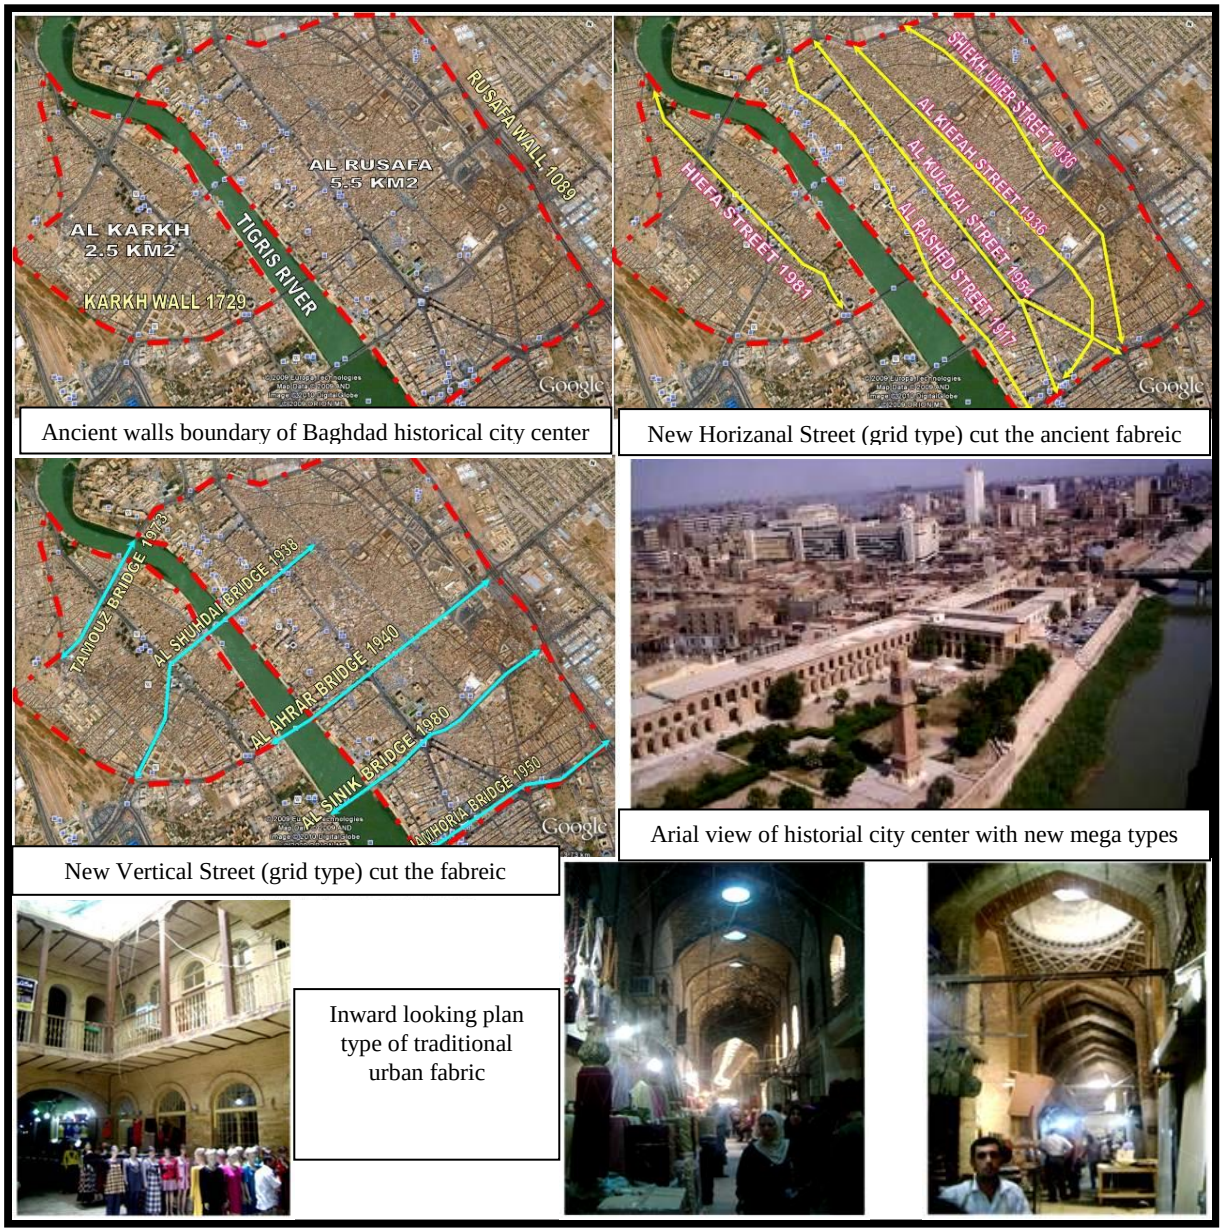

Fig. 1: Transformation of Baghdad city center (Author, 2010)

10 CONCLUSION AND URBAN SOLUTIONS TO SOLVE THE TRANSFORMATION OF THE CITY

- The types of Utopian city Failed to submit solutions that assumed the future of cities, because it was based on expectations of real-time variables which not proved on the reality, not based on what can be considered as constants of the natural system.
- Stay away from human nature (Right Innate) as a result of modern technology creates totally alien environment to the sense of human culture, while the traditional city has maintained to achieve the humanitarian and technical requirements but without the crushing human rights.
- Transformation of residential urban fabric: Regeneration of areas and neighborhoods which are in crisis or depressed; Activities in social or public housing as an instrument of integration and urban cohesion; Integrated neighborhood plans in all their social, economic and town planning aspects, with citizens' participation; and the historic centers, with policies of rehabilitation that are complementary to these plans. All of these are needed to adopte in the city in Twenty one century.

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

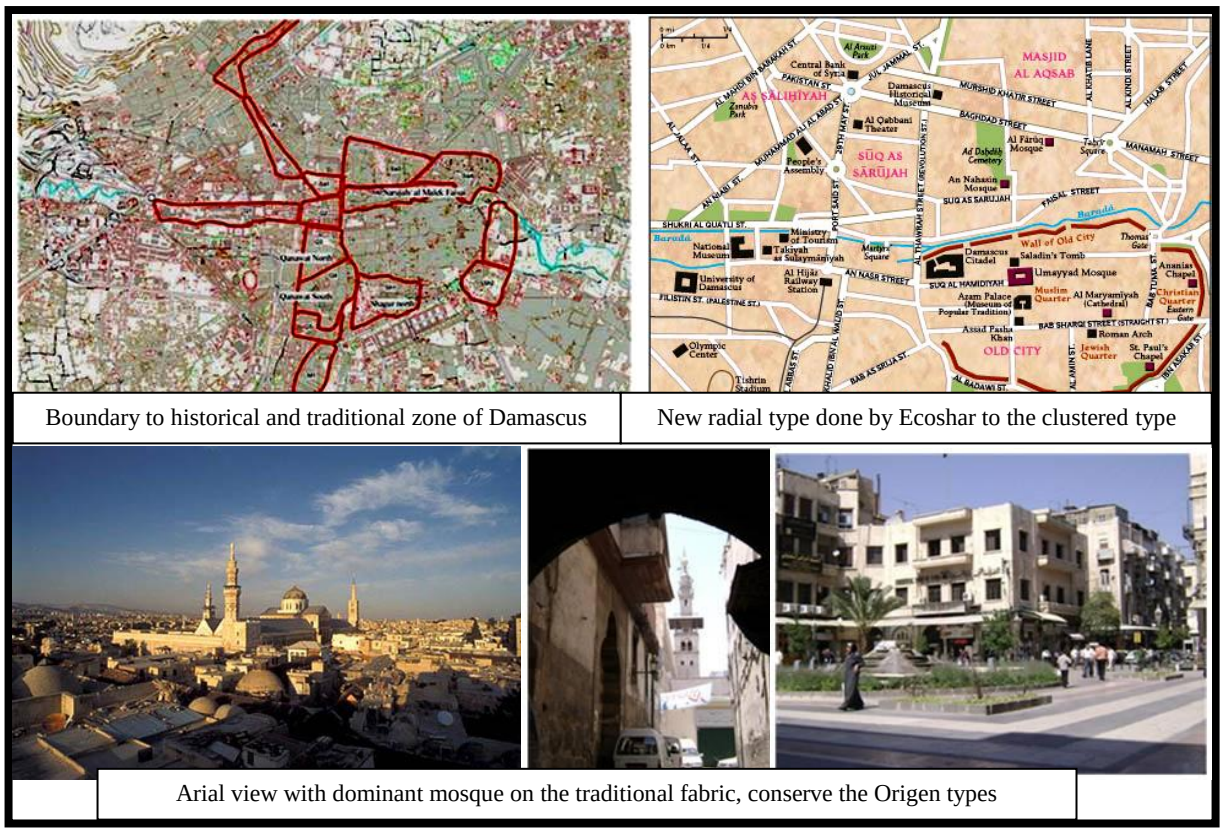

Fig. 2: Transformation of Damascus city center (Inernet, 2012) (Author, 2008)

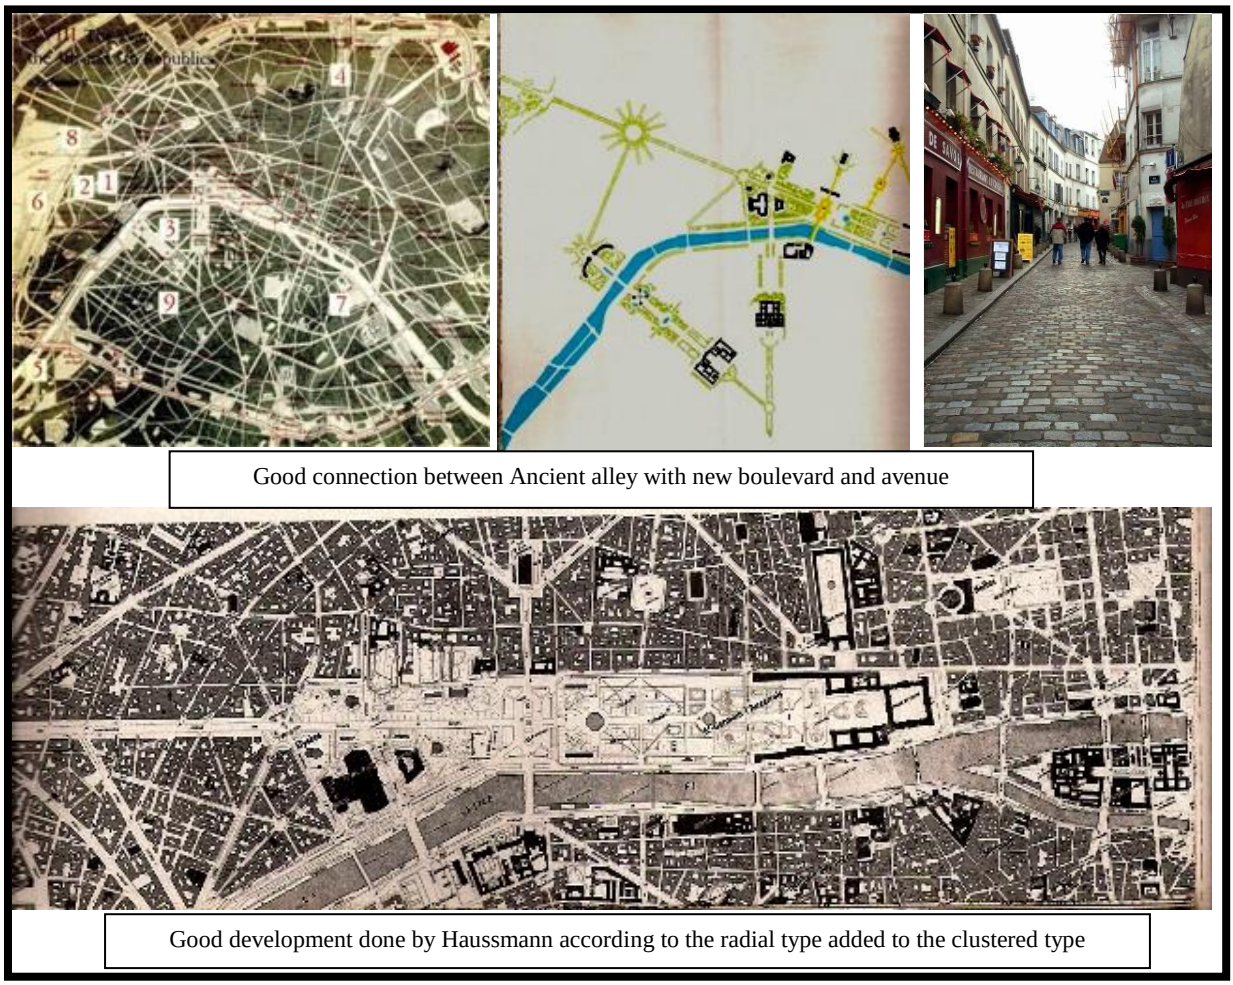

Fig. 3: Transformation of Paris citry center (Bacon, 1978, pp.192-193) (Author, 2010)

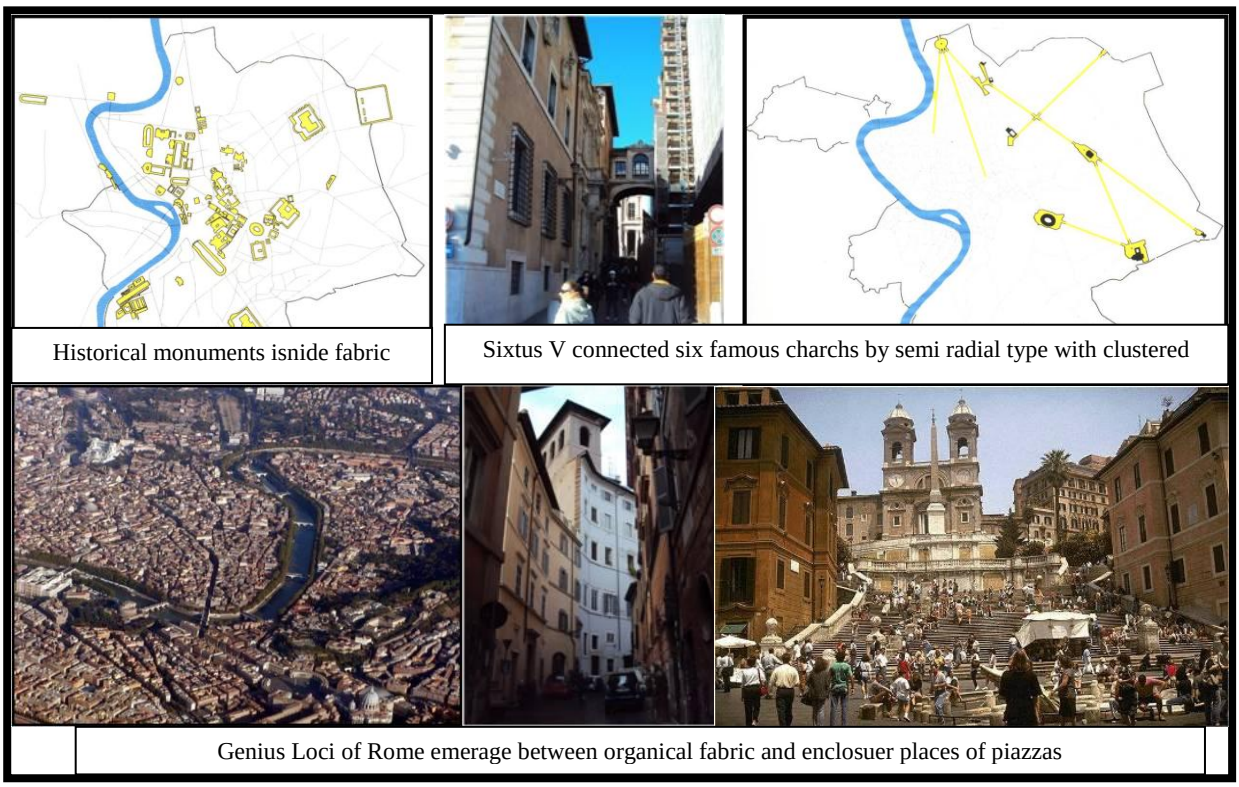

Fig. 4: Transformation of Rome city center (Bacon, 1978, pp.86-87) (Author, 2010)

- The traditional Islamic city works in the general framework as a single unit connected with the status of one center returning to the main roads, but it is also divided into smaller groups "neighborhood unit" and this division to achieve (humanitarian purposes, security, practical) this confirm the reference to the flexibility of this system in adapting the future transformation of the city, which reflected in the proposals of Christopher Alexander - A city is not a tree, Oscar Newman - Defensible space, and Jane Jacobs - Behavior territory.
- Urban renovation processes combine with expansion new types and requirements for, urban spaces. It is characterized by the overall transformation of wide spaces, not just in specific activities, of an urban area. Generally, this relates to activities in old cities. Renovation, like urban improvement, is linked to the culture of the 19th-century urban types, and they are different in the scale and scope of the transformation project.
- Human is the scale of the city in the ancient architectural movements and intellectual trends, turned out to be (vehicles, sciences, atom and thus the universe) are the scale of the city in the new direction of the twenty one-century. This led to many problems at different types of the city level, and therefore the man who lives there. So the research determines respect the human scale and human relations in building the future cities.
- The changing and transformation is the characteristic of the livable city systems evolutionary, so city need to adapt Transformation of the urban structure; waterfronts and different types of urban ports; Road accesses and axes of regional connection; Renewable energies; Large scale urban public spaces; Green zones and urban parks, the elements of sustainable urban mobility, and especially new forms of urban transport.
- The transformation of the traditional street and alleys from cluster type to the radial type (like Paris historical city center developing master plan) more useful than grid iron type (like Baghdad historical city center developing master plan).
- Put forward the concept of zoning of the contemporary city, as one of the most prominent reasons which have led to increased social isolation and an imbalance in the performances of urban space, contrary to what is known by the traditional city.

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

- Nature presence to give the modern man, human technology, the rapid changes and variables emergency, take specific moments to possess his tired breath of the life problems and complexities of social life associated with the types of automation progress, industrial and racing technology, which led to the disruption of balance in order to make integration between matter and spirit.
- The urban fabric of the traditional city which was built according types with main components appear in unison as a single indivisible parts, where the building linking the two actions in the architecture, the first represents the building itself and the second is to make the building part of each context. As contrast with types of contemporary urban experience of the (fragmentation, disintegration, disharmony) phenomenon caused by the slogan of modernity and modernization, and thus no longer architecture reflects the collective project through which the expression of collective cooperation and rationality in the urban design development, but to rely on the (relative, partial, individual, competition).
- The necessary perspective for transformation of cities to adapt the new demands for uses and activities, the process of post-industrialization and of new tertiary activities. Key processes for the current new economy deriving from competitivenes typess, while the traditional city shown as cooporativeness types, but also from the internal demands of its urban systems.

Finally, we find out how to interpret essential aspects of "life and place" by evaluating the transformation of types in these cities. The research has a unique understanding of cities and how they work. So it offers clear vision to the future of inventive new solutions to familiar urban problems.

Urbane Sicherheit – eine Gemeinschaftsaufgabe vieler Akteure

Holger Floeting, Antje Seidel-Schulze

(Dr. Holger Floeting, Deutsches Institut für Urbanistik, urbane-sicherheit@difu.de)
(Dipl.-Sozialwiss. Antje Seidel-Schulze, Deutsches Institut für Urbanistik, urbane-sicherheit@difu.de)

1 ABSTRACT

Sicherheit und Ordnung in Städten und Gemeinden werden – meist bezogen auf aktuelle Anlässe – in der Öffentlichkeit kontrovers diskutiert. Reale Sicherheitslage und öffentliche Wahrnehmung unterscheiden sich oftmals. Das Gefühl von (Un-)Sicherheit in den Städten verändert sich, ebenso die Arbeitsteilung der Sicherheitsakteure. Urbane Sicherheit ist eine Gemeinschaftsaufgabe, die nicht nur von der Polizei wahrgenommen wird, sondern an der eine Vielzahl von Akteuren direkt und indirekt beteiligt ist.

Das Deutsche Institut für Urbanistik, die Forschungs-, Fortbildungs- und Informationseinrichtung für Städte, Gemeinden, Landkreise, Kommunalverbände und Planungsgemeinschaften, hat im Rahmen des Forschungsprojektes „DynASS – Dynamische Arrangements städtischer Sicherheitskultur“ im Jahr 2011 zwei Kommunalumfragen in den deutschen Städten mit 50.000 und mehr Einwohnern zum Thema „Sicherheit in deutschen Städten“ durchgeführt. Die Befragungen sollen einen systematischen Überblick über das Verständnis von städtischer Sicherheit, über Akteure, kommunale Aktivitäten im Bereich Sicherheit sowie Einschätzungen zu „sicheren“ und „unsicheren“ Orten in der Stadt ermöglichen. Befragt wurden die Leiterinnen/Leiter des Ordnungsamtes bzw. des Fachbereichs Sicherheit und Ordnung sowie des Amtes/Fachbereiches Stadtplanung/Stadtentwicklung/Stadterneuerung.

Das Projekt DynASS wird als interdisziplinäres Verbundprojekt durch das deutsche Bundesministerium für Bildung und Forschung (BMBF) im Rahmen des Programms der deutschen Bundesregierung „Forschung für die zivile Sicherheit“ gefördert.

Der Beitrag verdeutlicht, wie urbane Sicherheit als Gemeinschaftsaufgabe in deutschen Kommunen wahrgenommen wird und geht besonders auf die Akteure urbaner Sicherheit, sichere und unsichere Orte in der Stadt sowie Konzepte und Maßnahmen zur Verbesserung der Sicherheit im öffentlichen Raum ein.

2 URBANE SICHERHEIT

Alkoholisierte Jugendliche, Party im öffentlichen Raum, Gewalt in der U-Bahn, Graffiti an den Wänden oder Hundekot auf der Straße: Sicherheit und Ordnung in den Städten haben viele Facetten. Auch wenn reale Sicherheitslage und öffentliche Wahrnehmung sich dabei zum Teil erheblich unterscheiden: Die vermeintlich Ungeordnetheit und Unübersichtlichkeit großer Städte wurde schon immer im Kontext von Sicherheit und Unsicherheit diskutiert. Mit den beispielhaft oben genannten aktuelleren Entwicklungen sind sichere Städte noch stärker zu einem Thema öffentlicher Diskussion geworden. Für Bürgerinnen und Bürger sind sie Teil der eigenen Lebensqualität. Das zwingt Kommunen zum Handeln.

Sicherheit und Ordnung in der Stadt sind kontrovers diskutierte Themen. Wie Sicherheit und Ordnung bewertet werden und welche Handlungsoptionen bestehen wird häufig ideologisch geprägt diskutiert: Setzt man eher auf das solidarische Verhalten der Bürgerinnen und Bürger, gegenseitige Rücksichtnahme, die Gewährung von Spielräumen und Aushandlungsprozesse im Umgang miteinander oder auf das Schaffen und Durchsetzen von Regeln, verstärkte Kontrolle und Ahndung von Regelübertretungen? Favorisiert man eher Top-down- oder Bottom-up-Ansätze? In welchem Maß hält man Prävention für notwendig und das Zusammenwirken von Prävention und Repression für sinnvoll? Wie bewertet man Störungsfreiheit und Lebendigkeit in einer Stadt? Alle diese Fragen entscheiden darüber, wie man sich persönlich zu Fragen der Sicherheit und Ordnung in den Städten stellt. Die Art ihrer Beantwortung prägt die lokalen Sicherheitskulturen. Als Sicherheitskulturen bezeichnen wir im Rahmen des hier vorgestellten Forschungsprojekts die Gesamtheit der Überzeugungen, Werte und Praktiken von Individuen und Organisationen, die darüber entscheiden, was als eine Gefahr anzusehen ist und mit welchen Mitteln ihr begegnet werden soll.

Im Zuge eines sich verstärkenden Diskurses über die urbane Sicherheit gewinnen Fragen der sicheren Gestaltung von Städten auch im stadtentwicklungspolitischen Kontext eine größere Bedeutung. Tatsächliche und vermeintliche Bedrohungen gehen dabei nicht nur von einzelnen Großschadensereignissen aus, betroffen sind auch nicht nur die Megametropolen und Weltstädte, sondern gerade alltägliche Kriminalität und

alltägliche Gefahren in städtischen Räumen stehen im Blickpunkt. Die subjektive Wahrnehmung der Sicherheit bestimmter Orte in der Stadt durch die Bürgerinnen und Bürger wird nicht nur geprägt durch die tatsächliche oder vermeintliche Kriminalität am jeweiligen Ort, sondern auch durch Störungen der Ordnung zum Teil weit unterhalb der Schwelle strafbaren Verhaltens und der vermeintlichen oder tatsächlichen Unübersichtlichkeit der städtebaulichen Gestaltung sowie der Sauberkeit und Ordnung an bestimmten Orten. Gerade urbane Transformationsprozesse mit ihren Strukturbrüchen und gravierenden sozioökonomischen Veränderungsprozessen bilden den Hintergrund für die Befürchtung, Stadträume seien unsicher oder könnten unsicher werden. Die kommunale Ebene nimmt diese Bedürfnisse wahr: „Von den Bürgerinnen und Bürgern wird … durchgängig die saubere und sichere Stadt ohne sog. Angsträume als prioritäres Ziel eingefordert“ (DST 2011: 5). Städte werden in der medialen Berichterstattung und öffentlichen Diskussion oft als Brennpunkte der Kriminalität dargestellt. Eine tatsächliche oder behauptete zunehmende Kriminalitätsfurcht bestimmt die Argumentation oft in stärkerem Maß als die tatsächliche Kriminalitätsentwicklung. Die Sicherheitslage in den deutschen Verdichtungsräumen ist aber „weit weniger kritisch als in den meisten Städten Europas und der Welt“ (DST 2011: 5). Allerdings gibt es gerade im Bereich der Metropolregionen „klare Signale dafür, dass unser Sicherheitssystem weiterentwickelt und ausgebaut werden muss“ (DST 2011: 5), um neuen Sicherheitsanforderungen gerecht zu werden. Zu den neuen Problemlagen werden beispielsweise gezählt:

- Gefahr von Segregation, „anstatt objektiv und subjektiv sicherheitsfördernder Integration“ (DST 2011: 5),
- organisierte Kriminalität und Korruption (DST 2004, DST 2011),
- Gefahren der Innenstadtentwicklung: „etwa durch einseitige Entwicklungen, wie die Ansiedlung von Spielhallen und ähnlichen Betrieben“ (DST 2011: 5),
- neue Sicherheitsprobleme in Gebieten mit negativer demographischer Entwicklung: „Wohnungsleerstände ebenso wie hohe Arbeitslosigkeit führen zu bedenklichen Schwächen sozialer Nahräume“ (DST 2011: 5),
- eine gewachsene Erwartungshaltung der Bürgerinnen und Bürger im Bereich der öffentlichen Ordnung und der allgemeinen Gefahrenabwehr (DST 2004: 1).

Obwohl Risiken und Bedrohungen sich natürlich lokal auswirken und Unsicherheitsgefühle vor allem lokal wahrgenommen werden („Kriminalitätsschwerpunkte“, „kritische Infrastrukturen“, „No-Go-Areas“ sind nur drei Begriffe, die die örtliche Verankerung von Sicherheitsfragen deutlich machen), gibt es bisher keine umfassende kommunale Sicherheitspolitik. Dennoch entwickeln sich aus dem pragmatischen Handeln neue urbane Sicherheitsregimes basierend auf spezifischen lokalen Sicherheitskulturen (vgl. Floeting 2006).

3 DIE BEFRAGUNGEN

Im Folgenden werden ausgewählte Ergebnisse zweier Kommunalumfragen vorgestellt, die das Deutsche Institut für Urbanistik im Jahr 2011 im Rahmen des Forschungsprojektes „DynASS – Dynamische Arrangements städtischer Sicherheitskultur“[1] zum Thema „Sicherheit in deutschen Städten“ durchgeführt hat. Ziel der Befragungen war es, einen systematischen Überblick über das Verständnis von städtischer Sicherheit, über Akteure, kommunale Aktivitäten im Bereich Sicherheit sowie Einschätzungen zu „sicheren“ und „unsicheren“ Orten in der Stadt zu erlangen (Floeting, Seidel-Schulze 2012).

Die Erhebungsgrundgesamtheit umfasste alle 188 deutsche Städte und Gemeinden mit mehr als 50.000 Einwohnern, sowie die 12 bzw. 7 Bezirke der Stadtstaaten Berlin und Hamburg (Stand 2010). Zum Thema „Sicherheit in deutschen Städten“ wurden die Amtsleiter/-innen bzw. Fachbereichsleiter/-innen von Ordnungsämternb und Stadtplanungs/Stadtentwicklungsämtern[2] befragt. Die schriftlichen Befragungen der Ordnungsämter und Stadtplanungsämter wurden nacheinander in einem jeweils fünfwöchigen Zeitraum

[1] Ausführliche Informationen zum Forschungsprojekt „DynASS – Dynamische Arrangements städtischer Sicherheitskultur“ finden sich in: http://www.dynass-projekt.de/.

[2] Die Fachbereiche Sicherheit und Ordnung bzw. Ordnungsämter werden im Folgenden synonym als Ordnungsämter bezeichnet. Analog werden die Fachbereiche bzw. Ämter für Stadtplanung und/oder Stadterneuerung und/oder Stadtentwicklung als Stadtplanungsämter bezeichnet.

zwischen Februar und Juni 2011 durchgeführt. Der Fragebogen für Ordnungsämter bzw. Stadtplaner umfasste geschlossene und offene Fragen zu folgenden Themenkomplexen:

- Allgemeine Angaben und Verständnis von kommunaler Sicherheit darunter Größe des Amtes und Zahl der Mitarbeiter,
- Informationsgrundlagen zur Einschätzung städtischer Sicherheit,
- Akteure, Gremien und Kooperationspartner bei der Wahrnehmung der Aufgaben im Rahmen der städtischen Sicherheit,
- Maßnahmen, Konzepte und Projekte zur Verbesserung der Sicherheit im öffentlichen Raum,
- „sichere" und „unsichere" Orte in der Stadt.

Die Rücklaufquoten der Ordnungsämter und Stadtplanungsämter lagen bei 49 bzw. 44 Prozent. Leichte Unterschiede im Antwortverhalten gab es je nach Stadtgröße. Bei den Ordnungsämtern haben überproportional viele Mittelstädte mit 50.000 bis 100.000 Einwohnern teilgenommen. Ihre Beteiligung lag bei über 50 Prozent. Bei den Stadtplanern hingegen war das Antwortverhalten besonders in den großen Städten mit mehr als 200.000 Einwohnern sehr gut.

4 AKTEURE URBANER SICHERHEIT

4.1 Ordnungsämter

In den Ordnungsämtern ist eine Vielzahl unterschiedlicher Aufgaben angesiedelt. Kernaufgabe der Ordnungsämter ist die Wahrung der öffentlichen Ordnung. Dabei sind die Zuständigkeiten in den einzelnen deutschen Kommunen aber sehr unterschiedlich verteilt. Die Aufgabenbereiche der Ordnungsämter haben sich in den letzten Jahren erweitert. Dies ist auch teilweise damit begründet, dass immer mehr ehemals polizeiliche Aufgaben von den kommunalen Ordnungsämtern wahrgenommen werden müssen (vgl. DST 2011). Wenngleich weit über 90 Prozent der Ordnungsämter angeben, dass die Zusammenarbeit mit der Polizei grundsätzlich gut funktioniert, wird gleichzeitig von rund drei Vierteln der Ordnungsämter beklagt, dass die Polizei immer mehr Aufgaben an das Ordnungsamt abgibt. Besonders Kommunen mit eigenen kommunalen Ordnungsdiensten sind davon betroffen: Einen kommunalen Ordnungsdienst oder eine Stadtpolizei, die Aufgaben über die Verkehrsüberwachung hinaus wahrnimmt, gibt es in rund drei Viertel der Städte. Mit zunehmender Stadtgröße steigt auch der Anteil der Kommunen mit Ordnungsdiensten.

4.2 Stadtplanungsämter

Obwohl eine Vielzahl von Planungsentscheidungen die Lebensqualität und damit auch das Sicherheitsgefühl in der Stadt beeinflussen, leistet nur ein kleiner Teil der Aufgaben – und dies im Vergleich zu den Ordnungsämtern auch eher indirekt als direkt – im engeren Sinne einen Beitrag zur Sicherheit in der Stadt. Nach Einschätzung der befragten Stadtplaner sind dies vor allem (in der Reihenfolge nach absteigender Häufigkeit) Gestaltungskonzepte für konkrete öffentliche Räume, die Erarbeitung von Innenstadtplanungen, die Durchführung von Maßnahmen der „Sozialen Stadt" und die Erarbeitung städtebaulicher Entwürfe. Mehr als 70 Prozent der Stadtplaner halten diese Aufgaben für „sicherheitsrelevant".Wenngleich eine gewisse Bedeutung für die Sicherheit in der Kommune fast allen planerischen Dokumenten zugemessen wird, werden Aussagen zur Sicherheit in der Stadt aber vor allem in den Integrierten Stadtentwicklungskonzepten niedergelegt. Politisch gefordert wird die Berücksichtigung des Themas „Sicherheit in der Stadt" in der Stadtplanung in nur knapp einem Viertel der Städte. Ebenso sind spezielle Konzepte oder Maßnahmen zum Umgang mit dem Thema „Sicherheit in der Stadt" (z.B. zur städtebaulichen Kriminalprävention) nur in einem Fünftel der Städte verbreitet. In 36 Prozent der Städte haben sich Stadtplaner noch nicht mit dem Thema "Sicherheit in der Stadt" beschäftigt.

4.3 Weitere Akteure mit Aufgaben für die urbane Sicherheit

Vergleicht man die am häufigsten von Ordnungsämtern und Stadtplanungsämtern genannten Kooperationspartner (vgl. Abbildung 1), so ähneln sich die Kooperationsstrukturen im Themenfeld „Sicherheit" deutlich: Neben dem jeweils anderen Amt werden von den Befragten (gemessen an der Häufigkeit der Nennungen) auf vorderen Plätzen Polizei und Feuerwehr, Jugendamt, Sozialamt und Schulamt, einzelne Bürger und Vertreter der Kommunalpolitik genannt. Auffällig ist die geringe Häufigkeit

der Nennungen von Sportvereinen und anderen Vereinen als Kooperationspartner durch beide Ämter, die in der öffentlichen Diskussion häufig als wichtige Akteure organisierten zivilgesellschaftlichen Engagements in den Städten genannt werden: Weniger als ein Viertel der Stadtplanungsämter und weniger als ein Fünftel der Ordnungsämter nennen diese Kooperationspartner. Sehr unterschiedlich häufig wird die Wohnungswirtschaft als Kooperationspartner im Themenfeld „Sicherheit“ genannt: von mehr als der Hälfte der Stadtplanungsämter, aber von weniger als einem Fünftel der Ordnungsämter. Hier wirkt sich offensichtlich die Nähe der Professionen untereinander und die Ähnlichkeit der Aufgaben (Raumbezug, baulicher und planerischer Zugang statt „ordnendem“ Zugang) auf die Kooperationsstrukturen im Themenfeld städtische Sicherheit aus (vgl. Abt/Meier 2012).

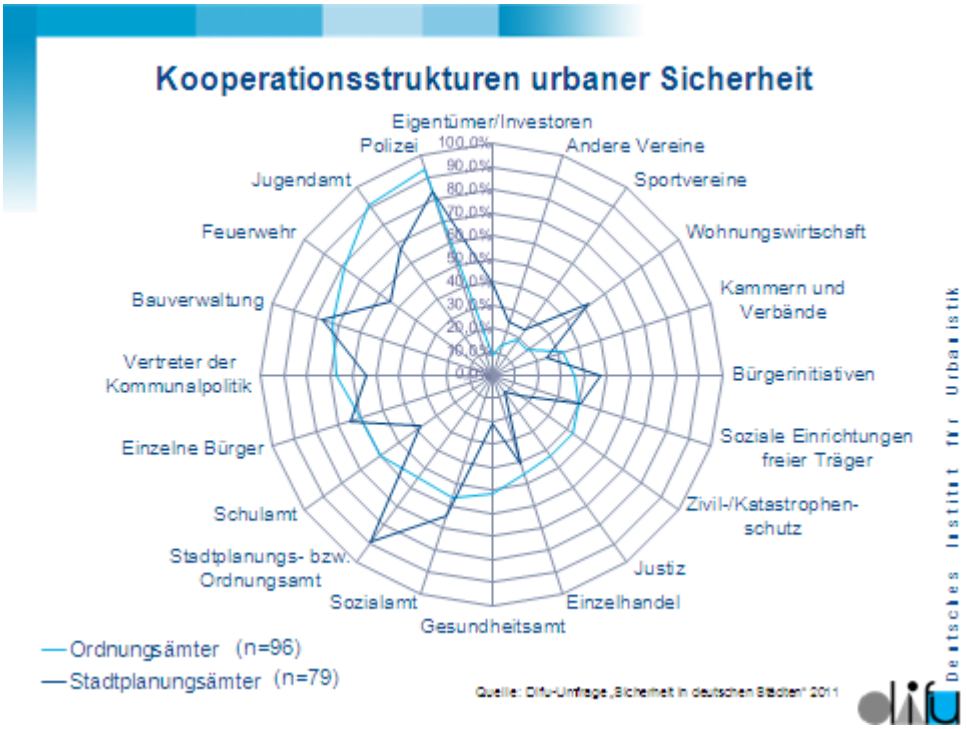

Abb. 1: Kooperationsstrukturen urbaner Sicherheit

5 SICHERE UND UNSICHERE ORTE IN DER STADT

In jeder Stadt gibt es Orte, die in der öffentlichen Wahrnehmung als eher „sicher“ oder eher „unsicher“ gelten. Das können Bahnhöfe, öffentliche Plätze, Grünanlagen, Einkaufsviertel, Wohngebiete sein. Die Gründe, warum Orte von allen oder von einzelnen Bevölkerungsgruppen als „sicher“ oder „unsicher“ wahrgenommen werden, sind seit langem Gegenstand der kriminologischen Forschung zum subjektiven und objektiven Sicherheitsgefühl (Bott/Coester/Kerner 2007, Glasauer/Kasper 2001). Eine zentrale Erkenntnis dieser Forschung ist, dass empirische Daten der (polizeilichen) Kriminalitätsstatistik die Kriminalitätsfurcht der Einwohner oft nicht erklären. So kann die Kriminalitätsfurcht an einem Ort hoch sein, obwohl die objektive Sicherheitslage dies nicht rechtfertigt. Kriminalitätsfurcht ist eine emotionale Reaktion gegenüber Kriminalitätsereignissen, die – wenngleich selten auftretend – als persönliche Bedrohung empfunden werden (Dittmann, 2005). Die subjektive Komponente der Einschätzung der Sicherheitslage und ihre Abweichung von objektiven Gegebenheiten bilden sich auch in Bürgerumfragen ab. Wenn dort nach dem Sicherheitsgefühl in der Nachbarschaft sowie der Gesamtstadt gefragt wird. wird die Sicherheit in der eigenen Nachbarschaft höher eingeschätzt als die der Gesamtstadt. Dies trifft sowohl für europäische als auch für deutsche Städte zu (Schoeb 2008, Waespi-Oeß 2008). Man spricht vom so genannten Distanzeffekt (Bott/Coester/Kerner 2007). In Nachbarschaften ist der Grad der Fremdheit eher gering. Man kennt sich, grüßt sich, in der Gesamtstadt ist das Element des Fremden groß oder wird zumindest eher vermutet. Moderne Städte produzieren aus sich heraus eine Vielzahl von Milieus, die einander fremd sind (Häußermann 1995, Häußermann/Siebel 2004). Ein Ziel der hier vorgestellten Kommunalumfragen war es, die Orte der Unsicherheit und Sicherheit und deren Veränderungspotenzial genauer zu untersuchen, denn Aufenthaltsqualität und das Image von Orten in der Stadt unterliegen Veränderungen. So können ehemals

unsichere Orte sicherer werden, ehemals sichere Orte unsicherer werden. In der vorliegenden Untersuchung wurde nach diesen Orten und ihrer Dynamik gesucht.

Grundsätzlich wurden von den Befragten mehr Angaben zu den sicherer gewordenen als zu den unsicherer gewordenen Orten gemacht. Angaben zu den sicherer gewordenen Orten wurden meist maßnahmenbezogen (Umgestaltung von Stadträumen, Aufbau eines Stadtraummanagements, Verkürzung der Reinigungsintervalle an bestimmten Orten, verstärkte Präsenz von Ordnungskräften, Kooperation von Sicherheitsakteuren usw.), zu den unsicherer gewordenen Orten meist delikt‐ oder störungsbezogen (Steigerung der Kriminalitätsrate, Zunahme der Problematik illegaler Drogen, neuer Standort für Alkoholiker usw.) erläutert. Die Beschreibung der konkreten Orte weist bei Ordnungs- bzw. Stadtplanungsämtern Übereinstimmungen aber auch deutliche Unterschiede auf. So werden von beiden Gruppen zwar alle Ordungsprobleme angesprochen, allerdings in unterschiedlicher Gewichtung (vgl. Abbildung 2). Während Stadtplanungsämter bei den unsicherer gewordenen Orten stärker nachteilige städtebauliche Eigenschaften sowie Leerstand nennen, sind für Ordnungsämter vor allem Orte im Blick, die ordnungsrechtliche Probleme aufweisen (z.B. Trinkerszene, Partymeile usw.).

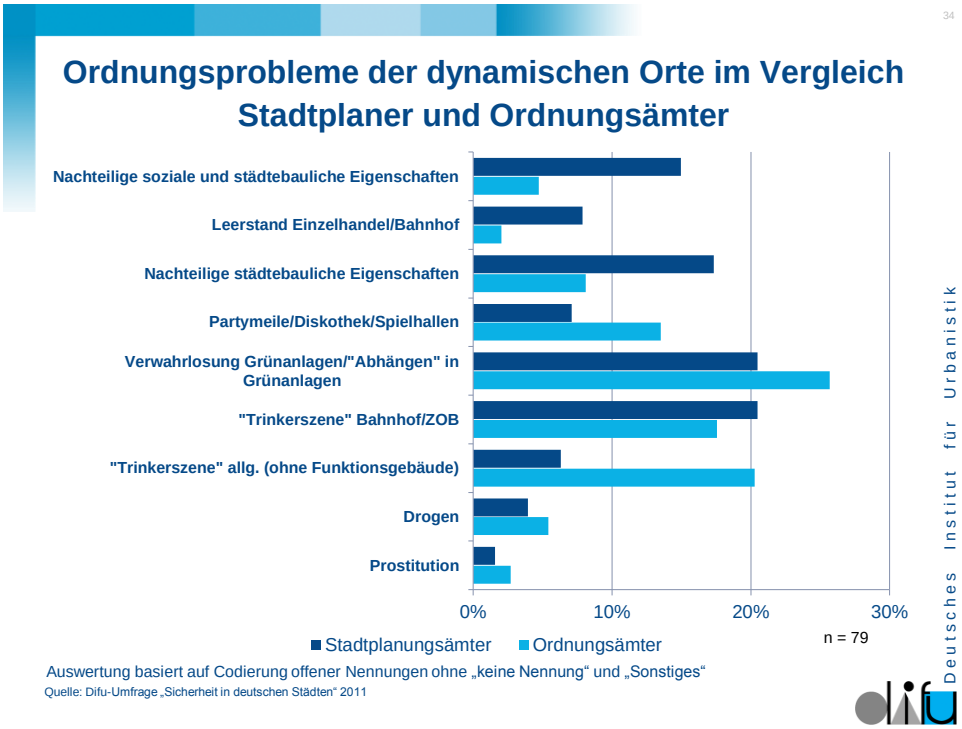

Abb. 2: Ordnungsprobleme der dynamischen Orte im Vergleich Stadtplaner und Ordnungsämter

Eine einheitliche Entwicklungsdynamik bestimmter Orte gibt es nicht. Gleiche oder ähnliche funktionale Orte in der Stadt werden in der einen Stadt als sicherer geworden, in der anderen Stadt als unsicherer geworden dargestellt. Trotz der bei Stadtplanungs- und Ordnungsämtern zum Teil abweichenden Nennung der Ordnungsprobleme stimmen die genannten Orte, wie Bahnhöfe, Zentrale Omnibusbahnhöfe, öffentliche Plätze, Grünflächen/Parks, Einkaufsstraßen/-viertel überein. Zwei Drittel aller genannten Orte verteilen sich auf diese Räume. Vor allem werden innerstädtische Orte genannt. In der Wahrnehmung der Akteure ist städtische Sicherheit also meist innerstädtische Sicherheit. Nur heben die Akteure, je nach Profession, die zumeist kumulativ auftretenden Ordnungsprobleme in unterschiedlicher Weise hervor.

6 KONZEPTE UND MAßNAHMEN ZUR VERBESSERUNG DER SICHERHEIT IM ÖFFENTLICHEN RAUM

In den Städten wird eine breite Palette von Maßnahmen und Konzepten zur Verbesserung der Sicherheit im öffentlichen Raum eingesetzt. Sie umfasst

- ordnungsrechtliche Maßnahmen wie beispielsweise rechtliche Vorschriften (z.B. zum Umgang mit Alkohol) und die Ahndung von Ordnungswidrigkeiten,

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

- personelle Maßnahmen wie die Präsenz vor Ort, den Einsatz ehrenamtlicher Sicherheitskräfte oder den Einsatz privater Sicherheitsdienste,
- technische Maßnahmen wie Investitionen in Beleuchtung oder Videoüberwachung/CCTV,
- baulich-gestalterische Maßnahmen wie die Verbesserung der Einsehbarkeit von Räumen, die Pflege und Instandhaltung des öffentlichen Raumes oder die Berücksichtigung von Mindestanforderungen für Sicherheitsaspekte in der Bauleitplanung bzw. beim Einsatz von Instrumenten des Baurechts,
- sozialräumliche Maßnahmen wie gezielte Investitionen in die soziale Infrastruktur, die Förderung der sozialen Mischung der Bewohnerschaft im Quartier, die Belebung des Raums durch Förderung von Aktivitäten, die Förderung von Partizipation, Aktivierung, Empowerment der Bürgerinnen/Bürger, Quartiersmanagement, Jugendarbeit und sozialpädagogische Angebote sowie Angebote sozialer Dienstleistungen (z.B. Schuldnerberatung),
- Kommunikation mit den Bürgern und die Information der Öffentlichkeit in Form der Veröffentlichung von Informationsbroschüren, der Durchführung von Informationsveranstaltungen, der Bereitstellung von Ordnungstelefonen oder Hotlines für Bürgermeldungen, Internetangeboten für Bürgermeldungen oder der Präsentation von Aktivitäten des Amtes in Fernsehen und Presse.

Die befragten Ordnungsämter sehen Schwerpunkte bei den ordnungsrechtlichen und den sozialräumlichen Maßnahmen und Konzepten sowie im Bereich Kommunikation und Information der Öffentlichkeit. Bei den personellen Maßnahmen werden besonders häufig die Präsenz vor Ort, bei den baulich-gestalterischen Maßnahmen die Pflege und Instandhaltung des öffentlichen Raumes genannt. Nach Angaben der Ordnungsämter wird eine Vielzahl von sozialräumlichen Maßnahmen zur Verbesserung der Sicherheit im öffentlichen Raum eingesetzt.

Von den Stadtplanungsämtern werden vor allem baulich-gestalterische und sozialräumliche Maßnahmen und Konzepte zur Verbesserung der Sicherheit im öffentlichen Raum angeführt. Als baulich-gestalterische Maßnahmen wurden vor allem die Neugestaltung des öffentlichen Raumes, der Beleuchtung und der Möblierung, die Verbesserung der Einsehbarkeit und die Pflege und Instandhaltung des öffentlichen Raumes, die Verwendung vandalismussicherer Materialien, die Markierung von Grenzen und die Beschränkung von Gebäudehöhen genannt. Auch unterschiedliche sozialräumliche Maßnahmen werden eingesetzt, die aus Sicht der Stadtplanungsämter der Sicherheit im öffentlichen Raum dienen.

Integrierte städtische Sicherheitspolitik muss Aussagen zu einer breiten Palette von Maßnahmen und Konzepten treffen, um die unterschiedlichen Adressaten in ihren Handlungsbereichen anzusprechen. Mehr als die Hälfte der Ordnungsämter geben an, dass sie in ihrer Stadt über integrierte Sicherheitskonzepte verfügen, währenddessen weniger als ein Fünftel der Stadtplanungsämter dies angeben. Dies lässt sich zum Teil aus Rücklaufunterschieden erklären: Es haben sich nur in einigen Städten beide Ämter an der Umfrage beteiligt. Auch wird der Begriff „integrierte Konzepte“, wie die Arbeit mit Fokusgruppen der Befragten zeigt, unterschiedlich verstanden. In der Stadtplanung werden integrierte Stadtentwicklungskonzepte genannt, die auch Aussagen zum Thema Sicherheit und Ordnung enthalten. Das ist eher seltener der Fall. Ordnungsämter fassen darunter sehr unterschiedliche Konzepte im Aufgabenfeld urbane Sicherheit zusammen, so z.B.:

- Konzepte, die viele Akteure einbeziehen,
- Konzepte als Leitlinie des Handelns im Bereich Sicherheit und Ordnung,
- Konzepte, die ein Thema oder eine spezifische Problemlage aus unterschiedlichen fachlichen Zusammenhängen beleuchten (z.B. zu Fragen der Sicherheit und Ordnung im Zuge der Zuwanderung aus Südosteuropa), die stadtweit gelten und vom Gemeinderat beschlossen werden,
- quartiersbezogene, kleinräumliche Konzepte,
- operative Handlungskonzepte (z.B. integrierte Sicherheitskonzepte für Großveranstaltungen, im Umgang mit „Drogen im Bereich von Schulhöfen, Parkplätzen“),
- Konzepte in Zusammenarbeit mit anderen Kommunen.

7 FAZIT

In den Ordnungsämtern deutscher Kommunen ist eine Vielzahl unterschiedlicher Aufgaben angesiedelt. Dabei sind die Zuständigkeiten in den einzelnen Kommunen aber sehr unterschiedlich verteilt. Die unterschiedliche Aufgabenverteilung bestimmt den Rahmen für die Wahrnehmung von Sicherheit und Ordnung. Die Aufgabenbereiche der Ordnungsämter haben sich in den letzten Jahren erweitert. Dies ist auch teilweise damit begründet, dass immer mehr ehemals polizeiliche Aufgaben von den kommunalen Ordnungsämtern wahrgenommen werden müssen. Zu dieser Erweiterung zählt auch die Schaffung kommunaler Ordnungsdienste.

Anders als die Ordnungsämter greifen die Stadtplanungsämter nur indirekt in die Sicherheitsproduktion ein. Spezielle Konzepte oder Maßnahmen zum Umgang mit dem Thema „Sicherheit in der Stadt“ (z.B. zur städtebaulichen Kriminalprävention) sind nur in wenigen deutschen Städten verbreitet. Viele Stadtplanungsämter haben sich noch nicht mit dem Thema "Sicherheit in der Stadt" beschäftigt. Obwohl eine Vielzahl von Planungsentscheidungen die Lebensqualität und damit auch das Sicherheitsgefühl in der Stadt beeinflussen, leistet aus Sicht der Ämter nur ein kleiner Teil der Aufgaben eher indirekt einen Beitrag zur Sicherheit in der Stadt. Wenngleich eine gewisse Bedeutung für die Sicherheit in der Kommune fast allen planerischen Aktivitäten zugemessen wird, werden ausdrückliche Aussagen zur Sicherheit in der Stadt aber vor allem in den Integrierten Stadtentwicklungskonzepten niedergelegt. Für Stadtplanungsämter sind anders als für Ordnungsämter Maßnahmen, die zur Sicherheit und Ordnung in der Stadt beitragen, nur eine von vielen Aufgaben. Die engsten Bezüge haben Stadtplaner im Rahmen der städtebaulichen Kriminalprävention und integrierter quartiersbezogener Ansätze stadtplanerischer Intervention.

Das Ordnungsamt agiert eher reaktiv, der Aufgabenschwerpunkt liegt auf der Beseitigung oder Verhinderung von Missständen. Das Stadtplanungsamt kann eher präventiv durch die Schaffung baulich-räumlicher oder sozialräumlicher Angebote mit Fragen von Sicherheit und Ordnung in der Stadt umgehen. Die Vorgehensweisen nehmen hinsichtlich der Verbesserung der urbanen Sicherheit nur teilweise Bezug aufeinander.

Ordnungsämter und Stadtplanungsämter nehmen urbane Sicherheit unterschiedlich wahr. Daraus ergeben sich z.T. unterschiedliche Sicherheitsbilder bzw. unterschiedliche Einschätzungen zu Problemkulissen. Dies bestätigte sich in der Umfrage bei den Angaben zu den unsichererer bzw. sicherer gewordenen Orten. Neben vielen übereinstimmend genannten Orten gibt es auch solche, die entweder nur von den Ordnungsämtern bzw. Stadtplanern genannt wurden. Hotspots für unsicherer als auch sicherer gewordene Orte waren öffentliche Plätze, Bahnhöfe, Grünflächen/Parks, Einkaufsstraßen/-viertel.

Von den Befragten wurde häufig angegeben, dass die jeweilige Stadt über integrierte Ansätze zum Umgang mit dem Thema urbane Sicherheit verfügt. Tatsächlich wird darunter eine Vielzahl unterschiedlicher Ansätze verstanden. Umfassend integrierte Ansätze, die sowohl die Integration unterschiedlicher Akteure, die Integration unterschiedlicher Handlungsebenen (strategisch, operativ) und die räumliche Integration (gesamtstädtisch, quartiersbezogen) umfassen, gibt es bisher kaum.

Städte und ihre Bürger werden sich in Zukunft in stärkerem Maß mit Sicherheitsfragen auseinandersetzen. Es entwickeln sich − eher als Reaktion auf konkrete Anlässe und ad hoc formulierte Sicherheitsansprüche als auf Basis integrierender konzeptioneller Überlegungen sowie durch persönliche Kontakte urbane Sicherheitsregimes. Für sichere Städte zu sorgen, bleibt dabei eine Aufgabe, an der viele Akteure beteiligt sind. Doch viele Akteure sind sich ihrer Wirkung auf Sicherheitsfragen in der Stadt kaum bewusst. Daher ist es zunächst einmal notwendig, das Bewusstsein für Fragen der Sicherheit und Ordnung bei den unterschiedlichen Akteuren zu wecken, nicht nur kooperative Strukturen aufzubauen, sondern auch praktisch kooperativ zu handeln und urbane Sicherheit – die einen wesentlichen Teil der Lebensqualität für die Bürger der Städte ausmacht – nicht nur als Handlungsfeld für „ad hoc Interventionen“, sondern als kontinuierliche Aufgabe und ein gemeinschaftliches Ziel der Stadtgesellschaft zu begreifen. Die Beschäftigung mit Sicherheit und Ordnung als Phänomenen, die sich in unterschiedlicher Auspägung in den verschiedenen städtischen Räumen zeigen, sollte nicht zu der verkürzten Schlussfolgerung führen, dass Probleme mit Sicherheit und Ordnung in der Stadt primär über stadträumliche Interventionen gelöst werden können. Zu vielschichtig sind die sozioökonomischen Problemlagen, die als Ursache von Fehlentwicklungen gelten können und die letztendlich als Erscheinungsformen von Unsicherheit in den Städten wahrgenommen

werden. Für den Erhalt sicherer Städte müssen räumliche Entwicklungen berücksichtigt werden, ohne Fragen von Sicherheit und Ordnung simplifiziert zu verräumlichen.

1 ABSTRACT

Today, due to increasing importance of preserving energy resources and using alternative energies, employing potentialities of cities to change them to dynamic cities is one of the major challenges in the modern world. Finding these potentialities and suitable usage of them helps us not only in preserving more non-renewable energies but also lets us have more clean air and meet our public needs by using clean energies. Rasht is one of the cities in north of Iran, surrounded by mountain and sea, has a moderate climate and fertile farm-lands.

This article examines the possibility of changing Rasht in to a dynamic city considering its current condition and geographical location.The overall aim of the research is to offer a model for a dynamic city which includes major characteristics such as supplying its heat, electricity, and even food with the least damage to natural environment and preserving its non-renewable energies.

2 INTRODUCTION

Cities in traditional societies especially in Iran were built according to sustainable and dynamic patterns. Variety of cities' structures show the complete adaptability to their surrounding environment. The main core of traditional cities was built around traditional markets. Beside such traditional markets, there were some other places called districts which were the place people used for social interactions and economic transactions , so districts played a major role in cities vitality and freshness. Due to several changes in cities throughout ages and as people-oriented cities replaced by machine-oriented cities, life-style underwent some changes as well. Constructing streets which had been adapted to different sizes of vehicles and new definitions of modern life from political, social, economic and cultural aspects resulted in dramatic changes in cities. However, unfortunately, what was ignored in constructing new cities was the importance of natural environment: huge constructions, big communication networks, mechanization, and environmental pollutions brought severe damages to the world during the last century. Irreversible fuels consumption and ecosystem demolition made city planners offer new patterns to rescue cities.

Sustainable theory is one of the most universally acknowledged theories today. World Natural Environment and Development Committee definition is as such:

"Meeting the current needs of people without jeopardizing the abilities of future generations for satisfying their demands." (Jin kim and Rigdon, 1998)

This article aims at analysing the concept of a dynamic city. Indeed, it should be noted that dynamism is more than sustainability. In other words, apart from sustainability, dynamism includes climate condition and ecosystem. The inhabitants of a dynamic city have continuous social and economic activities and employ the whole city potential to develop such vitality and dynamism. The concept of dynamism can be recognised when food production and citizens' participation would be considered from all aspects.

One of the metropolitan cities in north of Iran is Rasht. Due to its climate condition and geographical location, Rasht has extraordinary potentials. So, the major attempt in this article is to focus on Rasht potentials in order to change it into a dynamic city, and then, a suitable plan will be offered to save its natural environment, to satisfy its habitants and to meet their daily needs.

3 DYNAMIC CITY

Population explosion, climate changes, excessive consumption of irreversible fuel recourses and environmental pollution are one of the biggest and most challenging problems in metropolitan cities in the world.

According to one estimation , 90% of the world population growth is in cities (Denig, 2010). Also, it is said that 75% of world energies is consumed in the cities of which 40% is used in buildings (Stampfl, 2010). Despite the fact that cities occupy less than 1% of the earth, they are the major reason for climate changes and water consumption (60%) (Denig, 2010). Nevertheless, the overall policies of a city should be in line with its improvement or even change to bring social and economic welfare to a society.

3.1 Charactristic of a dynamic city

A dynamic city is a kind of city which employs the most un-destructive of its minimum potentials. In other words, a dynamic city provides its habitants with best social services such as social welfare, supports their financial interests, and consumes the minimum amount of its energy resources by co-operation between its people and government and improving its infrastructure. One of the main features of a dynamic city is its productivity. For example, supplying food is one of the most important goals in cities. These products are transported from villages or countryside. For example, in highly populated countries like China and India, which enjoy urban life, the demand for food increases constantly. Then, unsurprisingly, a city is dynamic when it would be independent in its food industry and sustainable in its food chain. Habitants of a dynamic city are the producers of their own food, produce the minimum amount of waste, and the minimum waste of energy. Besides, the future development of a dynamic city should be efficient and in accordance with its dynamism plans in a way that its habitants ought to be able to adapt to the unexpected conditions. All districts are equipped with intelligent building systems in a dynamic city which are controlled by municipality.

Indeed, such coordinated system can manage all the district and regional crisis, such as traffic, in emergency situation. According to the given definition, a dynamic city is build based on the pattern of districts of traditional cities employing modern information and communication technology. One of the advantages of such a city is the interaction between its inhabitants and policy makers.

In fact, such intelligent systems can satisfy all basic needs of districts, and manage traffics and emergency situations.

Overall, the major goals of a dynamic city are:

(1) Preserving and developing green nature in a city (i.e. in parks, districts, green buildings, etc.).

(2) Optimizing energy consumption (a minimum consumption of irreversible energies, a maximum consumption of reversible energies).

(3) Consuming water in a sustainable cycle and its recycling

(4) Minimizing industrial and household waste

(5) Managing transport system in a suitable way especially according to reversible energies.

(6) Preserving natural environment and reducing destructive effects.

(7) Producing food in cities and using fertile farm lands.

(8) Employing intelligent information and communication technologies for optimum functioning of cities.

3.2 Samples of sustainable cities which can be changed to dynamic cities

Some countries have taken some measures to change their cities to sustainable cities. As mentioned above, some of the characteristics of a dynamic city are its productivity, adaptability to nature, capability for optimum improvement and development which if they will be applied to a sustainable city it can be changed into a dynamic city.

For example, Australia has taken some measures in order to build some cities based on a green environment and to meet its social and economic needs (URL 1). Similarly, Germany, Sweden and Holland have taken some approaches towards their future cities such as suitable consumption of energy resources, clean transport system, healthy productions, reducing green-house emissions, some national TV and radio programmes to make people save energy and preserve their natural environment and developing open air spaces (Peric and Furundzic, 2010), also the Caofeidian city in Tangshan in China, Luadian town in Shanghai, and Hammarby sjostad in Sweden are Eco cities which are supposed to be built based on suitable natural environment and sustainable development patterns (URL 2).

3.3 Which cities can be changed to dynamic cities?

Historically speaking, a good city is built according to its vernacular, cultural and historical features. Furthermore, those cities which have suitable structures make a balance between traditional characteristics and environmental goals. These ever-lasting cities are typically protected (Mahmoudi and Fanaei, 2009).

As a matter of fact, even if all necessary potentials such as climate condition, suitable natural environment, and energy resources are not available, high social interactions and cultural levels of habitants in accordance with determined policies will enhance the dynamism of a city. In a sense, finding some ways to adapt with surrounding environment is part and parcel of a dynamic city. So, if the aforementioned features are available in a city, it will have more efficiency. Generally speaking, it is possible that each city to be changed into a dynamic city. To do so, recognizing its potentialities and infrastructure planning are essential. Such various conditions are possible in many cities in Iran.

Rasht, the capital city of Guilan province in north of Iran, has the potentiality to be changed into a dynamic city thanks to its suitable climate condition, and natural environment. Obviously, if such potentials will be recognized based on sophisticated studies and policies, the city can fulfill the objectives of a dynamic city.

4 RASHT LOCATION

Rasht is the capital city of Guilan province in north of Iran. Rasht is located in 49° and 36' by east, 37° and 16' by north GMT near to Caspian Sea. (Fig.1)

Fig. 1: Rasht location

Rasht lies on a steady slope from south to north and is surrounded by two rivers called Siahrud and Goharrud both of which flow down into to Anzali lagoon. Because Rasht is located along Alborz Mountains from south, Caspian Sea from north, prairies on the east and west, has special climate condition. To be more precise, because of Rasht's Mediterranean changing temperature, and humidity the difference between night and day temperatures is insignificant. Also, the amount of precipitation is 2000mm in Rasht (Taheri, 1996).

5 RASHT: PROCESS OF BUILDING

It is said that Rasht was a big village surrounded by a jungle. While visiting Rasht in King Safavid time(1637),Adam Olearius[1] describes that the houses are hidden behind trees in a way that when one steps in the village it is as if s/he enters a jungle. Jacque Demorgan[2] says that city is lost amidst its branches and leaves (Taheri, 1996).

The first residential areas were randomly located in gardens and farmlands and mostly built around religious places in Rasht. Later with the city economic and market development the districts which were separated by

[1] A German scholar, mathematician, geographer and librarian.
[2] A French mining engineer, geologist and archaeologist.

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

small rivers disappeared and replaced by residential areas. Generally, the city has a main core shaped like spider web where all road networks lead to the main core.

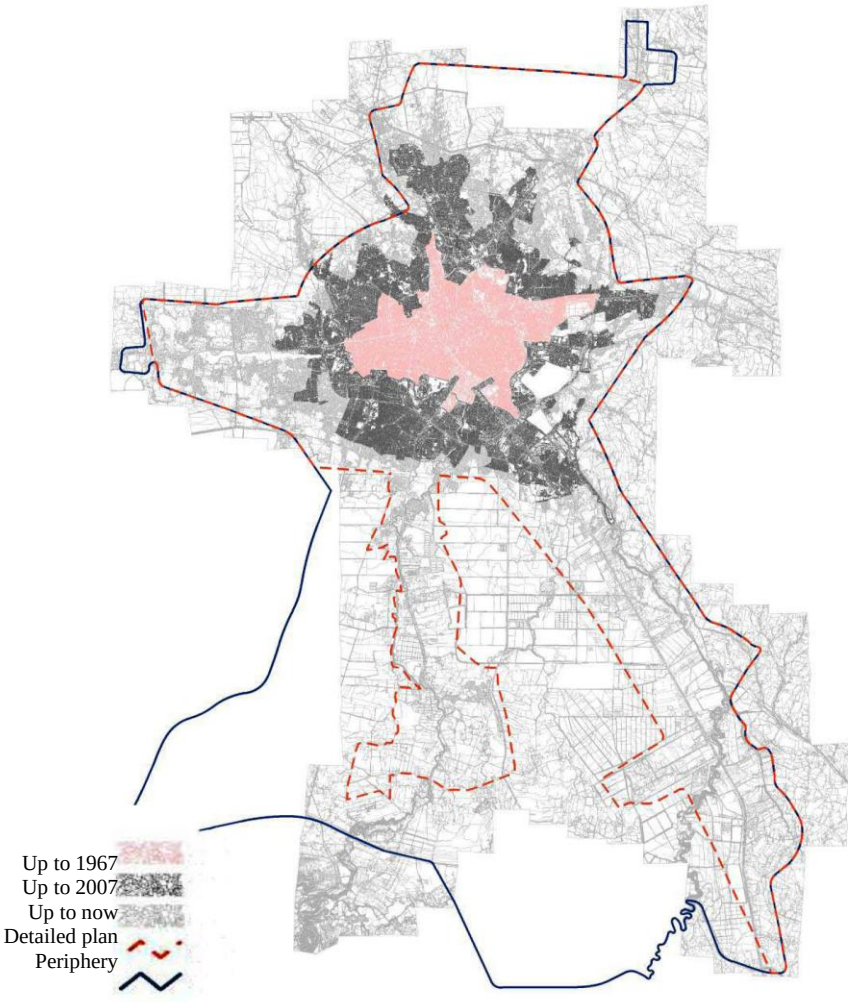

Fig. 2: The process of Rasht development (Rasht master plan, 2008)

Rasht municipality building was built in 1863 and it was considered as the city centre since all main streets led to it. One of the city's first greenery was City Park with 144000 km2 beside Guharrud River and Sabze Meidan (Green Square) park with 15000 km2 which were nearly located at city centre.

6 CURRENT SITUATION OF RASHT

According to Statistical Centre of Iran the number of population in the city in 2006 was 633940. In comparison to its total land area, Rasht has high population density due to its suitable climate condition and consequently organising the population led to spreading of the city(URL4). The growing population has destructive effects on natural environment such as farmlands and gardens and they are replaced by consuming buildings. In the same way, the current green environments do not play any major role in its urban space. Figure 3 shows the current green nature condition in Rasht.

It is needless to say that overall development of Rasht during recent years led to constructing many streets and avenues, which due to lack of suitable infrastructure for public transport system, result in using private vehicles, heavy traffic congestion and pollution. As it was mentioned earlier Rasht was located between two rivers which had clean and fresh water. However, because of urban development two rivers flow through the city now and since there are no suitable sewerage systems all waste are charged in these rivers and as a result they are highly contaminated.

Overall, the most important problems of the city are:

(1) Natural environment pollution especially of surface water and ground water pollution.

(2) Wide-spread urbanization, immigration, and marginalization.

(3) High rate of unemployment.

(4) Lack of public transport infrastructure.

(5) Ineffective traffic rules.

(6) Old public transport systems.

(7) Uneven distribution of water for agricultural, industrial and domestic consumption.

(8) Lack of implementation of urban sewerage and waste recycling.

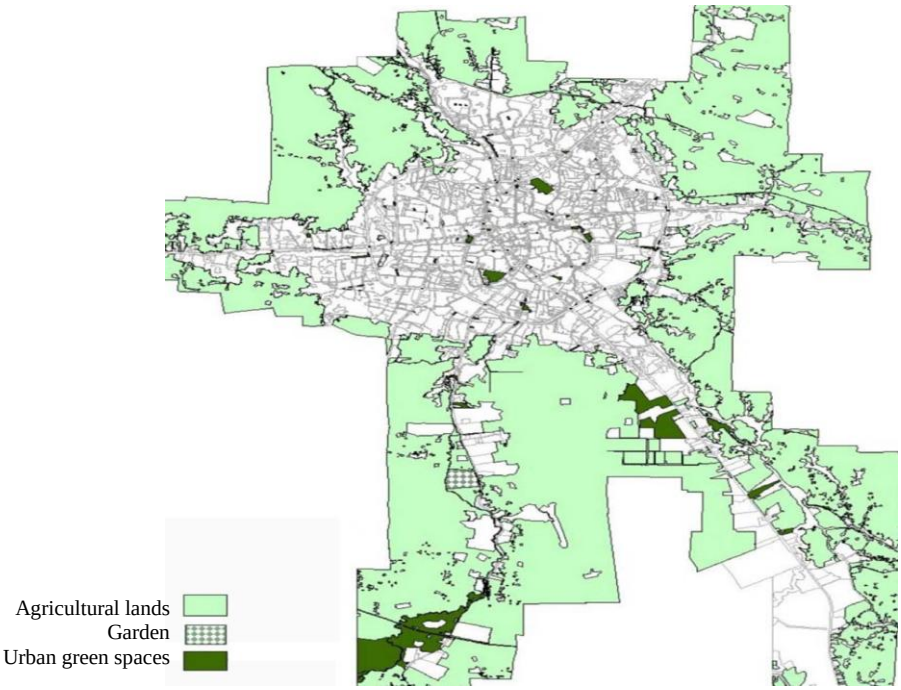

Fig.3: Current urban green nature condition in Rasht (Rasht master plan, 2008)

7 ANALYSING RASHT POTENTIALITIES IN ACCORDANCE WITH ITS DYNAMISM

Rasht enjoys a suitable climate condition and geographical location such as fair weather, fresh water, and rich soil. For instance, if there will be a barren land because of regular seasonal raining some plants grow naturally. As a result, with efficient planning, these lands can be used effectively in order to provide the inhabitants with new jobs. Economy of the city is based on agriculture and since Rasht is the capital city of Guilan province, offering services play an effective role on its economy. However, the sole reliance on agriculture makes organizing agriculture industry necessary (Nikouye,2008). Being located next to sea, variety of animal and plant species are part of those suitable features which apt Rasht to reach objectives of a dynamic city. It is clear that rivers are important factors in a city. If they would be cleaned and used effectively they can play a major role in food production (aqua-culture). Similarly, rivers can be the best spot for tourist attraction which can bring prosperity to the city from economic point of view.

During recent years separation of urban sewerage from surface water, gathered from rainfall precipitation, has been finalized. If such plans would be fully implemented it should be said that some primary measures have been taken for improvement of current situation. One of the strong points which improves the current situation of the city and changes it into a dynamic city is the co-operation of all inhabitants. Fortunately, the historical, cultural, social, and scientific backgrounds of its inhabitants show that they welcome such plans. In comparison to other cities, people from Guilan are well known for their social and cultural activities and people interactions have continuously improved in different issues.

8 SUGGESTIONS AND SOLUTIONS TO CHANGE RASHT INTO A DYNAMIC CITY

As far as Rasht has the most potentialities for dynamism, a sophisticated investigation, proper aims, basic planning, and applicable efforts can be considered as features which can change the city into a dynamic city with clean air and natural environment. For so doing, some suggestions can be made:

(1) Trying to preserve the green environment of the city: green nature apart from its growth and dynamism can trigger the sense of vitality and freshness in a society. Consequently, preserving and developing urban green environment is the first step for building a dynamic city.

(2) Monitoring different districts by using information technology: providing social security to all inhabitants with suitable quality and updating necessary information.

(3) Using green buildings in the city which gives a significant outlook to the city and its dynamism:

Green roofs and terraces can be good places for neighbours' interactions. They also can be suitable places for planting vegetables and fruits. Green walls can function as a heat and noise insulator, so they can reduce energy consumption, add to urban space beauty, and help to dynamic and live context of the city.

(4) Cultural programmes to encourage inhabitants to preserve fruit trees and vegetables.

(5) The minimum use of irreversible energies (using light absorbing windows and supplying building energy by photo-voltaic system, and etc.).

(6) Using recyclable materials and reducing poisonous materials in different industries.

(7) Equipping buildings with collecting rain water system and using it for watering green nature: regarding annual rainfall in Rasht, it is a main resource for life. Collecting and keeping rain water and re-using it in agriculture industry and flash tanks are necessary.

(8) Separating, packaging, and recycling urban waste: to do so, the separation process should be started in houses and special places should be considered in each district.

(9) Managing water consumption, water purification, and recycling for urban consumption (irrigation, and etc.).

(10) Developing public transport system using reversible energy resources in order to reduce using private vehicles, air pollution, and traffic congestion.

(11) Cleaning rivers in Rasht and enhancing aquaculture. Building parks next to rivers so such ecosystem can establish a peaceful relationship between inhabitants and different kinds of animal species: apart from beauty, such plans can encourage healthy activities and exercises. Moreover, the polluted rivers can be for the economic purposes. . Cleaning river plan is carried out by two organisations, Municipality Organisation and Department of Environment. Avoiding sewage to flow to rivers, cleaning rivers, and landscaping plan along rivers will help preservation of ecosystem.

9 CONCLUSION

Inhabitants of metropolitan cities spend most of their time in closed official or residential spaces. While passing the streets pedestrians just see high-rise buildings or even have no time to take a glance at all. Inhabitants are not satisfied with such life style. Consequently, despite scientific progress and technology, such cities are not dynamic. This is why decision makers, policy makers and politicians are seeking new ways to overcome those problems especially in big cities. Indeed, the major applicable items discussed in this article can play a major role in healthy life of human being. The experience of traditional cities is best examples of peaceful relationship between human being and nature in all over the world. So, combinations of traditional patterns with new technologies are of great help. In this regard, paying attention to cultural aspects is of highest importance. Moreover, taking suitable cultural measures and spreading the culture of building dynamic cities make the public participation possible in order to achieve goals.

Visibility Analysis of the Capital District in the 2030 Master Plan of Abu Dhabi

Rim Meziani

(Assistant Professor Rim Meziani, Abu Dhabi University, Po.Box 59911, Khalifa city, Abu Dhabi, UAE, rim.meziani@adu.ac.ae)

1 ABSTRACT

The 2030 master plan of Abu Dhabi describes the new zones of urban development in Abu Dhabi city: The Central Business District (CBD), The Capital District, the Grand Mosque District and the LULU Island District. It highlights the new vision of the UAE via its political capital: Abu Dhabi.

In this paper, the author is interested in the Capital District as the core of the city that has a variety of land use from low to high rise residential buildings, to institutional and commercial buildings to offices/retails, Governmental buildings, etc., besides the landmarks and great open spaces planned in order to highlight the image of Abu Dhabi city as the Capital of UAE.

A newly introduced mean of public transportation: the metro is expected to increase the pedestrian flow from and to these buildings. In order to optimize mobility and to raise the pedestrian movement growth to open public spaces in particular and to provide a lively, easy and pleasant walkways with high visibility and good accessibility to landmarks, natural settings, national symbols, monuments, neighborhood facilities, open spaces, etc. In this paper the author using the visibility analysis, mainly axial lines and segments maps. The urban structure framework, the land use, streets hierarchy, cycling and walking maps proposed in the Abu Dhabi 2030 master plan will be taken in account. Climatic factor and environmental Leadership will be the aim of a further study.

The methodology we followed consists of applying space syntax and GIS to analyze both the visibility and accessibility of open spaces (gardens, plaza, etc), pedestrian pathways, landmarks, facilities and important buildings.

The outcomes of this research will be combined with the study of the climate comfort in further research to translate the sustainable directions to specific recommendations and designs and try to refine the vision and themes represented in the 2030 plan ,which is subjected to detailed evaluation and confirmation in further planning and design.

2 INTRODUCTION

This paper presents a small part of a research that tries to cross three factors: 1) visibility of important buildings, open spaces, roads of the capital district, 2) buildings forms and arrangement and 3) the micro-climate, in order to propose kind of guidelines or orientations for land use, transportation planning, urban forms, etc which provides: 1) livable and pleasing walk paths in an optimum time to the city functions, 2) climatic comfort for pedestrian's walk, mainly shaded and ventilated streets and open spaces and 3) high visibility to landmarks, natural settings, national symbols and monuments, etc.

In this research the author has chosen Abu Dhabi 2030 master plan as a study case, in particular the capital district for its importance. Though it is a proposed plan and a practical research on site cannot be conducted, the author finds this interesting since finding of the research may help in orienting/ guiding future development and design based on simulation and analysis in a small areas, that the master plan did not cover because of the scope.

The author used Depthmap and axial line as many research have been recently made about walkability and accessibility by using axial lines and segment map analysis, together with the using of Geographical Information System (GIS). We found the this computer programs are suitable for this research as by the capabilities of these tools in representation and analysis demonstrated in many papers.

This paper presents first the study case then the methodology and ends with a conclusion that summarizes the findings and presents the limitations of the this research, which will be developed in further work.

3 PRESENTATION OF THE STUDY CASE

3.1 Abu Dhabi city

The united Arab Emirates (UAE) is a country situated in the southeast of the Arabian Peninsula in Western Asia on the Persian Gulf, bordering Oman, and Saudi Arabia, and sharing sea borders with Iraq, Kuwait, Bahrain, Qatar, and Iran (according to Wikipedia) (Figure 1).

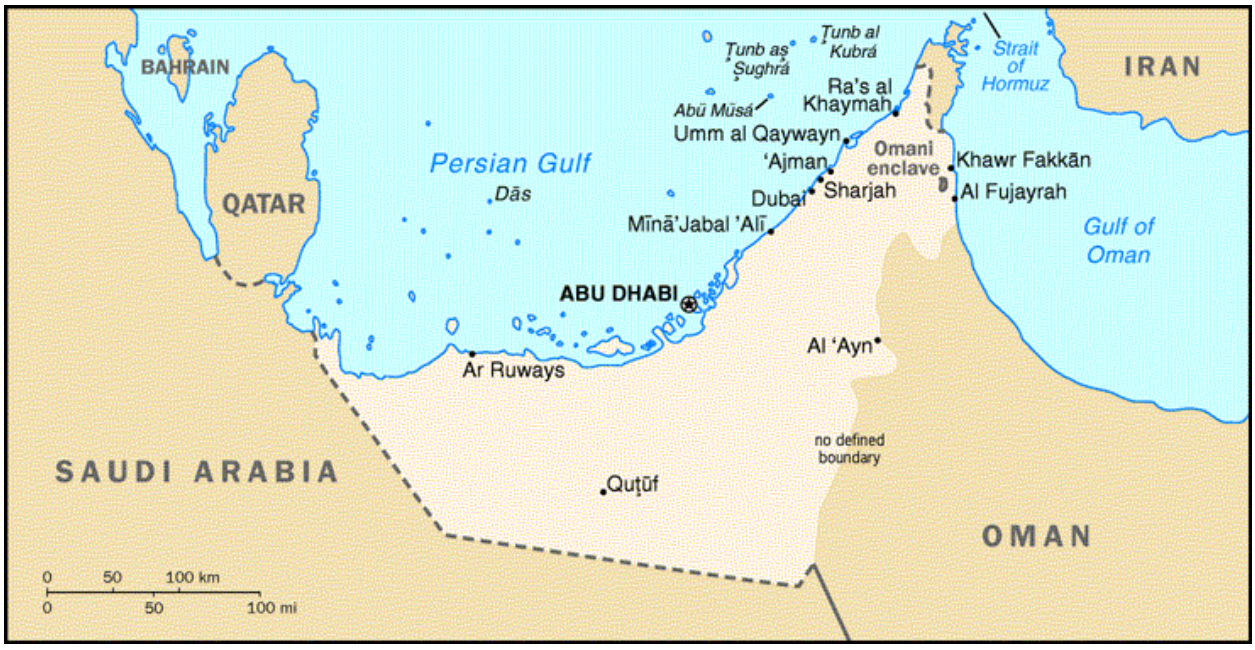

Figure 1: Geographical location of the United Arab Emirates. Source: http://geography.about.com/library/cia/blcuae.htm

The city of Abu Dhabi, which is currently the capital city of UAE with less than one million people, was established in the middle of the 18th century based on hunting and pearling activities. It has grown economically in the middle of 20th century with the discovery of oil and later politically to become the capital city of the United Arab Emirates after the Union of the 7 Emirates: Abu Dhabi, Dubai, Fujairah, Ras al-Khaimah, Sharjah, and Umm al-Quwain in 1971 to form one country (1).

3.2 Abu Dhabi 2030 Master plan

Abu Dhabi 2030 master plan was designed and implemented in 2007 in order to plan, manage and describe the future growth of the city. The continued expansion of the economy, the rapid population growth, the liberalized real estate law, the significant foreign investment and the construction projects of unprecedented influenced the birth of this master plan. The challenges that the master plan 2030 faces are: the creation of a sustainable livable urban environment and guarantee a balance between the mixed cultures existing in the cities with the preservation of the cultural character and traditions of Abu Dhabi as an Emirati and Arab city (1).

Hence, the urban structure framework plan was produced to make Abu Dhabi match its current financial and social capital to become the "Urban capital" with an expected population of 2 million residents and 4.9 million annual tourist in 2020 and 3.1 million residents with 7.9 million of annual tourists in 2030 and up to 5 million residents after a continues growth (1).

It is important to note here the urban structure framework plan was not geographically limited by the administrative boundaries of the city, but included its urban region and furthermore its natural boundaries (2), as for the Lulu island which is one of the new zones of urban development: The Central Business District (CBD), The Capital District, the Grand Mosque District and the Lulu District (Figure 2).

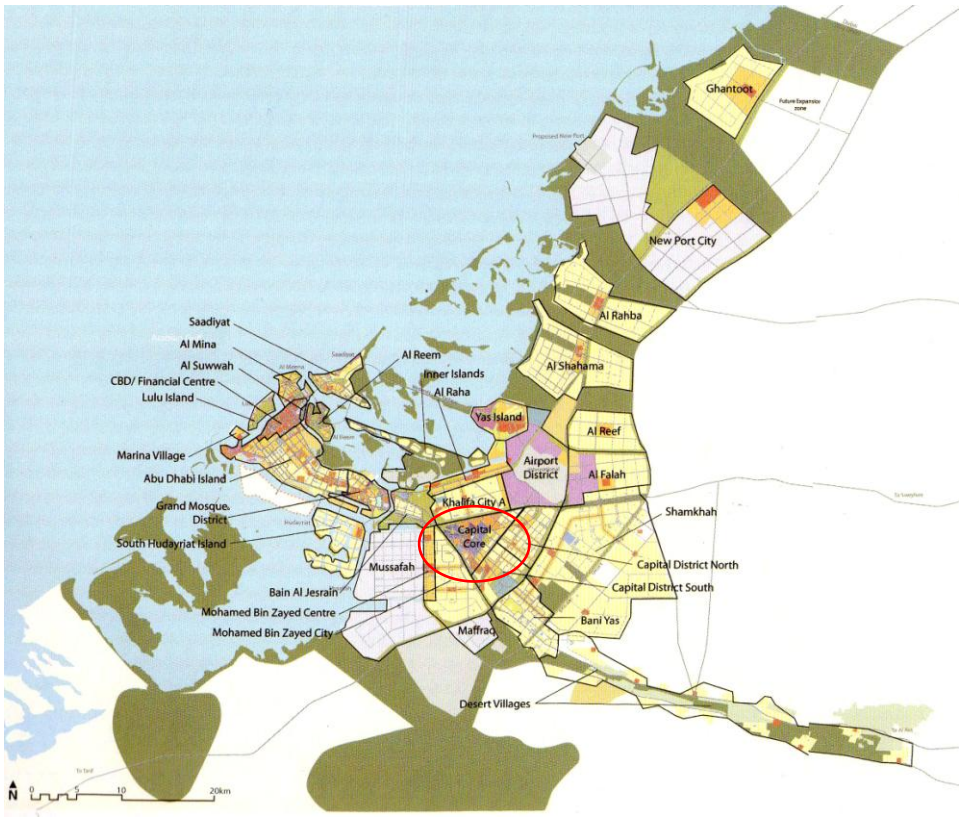

Figure 2.The location of the new zones of urban development. Source: The Abu Dhabi Urban Planning Council, 2007

These districts belong to the two major parts of the Abu Dhabi 2030 plan, which are connected by a developed transportation infrastructure based on the transit system. The first core is situated in the northeast of Abu Dhabi island and includes the historic center and the expanded Central Business District (CBD). The second one contains the new capital district located in the south of Abu Dhabi Island and will represent the second downtown of the city which will be designed to reflect the role and image of Abu Dhabi city as the capital of the federal government and a modern, sustainable Arab city (figure 3). Hence we are interested to take the capital district as a study case in this research.

Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

3.3 Capital District

That capital district is planned on 45km2 of land for a population of 367,253 residents and 813,650 of daytime population and will provide 100,000 jobs (1). It is well connected to the first part of the city through highways, trams and metro networks. Its urban structure and urban forms are designed in way to orient its visual axes to the CBD and to end with the Federal Precinct that represent landmarks and important buildings not only at the level of the city, but also the nation (Figure 4).

Its planned sustainable compact mixed uses distributed in different heights and densities makes from the Capital city a good place for integration between Emirati people and other ethnic groups, between different working classes in the society and a perfect mix of different cultures. From one hand low rise buildings of universities, research centers, mosques, community neighborhood with all the necessary facilities, sports and conference venues, embassy neighborhood, and from other hand high rise buildings of offices and commerce, national governmental house and buildings (Figure 5). They are distributed in the 2030 master plan to six major precincts: Federal Precinct, City Center Precinct (CBD, Souk District, North Spine District, Federal Mosque District), Emirati Neighborhood, Sport Hub Precinct, South Spine Precinct and Palace Precinct, based on land use distribution, location to transit infrastructure, density, urban form and open space (2) (Figure 6).

Figure 5: land use map of the Capital district- Abu Dhabi 2030 Master Plan. Source: The Abu Dhabi Urban Planning council, 2007

4 METHODOLOGY

The software applied in this research is Depthmap by UCL and the map we used is the urban spatial structure of the capital district designed by the Abu Dhabi Urban Planning Council. We used Axial map in order to check the integration and accessibility related to visibility of open spaces and roads within the whole urban system of the capital district.

The author first created automatically the axial map from the drawing file of the urban spatial structure of the capital district (Figure 7). A segment graph was generated from the axial map in order to conduct a detailed analysis through a segment analysis smaller scale: streets The resulting graph was after that analyzed according to the connectivity, Integration, total depth, choice, node count, etc (8). Later on an analysis using metric type of radius was run.

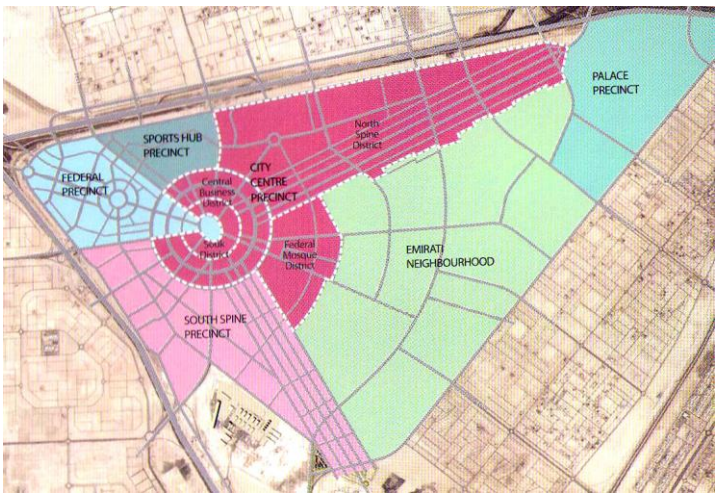

Figure 6: The six major precincts of the Capital District. Source: The Abu Dhabi Urban Planning council

The author chose 5mn, 10mn and 15mn of walking , which is equivalent to walk 400m, 800m ,1200m and cycling 7.5minutes and compare it with the walking and cycling map, which represents the tram and metro stops and the related 5mn walking distance from them, the streets hierarchy and the land use maps in order to identify which area from the capital district is well integrated in the whole system of the urban structure and more accessible and also to check if the walking distances proposed in the plan is enough to reach comfortably in an optimum time different destinations: open spaces and facilities, land marks, etc, especially in the hot climate of UAE.

Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

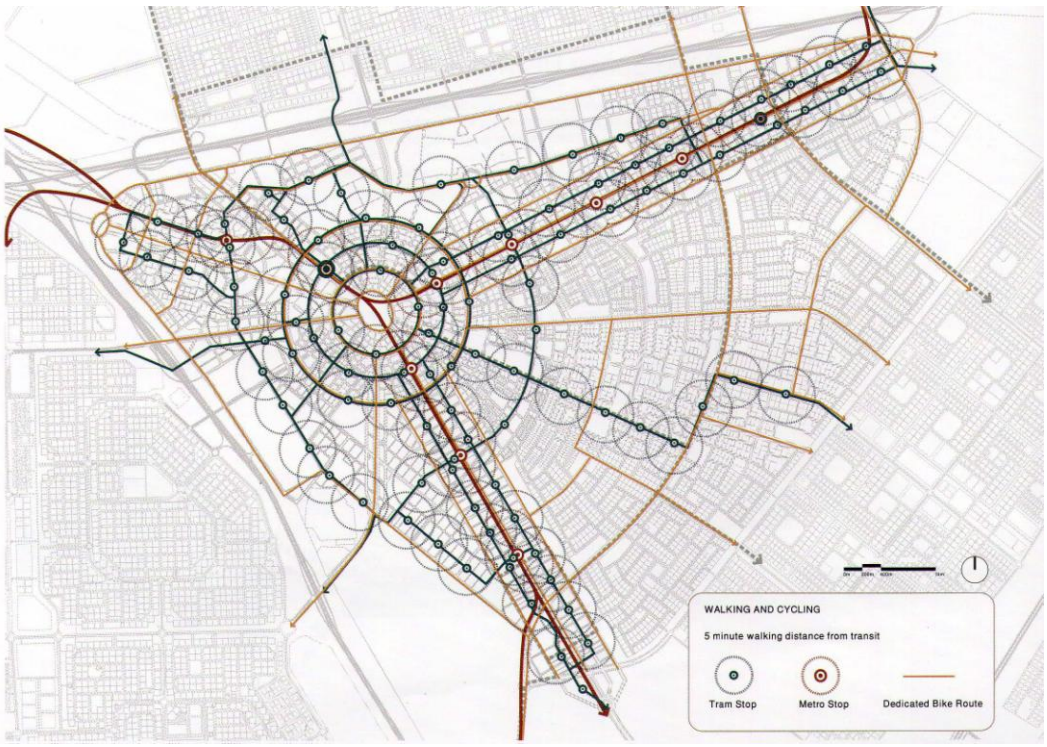

Figure12 : Walking and cycling map of the Capital District. Source; Abu Dhabi Planning council, 2007

5 RESULTS ANALYSIS AND FINDING

Before starting the analyze it is important to understand the meaning of the total depth. Turner (9) defined the total angular depth as: *The cumulative total of the shortest angular path to the segments.*

The total depth values are represented in the graph by a gradation of color by default from blue: Lowest value to green, to red: highest value. The total depth graph generated for the Capital district area (figure8) indicates that both collectors and local streets in the Emirati neighborhood (Figure11) has high value than the major arterial, which means that a large number of shortest path are connected to them.

Where comparing the total depth graphs (segment Analysis) for a radius of 200m, 400m and 800 meters that is equivalent to 5mn, 10mn and 15mn of walk (figure 8, 9, 10) , and the land use, the streets hierarchy maps with the walking and cycling map (figure 12) we found out that:

(1) The segments in the graphs with 200m, 400m and 800m radius (figure 8, 9, 10) related to the neighborhood area that represent the cycling routes and the major bus routes in the urban structure of the capital district have less total depth values (blue) that means that they have a small number of shortest angular paths connected within the walking distance mentioned above.

(2) The non residential land use planned in the neighborhood such as facilities for example: schools, mosques, healthcare, and open spaces are not always located near the public transportation stops. Knowing that riding bikes by the women is not popular because of a cultural issue, plus the hot climate represent constraints for cycling long distances.

(3) Only one major arterial entry boulevard and one collector have tram stops, which leave people with a long distance of walking. Furthermore, dedicated bike routes that are connected to the major arterial-entry boulevards, radial boulevards, central boulevards from one hand and to collector and collector-capital boulevard are the one with low value of total depth, which means that people will need more time to reach their destination, since they will take their bikes near by the trams and metro stations, and have to take a longer route. This does not promote the transit oriented model, at the contrary encourages the use of cars.

It is important to note here that 115.677 of the total expected daytime population and the 69.728 of the total residential population in the neighborhood precinct of the capital district (2) will circulate in and out in the neighborhood area. Hence, cycling routes have to be reconsidered and public transportations have to be integrated more in the neighborhood, in particular stations have to be planned near by the facilities at a optimum walking distance that is 5mn to 10mn. In this case, bus as a transportation mean will be a good

solution if extending trams and metro lines inside the neighborhood area is not possible for an economical or physical factors for example.

6 CONCLUSION

Depthmap by UCL was applied in this research and axial lines with an analysis of segment maps of the neighborhood area within the capital district, one of the most important district of the future development of Abu Dhabi was used together with land use maps, streets hierarchy and walking and cycling maps proposed in the 2030 master plan of Abu Dhabi of the urban spatial structure of the capital district designed by the Abu Dhabi Urban Planning Council in 2007. We used Axial map in order to check the integration and accessibility related to visibility of open spaces, facilities and roads within the whole urban system of the capital district and used the segment graphs for a detailed analysis at the level of streets.

We found out that that the proposed cycling and major bus routes and are planned far away from the facilities and open spaces that represent the major attraction points to the daytime population of the neighborhood which is planned as more than 100.000. The graphs showed that these routes have a small number of shortest path even walking 15mn, which does not help having a comfortable walk to optimize mobility and to raise the pedestrian movement growth all over the year and influence the livability of the city that is one of the goals of the future development of the city. Hence this part shall be reconsidered accordingly.

Encouraging walking and cycling under a hard climate such in the UAE cannot be made without providing climatic comfort, like cooling and shading through specific urban forms, good arrangement of buildings and open spaces, etc, and also urban scale street designs.

This paper presents a small part of a research that tries to cross three factors: 1) visibility of important buildings, open spaces, roads of the capital district, 2) buildings forms and arrangement and 3) the micro-climate, in order to propose kind of guidelines or orientations for land use, transportation planning, urban forms, etc which provides: 1) livable and pleasing walk paths in an optimum time to the city functions, 2) climatic comfort for pedestrian's walk, mainly shaded and ventilated streets and open spaces and 3) high visibility to landmarks, natural settings, national symbols and monuments, etc.

Even though this work focused on the neighborhood area of the capital district of the 2030 Abu Dhabi master plan due to lack of time, our target in further research is to conduct an analysis on the whole district including its 6 parts in order to study their interrelation and their integration in the whole system of the proposed urban structure of the capital district.

7 ACKNOWLEDGMENT

The author presents her thanks to Abu Dhabi Urban Planning Council which provided her with the data necessary to conduct this research and also to the Abu Dhabi University which funded this research and the author's participation to the REAL CORP 2012 conference.

Wayfinding Performance of Visually Impaired Pedestrians in an Urban Area

Aida E. Afrooz, Toktam Hanaee, Bruno Parolin

1 ABSTRACT

Movement from an origin to a destination within a city is an inevitable activity for all inhabitants, especially for those who are commuters. For the visually impaired, this movement task is a difficult activity, given inability to use visual properties and hence reliance on hearing and smell for navigation. This study seeks to determine the type of information that is acquired by the visually impaired to navigate from an origin to a destination. In essence the study is attempting to determine the wayfinding process in familiar environments among the visually impaired. An experiment with 12 totally visually impaired and 12 partially visually impaired students was conducted in Mashhad city. Our method is based on an analysis of wayfinding from a school for the visually impaired to a familiar destination in the urban area of the city. Questionnaire survey methods were used to determine reference points, which senses (hearing, touch, smell) were used and problems experienced in reaching the destination by walking. The key findings show that there are differences between the two groups in terms of their use of reference points, use of the senses and problems encountered on the wayfinding trip to the destination. The totally visually impaired displayed a reliance on touch, smell and hearing for gaining information from the environment, as opposed to the partially visually impaired who could rely on sight and other senses for their information. As a result of the study it is suggested that those who design aids for the visually impaired should have stronger experiences of the perceptions of the needs and problems encountered by the visually impaired during the wayfinding process. For urban planners and designers the results suggest the need for greater consideration of the problems and needs of the visually impaired in terms of street layout and pattern, pavement slope and material, and safety and security.

2 INTRODUCTION

Finding one‘s way is a significant task for individuals engaged in daily activities. However, being oriented in a place with regard to objects and knowing where to go next, and ultimately how to return, is a main concern for inhabitants and, in particular, the visually impaired. Orientation refers to an individual’s awareness of his/her position in the environment by maintaining the relationship to other objects (Hersh and Johnson, 2008). Sighted people in an airport would be aware of their position at that moment, similarly for the visually impaired who can hear the verbal announcement of the flights. But what about being in a large public space where there are no verbal announcements for blind users. Lack of information for the visually impaired about the potential to encounter different temporary obstacles or hazards, as well as deficiency in gaining information about distant landmarks, make wayfinding a serious problem for this target group (Loomis et al. 2001). This leads to not making independent journeys outside their neighborhood areas, or only to restricted or familiar areas (Clark-Carter, et. al, 1986).

The present study addresses path integration in a wayfinding process among a sample of blind and visually impaired students in a familiar area as regards both navigation-based and resource-based learning strategies. The questions the present study attempts to answer are whether blind and low-vision persons keep reference points in mind instead of visual cues, as opposed to those who are sighted. What are the characteristics of these reference points such as the type and frequency of usage of them among the blind and low-vision users separately? What sort of visual cues, if any, do low-vision students use? What are the other kinds of aids they may use? What is the dominant sense for the target group in deficiency of vision? How can street pattern influence the wayfinding process? And finally, how do blind students differ from low-vision students in their wayfinding process? To grasp the importance of information in visually impaired wayfinding, we hypothesize that one’s wayfinding process and, in particular, the reference points that are used depend on his/her ability of vision. In other words, if the user is visually impaired (either blind or low-vision), then reference points are used to obtain information in familiar environments. Accordingly, the main hypothesis could break down to a sub-hypothesis; if the user is blind, then the dominant sense is to rely on familiar

urban areas as a tactile experience. If the user is low-vision impaired, then visual cues similar to those used by sighted people are used for wayfinding. If the user is visually impaired, we argue that the grid street pattern is clearer and more legible for him/her in their wayfinding process. To test the hypotheses, we surveyed visually impaired students in a setting with which they are familiar in terms of the variety of landmarks and where they have a higher likelihood of using different senses. Furthermore, we clarify some definitions and related theories in wayfinding performance. In section 4, visual characteristics of the study area and respondents are presented. The relationship between reference points, familiarity, street layout and, ultimately, the problems encountered in the area are categorized in Section 5. The final section provides conclusions and directions for future work.

3 LITERATURE REVIEW

3.1 Wayfinding concepts

Wayfinding is the ability of travelling between locations either with an internal or external map of the environment (Kalia, 2009) as purposeful and directed movement from an origin to a specific distant destination (Allen (1999) and Golledge, 1999). Such behavior involve interactions between the traveler and the environment (Raubal, 2001). Further, wayfinding is a behavior (Bechtel and Churchman, 2002, p, 427) which cannot be successful unless you know where you are, know your destination and follow the best route to your destination, recognizing your destination and finally being able to find your way back (Carpman and Grant 1993). Thus, it is the process of collecting information from our built environment, to know where we are related to where we want to go and how to get there (Woyciechowicz and Shliselberg, 2005). In addition, wayfinding is one aspect of people's cognitive map knowledge which includes all aspects of encoding, processing, and gaining information about the environment (Blades et. al. 2002). Basically, two components of wayfinding are movement and decision-making (Xia et. al, 2008). Seamless integration of movement, perception and memory are required for successful wayfinding (Kalia, 2009). Indeed, path integration - obtaining information while walking- is one source of information for humans which assist them in determining their location in urban areas (Kalia 2009). Thus, wayfinding, a cognitive process (Golledge, 1999), can be defined as spatial behavior (Julian, 2010) that involves the ability to learn a route and retrace it from memory (Blades et. al. 2002), to move from an origin to a destination while maintaining orientation in and around objects, people, and spaces.

3.2 Commuters and the level of familiarity with the environment

Wayfinding or being oriented within an urban area is an important task which involves interaction among people and the environment while undertaking daily activities. It is of high importance especially when travelers are commuters -those who travel back and forth on a regular basis- and require frequent navigation within cities. Commuting enables people to live in areas and work in a place spatially separated from their living places (Heinen et. al, 2011). This would increase their familiarity with the environment through which they are travelling as they regularly travel to and from a particular place. As familiarity with an environment increases, performance in wayfinding and spatial orientation tasks improves (O'Neill, 1992). Understanding and awareness of surroundings provides a sense of security for individuals (Kaplan, et. al, 1998 and Cutting, 1996). Therefore, users' feelings of safety follow from understanding a place, and familiarity, in turn, can increase this feeling. Commuters regularly follow the same order of routes or use the same reference points to recognize their ways. Nevertheless, people may choose different reference points, and landmarks may vary depending on the environment they are moving through (xia, et. al, 2008).

3.3 Reference points

According to Lynch (1960) inhabitants have a shared image of their resident area. A clear image of the city makes it possible for the users to navigate freely within urban areas. Familiarity with a neighborhood can be defined as having a "clear image". A clear image of the environment makes it possible for individuals to know the spatial position of places they are traveling through. Hong (2007) notes an interesting point on the five elements Lynch proposed- edges, nodes, landmarks, districts, paths. He stated that one similar function among all the five elements is geo-referencing. This indicates the role of image these elements have in a users' cognitive map to be utilized as a "reference point" (Hong, 2007). In other words, to have a clear image of the environment one requires knowing and storing the spatial relations among the five elements within an

urban area that is similar to the "anchor point" theory of Golledge (1999). "Anchor point" theory indicates spatial relations of landmarks, familiar districts and path segments as laying the foundation on which other information is anchored in cognitive maps. As an image develops based on a two-way process between man and environment (Lynch, 1960), it can be strengthened by either the perceiver to be retrained or the surrounding be reshaped. In addition, disorientation can take place when landmarks are unavailable (Dudchenko, 2010). But what if the user cannot see the surroundings properly?

3.4 Visually impaired and spatial information

Regardless of loss of vision or being visually impaired, obtaining information from the environment through which navigation is performed is important for commuters and would be a prerequisite for them. One needs to know the spatial relations between self and object as well as updating that to perform an efficient wayfinding (Turano et al. 2005). This information can be taken in two different ways, either from knowledge in the environment or knowledge in one's head (Raubal, 2001). Nonetheless, vision plays a primary role and provides plentiful information for helping the wayfinder to orient oneself in regard to spatial relations among objects. Previous studies on the visually impaired show that there are two main levels that the blind and visually impaired use to attain knowledge for orientation and mobility, namely perceptual and conceptual (Ungar et. al, 1996; Schloerb et. al, 2011). "Mobility" refers to being able to move from one point to another safely and efficiently (Hersh and Johnson, 2008). Hill and Ponder (1976) define it as the capacity to move, the readiness and the facility to move. This will involve negotiating any obstacle in sidewalks which would be temporary or any unexpected change in direction. "Navigation"refers to travelling from one place to another by using mobility skills while keeping oriented in relation to the purposeful course (Hersh and Johnson, 2008). At the perceptual level, other senses perceive information due to lack of vision or certain ability to overcome the impairment in the best way (Schloerb et. al, 2011; Goldstein 1999). The conceptual level focuses on developing strategies for mapping of space and generating an orientation path (Schloerb et. al, 2011). Furthermore, according to Hersh and Johnson (2008), and related studies, there are two perspectives for gaining spatial information; navigation-based learning and resource-based learning strategies. The difference between these two processes lies in experiencing the environment. Whereas in navigation-based learning the user experiences the environment directly, in resource-based learning information is acquired from diverse sources like TV, maps, asking others, or for the visually impaired from tactile maps, braille newspapers and so on. In spite of this, however, visually impaired users express their spatial knowledge differently in comparison to sighted people. As an example, Bradley and Dunlop (2003) stated that visually impaired provide more information while they were describing a path they have taken in comparison with sighted people. This difference in expression also differs among different visual impairments (ie. peripheral vision loss, central vision loss and so on) (Bradley and Dunlop, 2003 and 2004). Blind participants and central vision loss, for instance, asked more questions regarding steps, distance, and obstacles along their way in comparison with peripheral vision loss participants (Bradley and Dunlop, 2004).

To recapitulate, the present study addresses path integration regarding navigation-based learning and resource-based learning among a sample of visually impaired students at a perceptual level of orientation in a familiar urban area.

3.5 Street patterns

Zannaras (1976) suggested that city structure has an important role in urban images. On the other hand, Appleyard (1970) and Lynch (1960) declared paths as the main elements and organizer of a city. A street pattern has diverse forms and varies from star-like, linear, circular, treelike, radial, grid to an irregular pattern (Heinzle et. al 2006, Marshall 2005, Zhang, 2004,). A grid pattern makes the block similar and Hall & Poterfield (2001) stated that a feature of the grid network that makes it successful is the predictability of intersections. They noted this feature as providing cues and reference points for users in wayfinding processes. From an urban planning view point, the grid layout provides permeability in addition to preventing rotating districts (Design guide, 2005). The grid pattern has some privileges as it is also characterized by highly connected streets with shorter distances, and more route choices (Southworth and Ben-Joseph, 2004).

4 DATA AND METHODS

In Iran unlike many other countries (e.g. Finland) visually impaired children without additional handicaps are educated in special schools distinctively designed for them. The respondents in the present study are students from such a school - a school for the visually impaired. The selected study area (Fig. 1) includes the educational area of a visually impaired high school in Mashhad City. The setting encompasses the school as the central focus, and approximately 500 meters away from the school is a well-known intersection named "Faramarz Intersection" (Fig. 2). There are three strip malls close to the intersection in addition to a clinic, two banks and several retail shops such as a bakery, fruit shop and supermarkets. In general, medium-income citizens are living in Faramarz district.

Fig. 1: The setting

Fig. 2: Reference Points

The street pattern in the surrounding area of the school is a typical rectangular street in a "grid-like" pattern which is converted to cul-de-sacs for vehicles. This pattern supports row houses and low-rise apartments in the Faramarz district. Faramarz Boulevard functions as a "Connector"route type, which is a main road in a connective grid network of the district that brings the stream of traffic in a hierarchy from the "cul-de-sacs" and "spines" to the "Fredosi Arterial Collector" (Fig. 1). Thus, the area consists of similar blocks and intersections. The education area is approximately one hectare which includes two schools for girls and boys, with separate dormitory facilities for those who come from rural areas or the suburbs.

4.1 Respondents and procedure

The survey's target participants were students in the Blind and Low Vision school of "Taghva" and "Omid "- two high schools for visually impaired students for females and males respectively. A group of twelve 15 to 18 year old girls and an equal number of boys within the same age range were selected for the study. Half the students from each group were totally blind and the others were low-vision impaired (N=12 blind, N=12 low sighted). All respondents were asked to come to the school library individually and answer a questionnaire survey. It was conducted in Persian and divided into 4 parts; selected socio-economic characteristics (age, gender and education), questions regarding landmarks or reference point for the target group, questions regarding wayfinding performance which, in turn, consisted of questions based on path preferences and their behavior in a new environment as well as finding their way in difficult situations without any aids and, finally, questions about the use of their senses to figure out how they are performing wayfinding given their deficiency of vision. A pilot survey was initially undertaken at the same schools to better develop the questionnaire survey. Having completed the interviews, the researchers took photos of the reference points that respondents mentioned and then categorized these with respect to height, color, and function.

Gender	Visual impairment	Frequency	Age		Years of Education		Years of blindness	
			Mean	Age	Mean	School level	Mean	Years(min-max)
Female	Blind	6	18	15-21	3.2	1-4	7.35	0[1]-21
	Low-vision	6	16.5	14-19	2.8	1-4	12.25	10-19
Male	Blind	6	18.5	15-22	3.5	1-4	6.5	0-22
	Low-vision	6	17.5	15-20	3.1	1-4	14.30	13-20

Table 1: Characteristics of respondents

Table 1 shows the characteristics of sample respondents. A diverse group of blind and low-vision sample respondents allow us to investigate hypotheses regarding relationships between visual impairment and reference points as well as the utilization of different senses. The average age of the sample is similar with a mean age of 17.6, as is the frequency of male and female visual impairments. Sample respondents were fairly homogeneous with respect to age and education. For example, they were all high school students from level one to four and the mean school level was 3.1 which indicates most of them were in their third year of high school. Years of blindness depicts the minimum and maximum years that respondents have suffered visual impairments. It varies from birth to four years for the female low-vision students and from birth to two years for the male low-vision students. For the blind respondents visual disability mainly appeared after birth.

5 RESULTS

This section describes the relationships among reference points, street layout and familiarity revealed by the sample of blind and visually impaired students. We find that the level of visual impairment among the sample, plus previous familiarity with the setting, generates differences in how they behave and perform wayfinding in an urban environment. Descriptive statistics (Chi-Square and Cramer's V) are used to test for association and correlation on predominantly categorical data.

5.1 Reference points

There were several reference points that the visually impaired sample students utilized, and were presented to them as visual cues in wayfinding performance including a Braille pavement, bakery, strip Mall, supermarket and fruit shop, bank, and finally school walls (table 2). We note here that the sidewalk in Faramarz Street is facilitated with the Braille pavement from the intersection to both "Taghva" and "Omid" schools. Interestingly, the reference points differ in how they are used by blind or low-vision students. Around 67% of low-vision students indicated the "Braille Pavement" as a reference point in comparison with the blind students (33.3%). However, the blind students, and most of the low-vision students, preferred not to walk on the "Braille Pavement" because of the uncomfortable feeling that it generated as a result of harsh materials and breaks and bumps on the surface. The smell (aroma) emanating from a bakery was one of the main guides for students, particularly for the blind students (60%). Strip malls (8.3%), the supermarket (12.5%) and school walls (12.5%) were other cues for both groups. Approximately 67% of the blind students, in comparison with the low-vision sample, made use of the school walls by touching them when

[1] (0) denotes being blind from birth.

Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

getting closer to their school. They find it different from other walls due to the painting on the wall that makes the brick walls become smooth and even; therefore, they used tactile senses (Fig. 1). Among all the elements mentioned by the student sample, the "Bank" was one of the main landmarks they indicated (25% of blind and 41.7% of low-vision students) followed by the bakery, Braille pavement, supermarket, and school walls. ATM's were also a reference point for them particularly for the low-vision sample as they stated that the queue of people is a clue for them. It is also worth noting that the "Bakery" and "Bank" were cues mentioned by about half (50%) of the blind student sample, this was followed by the supermarket and school walls. It appears from the data that the reference points the target group can use to pinpoint their location in the urban area are more related to senses other than vision. Even though low-vision students named banks (41.7%) as cues, (which have different forms and functions in comparison to residential buildings that can be distinctive for them), they rely more on hearing people's sound. In other words, it is not the façade or the shape of the building that is functioning as a clue for them but the sound of crowds of passing people or people passing along commercial buildings such as the strip malls.

Our data highlights a significant finding - while all the blind respondents find using the Braille pavement helpful, most of the low-vision respondents (66.7%) did not find it practical. Further analysis shows that they prefer to have different colours on the pavement to help them get around the city. Some visual impairment leads to not being able to see some colors like white and gray. Thus, respondents made requests for the use of colors in urban areas; for example, at stairs to guide them to find out where the steps are. This suggests the use of suitable colors in walkways to be used as a guide for the visually impaired. Colour should be distinguishable even in the high light at noon or the lower light during night time. Therefore, this would require the sidewalks to have a high contrast with the environment and background, and indeed avoid using colours that are not suitable for color blind people. The most common type of colour blindness is "red-green" such that dark green, for instance, may appear black to them (Hersh and Johnson, 2008).

The respondents were asked to describe what they imagine in the selected study area around their school to focus on the cues they utilize as reference points for their wayfinding. The researchers categorized the elements indicated by respondents in terms of frequency and types (table 3). Among all the respondents 75% named "Hatami primary school" and "street trees" in Faramarz Avenue. "Hatami School" is a primary school located close to the "Taghva" and "Omid" school (Fig. 2). Almost half of both blind and low-vision respondents mentioned "Hatami School" because of the sounds of playing at school in the morning before entering the school, or at noon when they are going back home. Another obvious element for the respondents was street trees. Faramarz Avenue is green with trees on both sides of the street as well as the middle island (Fig.1). Trees, in general, are ideal elements for the target group.

They can feel the freshness and smell of trees or grass and enjoy walking in walkways equipped with green facilities. People waiting in line at a bus stop are another cue for the low-vision respondents in the area surrounding their school. In addition, they experienced other alternative cues like the bleeping sound at pedestrian crossing walkways which inform them of safety to cross the street (Fig. 2). This suggests that this target group should be equipped with devices focusing on the hearing sense. On balance, an urban area should also have a plentiful distribution of green facilities for the target group. There are two major reasons for this; first, the good feeling they get while walking along a green walkway results in a sense of security, and second; green facilities function as an insulator of sounds from vehicles and according to what the respondents stated, they get confused in a busy area full of vehicle noises and cannot continue walking.

What are the reference points you keep in mind when finding your way between Faramarz junction and the school?			
	Blind (%)	Low-vision (%)	Total (%)
Braille pavement	33.3[2] - 8.3	66.7 - 16.7	100 - 12.5
Bakery	60 - 25	40 - 16.7	100 - 20.8
Strip Mall	50 - 8.3	50 - 8.3	100 - 8.3
Supermarket	66.7 - 16.7	33.3 - 8.3	100 - 12.5
Bank/ATM	37.5 - 25	62.5 - 41.7	100 - 33.3
School walls	66.7 - 16.7	33.3 - 8.3	100 - 12.5

Table 2: Landmarks and reference points

[2] Note: The first percentage value represents the row percent; the second percentage value represents the column percent.

Describe your imagination during your way when finding your way between Faramarz junction and the school?			
	Blind (%)	Low-vision (%)	Total (%)
Park	66.7 - 16.7	33.3 - 8.3	100 - 12.5
Shops	100 - 8.3		100 - 4.2
Hatami School	44.4 - 33.3	55.6 - 41.7	100 - 37.5
People waiting at bus stop		100 - 16.7	100 - 8.3
Street trees in Faramarz st.	55.6 - 41.7	44.4 - 33.3	100 - 37.5

Table 3: Cues utilised as main reference points

Table 4 highlights that bus stops (50%) and counting junctions (33.3%) as a cue for the blind respondents in contrast to high buildings (41.7%) and shops (50%) for the low-vision respondents. It is significant that the blind student respondents rely on cues that are more related to other senses like hearing the sound of people waiting in line for the bus as opposed to low-vision student respondents who try to rely on their vision but also need to use other senses. As an example, low-vision student respondents were not able to see the height of buildings but they can see the buildings shadow and felt cool in the shade. In addition they heard about the specific strip mall, for instance, that is located close to the intersection. So they knew the approximate location of some buildings. Most of the respondents, whether blind or low-vision, had some familiarity with different buildings, besides residential ones, in the area as their friends or parents accompanied them only for the first or second trips there. Most were afraid of entering a new area and heavily rely on their parents for describing the area to them as part of their first timid steps in visiting a new environment. Gradually they try to understand the whole area but still do not have the confidence to perform an individual trip. Although gender differences are not a focus of this study, it is likely that the fear of entering a new area decreases more among boys as they have more confidence in exploring new areas.

Which factors help you more to find your way?			
	Blind (%)	Low-vision (%)	Total (%)
High buildings		100 - 41.7	100 - 20.8
Bus stop	85.7 - 50	14.3 - 8.3	100 - 29.2
Counting junctions	100 - 33.3		100 - 16.7
Shops	25 - 16.7	75 - 50	100 - 33.3

Table 4: Factors that assist in wayfinding

5.2 Wayfinding process

A chi-square test was performed to find the relationship between being blind or low-vision and the approach respondents would take to find their way when they get lost. In order to reduce the options for the question of "How would you find your way when you get lost?" there was a pre-test which summarized responses into the two categories - "asking residents" and "keeping in mind some elements as clues". As highlighted in Table 5 the chi-square value is 6.171 with p-value of 0.018; this implies a statistically significant relationship between the two groups we are comparing. Those with total blindness are being used to asking residents in these situations (83.3%) while different pattern is repeated for the low-vision students. Most of them try to keep in mind some landmarks or reference points as visual cues to assist them find their way (66.7%). The overall pattern seems being based on social matters. On the whole, it seems best that neither of the respondents want to ask others. They prefer to perform independent trip however, those who are blind got more stresses and cannot remind the clues they had previously used in such situations. Low-vision students seems to be more confident and try not to ask anybody but keep going to reach to their visual cues. Not using any devices like the white cane, has such drawbacks for them but calming down the car noises, utilizing suitable materials in the Braille pavement, using tactile graphics on walls, using reasonable size characters on the signs with high contrasts in colour would be definitely helpful for the target group.

How would you find your way when you get lost?			
	Blind (%)	Low-vision (%)	Total (%)
Ask residents	71.4 - 83.3	28.6 - 33.3	100 - 58.3
Keep in mind some elements	20 - 16.7	80 - 66.7	100 - 41.7

Table 5: Association between level of blindness and reference points to find the way

To be able to obtain the exact reference points used by the target group, other than understanding the differences in their wayfinding performance, we asked some similar questions but in a different way. For instance, in addition to the previous questions which were based on landmarks the following question was asked in another way to find out the cues they refer to (table 6). It is amazing that only 25% of the blind

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

respondents reported that they rely on the Braille Pavement; however, they all mentioned it as a practical and useful element in their wayfinding process. This finding suggest that the blind respondents do rely on the Braille pavement but they do not want others to believe they have a disability and are therefore inclined to be more independent. Table 6 reveals that the majority of respondents (87%) rely on their sense of hearing in getting closer to their school. This includes either the sounds of children playing or the pedestrian bridge beside the "Hatmai" primary school. The reason for mentioning the pedestrian bridge is that they hear people going up and down the bridge when they get closer to it.

How do you understand when you are getting closer or reaching to school?			
	Blind (%)	Low-vision (%)	Total (%)
Braille pavement	100 - 25		100 - 12.5
pedestrian bridge	50 - 25	50 - 25	100 - 25
children's noise in the Hatami school	40 - 50	60 - 75	100 - 62.5

5.3 Senses

To answer the question of which senses do the target group rely on with a deficiency of vision, some parallel questions were asked of the respondents. To figure out whether they use the sense of smell, all the respondents trust their sense of smell (100%). They recognize the bakery before passing it or the fruit shop and the flower shop as well. It is noteworthy to mention that these shops function as cues for them in their trips as being commuters. The two principal factors the target group realizes by entering an open space or intersection in the city are the sound of a crowd sound and the noise of vehicles, and at the same time feeling a vacant or open space (table 7).

Table 8 highlights that, among those who answered 'yes', the overwhelming majority are blind respondents who indicated that vehicle noise helps them in their wayfinding. Among those who answered 'no', the differences between the blind and low vision respondents are less marked. For these latter respondents, vehicle noise meant they were not able to concentrate as well on their current location and perform wayfinding within a busy environment. This was true among almost all the low-vision respondents (91.7%) and most of the blind respondents (66.7%). In contrast, these two target groups were satisfied with the crowd sounds 100% and 58.3% respectively (table 8). Crowd sounds would only become devastating for them when it becomes too high or noisy that would confuse them of understanding their spatial location. Otherwise, it helps them understanding where the others are to make decision of what space it would be (i.e. for example, whether they are passing a mall or it is a school they are passing).

How do you understand when you reach a junction or an open space in the city?			
	Blind (%)	Low-vision (%)	Total (%)
noise of vehicles and the sound of a crowd	54.5 - 50	45.5 - 41.7	100 - 45.8
feel a vacant and open space	46.2 - 50	53.8 - 58.3	100 -54.2

Table 7: Reliance on sense of hearing

Do noises from vehicles and the sound from crowds help you in wayfinding?						
	Blind (%)		Low-vision (%)		Total (%)	
	Vehicles noise	Crowd sound	Vehicles noise	Crowd sound	Vehicles noise	Crowd sound
Yes	80 - 33.3	63.2 - 100	20 - 8.3	36.8 - 58.3	100 - 20.8	100 - 79.2
No	42.1 - 66.7		57.9 - 91.7	100 - 41.7	100 - 79.2	100 - 20.8

Table 8: Use of vehicle noise and crowd sound in wayfinding

To sum up, hearing is a sense that a sizeable proportion of the respondents get help from. It follows that devices which make use of hearing sense would be ideal for these respondents; however, we did not test different devices on respondents, that is the subject of a future study.

5.4 Problems

Table 9 illustrates the problems that blind and low-vision student respondents have in the selected study area. A comparison between the two groups indicates that the blind generally feel unsafe and did not find the walkway to be of good quality. Unevenness, inundations and steps of pathways were three often mentioned problems (most of these are due to poor maintenance). On the other hand, low-vision respondents, in most cases, were not satisfied with signage (83%) and barrels on the pedestrian walkways (67%). The problems encountered by the low-vision respondents were the result unexpected and temporary obstacles on the sidewalk such as temporary digging for water pipes or even cars that are parked in front of houses. They

indicated that they are afraid of not recognizing these obstacles or of colliding with them while walking as part of the wayfinding process. Generally, the blind student respondents require a flat sidewalk while low-vision respondents have a need for special signage with larger letters and suitable colors to be placed in advance of the obstacles. Further, the visually impaired respondents indicated that they do not intend to use any aids such as a white cane, thereby enabling them to be just like other pedestrians. The absence of a cane means they are not recognized as being visually impaired. However, non use of a cane can become a high risk for this group when they are crossing streets.

What problems do you have on pedestrian pathways?			
	Blind (%)	Low-vision (%)	Total (%)
unsuitable walkway	72.7 - 66.7	27.3 - 25	100 - 45.8
barrels on the pedestrian pathways	33.3 - 16.7	66.7 - 33.3	100 - 25
unsafely	100 - 8.3		100 - 4.2
lack of suitable signage for visually impaired	16.7 - 8.3	83.3 - 41.7	100 - 25

Table 9: Visually impaired and problems encountered on pedestrian pathways

5.5 Street pattern

With regard to street pattern most of the respondents prefer to pass through straight streets (table 10). A grid pattern or straight street pattern is generally a much easier pattern to learn and experience; however, the low vision respondents in particular seem to like to walk through curvilinear paths, thereby adding an element of mystery and exploration (of diverse alleys) to the wayfinding process.

Do you prefer to walk through a curvilinear path or a straight one?			
	Blind (%)	Low-vision (%)	Total (%)
curvilinear	20 - 8.3	80 - 33.3	100 - 20.8
straight	57.9 - 91.7	42.1 - 66.7	100 - 79.2

Table 10: Visual impairment and path preference

We used Cramer's V test to indicate if there is a relationship between the level of disability of visually impaired (blindness or low-vision) respondents and taking the same or different path. The test statistic for Cramer's V is 0.458 with a p-value of 0.025. In other words, being blind or of low-vision has an effect on choosing the same or different path. Table 11 indicates that a high proportion of blind student (92%) respondents always use the same path while is the reverse tends to be true for low-vision respondents. Half of the low-vision students take either of the paths; however, compared with the blind students almost 86% of the low-vision students take a different path in going to and returning from the school.

Do you prefer to walk through a different path or the same path?			
	Blind (%)	Low-vision (%)	Total (%)
same	64.7 - 91.7	35.3 - 50	100 -70.8
different	14.3 - 8.3	85.7 - 50	100 - 29.2

Table 11: Visual impairment and path preference

6 CONCLUSION

This study underscores the relationships between visual impairment- being either blind or low-vision- and the reference points the target group utilizes in comparison with the visual cues used by people with sight. The reference points the target group have utilized in our study –bakery, diverse retail shops like the flower shop or fruit shops, ATM's, "Hatami" school, street trees, school wall, pedestrian bridge, and the Braille pavement- were all related to those senses other than that of vision. Low-vision student respondents and showed similarity to the blind respondents in selecting some common cues such as the bakery, flower shop, crowd noise, street trees, and "Hatami" school. Moreover, the principal sense that both groups relied on was hearing. The sense of hearing was the principal sense they utilized and this is in contrast to our hypothesis that the sense of touch would be predominantly used. Further, smell emanating from particular shops such as the bakery and flower shop proved very practical in guiding them to understand their current position in relation to other elements in the area. It can be concluded that wayfinding aids for the visually impaired were based primarily on reference points that one can hear such as the cluster of people at a mall, and in some cases smell such as that emanating from a bakery.

Our findings suggest enhancements to the quality of life of the target group in the selected study area regarding reference points they gain information from to continue their walking and wayfinding. One immediate outcome is the need to insulate walkways with green facilities to reduce the problem of noise.

Sound-proof green facilities allow the target group to be relaxed as well as to feel safe while concentrating on their walking. In terms of street pattern, the target group indicated they were afraid of exploring curvilinear paths even though some of them, particularly among the low-vision student respondents- were inclined to experience different paths. Based on this finding, one suggestion is for city planning officials to avoid designing complicated curvilinear paths, especially in areas which are likely to be used by the visually impaired.

6.1 Future works

This paper serves to assist those who design aids for the visually impaired to understand their behavior in the simple case of a familiar environment. They can plan for methods to be utilized that make use of the dominant sense of hearing to assist the visually impaired in their daily trips and in experiencing new environments. Future study will need to focus on diverse tools the target group could use to support their movement in unfamiliar settings. More research is required on signage -size and characters– and considerations for the color-blind and various low-vision users. Urban Planners and designers should consider the needs of the target group in performing not only daily trips but also exploring new settings through facilitating walkways free from unexpected obstacles or barrels. Designers should consider the size and color of the signage for low-vision or color blind pedestrians.

7 ACKNOWLEDGEMENT

Thanks are extended to Dr Rahman Tafahomi for his feedback on the questionnaire survey and referee letter to the schools. Finally, the authors thanks “Taghva” and “Omid” school managers and survey respondents for their participation in the study.

Without Planning? Incremental Emergence of High Density Mixed Use Centres in Mega Manila

Stefan Rau, Art Corpuz

(Dipl.-Ing Stefan Rau, Manila/Shanghai, stefanrau@metrosynergies.com)
(Dr. Art Corpuz, Manila, corpuz.art@ayalaland.com.ph)

1 SUMMARY: EMERGENCE OF MULTI-TIERED POLY-CENTRAL AGGLOMERATION BY MARKET FORCES

Regional Growth patterns. Metro-Manila, also referred to as the National Capital Region (NCR) of the Philippines, is composed of 16 cities and one municipality and is home to about 12 million residents. The conurbation Mega-Manila includes Metro-Manila and several provinces in its periphery. It has been the traditional focus of the national economy and is continuing to grow beyond 26 million, more than one fourth of the country's population. Its recent spatial development patterns can be described as: 1. Expansion at the peripheries mainly north and south due to topographical context, 2. Growth of higher density areas from the core out into the region and increases in densities of centre cities 3. Growth of regional cities skewed towards the direction of Manila, 4. Land use segregation and primarily horizontal developments at the periphery - but notably with heightened densities for the various typologies, 5. Expansion of urban centres with increasing compactness, densities and land use mix, 6. Emerging new centres and centre clusters at locations with preferential access. (For 1-3 compare: Corpuz, Art 2010).

New, distributed compactness. Urban centres are increasing in density and expanding geographically, and high-density integrated clusters are starting to develop at transit stations. Pedestrian circulation and the acceptance of public transit, especially of the younger middle class, are increasingly significant. Despite high temperatures and tropical rains, outdoor activities for public gatherings, festivals, markets, concerts and daily activities such as al-fresco dining, taking a stroll along a shopping street and a park, children's play in parks and playgrounds, jogging etc. are becoming more visible. This seems true for all strata of the broad low-middle-high middle class and has a tangible impact on the urban environment. Commercial, entertainment areas and malls are starting to add multi-level outdoor spaces, plazas and pedestrian streets and landscaped sidewalks with shops at ground floor levels. The desire to live in these mixed use centres, being able to avoid traffic congestion, as well as a new young middle class that can afford small condominium units and investments by overseas workers are drivers of residential high-rise and integrated developments.

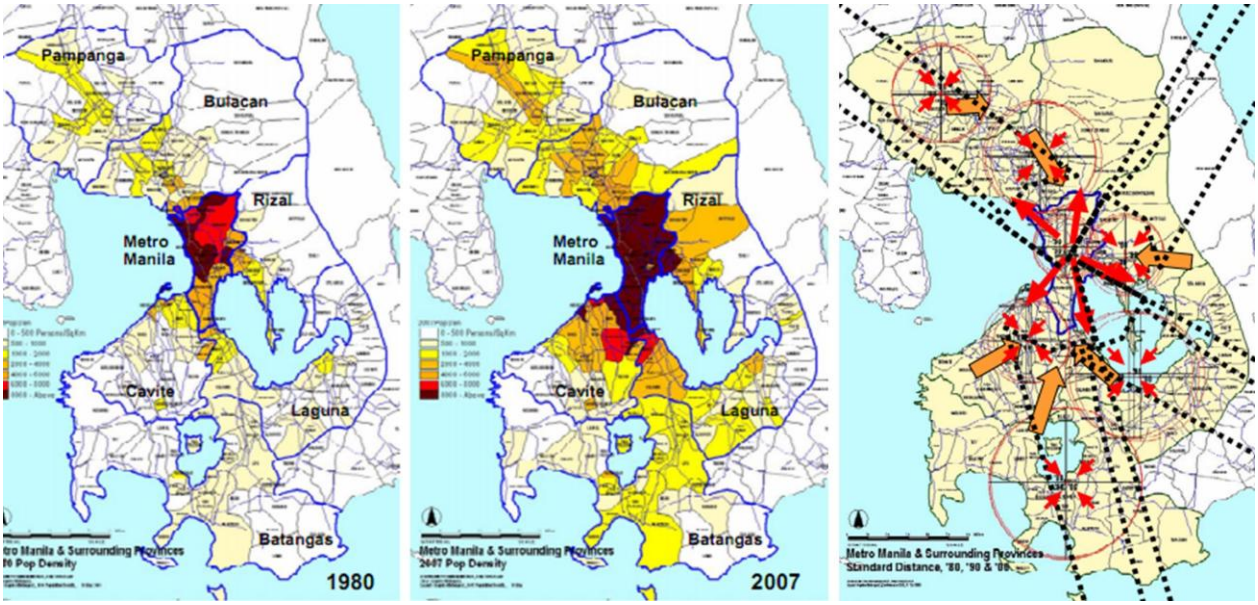

Image 1: Mega Manila population density and spatial development trends. Source: Corpuz, Art 2010.

A multi-tiered, poly-central region is emerging one could almost say 'naturally' following market demand. This appears consistent with a more compact and eco-efficient land use pattern. Market forces, however, inefficient, seem to be the primary driver with private sector initiatives guiding as well as following lifestyle preferences in their competition to attract customers. Although individual city and land use plans exist, formal, institutionalized planning seems to play a marginal role due to a weakness of implementation as well

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

as the lack of an effective metrowide plan. But there appears to be a renewed recognition for inter-municipal coordination e.g. the recently announced Metro-Manila Greenprint 2030 initiative in March 2012. Metro Manila and its surrounding provinces continue to face many pressing problems (e.g. traffic congestion; lack of affordable housing, open space and recreational areas; increasing risk from natural and man-made disasters; poor air quality). But thepotential for more active and purposeful planning to guide and support current development trends and opportunities is increasing even as it remains unfulfilled.

2 PLANNING SYSTEM: DEVOLUTION VERSUS CENTRALIZATION, PLANNING VERSUS IMPLEMENTATION

Devolution following centralization. To understand why governmental, institutionalized planning at the regional level is relatively weak, one must understand a basic aspect of administrative culture and look at a specific piece of history following the ouster of former President Marcos in 1986. The landmark Local Government Code of 1991 devolved administrative powers to local government units. That included selected tax resources and responsibilities for providing a defined set of comprehensive services to the local community. The result has been unprecedented local autonomy, particularly for cities and municipalities, at the expense of metropolitan and regional institutions. The benefits accruing from local autonomy are clear—including greater local participation and stewardship and potential for bottom up innovation—although it has also led to a fragmented planning and governance structure to the extent that a federal system has been proposed as an intermediate level to overcome the challenges that have risen from devolution.

Barangays. Below the city level and sometimes only a few blocks in size, is the Barangay level, which can translate into the local village or neighbourhood level. Barangay administrative authority is limited to its relatively small area of jurisdiction but its leaders (Barangay Captains) can sometimes wield significant political power especially if they are closely allied with the City or Municipal Mayor. In some cases this leads to fragmentation of planning and implementation, which tend to fall along local political alliances and corresponding decision making processes.

Cities/Municipalities. Formal planning authority, particularly land use planning and zoning, lies with cities and municipalities. Local plans are ratified by provincial and regional committees and in some cases the national level Housing and Land Use Regulatory Board, but as a whole, cities and municipalities enjoy substantial autonomy in local governance and planning. Nonetheless, local land use and development plans appear to have had limited impact on development. Only a minority of plan, projects and activities identified in local plans (about 15%-30% according to one provincial level study) have been budgeted and implemented. And the key contstraints relate to inconsistent planning practices and processes, lack of enforcement and political interference. Typically, the weak planning and implementation role of government has allowed private developers, especially those with relatively large landholdings, to drive urban growth trends and directions with their large scale developments. These include the provision of public transportation and other infrastucture, land use management, and other quasi-public services.

Metro- /Mega-Manila. One of the major casualties of local autonomy is the Metro Manila Development Authority (MMDA). Once at the leading edge of metro-level governance, planning and management (prior to the passage of the Local Government Code), the MMDA now has limited legislative and executive authority, with jurisdiction only with respect to a few metro-level concerns such as selective transportation management, waste management, flood control and a few other tasks. Current plans to extend two light rail lines and the addition of another line are in place but these are under the jurisdiction of national agencies (i.e. Departments of Transportation and Finance). No substantive strategy exists as far as the structure of Metro Manila is concerned and it appears that without further major intervention, it will develop according to the incremental impacts of various uncoordinated and separate sectoral investments (i.e. public works, transportation and communication, tourism, etc.) driven by national level agencies and the private sector. Mega Manila, meanwhile, has no formal status and authority or organizational body and is used solely for statistical purposes and planning considerations.

Provinces and Regions. Formal planning exists at the provincial, regional and national levels. The National Economic and Development Authority (NEDA) is responsible for making long and medium term national development plans and, through their regional development offices and councils, regional development plans. Each of the 14 regions of the country includes clusters of the provinces. Regional councils are

administrative and planning organizations without political mandates and are governed by representatives of local governments and national agencies, with the regional NEDA office serving as technical secretariat.

Mega-regions. Like other administrative regions, Regions 3 and 4 have their own regional development plans and each of their component provinces have provincial development plans. Because Regions 3 and 4 surround Metro Manila, they are collectively referred to as "Metro- Luzon"--one of four so-called Mega-regions in the country. Metro Luzon forms the economic core of the country, accounting for the bulk of national economic output. Metro Luzon is used only for planning and statistical purposes, primarily by NEDA.

Opportunity of alliances for planning? It seems that key challenges for Metro and Mega Manila are the coordination of fragmented plans of their constituent local governments and with implementation. Many local government units have limited financial resources to provide for relevant infrastructure. At the regional and national levels, enforcement of regulations, successful financing mechanisms, implementation of plans and cohesive decision-making through the various administrative levels and lining up budgets and financing of projects following integrated plans is severely constrained. And yet despite these challenges, there is a discernible trend within Mega Manila towards a consolidation of a multi-tiered spatial structure with higher densities, compact centres and public transit links. If inter-municipal cooperation as well as coordination among large private sector players and involved institutionals can be organized effectively, then the opportunities to build on and enhance this trend through more efficient planning, financing, implementation and enforcement are likely to produce even much greater results.

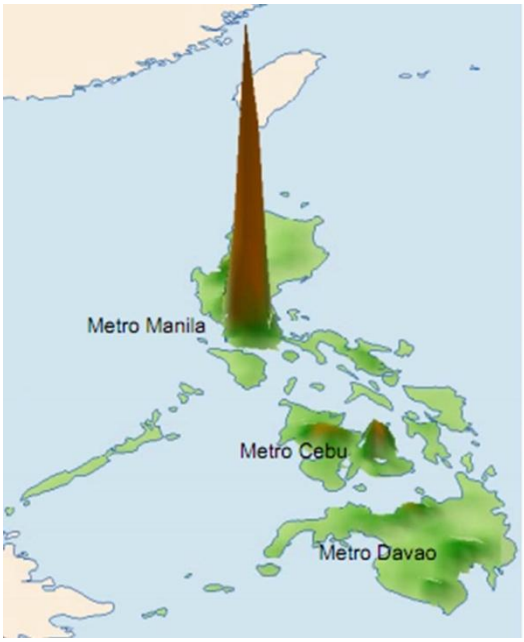
3 CONTINUED GROWTH OF METRO- AND MEGA-MANILA AND METRO-LUZON: THE NATION'S FOCUS

Economic growth. Following the Asian crises in 1997 the Philippine economy has fully recovered and grows at a rate of 4%-7% annually. Selected sectors are driving the country's income namely BPO (business process outsourcing often referred to as call-centres), manufacturing of consumer electronics for export, tourism, mining, agriculture, furniture, trade, logistics. Also the growing number of Overseas Filipino Workers (OFWs) and their remittances to their families have become a significant contributing factor to the national economy and domestic consumption. All these promote urban development and, in particular, the real estate business industry in the capital region.

Concentration of economy in Manila Region. Most of the economic activities continue to locate in the larger Manila region creating jobs and attracting new residents. One third of the country's GDP is generated in Metro-Manila, even more than one half in Metro-Luzon and 26% of the 102 million Filipino population reside in Mega-Manila. This trend allows for a regional economy of significant scale with synergies and efficiencies as various economic sectors cluster in this region. The flip-side is that such concentration

burdens technical and transportation infrastructure as well as the integrity of the physical environment. Social disparity and spatial polarizations are also more apparent. These are severe challenges which require solutions at the regional and local levels.



Region	Population Density (persons/sq km)			GDP at current prices (in million pesos)	
	2007	2000	% Increase	2006 1/	2000

4 SPATIAL DEVELOPMENT AND LOCATION PATTERNS IN METRO MANILA: DENSER, HIGHER AND MORE MIXED IN THE CORE

Expansion with higher densities and centre-clusters at the periphery. Compared to previous peripheral developments in the region, recent growth at the fringes are of higher densities. Even with single family subdivisions, lots tend to be smaller and thus lead to higher density developments. Mid-rise and in some cases even high-rise residential and office developments are now visible in new clusters at the periphery, e.g. the consolidation of Alabang Town Center in Muntinlupa City as it expands as a commercial and business centre with some high-rise office and housing. The average density of Metro Manila is about 20,000 people per square kilometer and some of the higher density core areas are twice to three times this level.

Expansion, densification and completed mix in existing centers. Mature centres, including the largest in the country (Makati and Ortigas) as well as others such as Binondo (Chinatown), Ermita/Malate etc, are likewise evolving with new developments that have a wider mix of uses (residential condominiums, offices, hotels, and entertainment and cultural facilities), higher densities (due to the continuous appreciation of land values) resulting in more compact urban forms.

New centre-clusters in the region's core at transit stations. High density mixed use clusters are emerging along the main arterial corridors of Metro Manila especially the ring roads EDSA and C5 and in proximity to transit stations. Typically developed with high-rise condominiums and shopping malls, these clusters are also attracting high-rise offices mostly catering to the BPO industry and leisure facilities. Examples are Pioneer Highlands, East Avenue Station, Magallanes Station and the Taft Avenue Corridor along the LRT2 line.

Limitations of transport and transit lead to constraints of centre locations. The current public transit system falls short of Metro Manila's requirements. Plans and budgets for two LRT line extensions are currently being worked out. This is a good start, but significantly more rail-based transit as well as BRT are needed, along with more effective management of other public and semi-public transportation services such as buses, minibuses ("jeepneys"), and tricycles. The demand for more transit lines is likely to increase, especially if traffic congestion worsens but even at current growth levels.

Image 4: Metro Manila Transit: One MRT, two LRT and two regional rail lines. Source: www.johomaps.com & www.urbanrail.net

5 MAIN DRIVERS FOR DENSITY AND COMPACTNESS: HIGH-RISE RESIDENTIAL AND OFFICE DEMAND

The overall economic growth the country has been experiencing over the past decade has accelerated activities in urban and real estate development and private investments.

Sectoral industry growth, especially the BPO industry, manufacturing of electronics for export, MICE, tourism and generally the service industry continues to create demand for space in various market segments:

- Demand for smaller condominium units by a growing young middle class with jobs in the BPO, manufacturing and services sectors.
- Demand for office space for BPO in lifestyle-themed places that are popular and accessible for young professionals; competition among BPO developers and locators have encouraged deconcentration even as the large metropolitan areas of Metro Manila and Cebu remain the preferred cities of address because of the availability of higher level services and transportation infrastructure.
- Demand for hotel rooms for a growing number of business travellers, MICE participants to Manila as well as recreational tourists visiting the country's abundant and picturesque beach destinations.
- Demand for retail, f&b and entertainment space mostly in integrated locations with higher densities.

OFWs have been sending remittances to their families at home, enhancing purchasing power for commodities and real estate products; Many OFWs directly invest in condominiums preferably in high rise mixed use developments similar to those in the foreign countries where they work.

With savings and cash reserves increasing, well to-do families are buying luxury condominiums in premium locations as investments in light of property price appreciation as well as to add to their personal portfolios a downtown residence in parallel to suburban single family residences.

6 EMERGING MULTI-TIERED CENTRES STRUCTURE WITH NEW TRANSIT ORIENTED CLUSTERS IN METRO MANILA

A differentiated centres hierarchy is emerging in Metro Manila following the general trend of increasing densities. Noticeably, the importance and relative weights among centres are shifting according to incremental developments and expansion of the core areas.

At the top of the list are two CBDs that serve as the primary, national-level centres of business in the Philippines: Makati and Ortigas (1A and 1B, with an estimated 3.5 and 1.5 million office gross floor area, respectively). Both have experienced robust growth with Makati clearly leading in terms of quality and coherence of development as well as delivery of services. The "new star" rising among Manila's centres is Bonifacio Global City. This 340 hectare, master-planned mixed-use urban district was developed starting in the mid-1990s and is rapidly becoming the preferred business and residential address of the metropolis; it is

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

approximately 30% built-up and, because of its proximity to the Makati CBD, may be expected to merge with the Makati to form the largest CBD of the country. A few second tier centres like Binondo Manila's Chinatown and others are in the process of incremental redevelopment through private investors that have added high-rise residential and office developments and upgraded retail malls. A major question mark concerns the future of the large scale reclamation area in Manila Bay that started with much promise many years ago but remains at the functional fringe of the primary CBDs of Metro Manila.

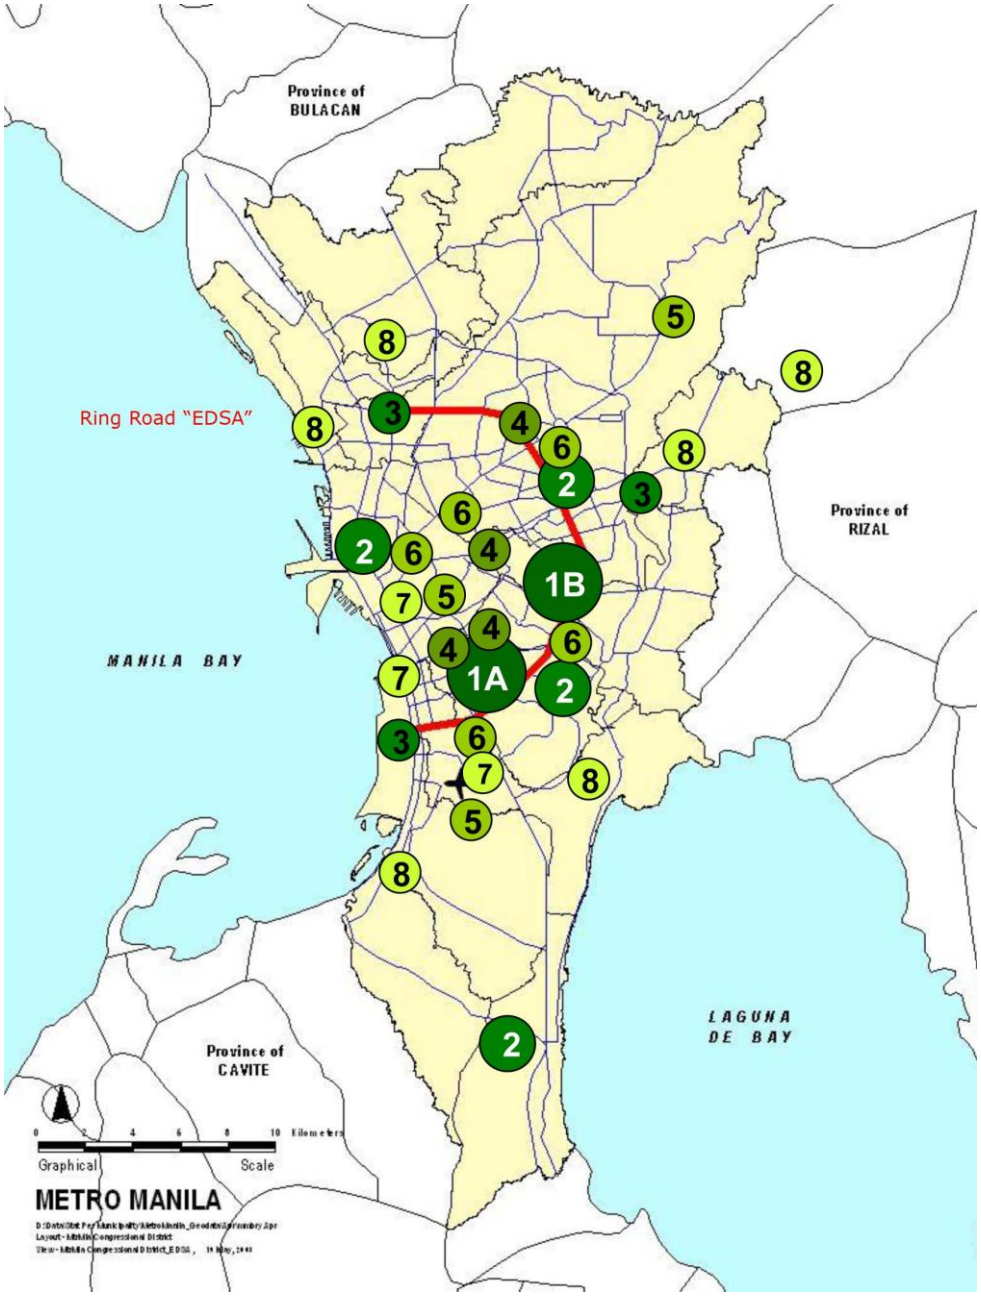

Image 5: Mapping Metro Manila's centres according to the hierarchy suggested above. Source: Art Corpuz

The current multi-tiered hierarchy of centres may be described as follows:

(1) Primary CBDs with international and national businesses and linkages, shopping, F&B, entertainment, residential, medical, government, hospitality, culture (Makati: 1A, Ortigas: 1B - Future: Makati + Bonifacio Global City 1A+, Ortigas 1B)

(2) Second tier CBDs (Bonifacio Global City (at present), Binondo-Divisoria, Cubao, Alabang)

(3) Centers with critical mass and mix that are focused on commerce (Manila Bay Reclamation with Cultural Center and Mall of Asia, Eastwood, Monumento, etc.)

(4) Mixed-use clusters and -developments as satellites to first tier CBDs or at arterial roads (Jupiter, Rockwell, Greenhills, North Triangle, etc.)

(5) Centres focused on government and institutions (Batasan Government Center in Quezon City, University Belt, NAIA Airport Complex, etc.)

(6) Emerging transit-based high-density mixed-use clusters (Pioneer/Boni Avenue, East Avenue Station, Quiapo, Magallanes Station, Banawe-Sta Mesa, etc.)

(7) Centres focused on entertainment, commerce, hospitality (Newport-Resorts World, EDSA / Roxas Ermita-Malate, etc.)

(8) Mixed-use districts and city centres, typically mid- and low-rise higher density (City centers of Taguig, Pasay, Pasig, Antipolo, Marikina, Valenzuela, Malabon, etc.)

7 METRO MANILA'S SHOPPING MALLS: COMPLETE INTERNALIZED CITY CENTRES – FOCUS OF URBAN LIFE

In discussing Metro Manila's centres, one needs to note the special relevance of shopping malls to the local culture in order to understand their extraordinary importance to public life compared to other countries. Local governments, through devolution, are tasked to provide a variety of public services and yet in many cases they have been unable to deliver—because of lack of funds, capacity and other resources. One key element that has not kept up with the increasing demand brought about by the increasing population and affordability is contemporary public spaces that can serve as centres of civic activity and public services. In its place, privately owned and operated shopping malls have become urban and civic centres in their own right where retail and other events that would typically happen in public spaces take place. Further, these malls are air-conditioned, an aspect that shouldn't be taken too lightly given the tropical climate. More important, the malls have become increasingly complex and complete in their mix of retail, food and dining, entertainment, professional, medical and educational services, cultural activities, and even religious worship. Undisputably, they have become the location of choice for all kinds of service providers, both public and private.

The church, the tax official, the car-registration office, the notary public, the attorney, the clinic, the hair-dresser, classrooms are next to the bingo-hall, retail stores, market stalls, supermarkets, food courts, restaurants, bars, movie theatres, farmer's markets, realtors, game-rooms etc. creating a complex, completed world that one hardly needs to leave. Malls have become the primary spaces of public life in Manila. And not surprisingly, malls have become attractors and catalysts for high-density developments with offices, residential and hotels.

8 PREFERENCES FAVOUR PUBLIC OUTDOOR SPACES

A fairly recent trend that can be observed is that public outdoor space is re-emerging as accepted places for public life, gatherings, al-fresco dining, cultural and entertainment events, markets, sports and recreation. Despite the unavoidable heat and rain of the tropics, pedestrian-based activities in public parks, plazas and sidewalks are becoming popular across a broad section of the middle class and across ages.

This trend and lifestyle preference is affecting a wide range of urban typologies. Shopping malls are adding outdoor spaces or are being reconfigured altogether to focus on green space. New malls are being designed around open spaces with open galleries blurring inside and outside spaces. Roads and sidewalks are being redesigned from being purely transportation corridors to becoming main-streets with improved sidewalks and added shops and show-windows on the ground floor, sometimes requiring modifications or even in violation of traditional zoning restrictions.

Image 9: Makati "Greenbelt". Open spaces and galleries are focus of new Malls. Source: Stefan Rau.

In new developments pedestrian-friendly design is being planned from the start, e.g. the case of Bonifacio Global City with its "High-Street" providing a heart to the district with a beautifully landscaped pedestrian public space west-to-east including inspirational and interactive pieces of public art and lined by attractive retail, restaurants and services.

Mixed-use developments directly link to transit stations allowing people to walk to public transportation, which is an accepted mode of transportation among the middle class. Throughout the metropolitan area, public transit enhancements are being planned and a BRT line has been proposed.

9 CONCLUSION: TRENDS LIKELY TO CONTINUE AND HAVE THE POTENTIAL TO POPULARIZE AND STRENGTHEN PLANNING

The emerging multi-tiered, poly-centred structure of Metro Manila is mainly a result of private ownership and market dynamics following economic growth and social behaviour. Formal planning has not yet had a large impact on this trend. Yet planning does have opportunities to play a more significant role building on two main trends in behaviour: increasing transit popularity and preferences for urban lifestyles and open spaces.

The trend of increasing compactness in locations with critical mass and transit-oriented development is a positive contribution to a more eco-efficient agglomeration. This trend will likely continue; at least two additional transit lines have been approved for implementation and this will only encourage further transit oriented developments. Given the large scale and high density character of Metro Manila, however, many more transit lines have to be planned and implemented in order to increase and improve linkages among existing centres and to create more opportunities for integrated nodes. With their growing popularity, the general public, developers, and other market players will appreciate the introduction of new transit lines.

The renewed acceptance of open, exterior spaces as a venue for a wide variety of activities among an increasing segment of the general public carries a great opportunity for a new understanding and appreciation of planning. Rediscovering the power that good public space offers as an instrument to integrate many aspects of community, sustainability, transportation and urban life can only enhance the value and popularity of urban design.

We wish to propose a few principles of how the profession and practice of planning can make a significant contribution towards the improvement of the quality of life in Metro Manila:

(1) Planners take the initiative and establish credibility and moral authority for strategic guidance, regional visioning, coordination and action, building on existing professional associations (i.e. Philippine Institute of Environmental Planning Advisory Committee) or creating a new one (e.g. Mega-Manila Planning and Policy Advisory Association)

(2) Develop and get broad consensus on a vision and principles for Metro Manila's future, recognizing its importance to overall national development and its leadership in establishing models of best practice among national leaders, regional and various competing local leaders and stakeholders as well as competing institutions, political and business players.

Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

(3) Prepare structural frameworks for various sectors (leaving local governments to handle detailed land use and master plans). These can include trunk or arterial infrastructure particularly roadway and rail networks, waterways, green network, social initiatives.

(4) Directly zoom in on a few, doable key projects, build consensus, coordinate and streamline action through all levels national, regional and municipal, identify business heavyweights for PPP to secure funding and timely implementation.

Zielgruppeneinbindung in Verkehrsplanungsprozesse mittels neuer Technologien?

Martina Jauschneg, Christoph Stoik

(DI Martina Jauschneg, MJ Landschaftsplanung e.U., Franz-Josefs-Kai 27, 1010 Wien, office@jauschneg.at)
(Christoph Stoik MA, FH Campus Wien, Favoritenstraße 226, 1100 Wien, christoph.stoik@fh-campuswien.ac.at)

1 ABSTRACT

Im Rahmen des Projekts „ways2gether: Zielgruppenspezifischer Einsatz von Augmented Reality und Web 2.0 in partizipativen Verkehrsplanungsprozessen“, gefördert durch das Bundesministerium für Verkehr, Innovation und Technologie (Programmlinie3 „ways2go“), wird erforscht, ob und wie neue Visualisierungstechnologien wie Augmented-Reality und auch Web-2.0-Einbindung die Beteiligung von Bürgerinnen und Bürgern an Verkehrsplanungsprozessen erleichtern können. In einem ersten Projektschritt, der hier vorgestellt wird, ging es darum, spezifische Hindernisse in der Beteiligung bei Planungsprozessen zu erheben. Diese Hindernisse wurden nicht allgemein identifiziert sondern in Bezug auf zwei wesentliche Perspektiven: Zum einen ging es darum solche Hindernisse zu identifizieren, die Anknüpfungspunkte für den Einsatz neuer Technologien anbieten, in dem Sinn, dass diese Hindernisse durch neue Technologien wie Web 2.0 überwunden werden. Zum anderen wurden Verkehrsplanungsprozesse identifiziert, bei denen Augmented-Reality (AR) eingesetzt werden kann um die Kommunikation in Planungs- und Beteiligungsprozessen zu unterstützen.

2 FRAGESTELUNG

Ziel dieses Forschungsprojekts ist es, Wissen für die Anwendung von AR- bzw. Web-2.0-Instrumenten zu generieren, die im Rahmen des Projekts in Testfälle einfließen, erprobt und geprüft werden. Dieser sehr anwendungsorientierte Zugang soll ermöglichen, das generierte Wissen in die Praxis der Beteiligung und in die weiteren Entwicklungsprozesse dieser neuen Technologien einfließen zu lassen.

Die forschungsleitenden Fragestellungen sind daher:

Welche Hindernisse können bei der Beteiligung von Zielgruppen können durch AR bzw. Web 2.0 wie (auf welche Weise) minimiert werden?

Welche AR und Web 2.0 Instrumente können die Beteiligung von bestimmten Zielgruppen verbessern? Was müssen diese Instrumente können? Was kann von diesen Instrumenten nicht erwartet werden?

Wie können durch technologische Instrumente (AR, Web 2.0) schwer erreichbare Zielgruppen erreicht werden?

Was ist bei der Gestaltung und Durchführung von Beteiligungs- und Planungsprozessen zu beachten, wenn technologische Mittel zur Reduktion der Beteiligungsbarrieren eingesetzt werden?

Um auch verallgemeinerbare Ergebnisse ableiten zu können, wurden die zu entwickelnden Testfälle nach unterschiedlichen Kriterien ausgewählt. Berücksichtigt wurden verschiedene Maßstabsebenen (zwischen Masterplan und Straßenraum), räumliche Differenzierungen (Stadt, Land, Bestand, Neubau), sowie mögliche Zielgruppen („bildungsferne“ Menschen, Menschen mit Betreuungspflichten, Erwerbstätige mit wenig Zeit, Kinder, EntscheidungsträgerInnnen) sowie unterschiedliche Prozessphasen (planungsprozessbegleitende Entwicklung einer AR-Anwendung und die Ergebnis-Visualisierung) .

Das Forschungsprojekt wird nun zu folgenden Ergebnissen führen:

(1) Wissen darüber, wie Zielgruppen, die sich üblicherweise weniger in Beteiligungsverfahren einbinden lassen, mittels dieser neuer Technologien besser erreicht werden können,

(2) wie sich erreichte Zielgruppen im Beteiligungsverfahren mittels dieser neuen Technologien in den Prozess besser einbringen können,

(3) in welchen Prozessphasen der Beteiligung und Planung diese neue Technologien eingesetzt werden müssen und in welchem begleitenden Setting diese angewendet werden müssen,

(4) welche Anforderungen für die technologischen Instrumente bestehen.

3 AUSGANGSLAGE

Die Beteiligung der Öffentlichkeit, insbesondere die Partizipation von Bürger und Bürgerinnen bei der Verkehrsplanungen und Verkehrsentwicklung ist auf nationaler und internationaler Ebene ein breit akzeptierter und erfolgreicher Ansatz in der (Verkehrs-)Politik und der Verwaltung (vgl. u. a. Europäische Kommission 2002; BKA 2009; Arbter et al 2005; Hamedinger et al. 2008). Bürgerinnen und Bürger erwarten mehr und mehr, dass sie in politische Entscheidungen einbezogen werden. Dabei entsteht – auch aus demokratiepolitischer Überlegung heraus – der Anspruch, dass die unterschiedlichsten Gruppen, Milieus und Altersgruppen einbezogen werden (z. B. Jugendliche, Bildungsferne, Personen mit Betreuungspflichten, Frauen, …). Diese Gruppen aber lassen sich nur begrenzt alle gleich beteiligen. Determinanten politischer Partizipation finden sich auf objektiv-struktureller und subjektiver Seite. Je nach sozioökonomischer Ausstattung, verfügbarer Zeit, Bildungsstand, Betroffenheit, bzw. materieller und personeller Ressourcen haben Menschen unterschiedlicher Milieus mehr oder weniger Zugang zu Partizipationsprozessen. Das Vorstellungsvermögen, Pläne und Modelle entsprechend lesen und verstehen zu können, hat ebenso Einfluss wie Erfahrungen darüber, wie Entscheidungsprozesse beeinflusst werden können. Aber auch das Beteiligungs-Setting hat Auswirkung darauf, ob sich Menschen beteiligen oder eben nicht. Versammlungen am Abend beispielsweise ermöglichen für die eine Gruppe die Integration in die Prozesse, während andere Gruppen gleichzeitig ausgeschlossen werden (z. B. Alleinerziehende). Mangelnde sozioökonomische Absicherung schließt Bevölkerungsgruppen tendenziell aus, weil diese Menschen die Zeit für das Überleben investieren müssen, während Menschen, die wichtige berufliche Funktionen ausfüllen auch aufgrund von Zeitmangel ausgeschlossen sein können. Menschen mit Migrationshintergrund mit nicht-deutscher Muttersprache sind benachteiligt, weil sie gefordert sind, ihre Interessen bzw. Betroffenheit in einer Fremdsprache einzubringen. Erst der Gebrauch einer altersgerechten Sprache ermöglicht es bestimmte Zielgruppen (z. B. Jugendliche) in die Prozesse einzubinden. Menschen mit weniger Bildung verstehen komplex formulierte Einladungen nicht. Aber auch eingeschränkte Mobilität behindert Menschen bei der Beteiligung (vgl. u. a. Munsch 2003; Lüttringhaus 2000; Herschkowitz 2007; Gruber 2007; Dangschat et al. 2000)

Aus der Gender-und Diversitätsforschung aber auch aus der Auseinandersetzung mit Raum als sozial produzierter und angeeigneter, sowie machtdurchzogener Raum zeigt sich, dass Menschen divers angesprochen werden müssen. Je mehr Gruppen und Milieus einbezogen werden sollen, desto differenzierter und zielgruppenspezifischer muss dabei vorgegangen werden (vgl. u. a. Damyanovic; Kessl et al. 2005; Löw 2001)

Diese zielgruppenspezifische Vorgehensweise differenziert sich weiter aus in Bezug auf die Prozessphasen und in Bezug auf die Beteiligungsintensität. So macht es einen Unterschied, ob es darum geht, dass Nutzer „nur“ informiert werden, mitreden oder sogar mitentscheiden sollen (zu den Beteiligungsstufen vgl. u. a. Lüttringhaus 2000).

Differenziert werden muss auch, ob es je nach Prozessphase darum geht, Nutzerinnen und Nutzer anzusprechen, einzuladen, „zu aktivieren“, in die Prozesse zu integrieren, oder die Beteiligten dabei zu unterstützen, ihre Interessen so einzubringen, dass sie in der Planung aufgenommen werden können. Je nach Phase und Beteiligungsstufe kommen daher unterschiedliche Methoden zum Einsatz (vgl. auch Ley/Weitz 2003; Kollmann et al. 2003, Diebäcker 2004; Krisch 2009; Riege et al. 2002): u. a. Information, Befragung, aktivierende Erhebung, Versammlungen, Arbeitsgruppen, Begehungen, moderierte Beteiligungs-veranstaltungen, Planungswerkstatt, Modellbau, Wettbewerbe.

Trotz einer Vielzahl an Methoden, werden nach wie vor nicht alle Gruppen ausreichend erreicht. Daher besteht die Anforderung, Methoden auf deren Wirkung zu untersuchen, weiterzuentwickeln und Methoden neu zu entwickeln, mit denen Zielgruppen erreicht werden können, die bisher schwer zu erreichen waren. Mit webbasierten und AR-Instrumente könnten technikaffine Zielgruppen erreicht werden (vgl. dazu auch Bundesministerium für Gesundheit, Familie und Jugend 2008), aber auch v.a. Gruppen, die über wenig Zeit verfügen. Möglicherweise können Benachteiligungen aufgrund mangelnden Vorstellungsvermögens ausgeglichen werden. AR-Tools können aber auch in Bezug auf die Schnittstelle zwischen Planung und Politik die Kommunikation erleichtern. Die Kommunikations-Schnittstellen zwischen den Planern/-innen und den Entscheidungsträgern/-innen sowie den Planern/-innen und den Nutzern/-innen sind daher die zentralen Ansatzpunkte im Projekt ways2gether für die Entwicklung von planerischen und partizipatorischen Ansätzen zur Implementierung von Web 2.0 und AR-Lösungen.

4 PROJEKTDARSTELLUNG

4.1 Projektakteure/-innen

Die Partnerinnen und Partner des Konsortiums sind: Joanneum Research ist als Leadpartner zuständig für die technologische Entwicklung des AR-Tool-Sets, das Institut für Landschaftsplanung (BOKU Wien) und das Kompetenzzentrum für Soziale Arbeit (KOSAR) sind verantwortlich für die wissenschaftliche Grundlagenforschung in Bereichen der Planungs- und Beteiligungsprozesse, das Ingenieurinnenbüro Jauschneg ist zuständig für die Konzeption des Tool-Sets für die Praxis anhand der Testfälle und die Forschungsgesellschaft Mobilität sowie das Verkehrsplanungsbüro verkehrplus sind zuständig für die Evaluierung des selbigen.

Die methodische Herangehensweise ist geprägt von einem sehr praxisorientierten Ansatz. So stellen Expertengespräche mit verschiedenen Planungs- und Prozessverantwortlichen die Grundlage für die Identifizierung von konkreten Anknüpfungspunkten für die Entwicklung des AR-Tool-Sets dar. In der Phase der Konzeption des Tools wird sehr eng mit Entscheidungsträgern sowie Prozessbegleitern in der Praxis zusammengearbeitet: Mit der Seestadt Aspern, der Entwicklungsgesellschaft 3420 wird an einer Visualisierung eines bereits fertig geplanten Straßenabschnitts gearbeitet. In Zusammenarbeit mit der Gebietsbetreuung im 20. Wiener Gemeindebezirk entstehen Tool-Bestandteile für planungs-begleitende Kommunikation und Visualisierung von Straßenplanungs-Projekten.

4.2 Beschreibung der Testfälle:

Es steht im Mittelpunkt der Konzeption der Testfälle aus dem möglichen AR-Tool-Set (browserbasierte online Tools und browserbasierte mobile AR Tools) verschiedene Anwendungsfälle zu erproben und damit die in der Systemanalyse getroffenen Annahmen bezogen auf die Anwendbarkeit und Nutzen etc. zu überprüfen und weiter zu entwickeln.

Überblick über das ways2gether-Tool-Set:

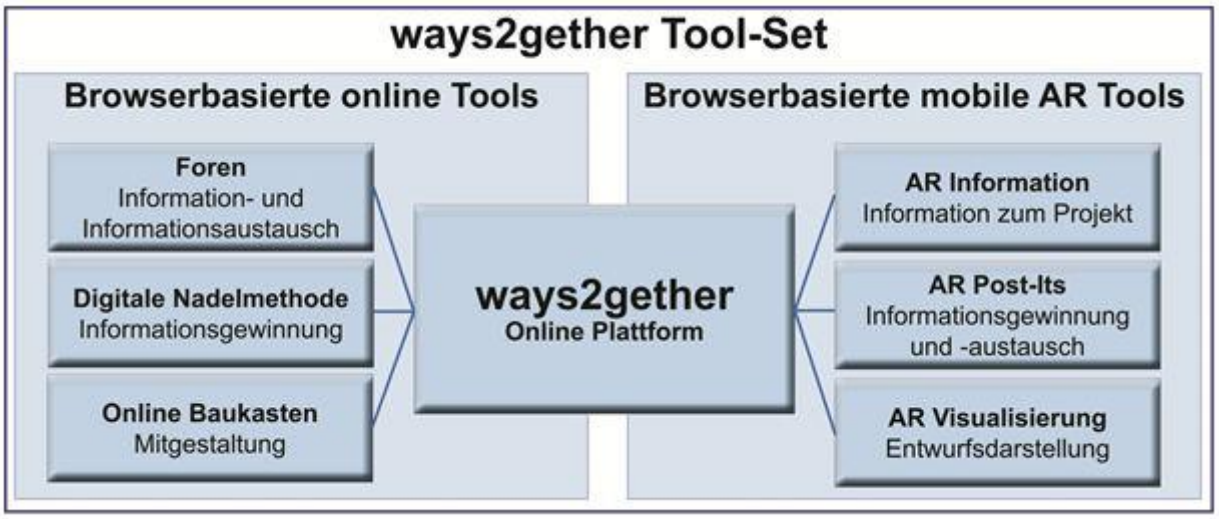

Abbildung: Tools des ways2gether Toll-Sets (Quelle: 2012, Reinwald, et al. 2012)

4.3 Konzeption der Testfälle

Bei der Konzeption der Testfälle für das ways2gether Tool-Set wird aus den bisher gewonnenen Erkenntnissen ein Design entwickelt, das sowohl Forschungsfragen im Bereich der technischen Entwicklung als auch im Bereich der Planung und Prozessbegleitung abdeckt. Dieses wird fallspezifisch an die jeweiligen Rahmenbedingungen, die sich vor allem aus der Planungsphase und den zu beteiligenden Zielgruppen ergibt, angepasst.

Forschungsfragen der Evaluierung zu AR Visualisierung:

- Welche Zielgruppe wird durch AR aktiviert?
- Wie ist der Aktivierungsprozess bei dem Einsatz von AR Instrumenten?

- Was verändert die AR-Anwendung für die Begehungs-Gruppe?
- Welche Interaktionen finden statt?
- Wie reagieren die Einzelnen und die Gruppe im Verlauf der Begehung?

Forschungsfragen der Evaluierung zur digitalen Nadelmethode/AR Post-Its:

- Welche Gruppe/welche Zielgruppe wird durch diese Tools aktiviert?
- Welche Kommentare/Informationen der Nutzerinnen und Nutzer bringen den Prozess und die Planung weiter?
- Wie können „nützliche" Kommentare generiert werden?
- Was ist der tatsächliche Mehrwert von AR und Web 2.0-Tools für Beteiligung und Prozess?

	Aspern	**GB20**	**Lange Gasse**	**Steiermark**
Zielgruppen	Entscheidungs träger, Fachplaner in Verwaltung	Kinder und Jugendliche sozioökonomisch Benachteiligte Menschen mit Migrations-hintergrund	Aktive, technik- und planungsaffine Bewohner	Personen mit Betreuungs-pflichten, Ältere

Beteiligungs-stufe	Information	Information, Mitsprache, Beratung	Information, Mitsprache, Beratung	Information, Mitsprache, Beratung

Tabelle: Überblick über die geplanten Testfälle und deren planungsprozessualer Charakteristika:

Bei den Testfällen kommen sowohl quantitative als auch qualitative Methoden der Evaluierung zum Einsatz. Das Setting der Evaluierung ist wie folgt geplant: Es ist ein Kontrollgruppen/Zielgruppen-Design geplant. D.h. zwei Gruppen begehen eine Straße mit je ca. 25 Teilnehmerinnen und Teilnehmern. Jede Gruppe macht eine Begehung: Die Zielgruppe macht die Begehung mit der AR-Methode. Mittels mobiler Endgeräte und mit Begleitung der Planer/Prozessbegleiter wird der augmentierte Straßenabschnitt begangen und die Planung begutachtet. Die Kontrollgruppe macht die Begehung mit der „old school" Methode, sprich sie gehen, angeleitet vom PlanerIn/ProzessbegleiterIn, mit einem analogen Plan/analoge Visualisierung durch die Straße. Die Evaluierung erfolgt sowohl parallel zur Begehung durch Beobachtungen der Interaktionen der Teilnehmerinenn und Teilnehmer, als auch im Anschluss an die Begehungen durch die Beantwortung eines Fragebogens.

Beispiel für das Konzept Testfall GB 20 – Wallensteinstraße:

Das Ziel dieses Testfalles ist der Einsatz des AR Tools in der Beteiligung bei Planungsvorhaben im Bestand. Die Maßstabsebene ist Detailplanung/Objektplanung im Straßenraum. Von den Instrumenten des Tool-Sets kommen AR Visualisierungen, Web 2.0-Information mit der Möglichkeit, Kommentare zu hinterlassen (digitale Nadelmethode, AR Post-Its) zum Einsatz. Die Nutzerinnen und Nutzer sollen über die geplante

Umgestaltung eines Straßenstückes informiert werden, ihre Meinung soll dazu eingeholt werden (sie haben aber geringe bis keine Mitbestimmungsmöglichkeiten).

Charakteristisch für diesen Testfall ist es, dass hier insbesondere eher schwer zu beteiligende Zielgruppen wie Kinder und Jugendliche und Menschen mit Migrationshintergrund erreicht werden sollen. Daher liegt hier der Schwerpunkt aus nicht-technologischer Sicht auf Methoden der Aktivierung dieser Zielgruppen und das begleitende Setting, in dem das AR-Toolset zur Anwendung kommen soll. Geplant sind persönliche Gespräche mit Multiplikatoren, das Herstellen von Flyern, die Verlosung eines Tablets sowie eine wiederholte Präsenz der Prozessbegleiter im Straßenraum. In Form von „Streetparties" an zentralen gut frequentierten Orten (Plätzen, Kreuzungsbereichen an Samstag-Vormittagen) soll über die AR-Anwendung niederschwellig informiert werden und die Möglichkeit bestehen, das AR-Tool-Set vor Ort auszuprobieren – zum Beispiel im Internet die digitale Nadelmethode anzuwenden. Dabei werden die einzelnen Prozesse, Kommentare, Gespräche im Verlauf des Austausches zwischen Prozessbegleiter und Nutzer als Reflexionsgrundlage dokumentiert und protokolliert.

5 VORLÄUFIGE THESEN ALS ZWISCHEN-ERGEBNISSE

Da die Durchführung der Testfälle noch nicht abgeschlossen ist, können hier nur thesenartige Zwischenergebnisse formuliert werden, die sich aus der Auseinandersetzung mit der Theorie und der Entwicklung der Testfälle gemeinsam mit den Praktikerinnen und Praktikern ergeben. Diese Thesen werden im Rahmen der Testfälle noch überprüft.

5.1 AR-Anwendungen haben Potenziale im Rahmen der Öffentlichkeitsarbeit und PR-Arbeit.

Im Rahme des Neubaus besteht von unterschiedlichen Akteuren (Bauträger, Kommune) das Interesse, die Attraktivität der Neugestaltung zu veröffentlichen und zu vermarkten. AR-Anwendung sind einerseits aufgrund des Images als innovative Technologie interessant, andererseits aktivieren AR-Anwendungen Zielgruppen dazu, sich mit dem Neubaugebiet vor Ort auseinanderzusetzen. Außerdem besteht die Möglichkeit potenziellen Zielgruppen durch die Visualisierung die zukünftige Gestaltung realitätsnäher zu vermitteln als über Modelle bzw. Pläne. Bildungsfernere Zielgruppen, aber auch Zielgruppen, die weniger Zugang zu neuen Technologien haben, dürften über AR-Anwendung allerdings schwer zu erreichen sein.

AR-Anwendungen können darüber hinaus (auch gekoppelt mit web 2.0 – Anwendungen) genutzt werden, um breite Öffentlichkeits- und PR-Arbeit zu unterstützen.

5.2 AR-Anwendungen benötigen spezifische Settings, um Zielgruppen besser erreichen zu können.

Über AR-Anwendungen ist es möglich, Zielgruppen zusätzlich zu anderen Methoden der Bürgerbeteiligung anzusprechen und damit in die Planungsprozesse mehr einzubinden. Aufgrund des starken Orts-Bezugs bei der Anwendung von AR könnten Nutzerinnen und Nutzer des öffentlichen Raums erreicht werden, die auch besonderen Anspruch auf den öffentlichen Raum haben. Insbesondere auch bildungsfernere Gruppen (auch Menschen mit Migrationshintergrund), Jugendliche aber auch ältere Menschen könnten besser erreicht werden. Das spielerische Moment könnte dabei förderlich sein. Entscheidend dabei ist, wie das Setting rund um den Einsatz der Anwendung gewählt wird. Dabei wird es notwendig sein, auf klassische Methoden der Bürgerbeteiligung zurückzugreifen. Es wird die Notwendigkeit bestehen, Aktivierungsarbeit, z. B. über ein Straßenfest zu leisten, und zur AR-Anwendung beispielsweise Gruppenbegehungen und -diskussionen durchzuführen und zu moderieren. Die AR-Anwendung benötigt außerdem eine gute fachgerechte Begleitung, um diese Zielgruppen besser ansprechen zu können. Aufgabe dieser Begleitung ist es, mögliche Hemmschwellen zur Technologie zu überwinden und die Diskussion anzuleiten (Begleitungs- und Prozesskompetenz, Planungskompetenz, Technologiekompetenz).

Nur wenn die AR-Anwendung allerdings weitgehend pannenfrei funktioniert, kann sie diese Wirkung auch entfalten.

5.3 AR-Anwendungen verändern die Auseinandersetzung der Zielgruppen mit dem Planungsprozess.

Im Vergleich zu Begehungen mit einem Plan wird die Begehung unter Einsatz einer AR-Anwendung, die Auseinandersetzung der Zielgruppen mit dem Raum und dem Planungsprozess sowie untereinander verändern (zwischen den lokalen Akteurinnen und Akteure untereinander und mit Planungsverantwortliche). Folgende Beobachtungen könnten gemacht werden:

- Der Raum wird mehr als Raum wahrgenommen und die geplante Veränderung wird realitätsnäher wahrgenommen,, was dazu führt, dass schneller über die Inhalte der Veränderungen diskutiert werden kann.
- Das Detail einer Darstellung rückt ins Interesse der Beteiligten und lenkt vom Inhalt ab.
- Die neue Technologie hat zur Folge, dass die Beteiligten sich weniger zueinander wenden müssen, da sie sich mehr mit der Technologie auseinander setzen können, was Aushandlungs- und Kollektivierungsprozesse erschweren könnte.
- Technologie-affine Personen können sich stärker und besser einbringen als Menschen mit Skepsis zu neuen Technologien.

Diese möglichen Beobachtungen müssen erst empirisch überprüft werden.

Diese Wirkungen können allerdings nur beobachtet werden, wenn auch die technologische Umsetzung gelingt. Eine wichtige Fragen dabei ist, wie ein erweiterter Raum dargestellt werden kann (z. B. Autos, die „wegretuschiert" werden müssen). Außerdem sollte die Darstellung nicht zu realitätsnah sein – einerseits um nicht manipulativ etwas zu vermitteln, was in der Praxis vielleicht nicht umgesetzt werden kann, und um die Diskussion nicht zu sehr dorthin zu lenken, sich mit der Darstellung von Details auseinander zu setzen.

5.4 AR erreicht Zielgruppen mit wenig Zeit nur, wenn zusätzliche Methoden (z. B. web 2.0) eingesetzt werden.

Es ist davon auszugehen, dass eine bloße AR-Anwendung die Beteiligung von Menschen, die über wenig Zeit verfügen nur begrenzt erhöht werden kann. Die Einbettung in web-2.0-Anwendungen allerdings könnte zu diesem Effekt führen.

5.5 Erweiterungsmöglichkeiten: Kinderperspektive

Durch animierte Anweisungen bei der AR-Anwendung besteht die Möglichkeit, sich mit anderen Perspektiven, z. B. der von Kindern auseinanderzusetzen. Mit einer Aufforderung mit dem AR-tool „in die Knie zu gehen" könnte angeregt werden, sich mit anderen Perspektiven als die eigene auseinanderzusetzen.

5.6 Einsatz: Aktivierung, Konsultation und Information

AR-Anwendungen könnten Wirksamkeit zeigen

- bei der Aktivierung von Zielgruppen, die sich traditionell weniger beteiligen,
- dabei, die Zielgruppen dazu anzuregen, im Prozess präziser eigene Interessen einzubringen
- und dazu, dass Zielgruppen über geplante Veränderungen realitätsnah informiert werden.

6 SCHLUSSBEMERKUNG

Der Mehrwert des Projektes ways2gether besteht darin, dass konkrete Praxiserfahrungen in Planungs- und Beteiligungsprozessen im Projektteam reflektiert werden und so erstmals konkrete planerische Anwendungsfälle konzipiert und durchgeführt werden. Damit können seit längerem in der Community bestehende Annahmen über Einsatzmöglichkeiten (vgl. Qualitätssicherung, Nash, 2010, vgl. Siegler, Wietzel 2009) überprüft und genauer erforscht werden. Zugleich liefert dieser Ansatz die Basis dafür, dass die Entwicklung von technologischen Kommunikationsmitteln für Planung und Beteiligung an die sich wandelnden Anforderungen der Praxis angepasst bleibt (sog. Fit-in-Lösungen).

1 ABSTRACT

The process of urban planning includes multiple task fields carried out by planners oder designers. They are confronted with complex planning procedure, complex data management, and multi-dimensional spatial presentation. The advanced computer technologies are able to aid and take over some workscopes in the planning process. The study introduces a developed program named 'eco-city Planning Support System (ePSS)' to help the ecologically oriented urban planning, especially for the planning practices like new town project or new city project which encompasse the entire process from land use decision to detailed building planning. In those planning procedure, the practices are far from ecologically sound planning because the urban planners are provided only some physical data and materials, not the environmental useful informatio, they are engaged in conventional development planning, and only little time is left to take the tasks to carry out additional ecological consideration.

In this background, the pivotal purpose of the introduced ePSS is designed to lead the planners to ecologically oriented planning. The program is composed of various functional subsets which are required during the urban planning procedure. One subset is designed to produce the ecological maps in the field soil, water, biotop, micro-climate, ecological connectivity and recreational suitability, in which result maps are served as spatial decision map for land use planning. This subsystem is constructed both to simply usability using Quick-Menu and to more detailed analysis and assessment. The next subsystem is designed to land use concept and land use plan in which not only 2- but also 3-dimensional planning are possible and the changeover can be simply done. The last part of the ePSS carries out environmental analysis and simulation like solar access, visual openness, and green visuality and visualization of of planning environment.

The end-users of this program are planners in planning companies and planner in engineering firms in Korea. The system is compatible with usual CAD and GIS data so that the wide usage is guaranteed.

2 INTRODUCTION

Sustainable use of natural resources is even more important now where the resources become scarce and therefore must play a pivotal role in the planning. But the reality of the planning is not supposed to reflect sufficiently the urgency to preserve and to use the rare resources sustainably. Analysis of environmental capacity and potentials of the natural resources has to play an important role in the sustainable Land Use Planning.

In Korea, there is a plethora of planning relevant regulations and planning process which make urban planning too complicated and difficult to understand fully. It is not an easily accomplishing task, to perform planning even for planners and civil servants. In particular, the lack of spatial planner's ecological knowledge and supporting planning instrument leads to ignorance and insufficient consideration in the spatial planning.

Often the citizens are excluded from the planning process or the participation is merely fulfilled in a formal way guaranteed by the regulations (Lee 2005), although the enormous progress in computer technologies in Korea might give opportunity to support planning more easily understandable (Kwon 2008).

There are already a number of planning support tools like planning support system (PSS), decision support system (DSS), spatial decision support system (SDSS), and the others in literature and in practice, though all with very different objectives. Geertman and Stillwell (2009) point out the computer-based support systems developed by researchers have not found its application in planning practice or policy making.

The main objective of this paper is to introduce a planning support system developed since end 2008. The software of this PSS is not designed to replace the planning or planner's task, but to facilitate and accompany their planning process and to help decision-makers and other participants understand spatial, contextual plan environment.

3 THEORY AND PRACTICE OF PLANNING SUPPORT SYSTEM

3.1 Definition of terms

PSS is relatively new in planning practice and theory introduced in the mid-1990s to support and improve the performance of those related to the planning (Batty 1995; Klosterman 1997). PSS is associated with GIS. GIS is a system which is serving as capturing, storing, manipulating, analysing and displaying spatial data, whereas PSS carries out GIS-functions and also is related to SDSS or SDD, but its main focus is to support specific planning tasks. PSS enables planners to better handle the complex planning procedure, resulting in the improvement of planning quality and reduction of time and effort (Geertman and Stillwell 2009).

Batty (1995) considers PSS as a subset of GIS which is designed to explore, represent, analyse, visualize, predict, prescribe, design, implement, monitor, and discuss planning related issues. Kim (2004) defines PSS as „computer-aided planning system combining geographic information system (GIS), urban models, and visualization tools, has been actively researched and applied in many developed countries".

Kim (2004) points out the key difference of PSS is to finde in adoption of visualization technologies and possibilities of collaborative planning process.

3.2 Spatial Planning Practice in Korea

The spatial planning system is associated with administrative hierarchy system in Korea. It is from comprehensive national territorial plan to comprehensive province plans, to Metropolitan city plans, and to basic urban plans. As the system indicates, it functions in a top-down approach, so spatial planning system should not contradict the higher-ranked planning system. Also on the ground that the spatial planning in the higher level deals with detailed spatial issues, the possibilities for flexible handling of lower-ranked plan are in general restricted. Moreover, because the basic urban plan is a long-term plan focusing at the comming 10 to 20 years, there is a lot of uncertainty in the planning to flexible, rapid respond and to deal versatile and swift change of planning situation.

The other characteristics of spatial planning in Korea is that the planning environment has been changed from top-down to bottom-up system and in the course of new city development planning many interest groups like communal government, city parliament, NGOs, civil activists are broadly participated. But even though planning participation includes diffent groups, the planning practices stick to the conventional ways, so there are increasing conflicts between different interest groups. This leads to various problems of delay, distortion, and change of the planning(Park 2001).

In order to improve such ineffectiveness of planning-related decision system, a comprehensive decision support system in spatial planning has to develop able to provide with spatial information, to widen civil participation so that the planning decision processes are more transparent both to the decision maker and to the public. For such system improvement, first of all the administration and institutions have to be changed and a supporting system is required to deliever information and data needed. The main aim to use PSS is to reduce irrational decision and to prevent errors resulting from planners' limited information, knowledge and experiences. Especially it is expected to be effective for the case of urban planning process entangled due to complex interests

The rational decision making of urban planning would be possible if there were spatial data available to clarify the spatial context and phenomena and to suggest objectively analysed information. Taking into consideration that a lot of planning participants are related and the interest conflict is anticipated, such data and information are more important.

4 OVERVIEW OF THE PROJECT

Here we present our software tool of an planning support system (PSS) which has been developted since end of 2008 in one of the national R&D Projects supported by Korean Minstry of Land and Maritime research project. The project was created in the response of governmental requests and needs to lead and create the future development power by Research and Development in field of construction technology. Reflecting this, the project has started to develope a ecologically oriented planning support system as a software tool to help the planners and decision-makers in the urban planning process. The Software will accompany the planning practice based on the planning system and practice in Korea.

The background to develop a planning support system is based on the circumstances that the planners devote most time to implement routine administrative tasks such as permit processing, so that little time is left to undertake true planning in conventional terms (Klosterman 2009). Taking into consideration that there is no legal ecological planning instrument like landscape planning, e.g. in Europe, prcaticies of land-use plannng practice in Korea are devoted generally to maximize the built-up environment only following the minimum standard of ecological regulations,. Urban planners are willing to have a ecological supporting tool at their disposal, because spatial decision would be more easily made if some leaning point and arguments would be given, which leads to more ecologically oriented spatial planning.

With regard to planning process which includes spatial analysis, evaluation, goal setting, spatial allotment and developing implementing strategies and last but not least participation of public and agencies, the planning support system is dedicated to provide the planner computer-based tools to handle the complex planning task. Otherwise, the spatial decision support system has its main function in support to find of optimal location for diverse demand on space in area by means of spatial analysis and evaluation.

The main user differ from the planner, decision-makers, planning consulting commitee, and citizens. The designed program is designed to facilitate planners time-consuming task on the one hand and to help decision-makers understand and control the context of space, content, effec of the proposed plans as a control and admission institution.

5 STRUCTURE AND FUNCTION OF "EPSS" PLANNING SUPPORT SYSTME

5.1 Structure of the Planning Support System "ePSS"

The presented eco-city Planning Support System (ePSS) is composed of four different subsystems: the ePSS-Analyzer as spatial decision support system (SDSS), the ePSS-Planner as land use planning support tool, the ePSS-Designer as a auxilary tool to take over the designing task, and the ePSS-Simulator for 3D simulation of the planning area (figure.1).

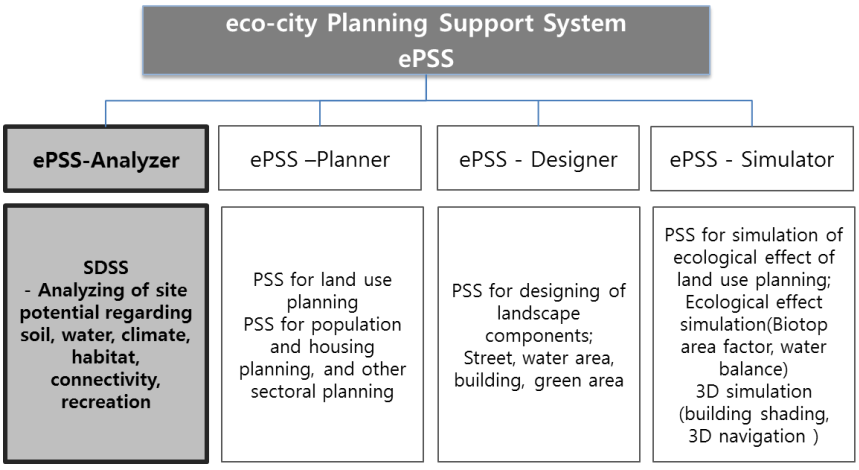

Figure 1: Structure and Submodule of the planning support system ‚ePSS'

The subsystems can operate independently, but are interlocked so that the whole system can be used or the individual subsystem is available for the planning use. The database management framework is integrated as basic system for managing integrated database to drive modules. A graphical user interface is designed.

5.2 Functions of the Planning Support System "ePSS"

The ePSS-Analyzer as a ecological spatial analysing system

The subsystem ‚ePSS-Analyzer' is constructed to analyze and assess the default environmental factors. For the sector of soil, water, climate, biotop (habitat), habitat connection, and recreational potential as natural resources, the default analyzing and assessing algorithm is installed. In case that other additional environmental or ecological sector will be desired, it can be also additionally installed.

This module is of great importance in Korea, because there is no ecological planning instrument with legal planning status. Therefore it can take over an important role for urban planning to lead more ecologically.

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

The instruments like strategic environmental assessment, environmental impact assessment have real influence to check and control spatial planning, even though the need for ecologically oriented planning is not controversial among the planning experts and civil servants (Lee & Suh 2007), there is no real ecological planning instrument.

Recently the discourse about sustainable development and the introduction of landscape planning or environmental planning finds a broad acceptance among planners and researchers and the relevant methodologies have been suggested (Jung 2010). The here proposed spatial decision support system is able to help planners and decision makers provide with useful ecological information and allow effective decision support by analyzing, displaying and visualizing ecological spatial Data applying computer-based information system.

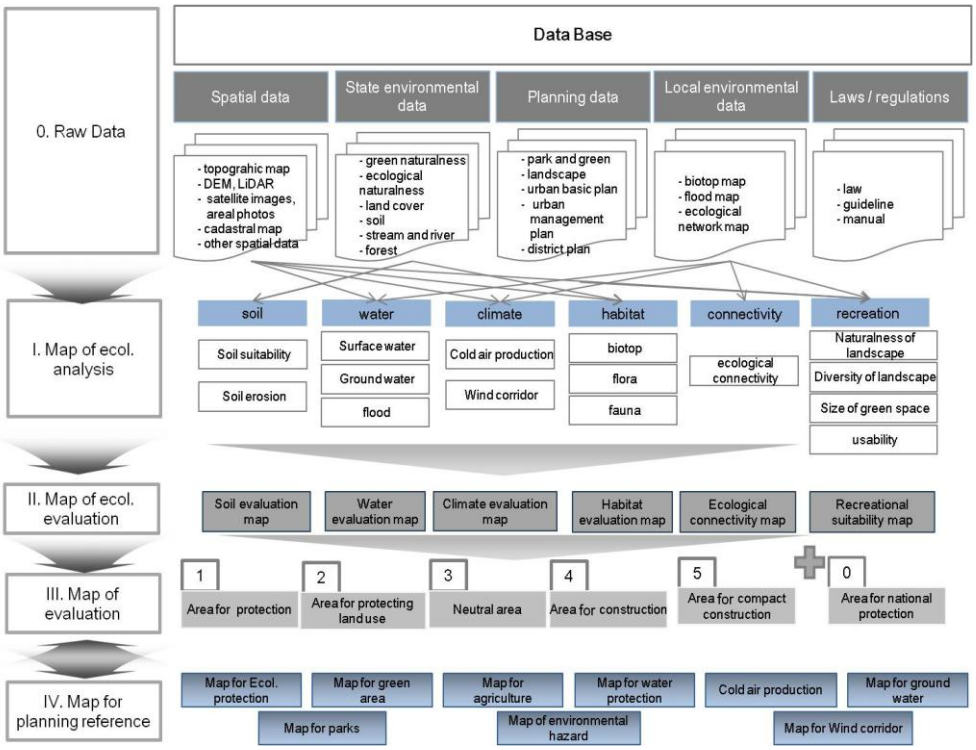

Figure 2 The general procedure of Spatial decision support system

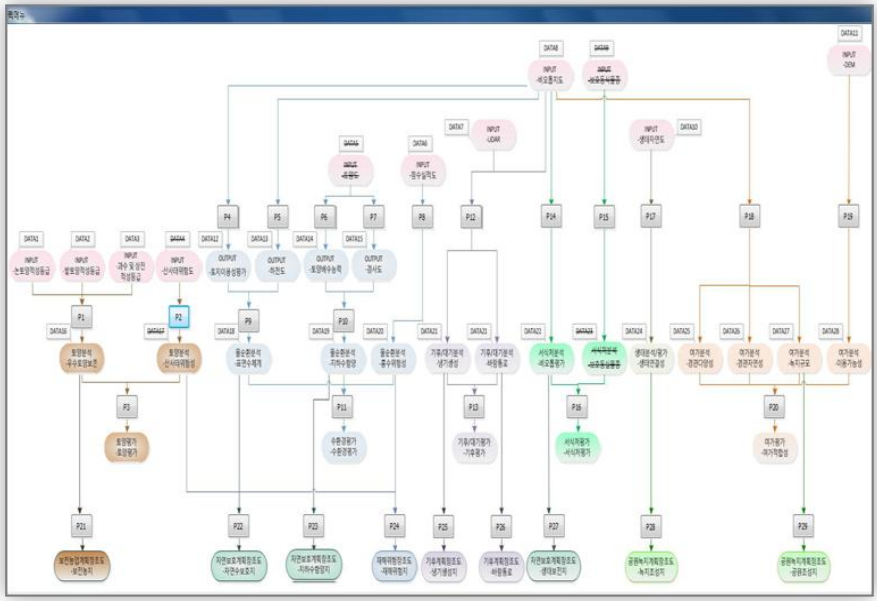

Figure 3: Quick module GUI of spatial decision support system

QUICK MODULE OF SPATIAL DECISION SUPPORT SYSTEM

The above described methodic procedure can be alternately done by "Quick Module" installed. The visual model which is consisted of graphical flow charts in sequence of analysis is an exploration to make the user acquainted to the complex program (Hocevar & Riedel 2003.) The quick module serves to combine the geo-processing into a sequential chain, which can operate automatically. The steps are the same as above mentioned, the quick module can be operated also manual or full automatically. The user can click the button where they want to produce the map, and the default analyzing process can be done. The corresponding raw data have to be uploaded beforehand in the defined folder, so that the process can grab the needed data. The GUI of "Quick Module" is designed in a tree structure, to provide user's convenience (figure 3).

This system is usefully applied, as far as the users have knowledge neither in analysis methods nor computing procedure. The advantage of using the quick module is to speed up the process and the users who have not profound knowledge in GIS and ecological analyzing methods can use the system effectively. The raw data required for this quick module must be beforehand installed in defined location.

The ePSS-Planner as a tool for 2D and 3D Land Use Planning

The ePSS-Planner is a tool to support planning tasks in new city development plan, city renewal plan, building renewal plan, and urban regeneration plan. The system supports to draw spatial structure and to show in 2D and 3D plan format according to plan goal and direction. For these, the ePSS-Planner has different functions as follows:

First, planners are able to inquire informations of landscape-ecology, urban planning, national spatial data etc. Also it enables visualization of the maps analyzed in the ePSS-Analyzer like analyzed, evaluated maps or planning reference maps.

Secondly, it supports for planners to draw land use concept. Land use concept means the procedure of schematic land use concept and structure in coarse level. Prior to the phase of land use plan, zoning the plan area, putting thematic axis, and designating spatial thematic issues (land use concept, settlement concept, green area concept, transportation concept, specialization concept etc.) are displayed in a planning area. The planner uses the drawing tools for these tasks.

Third, it supports the phase of land use plan. The functions are to draw street, and to form blocks, to dedicate land use purpose and density, to construct 3D building, and at last to give planning report.

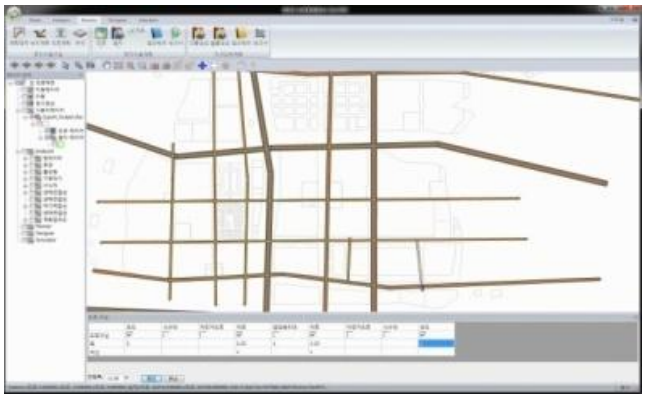

Figure 4: Formation of Road and Block

The ePSS-Designer as a Design tool of planning components in Land Use planning

This system supports to visualize components consisting of urban spatial structure from 2D to 3D map components. By means of this subsystem, components of virtual planning area are provided, so that planner, administrative personals and the public can understand better the spatial structure and contents of the plan. The main design components are building, street, street trees and other outer space elements like topography, green area, and water.

The difference to construct 3D building mass between the ePSS-planner and the ePSS-designer is that building can be drawed easy and rapidly out of the building type library

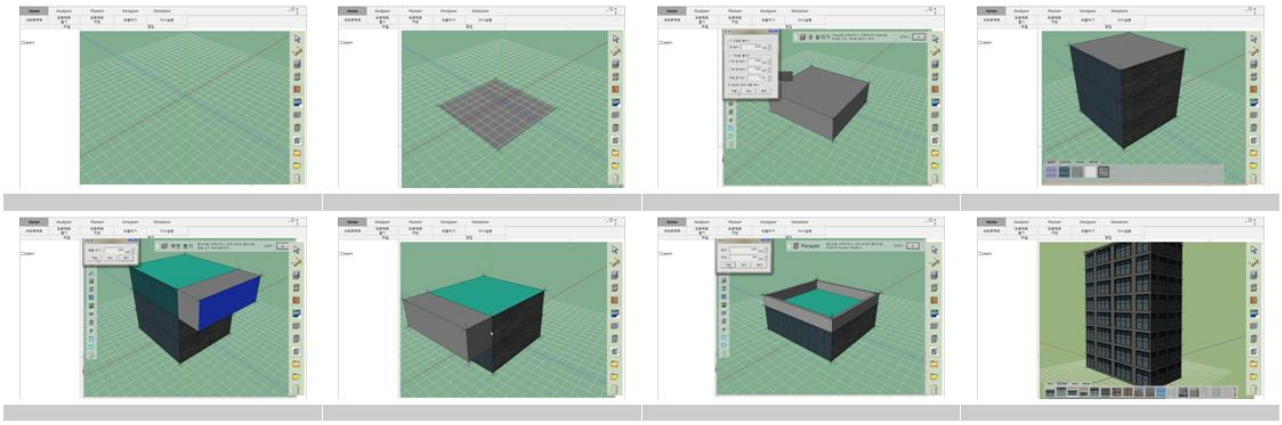

Figure 5: Building Modeling Process

The tool of street designing is to help to design lane type, lane width, pedestrian lane, bicycle lane, street tree lane, or central strip and to enable 3D street modelling. The planner can design and change tree planting intuitive using Drag and Drop function, in which type, shape, number, and space can be determined and visually confirmed.

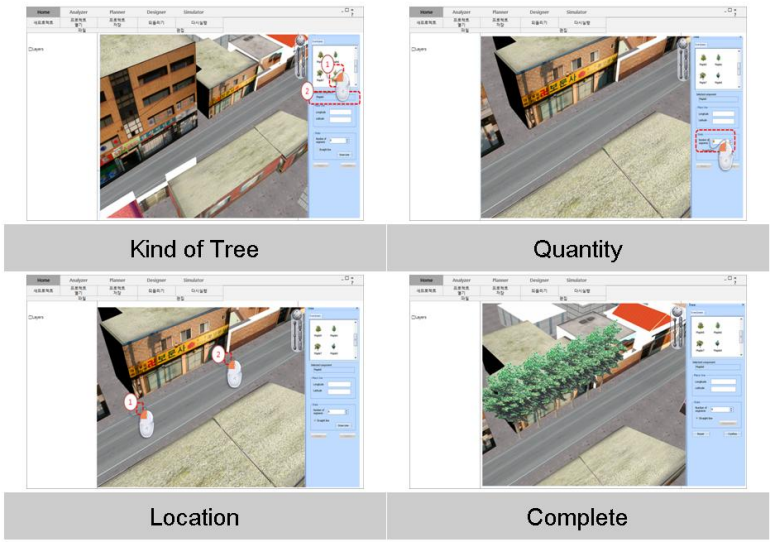

Figure 6: Street Tree Modeling Process

The planner can make and change elevation of topography, and the surface can be decorated with given texture. Within this topographic modelling, lake, see and stream can be made and visualized.

The ePSS-Simulator as a 3D virtual simulation and spatial analysis tool

The ePSS-Simulator facilitates to analyse the 3D-based spatial environment designed by the ePSS-planner and the ePSS-designer. This subsystem is important because environment and visual landscape can be analysed by changing 2D space to 3D space. The main functions of the ePSS-simulator vary from solar access analysis, visual landscape analysis to moving simulation.

The analysis of solar access gains in Korea its importance since high-reise buildings are very common, so that solar accessability is often deterred by neighbour buildings. This analysis can help to avoid later issuing conflict and to improve residential quality previously. This system provides planners with analysis result of solar accessibility and solar duration and thereafter basic dicision information to regulate location, distance, and height.

The analysis of visual landscape varies from visual analysis, panorama, virtical view shielding, to green visibility analysis. The system can calculate visible boundary from certain locational point and draw visibility rate. Panorama analysis enables analysing of sequential view by using visibility amounts. Virtical view shielding calculates the ratio of building-shielded area against targeted landscape object.

Moving simulation is for visualization of planning space observing from the object view point. The moving path, observer's height, and moving speed can be operated, so that visual simulation is carried out from the view point of car driver, bicycle rider, and flying object. Using this visual simulation, various planning environment can be controlled.

Biotope-Area-Factor calculator (BAF-Calculator) as a ecological settlement control instrument

In order to improve the ecosystem's functionality and promoting habitat quality in cities, Biotope Area Factor is recently introduced in Korea. By this control instrument, natural circulation balance of natural ecological components soil, water, climate, living organisms will be promoted and species habitat is not disrupted by soil sealing. Similar to the urban planning parameters, the BAF calculates the spatial ratio of an area that serves as a location for plants or assumes other functions for the ecosystem of the total proposed area.

The BAF-Calculator enables automatically or half-automatically the calculation of the relevant space. BAF is used as a criterion in Environmental Impact Assessment in Seoul, and newly applied in strategic environmental impact assessment, environmental impact assessment, so that its importance in the spatial planning is increasing(Jang & Kim 2008).

The BAF-Calculator is developed as a separate program installed on PC, by which ecologically relevant area can be promoted in development plans and projects. This program can be linked to the ePSS-simulator.

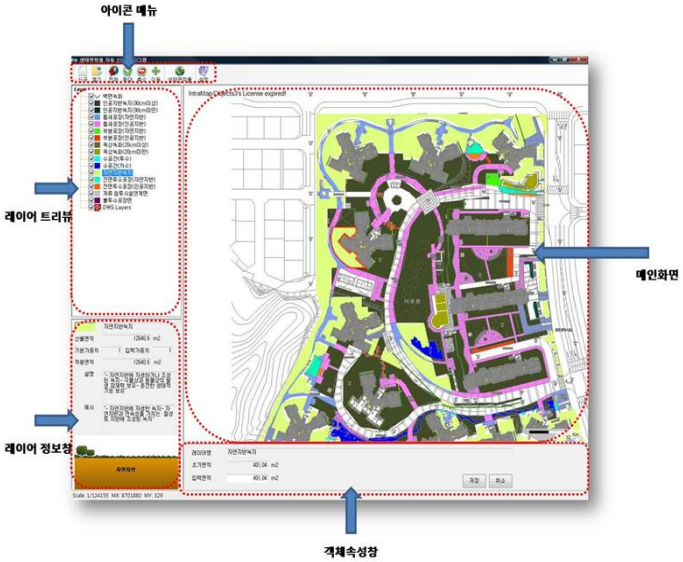

Figure 7: Biotop Area Factor calculator

6 APPLICABILITY OF THE EPSS

In Korea there are meanwihle a lot of spatial data available. Since GIS has been introduced in 1980th, and in 1995 the project for the establishment of GIS basic plan in Korea and the respective regulation and institution framework has begun, the state, local government, and civil organization have tried to establish for a long time diverse data for diverse purpose. But there is still no effective cooperation between the ministries and governmental agencies and the overlapping investment has been criticized (Lee 2006). The data acquisition required for spatial planning is still a difficult, long-lasting task. Another example is the biotop mapping implemented since 2001 by a lot of municipalities in Korea (Ministry of Environment Korea 2010, Moon et al. 2009), which means a valuable data for the analyzing methods of the system.

As the presented PSS, some utility programs for urban planning have been developed. Although we are now facing against some implementation hindrances to combine the spatial DB and implementing tools, there is a hope in near future to coordinate two system fields and to carry out urban planning more effectively and sustainably.

The possibilities to apply the developed PSS are manifold. Taking the fact into consideration that the PSS program has developed recently, the potential user groups encompass from local government, state-run agencies, city-based agencies, planning and engineering firms to architecture and landscape architecture. Since the entire program ePSS is equipped with diverse functions and possibilities of spatial suitability

analysis and evaluation, land use plan, and simulation, the user can choose what they need for their work scope.

As divers in user groups, the PSS is to anticipate multiple applications. As already mentioned, the planning reality which there is no landscape planning in Korea, the PSS can accomplish an important role in urban planning. In Korea, there are many laws and regulations regarding urban development project like urban reconstruction project, housing project, urban regeneration project. Also in outskirt of city there are also many land developing planning and projects like housing, new city, new specialized city, industry, recreation development. The latter occurs in suburbs or natural intact areas, so the environmental destruction of relatively natural areas will be lasted through the respective project. Even though the environmental plan is obligatory, the consideration of environmental aspects into the development plan is not satisfactory, in particular because of the absolute lack of planning time. Characteristic for the PSS is its rapid implementation speed and the quality of the results.

7 CONCLUSION

Recent advances in computing technologies enable the evolution to produce a variety of planning support software, on the other hand networking technology make possible the participation of many groups in the planning process (Kim et al. 2009). There are a lot of developments of planning support system in theory and practice. One of the widely practiced spatial decision support system in Korea is Land Suitability Assessment System.

The program PSS introduced in this study is conceived to perform various tasks needed for spatial planning in Korea, and one special purpose of this PSS is to facilitate planners to ecologically oriented planning. The program supports satial anaysing, land-use planning, spatial designing and plan simulating.

The program is composed of four functional subsystems which are required during the urban planning procedure. One subsystem „ePSS-Analyzer“ is designed to produce the ecological maps in the field soil, water, biotop, micro-climate, ecological connectivity and recreational suitability, in which result maps are served as spatial decision map for land use planning. This subsystem is constructed both to simply usability using Quick-Menu and to more detailed analysis and assessment. The Subsystem „ePSS-Planner“ as a land-use planning supporting tool is developed to carry out land use concept and land use plan in 2- ando 3-dimensions. The Subsystem can be defined as a supporting tool to visualize components consisting of urban spatial structure from 2D to 3D map components. The ePSS-Simulator carries out environmental analysis and simulation like solar accessibitlity, visual openness, and green visuality and visualization of of planning environment.

The end-users of this program are planners in planning companies and in engineering firms in Korea, and also civil servants in admistration. The system is compatible with usual CAD and GIS data so that the wide usage is guaranteed.

The mentioned program is expected to find versatile uses in planning praxis like planning practices and administrative personnel who are responsible for permission of planning in city government or other planning-related agencies. In order to enhance the usability of the program, it is tried to garner and integrate the needs and requests from the city administration and planning companies.

An Introduction to Major Challenges of Urban Transportation in Metropolises of Iran

Eshagh Rasouli Sarabi, Shahryar Shaghaghi G.

(Lecturer Eshagh Rasouli Sarabi, Islamic Azad Univdrsity, Shabestar Branch, Shabestar, Iran, e_rasouli_sarabi@iaushab.ac.ir)
(Assistant Prof. Shahryar Shaghaghi, Islamic Azad University, Shabestar Branch, Shabestar, Iran, sh.shagagi@iaushab.ac.ir)

1 ABSTRACT

The rapid growth of population and the consequent utilization of urban facilities and infrastructures has become concurrent with urban development criteria and also has lead to new challenges and problems specially in the domain of urban transport.

Iran was no exception and rapid as well as unexpected growth of urbanization and population in last 3 decades has created enormous problems.

In Metropolises of Iran, due to different reasons such as rural to urban immigration, insufficient development of urban centers, lack of planning and management frameworks of urban growth particularly in city centers and historic centers has maximized the problems facing urban transportation

In this paper, major and common characteristics of Metropolises in Iran are introduced and then obstacles of achieving optimum urban transportation systems will be introduced and analyzed. Among the major problems regarding the urban transportation in Iran, issues such as lack of harmony in urban neighborhoods, destruction of historic heritage, degradation of environment high rate of urban trips and high service of routes, lack of transport infrastructures, urban furniture and so on are introduced and discussed in this paper.

2 INTRODUCTION

Nowadays the main problem with which the societies face is the problem caused by the development of cities and the need for solving the problems of city- dwellers. In Iran as one of the developing countries, development of city- dwelling has progressed over the recent 50 years.

Enhancement of city population from 9895000 people in 1966 to about 50000000 people in 2012 indicates the importance of considering the issue (Table 1).

Number of cities	Average of Growth	Population inhabited in cities	All of population	year
200	-	6002621	18954704	1956
272	02.5	9795810	25788722	1966
373	93.4	15854680	33708744	1976
496	41.5	26844561	49445010	1986
512	47.3	31836598	55837163	1989
612	95.2	36817789	60055488	1995
1012	74.2	48259964	70495782	2006

Table 1: Variations of population in cities in Iran (1956-2006)

Enhancement of population in the cities is not monotonous for various problems. The climate differences in various locations, unsuitable dispersion of facilities in different cities etc. have caused that the development of urban population around some cities becomes more than other cities which has caused the creation of new metropolises in Iran over the past 30 years.

3 CHARACTERISTICS OF IRANIAN METROPOLISES

The process of city- dwelling over the recent years has caused the appearance of new metropolises in Iran, including Tehran, Mashad, Isfahan, Shiraz and Tabriz. Table (2) shows the features of these cities.

Name of Metropolis	**Population**	**Area (Km^2)**	**Congestion (Persian in per Km^2)**
Tehran	8429000	730	10555
Mashhad	2510000	458	9150
Esfahan	1602000	267	5240
Tabriz	1459000	252	7780
Shiraz	1455000	178	6890

Table 2: Characteristics of the main metropolises in Iran

As it is observed, uncontrolled development in these metropolises is due to the unequal development of other cities, centrality of them in geographical limitations, being tourism, religeous and industrial places around

them possibility of earning high incomes as compared with income of some jobs like agriculture and husbandry.

This process has created more problems in different areas. Considering the little space of the paper, just the main traffic problems related to the main urban issues in these metropolises are considred.

4 THE TRAFFIC PROBLEMS OF URBANIZATION IN METROPOLISES OF IRAN.

The traffic challenges on the requirements of developing the land uses and the urban spaces necessary for the development of metropolises in Iran are:

4.1 Problems caused by disregarding the localization of land use

In most of the metropolises, different land uses are established without suitable localization, and unfortunately access to the land use is not possible for disregarding the rules of determining the appropriate place of land uses and also disregarding the relevant models (gravity model and land use allocation model), distribution of the necessary traffic systems and the nature of access to the land use. This violates the essential rules on classification of urban ways and access hierarchy

4.2 Disregarding the logical distribution of land uses.

Disregarding the nature of trips distribution in the spatial organization of cities in principle causes disregarding the situation and the quantity of land use effective in production and attracting the urban trips including trade, sport, educational, administrational and recreational centers, and this causes creating extra trips.

The correctness of this subject can be observed as compared with the rate of trips in lieu of every person or family comparing the ownership coefficient of automobile; the rate of trips is more than the ownership coefficient of automobiles in metropolises which is more as compared with the developed countries.

4.3 Problems caused by the unsuitable determination of compressions considering

The discussion of determining the suitable compressions like population and structural ones creates a balance in supply and demand, and creating the suitable compressions with urban facilities causes order in different districts over the recent years, with regard to using the self- rule policies of municipalities, unfortunately of the main ways of earning the income of municipalities has been the uncontrolled sell of residential, commercial and administrative compression disregarding the capacity of neighbour hoods.

the lack of development of directions has created more traffic problems, increasing the duration of trips and decreasing the service level of ways.

4.4 Disregarding the pre capita of different spaces

Considering the spaces allocated for the residential and commercial spaces, as compared with the per capita allocated for the traffic spuces and parkings, it is observed that disregarding the suitable per capita for the traffic network, disregarding the suitable rates enhances the capacity of passageway network and high density, and the service level is decreased.

4.5 Disregarding the appropriate zoning

Disregarding the zoning of metropolises, the residential, work and recreational performances as well as impossible performance of spaces, integrating these spaces makes the anticipation of the necessary passage way network impossible; and in the future developments of passageway network, more problems have been raised.

4.6 Non- integrity of neighbor hoods

considering what was mentioned before, disregarding the density in establishment of various units causes unappropriateness between the passageway network connected to the land use (especially in old- texture areas_ and other problems raise on direction development (which requires more expense)).

4.7 Destruction of historical and cultural structures and green spaces for passageway development.

The cases mentioned before accompanies another problems including destroying the spaces to develop the directions and to improve the passageway for the new land use which is observed in most metropolises. It harms the old and historical texture of the city and decreases the green space per capita.

4.8 Disregarding the original and destination distance of trips

Unfortunately the lack of comprehensive traffic studies on metropolises or disregarding their exit has caused that the original and destination distance of trips are not considered. Sometimes this problem causes extra trips and traffic difficulties.

4.9 Problems caused by concentration of trade centers on the old and central texture of metropolises

Considering that the growth of Iranian old metropolises has been performed disregarding the essential urban problems, the central sections of these cities have always attracted more passengers. The impossibility of passageway development has been a challenge on this subject, considering the old urban texture, more cost or destruction of old spaces. This has caused more traffic problems in spite of the demand decrease and other traffic management plans in these districts.

4.10 Problems caused by non- development of high- capacity public traffic

Due to the lack of performing the comprehensive traffic plans over the recent years and the lack of metro or motor rail, using the private cars or bus does not meet the traffic needs.

5 CONCLUSION

The Iranian metropolises are the result of the development of old cities, and the lack of their balanced development due to the uncontrolled immigration from the around villages and cities has made that they face with more traffic problems.

Such problem as the lack of comprehensive plans in metropolises, unappropriate localization of land use, illogical distribution of land uses, problems caused by the unsuitable allocation of densities, disregarding the various space per capita, the lack of integrity in neighborhoods, disregarding the access in planning the urban passageways, destroying the old structures and green space, disregarding the original and destination distance in trips and extra trips, uncontrolled land use in the central districts of cities and the undeveloped traffic systems are the most problems that have caused more traffic problems in the metropolises of Iran, which were considered briefly for the little space of paper.

An Introduction to Socio-spatial Consequences of Urban Poverty in Iran

Mir Saeed Moosavi

(Department of Architecture, Tabriz Branch, Islamic Azad University, Tabriz, Iran, e-mail: msmoosavi@iaut.ac.ir)

1 ABSTRACT

Urbanization is proceeding at an unprecedented scale creating many challenges, especially about how - in a sustainable way - to feed, shelter, and generate employment for the people projected to be added to the population of cities. In cities across the globe, especially in developing countries, hundreds of millions of people live in desperate poverty without access to adequate shelter, clean water, and basic sanitation.

In developing countries like Iran, overcrowding and environmental degradation make the urban poor not only vulnerable to the spread of disease, constant threat of eviction, crime and violence but also affect urban spaces and environments both socially and spatially and given the weaknesses of governance structures, the appalling environmental conditions that already exist in many cities, and existing infrastructure and service shortfalls all lead to manifestation of urban poverty and then, meeting the needs of these people appears an almost impossible task. In this process of urban growth and poverty, slum settlements emerged in most cities of developing countries. These settlements have some characteristics in common with other slum settlements across the glob as well as some unique features related to the history, culture and economy of the area. In Iran, while natural population growth has been the major contributor to urbanization, rural-urban migration continues to be another important factor leading to great increase of urban poverty and negatively affecting the social and spatial dimensions of urban life. In this paper the intention is to analyze the causes and socio-spatial consequences of urban poverty in Iran.

2 INTRODUCTION

According to the United Nations, the global urban population will grow from 3.3 billion people in 2008 to almost 5 billion by the year 2030 (UNFPA 2007, 1). This urban expansion is not a phenomenon of wealthy countries. Almost all of the growth will occur in unplanned and underserved city slums in parts of the world that are least able to cope with added demands. The pace of urbanization far exceeds the rate at which basic infrastructure and services can be provided, and the consequences for the urban poor have been dire. Failure to prepare for this unprecedented and inevitable urban explosion carries serious implications for global security and environmental sustainability [1]. In cities across the globe, hundreds of millions of people exist in desperate poverty without access to adequate shelter, clean water, and basic sanitation. Overcrowding and environmental degradation make the urban poor particularly vulnerable to the spread of disease. Insecurity permeates all aspects of life for slum dwellers. Without land title or tenure, they face the constant threat of eviction. Crime and violence are concentrated in city slums, disproportionately affecting the urban poor. Most slum dwellers depend upon precarious employment in the informal sector, characterized by low pay and poor working conditions. Illegal settlements are often located on hazardous land in the urban periphery. Perhaps most alienated in city slums are growing youth populations whose unmet needs for space, education, health, and jobs can lead to social problems, further undermining security in urban areas.

3 POVERTY AND URBAN LIFE

Most studies attempting to describe urban poverty have focused on drawing out the characteristics of urban poverty, often by comparing rural with urban poverty. However, there is still much debate as to whether urban poverty differs from rural poverty and whether policies to address the two should focus on different aspects of poverty. In some views, rural and urban poverty are interrelated and there is a need to consider both urban and rural poverty together for they have many structural causes in common, e.g. socially constructed constraints to opportunities and macroeconomic policies. Many point to the important connections between the two, as household livelihood or survival strategies have both rural and urban components (Satterthwaite 1995). Baker (1995) and Wratten (1995) illustrate this point in terms of rural-urban migration, seasonal labour, remittances and family support networks and Baker (1995) illustrates how urban and rural households adopt a range of diversification strategies, by having one foot in rural activities and another in urban. Conceptualizing urban poverty as a separate category from rural poverty is also problematic because of different yardsticks for defining urban in different countries. The urban-rural divide is more a continuum rather than a rigid dichotomy [2]. In urban areas, an important aspect of poverty is often

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

manifested as the lack of adequate housing and infrastructure. Poor people in cities may have greater cash incomes, but these may be unstable and inadequate, especially when considering the higher costs of living in cities, such as transport and housing. With a lack of formal housing options, many are forced to settle in slums and informal settlements, often on unsuitable land, or live 'invisibly' in overcrowded buildings, and far from employment opportunities. As they often do not own the land they occupy, or possess housing registrations and building permits, they lack a stable asset base, access to credit and basic services [3].

4 URBAN GROWTH AND POVERTY IN IRAN

In Asia, there are wide differences in the urbanization experience both between and within countries. This is illustrated by the differences in the extent of urbanization and projections for the future between countries. In general, there is a strong relationship between urbanization and economic development. Higher-income countries are generally more urbanized than lower-income countries, and urbanization increases more rapidly with economic growth in lower-income countries than in higher-income countries. Over the last five decades, Asia has seen some enormous demographic changes. One of the most dramatic changes of all has been the movement of people from villages to cities. The percentage of people living in Asian cities and towns, as compared to total country populations, is increasing fast. In 1950, about 232 million people lived in urban areas, which represented about 17% of Asia's total population. In 2005, Asia's urban population had risen to 1.6 billion people, or about 40% of the region's total population. There's no doubt that as the Asian region continues to develop, the level of urbanization will increase. The United Nations estimates more than half of Asia's total population will live in urban areas by the year 2025, and by 2030, it is expected that 54.5% of Asia's population will be urbanized. This means that by 2030, one out of every two urban residents in the world will be in Asia [3].

As in many other developing countries, Iran experienced an unprecedented population growth in the second half of the twentieth century. The population of Iran was reported to be about 19 million according to the 1956 census while the 1996 census recorded a figure of more than 60 million for the country's total population. Total population is now estimated to be more than 70 million persons. While the country's rural population has continually increased in the last decades, its proportion to the total population has shrunk from more than two thirds to about one third of the total population, based on recent estimates. The rapid expansion in urban population in Iran between1980-1990 has occurred without the needed expansion in basic services and productive employment opportunities. The problem was compounded by weak urban government structures with very limited capacity to stimulate economic growth, mobilize resources and provide the most basic services (The war between Iraq-Iran caused a delay in planning and preparing a long term Master plan). Investment in urban areas does not mean to undermine rural development.

The concentration of population in the capital and to a lesser degree in other urban centers, along with tertiary sector enlargement, motivate more and more people to leave tribes, rural areas and smaller towns and cities and reside in the capital and other major urban areas. Concentration of population in itself, coupled with class polarization and informal sector's enlargement, means the availability of more and more urban parasite work. Availability of this kind of employment in its own turn leads to the attraction of more migrants into the major urban centers. As migrants arrive at cities looking for any job to get by, the increasingly acute shortages of housing, overcrowding, and inadequate social services, become a part of daily life in urban centers. At the same time land and housing speculations which are routine practices in an economy in which the tertiary sector has the upper-hand, prevent masses of urban poor especially those who are not organized and work in the informal sector, to find shelter in cities [4]. In this process of urban growth, slum and informal settlements emerged in most cities of Iran, especially in the capitals of provinces. These types of settlements represent the constant struggle of the poor to cope with inequalities that are institutionalized and reproduced within societies. In Iran, the cost of housing has always been considered to be the most important item within a family's expenditure basket. On the other hand, for a slum settler securing a shelter, no matter where and under what circumstance, means the elimination of rent and at the same time excluding better nutrition and clothing. The make-up and appearance of many informal settlements are very often misleading. There is no doubt that such settlements are poor, the majority of the population has miserable lives, and the basic needs of many families cannot be met. But the appearance of the neighborhoods, due to a number of cultural factors, habits, and living styles, may be far worse than what

it actually is. Additionally, it is important to understand the dual and contradictory nature of informal settlements in Iran.

5 UPGRADING PROJECTS FOR SLUM SETTLEMENTS

Widespread problems resulted from formation of informal and slum settlements urged many international organizations, donors, and community groups to address the increasing scourge of urban slums worldwide. In the early Twentieth Century, slum improvement programs in many countries were equivalent to slum clearance—hardly a solution to the problem of lack of adequate housing in developing country cities. Beginning in the 1970's the strategy shifted to one of improving and consolidating existing housing—often by providing slum dwellers tenure security, combined with the materials needed to upgrade their housing or—in areas where land was plentiful—to build new housing. Emphasis on in situ improvements has continued to the present. These improvements may take the form of providing infrastructure services and other forms of physical capital, but also include efforts to foster community management, and access to health care and education. At the same time, some have called for replacing slums with multiple story housing either at the site of the original slum or in an alternate location [5]. Among different kinds of projects planned to address the issues of slum settlements, one of the recent and most common projects regarding slum settlements is referred to as upgrading project. Slum upgrading, as opposed to slum redevelopment or slum clearance, is now widely acknowledged as one of the more effective means of improving the housing conditions of the poor and has been hailed as a 'linchpin' of any urban poverty strategy. It has been defined by the Cities Alliance as consisting of 'physical, social, economic, organizational and environmental improvements undertaken cooperatively and locally among citizens, community groups, businesses and local authorities [6]. Most of the core elements of a slum upgrading project involve construction of physical infrastructure: water lines, sewer lines, pumping stations, street paving, schools, clinics or hospitals. These elements require the investment of capital in or very near the slum. Improvement of the houses in the slum also requires capital. Since slums are typically densely settled areas, these capital investments produce economic benefits immediately at a per capita cost that is quite reasonable [7].

Urban Upgrading and Housing Reform Project (UUHRP) for the Islamic Republic of Iran funded by the word Bank was implemented in 2004. Iran has received financing in the amount of US$ 80 million equivalent from the World Bank toward the cost of the Urban Upgrading and Housing Reform Project, and it intends to apply part of the proceeds to payments for goods, works, related services and consulting services to be procured under this project. The project is to be implemented in cities of Zahedan, Bandar Abbas, Kermanshah, Tabriz and Sanandaj and includes three components in which component A lays the foundations for launching and sustaining country-wide urban upgrading programs. Component B aims at enhancing housing affordability and the efficient functioning of the housing market. It will consist of foreign and local technical assistance, training and equipment for further defining and implementing the priority actions identified in the Housing Sector Strategy and component C will finance the cost of office and equipment that are required for project management and implementation. To achieve the above, a three phase Adaptable Program Loan was prepared and is spread over a period of twelve years. The key development objectives of this project are to (i) improve the living conditions in under-serviced neighborhoods in up to five provincial capital cities and; (ii) prepare the systems, capacity, and regulatory foundation and initiate market based housing sector reforms. Like UUHRP of other pilot cities in Iran, first phase of the project for Tabriz which included collection, classification and analysis of data is almost fulfilled, but the consequent phases have not been accomplished yet.

6 CONCLUSION

It is important to recognise that the performance of a number of cities in Iran in carrying forward major pro-poor reforms and programmes in land and housing provision has been encouraging. However, for such slum prevention policies to have an impact on the ground there seems to be need for a lapse in time. Generally, the replication and scaling up of successful initiatives in a particular city to national level remains a serious challenge, and meeting the targets is particularly difficult because of inherent complexities due to unique topography of the area, the number of actors and their diversity, the pervasive effects at all levels of inadequate policies, regulations and their enforcement, the lack of adequate information and the need to find

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

solutions tailored to suit local conditions. Given the region's relatively high slum prevalence and slum growth rates, the immediate steps toward meeting the upgrading targets must be accompanied by actions aimed at reducing the current rate of formation of new slums, that – if unaltered – would lead to much more slum dwellers in the area. Therefore, actions on two directions are required: upgrading of existing slums and prevention of new ones. To this end, both adaptive and preventive strategies have to be applied simultaneously in addressing the slum challenge in this area: firstly, a participatory approach to upgrading of existing slums; and, secondly, adoption of urban policies designed to prevent the emergence of new slums.

1 ABSTRACT

The population growth and human's need for a suitable settlement, serious increase in energy and fossil fuel consumption over the past years and human interference in the nature led him to think of new methods of climatic design of the settlements and conservation of fossil fuel that he could get his requirements without harming the natural environment.

The village of Hawramane Takht is the centre of Hawraman township of Servabad country which is located in the southwest of Kurdistan province, Iran.

The village is a precious form of climatic and natural architecture which can be seen as an extreme use of solar energy and fossil fuel conservation. The fabric and spatial structure of Hawramane Takht village is generally formed by a set of neighborhood units, footpath and public open and enclosed spaces which are on a high slope in the middle of the mountains by a close relation to each other and an organic interaction with natural environment.

Severe shortage of land to be developed, cold climate and mountainous area are the leading causes of a dense complex settlement in the middle of mountains which provides a combination of positive and negative surfaces. In this pattern of mountainous architecture, the roof of each house (building) is the yard of the house above or a part of public footpath. The connection and coherence on public context image and serial juxtaposition method toward south in order to prepare the light and heat are features of this architecture.

Now in the analysis of fabric structure and architecture of the village, the role of the architectural design to respond climatic issues is more understandable. Organic and entirely functional structure has composed a special typological architecture which has its own sensible traits as following items:

1. Adapting to Organic architecture basis.

2. The lowest interference in the natural environment.

3. Harmony of structural architecture with the organic typography and natural environment.

4. Applying the local natural materials.

Precise analysis of the fabric of this village, could lead us find best methods to design new settlements especially in cold regions, more climatically to make a better environment and save more energy to conserve it to next generations.

Keywords, Hawramane Takht village, climatic design, energy conservations, fabric of village

2 INTRODUCTION

Human has thought of settlement to protect him from learning wild animals, extreme weather and any dangers which might threatens them. It is noticeable that architecture has not been formed from the begging and as times went on and human's try efforts and the lasting influence of environment on human to have the idea of improvement are most important elements of forming the conceptual architecture.

3 REASERACH METHODLOGY

In the theoretical research relevant concept and definitions of sustainability and vernacular settlements were studied in the experimental research, required information was collected through survey methods in a descriptive –analytical way in Hawraman-e Takht village. In this research by analysis of the village of Hawraman-e Takht and its architectural and environmental features and also by paying attention to theoretical methods of organic architecture and using solar energy in this village, a complete report of fabric texture and location is achieved that can be gained a special climatic design which can be used in similar areas.

4 IS THE ARCHITECTURE IN HARMONY WITH THE NATURE?

Could human improve his architecture without harming the nature and its environment? The village of Hawraman-e Takht is a valuable paradigm of an organic architecture with its residents by having a good concept of the nature and environment ,climatic designing and best usage of solar energy could build a village like a town without damaging the nature and environment, which although is located in ragged mountains but could have the communications with its own feature for the sites which have similar climatic conditions.

5 GEOGRAPHICAL LOCATION OF THE VILLAGE OF HAWRAMAN-E TAKTH (HAWRAMAN-E TAKHT FROM THE HEIGHTS)

It is the center of Uramanat which is located in southeastern Marivan with a 75Km road linking to Marivan this village is located in an East –west valley in a steep declivity opposite the northern side of the Takht Mountain. [1]

Fig. 1: Satellite map of Hawraman-e Takht

5.1 Why this area is called Hawraman Takht?

Hawraman is comprised of two words "Hawra" or "Hura" which means Ahura and "Man" the meaning house, a place and land. Therefore Hawraman means an Ahuraic land or the land of Ahuramazda. In Avesta "Hur" means the sun and Hawraman means the place for the sun. [2]

6 CLIMATIC CONDITIONS OF THE VILLAGE OF HAWRAMANE TAKHT

Hawraman-e Takht and Marivan are located in a very cold mountainous region which has cold winters with long snowfalls and short and cold summers. This area is very high in comparison to the sea and is surrounded by Northern Zagros mountain range which causes extreme weather and difficult climatic conditions.

Fig. 2: Hawraman-e Takht in winter

7 WATER RESOURCES

Permanent spring waters, and water well and "Sirvan" river are the main water resources. Sirvan is a significant water resource that two parts of this river reach this area from North and southeast, and after they meet each other in a place called "Duab" and then leaves Hawraman and Kurdistan province and finally reaches to Darbandikhan dam in Iraq. [3]

Fig. 3: Sirvan River

8 LAND USE IN THE VILLAGE

The natural environment including high slope lands, stones and root rocks have made almost 52.7% of the village lands to be useless but the main land usage is residential (26%) and street networks (13.8%) and the other land uses are educational religious, healthcare , business and manufacturing.[4]

9 ARCHITECTURAL TEXTURE OF THE VILLAGE

The village is a precious form of climatic and natural architecture which can be seen as an extreme use of solar energy and fossil fuel conservation. The fabric and spatial structure of Hawraman-e Takht village is generally formed by a set of neighborhood units / footpath and public open and recloses spaces which are on a high slope in the middle of the mountains by a close relation of each other and an organic interaction with natural environment. Severe shortage of land to be developed, cold climate and mountainous area are the leading causes of a dense complex settlement in the middle of mountains which provides a combination of positive and negative surfaces. In this pattern of mountainous architecture, the roof of each building is the yard of the building above or a part of public footpath. The connection and coheres on public texture image and serial juxtaposition method toward South in order to prepare the light and heat are features of this architectures.

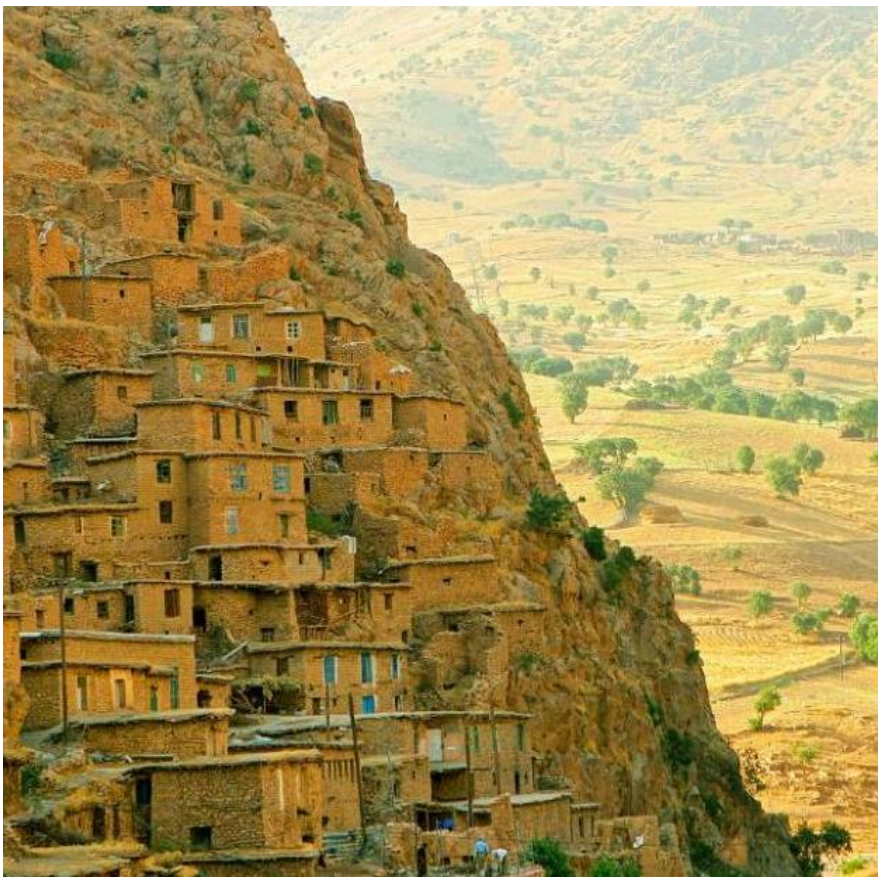

Fig. 4: Hawramane-Takht Texture

10 ARCHITECTURAL FEATURES OF THE VILLAGE

One of the most important architectural features of the village is obeying the architecture rules; here are some of those features:

10.1 Nature and environmental conservation:

The construction in the village has not damaged the nature, unique stairway architecture is according to the high slope of the mountains there, that the village is constructed on a very high slope of the mountain base .This form of architecture even does not harm the nature and is accepted as a part of the nature which is a kind of respect for the nature and the facade is like to come out of the nature and is a part of the mountain itself.

10.2 Using the local materials:

Local and mountainous materials have been used in the architectural texture construction of the village in which houses are built with pieces of stone piled upon each other without the use of any construction materials. Any materials which harm the nature are not seen at all in this village, the texture of each building in the village is quite similar to the nature of Hawraman which is seen as a part of the nature.

10.3 Form follows function

In the construction of the village the function is not only considered although form and function are combined, for instance, in the stair way shape of the village the roof of each house (building) is the yard of the house above or a part of public footpath as a response to high slope of the mountain and the form completely follows the function.

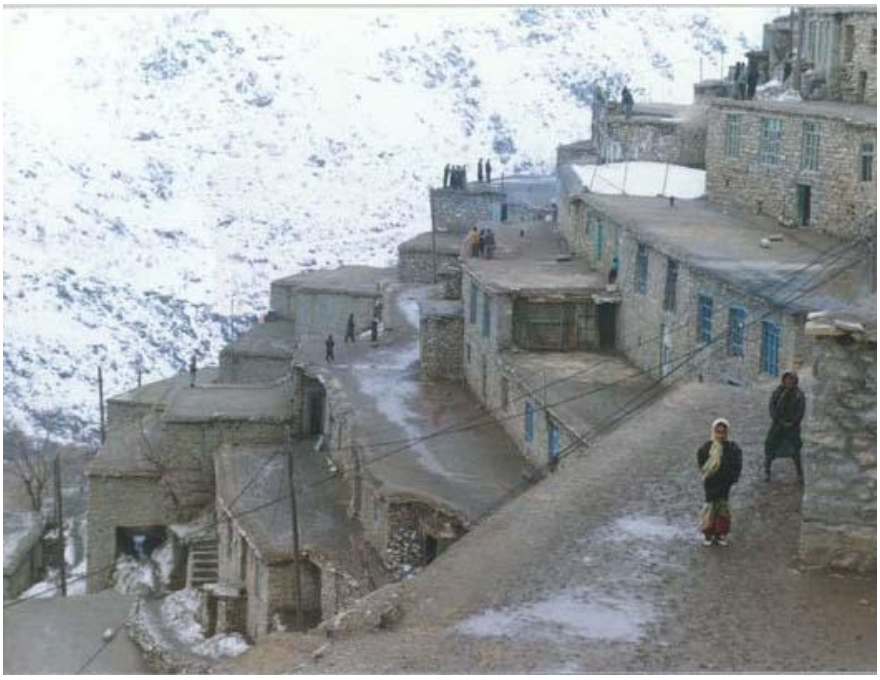

Fig. 5: Stair way shape of the village

11 ARCHITECTURAL FEATURES OF THE VILLAGE IN RELATION TO CLIMATIC DESIGN

We could consider the feature below in climatic design and features of fabric texture design of the houses of the village.

11.1 Orientations of the buildings

The connection and coheres on public texture image and serial juxtaposition method toward South in order to prepare the light and heat are features. Using solar energy is very vital due to difficult transportation of fossil fuel.

Fig. 6: Buildings toward South (using solar energy)

11.2 Access for pedestrian and motorist

Because of high slope of the village the access of the motorist is just in the entrance of that via asphalt way, and the whole part of the village there is only pedestrian access, the mountains which its width sometimes are less than 2m and continues it the summit of the village by passing over the roof of the buildings

11.3 Dimensions of the windows

The windows are designed on the Southern and Eastern sides in which are vertical and their width are 1.40m maximum in order to use the maximum solar energy in cold seasons. In some cases that windows could cause heat loss, they are eliminated. In fact minimalism is noticeable. If Usage of windows is necessary, they are thin, otherwise the wall texture is without an opening.

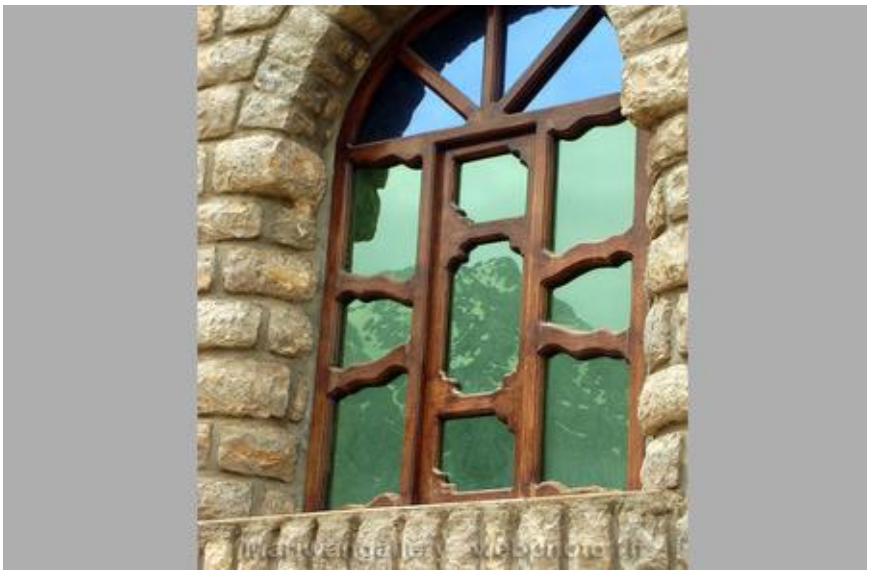

Fig. 7: Window

11.4 The gauge (thickness) of ceilings and walls

The thickness of ceilings and walls are, in a specific shape which heat conductance is prohibited, it means that the walls and ceilings with high thickness protect the inner heat in winter and the buildings stay cool in summer.

11.5 Materials

The materials which are used have high heat capacity; they hold heat and prevent the heat loss. Local wood has been used in making doors and windows and also wood has a vital role in columns and covering the ceilings.

Fig. 8: Stones without the use of any construction materials

12 CONCLUSION

In the analysis of the village of Hawraman-e Takht by consideration of climatic architecture design basis, a conclusioncan be reached that in the modern world which technology and population growth rate and fossil fuel consumption is very high and energy resources have decreased significantly in recent years, by analyzing environmental features of each area on organic architecture basis, fossil fuel conservation and pollution reduction would be gained and by using local and organic materials and solar energy, leads us have an organic sustainable architecture which is economically reasonable.

1 ABSTRACT

Visually disabled people have striking needs for trustfully navigation systems enabling for efficient mobility services, mainly considering safety and autonomy. In this context, satellite-positioning and navigation technologies available are being implemented in innovative personal navigation devices. But existing products and solutions based on GNSS (Global Navigation Satellite Systems) fail because they lack accuracy and intergrity, they do not provide a suitable and efficient man-machine interface adjusted to this user segment, or rely on costly infrastructure.

The ARGUS project focuses on a satellite based navigation (GNSS/EDAS – EGNOS Data Access System) terminal for people with impaired visually capabilities, guiding them along pre-defined tracks using specifically designed HMI (Human Machine Interface) such as tactile, acoustic and haptic signals. It introduces the opportunity to develop an innovative guidance support system for visually impaired people based on the provision of a virtual-lead-line perception to the end user that can be perceived and followed. This will provide "track navigation" instead the classical "waypoint or route navigation" which is used for car navigation or people with all visual capabilities.

This system will be also usable for professional, scientific and sport activities developed in reduced visibility scenarios that could require accurate guidance on normal or emergency situations, as well as for other people working in reduced visibility environments needing guidance and assistance.

2 INTRODUCTION

Almost 300 million people in the world are visually impaired. About 90% of the world's visually impaired live in developing countries, and about 65 % are aged 50 and older, with an increasing elderly population in many countries, more people will be at risk of age-related visual impairment.

The global response to prevention of blindness have had specifi results in areas of progress over the last 20 years including prevention, eye care servicies, development of policies and strategies, campaigns to raise awareness, and stronger international partnerships with engagement of the private sector and civil society.

But this global response have also had one of the main areas of progress on the developmentet and implementation of technical assistance to the users. Despite the technology state of the art many questions remain open concerning autonomous navigation, acuracy, integrity.

3 MAIN OBJECTIVES OF THE PROJECT

The ARGUS project focuses onto the development of a service platform and a satellite based navigation terminal for people with impaired visually capabilities, to guide them along a pre-defined track, using acoustic and audio-haptic signals. In this sense, the ARGUS system provides a virtual guidance rope for blind and partially sighted persons or people working in environments with low visibility (emergency and rescue services, etc.). Based on GNSS systems, ARGUS acts as a leading climber providing a safety rope to the persons following, leaving for them a secure path.

The main goal of the project is to develop a GNSS based mobility service for people with impaired visually capabilities, to guide them along a pre-defined track, using acoustic and audio haptic signals, which meets the level of accuracy, integrity and reliability they need in urban and outdoor environment for improving their day to day life autonomy.

ARGUS project primarily retrieves benefits from satellite navigation services and technologies to increase the level of positioning accuracy and reliability as well as the level of service availability. But the ARGUS project will also develop a whole set of services aimed at pragmatically support visually impaired people in their day-to-day life mobility. For this purpose, some specific objectives are considered:

- To build up a commercial navigation product for visually impaired people which guides them with acoustic and audio-haptic signals along a secure, pre-defined track. The positioning component uses satellite based positioning
- To develop tactile signals, acoustic and audio-haptic ones, for providing a non-visual track perception and mental map of the path, and supporting the guidance of visually impaired people along a pre-defined track.
- To develop an application for authorised third parties. With the application software, stored pre-defined tracks can be transmitted to the user terminal on demand. Furthermore, the application software uses the positioning information from the user terminal to compute protection levels and re-transmit alerts in case of emergency (e.g. degraded positioning accuracy, etc.).
- Provide an intelligent guiding portable device to support ageing population and visually impaired people.
- Provide updated data through a public Web services sharing information collected by ARGUS users with other ARGUS users or with general public

4 HOLOPHONIC SYSTEM

Throughout history, multiple solutions have been designed to help in guiding blind or visually impaired people, based on different technologies. Speech based techniques, as well as more sophisticated devices based on handheld haptic display using verbal and non-verbal communication technologies for visually impaired pedestrians have been developed and compared. However, the ARGUS project will focus on a specific audio-haptic signal, which is holophony, providing spatial information through three dimensional sound perception.

Therefore by using the holophony the users perceives 3D sound positioning. Based on this holophonic sound perception, the main goal of this project is to guide the visually impaired person through a preselected route. This route can be selected over previously recorded tracks (natural routes: no multilayer cartography available) or selecting origin and destiny (city or urban scenarios, multilayer cartography available). This route is a series of continuous geolocated points in 2D, therefore this geographical map has to be translated into a sound map (holophony) as it is shown in the next figure.

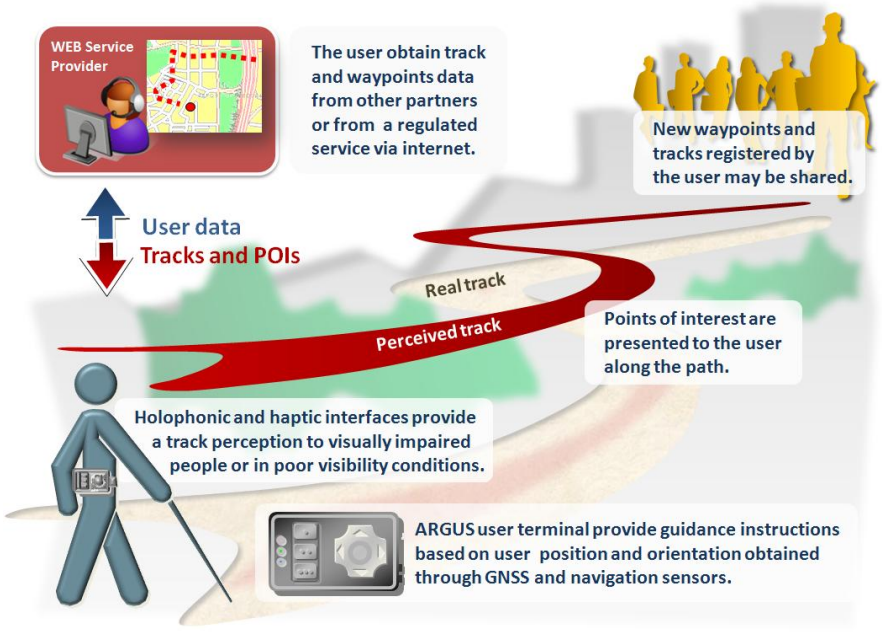

Fig. 1: Navigation based on track perception

Holophony technology record the wave sounds, the way those are received at the tympanic membrane. For that purpose, holophony use auditory system dummies, capturing even the slights differences perceived by the ears caused by direction of the coming sound. Then, holophonic sound recorded may be reproduced by a stereo headphone creating the illusion that sounds come from specific directions and distances.

5 SYSTEM ARCHITECTURE

The ARGUS system will be compound by the next elements:

- A user terminal that corresponds to a portable GNSS based navigation terminal capable of guiding the user along a pre-defined track, using acoustic and audio-haptic signals, and allowing internet access for remote service supply and navigation augmentation.
- A service platform corresponding to the assistance and service platform based on a client-server architecture which will offer services all along the three travel stages i.e. before (planning), during (visiting destination) and after (remembering and sharing experiences).
- Personal user software that corresponds to the software for personal usage to configure the user terminal or load particular navigation information to the user terminal.

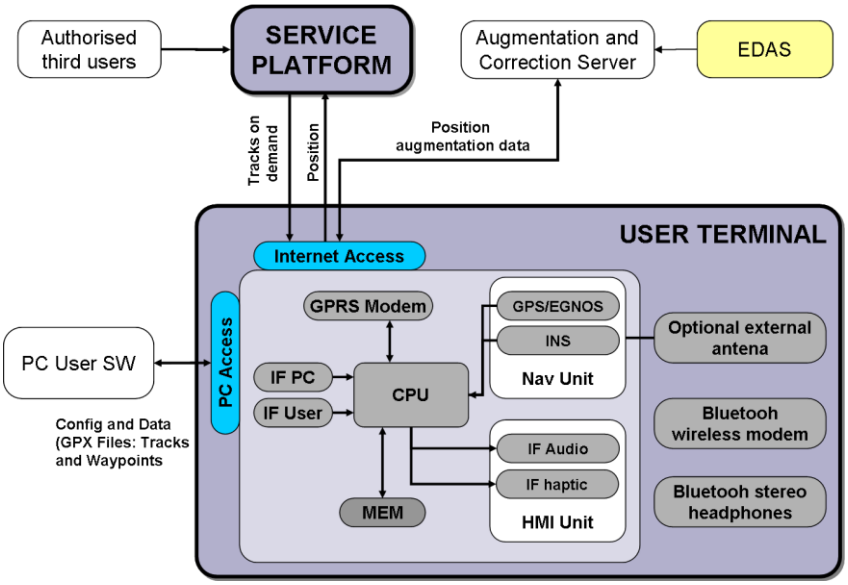

Fig. 2: ARGUS system architecture

5.1 Service platform

Assistance and service platform will be based on a client-server architecture which will offer services all along the three travel stages i.e. before (planning), during (visiting destination) and after (remembering and sharing experiences) in order to:

- Prepare their itinerary at home, taking into account specific scoring processes enabling the integration of route safety in the itinerary calculation.
- Manage their itinerary in real-time, with an accurate positioning.
- Contact the call centre for any technical or practical request (such as programming a modified itinerary or new track request).
- Share experiences with other users, improve the system and enrich the locations database with personal comments and points of interest (POI), trough the community website (social network).

5.2 Multilayer database structure

For routing calculation GIS (Geoinformation system) information is required, therefore different kinds of GIS systems will be tested. On one hand commercial cartography such as Teleatlas and/or Navteq and, on the other hand, local GIS information if it exists. Additionally OpenStreetMap cartography will also be tested since this is an open source initiative and could be added to the product with no extra cost.

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

Nevertheless ARGUS is not a replacement for the white cane so the accuracy of the positioning for guidance is important but is not necessary in the cartography where map matching techniques will be used.

Geodata strategy is based on database interconnected layers. Three different layers (data based structured) will be used (TBC) to tackle the objective of the project. This data bases are queried by the algorithms to get the required information so that the accurate itinerary can be defined

- City GIS Database, OpenStreetMap, or commercial database Teleatlas/Navteq
- General information layer
- User generated personal data based: accessible through a web based social network

5.3 ARGUS Website Structure

The project includes setting up and maintaining a public Website providing different services to the users of the ARGUS device, and a collaborative environment open to any persons and organizations that can participate in a social network to help improving the experience of the main users.

The main functionalities implemented in the website will be:

- POIs management: This block allows the users to manage personal Points of Interest and share them with other people.
- Route Calculation: The application to calculate routes from one location to another. Information about the trip, including POIs, will be send to the server where an algorithm will calculate the optimal route taking into account the restrictions of the POIs. Finally the algorithm gives back a file containing the indications to be followed by the user. This file can be stored in the computer and /or loaded into the embedded device.
- Web 2.0: It is dedicated to share experiences of the user and acts as a social network for visually disable people. Any other person (not only visually impaired) could also register in the system so that they can collaborate with auxiliary tasks such as collecting data to feed the system, validate the quality of the data and ensure that there are no changes that could imply risks to the users, or communicate with the users of Argus to share experiences.

6 CONCLUSION

The technical challenges comprise the overall development of a guidance system, which enables the users to follow a pre-defined path autonomously without seeing it by using tactile, acoustic or audio-haptic signals. One main challenge is the tailor-made development of a suitable Kalman Filter for the application under consideration in order to adapt it most suitable to the dynamic behaviour and thus the so-called dynamic movement model. Thus, extensive work will have to be spent onto this issue. Furthermore, the protection level algorithm has to be tailored carefully taking into account the target environments and ways of the potential users. The HMI which integrates multisensory actuators (acoustic, audio-haptic, and visual) is also a very challenging part of the development because of the necessity to integrate the different actuators in a most suitable strategy.

In order to accomplish the track guidance, it will be necessary to develop the holophonic sound map. It will allow accomplishing an innovative solution for the user perception of a non visible track path, and the development of the system that will allow visual impaired people to navigate the track in a safe way.

7 ACKNOWLEDGEMENTS

Acknowledgements: ARGUS project is a collaborative project funded by the European Commission with the Grant number 288841of the Objective: ICT-2011.5.5. This publication reflects the views only of the authors, and the Commission cannot be held responsible for any use which may be made of the information contained therein.
This project is being conducted by several entities: Ceit Alanova, TeleConsult Austria, The 425 Company, Siemens AG, OK Systems and Vicomtech-IK4 (coordinator).
Authors would want to thank some visual impaired associations that are actively collaborating for those tasks involving final users: Opensight in UK, HILFSGEMEINSCHAFT in Austria, Fundación Tecnológica Social

(FTS), Gebocyl, University of Deusto, University of Basque Country and INGEMA-Social Science Expert Group in Spain,
Finally, this project is being partially support by the FP7 programme under the call FP7-ICT-2011-7 (grant agreement 288841).

Building up Land Use Management Skills

Jiřina Bergatt Jackson

(Jirina Bergatt Jackson, Institute for Sustainable Development of Settlements, jjackson@volny.cz)

1 ABSTRACT

Structural changes in society, particularly those that have rapidly occurred in the New Member States (NMS) over the past two decades, resulted in pressures on urban land use management, which ordinary planning procedures were unable to understand or address. This led to planning systems not being able to react to new forms of development pressures arising from new demand patterns. Consequently, it had resulted in a large amount of underused and dilapidated urban land, while at the same time ever increasing Greenfield developments caused a deterioration of land use sustainability and a reduction of local competitiveness.

This paper will discuss approaches of various EU-financed projects focused on building up urban land use management skills in the Central Europe area, especially in the NMS. Five projects from two different EU programs will be reviewed, all with a focus on upgrading urban land use management skills. These approaches, the spectrum of their beneficiaries and their outputs would be examined. The projects LEPOB, BRIBAST and BROWNTRANS from the programme Leonardo da Vinci would be discussed in detail and their local impact would be assessed. From the programme Central Europe, the projects CobraMan and CircUse would be considered and their reach and potential benefits to participants and to local stakeholders would be described.

2 BACKGROUND TO THE URBANISED LAND USE SITUATION IN CENTRAL AND EASTERN EUROPE

The societal and system changes of 1990 installed democracy and market economy to the Central and Eastern Europe states, but they have also put these states through a steep learning curve, which have necessitated an adaptation of their governance formats, changes to their legal frameworks, amendmends to their production or security patterns and reshaping of many of their societal processes and relationships. Furthermore, to attain EU accession prior to 2004, these countries also had to absorb a large amount of EU directives into their already rapidly changing legal frameworks. For a number of issues covering the accession agenda, the candidate states have received ample Technical Assistance from their EU peers. But there was no EU Technical Assistance channelled in the direction of spatial planning and urban development skills, because these fall under national responsibility. And at that time, having their hands full with the accession process, these candidate states failed to address their national, regional and local urban development issues correctly. The changes in society and economy, combined with an absence of spatial planning and urban development skills able to cope with free market situation, have caused a vast amount of an underused Brownfield land to emerge in the candidate states by the beginning of the third millennium, while Greenfield developments have sprung in ever increasing numbers. Upon joining the EU, these NMS were placed in a position where they had to compete on an even footing with much more sophisticated urban management processes in the "old" EU member states.

The lack of development knowhow combined with subsidarity governance principles and unmonitored local planning powers have rapidly worsened land use sustainability in many local communities. Often, local governments considered increases in urbanised land (in no way matched by population increases) for a symptom of local growth. This has caused a large loss of agricultural, natural and forest land to various development activities, produced unsustainable urbanised land use and increased costs of externalities. It has also lowered local, regional and national competitiveness. The societal loss of soil environmental services, which have occurred due to such urbanisation, was not and till today is still not, sufficiently valued or sufficiently compensated. Back in 2003, the EU candidate states had access to EU ISPA funding. But the ISPA funding priorities had no urban dimension and therefore sustainable urban land use – such as Brownfield redevelopment is - could not attract any of the EU funding support. Local support to Brownfield reuse was also problematic. This was mainly due to gaps in land use management skills and to the fact that Brownfields as such were not a "recognised" planning issue or national programs priority.

3 CZECH NGO INTERVENTION

Faced with these difficulties a Czech NGO, the IURS – Institute pro urdžitelný rozvoj sídel o.s. has addressed this lack of Czech land use management knowhow, initially with the aid of an US grant funding. At beginning of its activities, IURS has concentrated on support for Brownfield reuse, as it was the least controversial and at that time the most pressing urban development issue. The First Czech Brownfield national and regional stakeholders seminars back in 2001 and the ensuing analyses have revealed the main causes for failings in the Czech Brownfield land reuse. These were:

- The Brownfield issue was not "labelled";
- Nobody was responsible for the issue (nationally, regionally, locally);
- No data was available to gauge the size of the issue;
- Multi-disciplinarity and complexity of solutions was not understood;
- Knowledge how to achieve successful solutions was absent;
- Training was nonexistent, Brownfields literature in local language did not exist;
- National priorities to deal with the issue were absent;
- Local authorities freely deregulated Greenfield land for development on a vast scale.

Back in 2003, IURS undertook four important actions aiming to improve urbanised land use practices and promote Brownfield regeneration. Firstly, IURS lobbied at the Ministry of Regional Development to make Brownfields into a "visible" issue and have forced the institution to allocate departmental responsibility for it. Secondly, it lobbied the preparation of the Czech National Plan 2004-2006 and achieved that urban Brownfield priorities were introduced, making Czech Brownfields eligible for EU ERDF funding 2004-2007. Thirdly, IURS lobbied the government to channel research funding and a research programme with a focus on Brownfield regeneration was opened up by 2004. And finally, IURS identified an EU funding source, which would on transnational bases finance the development of teaching materials focused on Brownfield issue. Brownfields training or knowhow resources in local language were then absolutely missing not only in the Czech Republic, but also in the other NMS. IURS first three actions have made changes to Brownfield regeneration in the Czech Republic. The fourth action has changed Brownfield regeneration chances in another 6 EU member states. It has also placed IURS in a position of participation on several other international project and have lead to a substantial enhancement of IURS´s own urbanised land use management expertise.

4 LEPOB PROJECT AND ITS IMPACT

Preparing Brownfield training products requires three preconditions:

- Skills and experience in Brownfield regeneration;
- Best Brownfield practise and global/EU knowledge;
- Suitable funding source(s).

The funding source identified at that time, which could support preparation of Brownfield training products, was the programme Leonardo da Vinci. This programme was focused on continuing professional education. Brownfields training aimed at practising professionals was a perfectly fitting subject. Furthermore, this programme also demanded an international partnership, which proved to be an ideal solution for the needed international knowhow transfer. A partnership of 9 partners from 5 countries was formed and the project LEBOB – Life long education project on Brownfields [1] was applied for and awarded. European best Brownfield practise and Brownfield regeneration expertise was contributed to the LEPOB project by its British and the German Partners, who were also the initiators of the then emerging European Brownfield network CABERNET [2]. The other partners were the Czech, Silesia and Slovakia Chambers of charted engineers and expert and educational bodies from Poland Slovakia and Czech Republic.

[1] http://fast10.vsb.cz/lepob, (Leonardo da Vinci program)
[2] http://www.cabernet.org.uk (5th RF program)

The key goal of the LEPOB project was to create straight-forward education materials in local languages. Then, the main educational objective was to improve local urban development practices and strengthen local construction professionals understanding of underused urban land – Brownfields. This was achieved by making available and disseminating (throug local professional chambers) transnationally prepared educational and training materials, which were adapted into "country specific" versions and translated into local languages. Materials were produced with a focus, and at a level, which would be accessible to various professions of local construction practitioners. Additionally, the university partners have reused LEPOB outputs for preparation of their first regular Brownfield regeneration courses [3]. The second LEPOB objective was to introduce Brownfields training materials to the other EU NMS. Two "innovation knowhow transfers" were intended in the original LEPOB application - one was for the Balkans and the other was for the Baltic countries.

The LEPOB project alone has reached around 25 000 chartered engineers in Slovakia and in Czech Republic. They were provided with a CD containing the LEPOB Brownfield handbook, in their national language. The professional chambers partners have mailed the CD to all their members. In the Czech Republic, the Brownfield skills development directed at such a large membership of construction professionals proved to be very useful in focussing the ERDF 2017-2013 funding priorities, and especially effective in responses, which the construction professionals were able to perform, while supporting the applicants for these priorities.

This and the other previously mentioned activities have resulted in the Czech Republic becoming the Brownfield knowhow leader amidst the NMS and the ERDF funding availability has substantially raised interests in Brownfield regeneration. In 2006, the new Czech Construction Law has acknowledged the Brownfield issue in spatial planning terms, setting up grounds for Brownfield inventorying and urbanised land use monitoring.

But a real change in land use practices, which would fully address land use sustainability, takes time. Hence, despite substantial improvements in regeneration knowhow increase, in Brownfield redevelopments take-up and in improvements to Brownfield development practices, today in the Czech Republic the agricultural land loss index is higher than in any other EU country. It takes very well focused policies, a suitable legal framework, integrated approaches (vertically and horizontally) supported by stakeholder participation and an efficient land use management system to address the "real" urbanised land use sustainability. Not only the individual Brownfield sites needs to be reused but the governance of the urbanised land as such needs to be improved and sustainable urbanised land management has to be intoduced and practised on local, regional and national level. But this type of knowhow is emerging only a decade later.

5 BRIBAST PROJECT

Building on the LEPOB project's success, the BRIBASTS [4] project (Transfer of innovation - Brownfields awareness in Baltic States) was submitted in 2008 to the same funding source. The partners to BRIBAST were regional educational institutions from Latvia and Lithuania and the project LEPOB Czech and Slovak partners. The focus of the BRIBAST project was to adapt the LEPOB original training materials for local use in local educational institutions in Baltic states. The LEPOB Brownfield handbook was expanded and included extended chapters relevant to the Latvian and Lithuanian realities. The training course was shortened and made more suitable for teaching local undergraduates. The teaching was demonstrated to local trainers. At this time the ex-LEPOB project Czech and Slovak partners have acted as the Brownfield knowhow transfer experts. BRIBAST project was evaluated by the programme to be the best "Inovation transfer project" of the year.

6 BROWNTRANS PROJECT

To fulfil the last part of the project LEPOB goals, a new knowhow transfer project BROWNTRANS (Brownfield Regeneration Know-How Transfer – Lifelong Educational Project) was prepared in 2O1O, focusing on Brownfield knowledge transfer to Bulgaria and Romania. The overall outcome of this project is yet again to accelerate local sustainable urban development skills. This will be achieved by delivering know-

[3] Project LEPOB lead partner, the VŠB Ostrava, teaches regular brownfields courses from 2007
[4] http://fast10.vsb.cz/bribast (Leonardo da Vinci program)

ISBN: 978-3-9503110-2-0 (CD-ROM); ISBN: 978-3-9503110-3-7 (Print)
Editors: Manfred SCHRENK, Vasily V. POPOVICH, Peter ZEILE, Pietro ELISEI

how and experience in Brownfield regeneration to practising professionals, representatives of municipalities and regions and to students who may once play an important role in local Brownfield regeneration. The specific aim of this project is to facilitate information and experience in Brownfield regeneration to the representatives of Bulgarian and Romanian municipalities and regions. The project will deliver training materials in local language and would also educate local trainers, in other that they are capable to teach aspects of a multi-disciplinary subject like the Brownfield regeneration. In the medium to long-term, the project outcomes would support Romanian and Bulgarian economic, environmental and social development in various activity sectors, and produce benefits for their whole society.

Materials generated by BROWNTRANS Could also serve for self-study of the interested public. The Brownfields handbook is going to be adjusted to contain legislative links in Bulgaria and Romania and would be available in these languages. The Brownfield Handbook and the Brownfield training course are to be published at the project website and shall remain there for several years, even after the project has ended. The training materials will be prepared in a format of e-learning course, which will be modelled on teaching materials from the project BRIBAST, but more emphasis would be placed on urbanised land use management. This is in order to accommodate the newest trends in supporting Brownfield regeneration.

The BRIBAST project will provide a multi-disciplinary background in Brownfield related knowledge, which would enable the Romanian and Bulgarian practising professionals to grasp the breadth of the Brownfield issue. It would also enable them to consider well-founded and integrated solutions. On a personal level, BROWNTRANS training brings to the participants an added value of the acquired knowhow, which would help them in their Brownfield regeneration jobs. On the national or regional scale, increases in Brownfield knowhow would help to address Brownfield regeneration in a more strategic manner and would lead to more sustainable urbanised land use management. Enhanced Brownfield knowhow (similar to the Czech example) is expected to increase the take-up and speed of Brownfield regeneration. That will be profitable for the Bulgarian and Romanian local municipalities, whose urbanised land use would become more sustainable. It would also be profitable for both societies, as it would contribute to more sustainable urban development.

7 COBRAMAN PROJECT

A few years later, in 2008, when the "Brownfields issue" became a more recognised label, the Central Europe programme's project CobraMan [5] has addressed the rising need of local authorities for a competent local Brownfield management (one of the key issues identified by the CABERNET network). This project has pooled experience of 9 partners from 5 countries, jointly working on compiling Brownfield manager courses, on training of Brownfield managers and on Brownfield inventorying techniques. It also created various land management tools, which the Brownfield managers could use. Some, but not all of this project's products are produced in local languages. Brownfield managers training was however available only in English. But the final Brownfields manager´s manual would be translated into local languages.

8 CIRCUSE PROJECT

Later in 2010, the project CircUse [6] has progressed the urbanised land use management know-how even further. CircUse has addressed the urbanised land use management as a cyclical process and advocated the principles of circular land use management. This circular land use concept was a know-how transfer of findings arising from the German research program REFINA. The CircUse project approach has introduced much broader urban land use categories into the urban land management process, which also included Greenfield sites. It promoted integrated approaches, based on wide stakeholder participation. Surveying of land use tools across the project partners countries have shown that the similarities and differences in the applied instruments were not the only factor of an efficient and sustainable land uses. Public awareness also played an important role, as well as optimisation of responsibility distribution and the ability to use available instruments in a creative way, while reflecting the specifics of respective social and natural environment. The main beneficiaries of the CircUse project are again the local authorities (but also various other local stakeholders), for whom the project prepares training products and urban use land management tools.

9 CONCLUSION

Transnational projects have positively contributed to Brownfield training and learning in the Czech Republic and together with a suitable local intervention and the ERDF funding sources availability were able to speed up Czech Brownfield reuse. There are 5 projects included in this paper, but during the last 10 years, many other Brownfield regeneration focused projects were financed by different EU programs sources and also from various members´ states funding . Many partner organisations have benefited from sharing expertises and learning.

Also, over the last decade, perception of the Brownfield issue as such has developed and shifted from initial soil contamination and soil remediation techniques to Brownfield remediation management (2003). In around 2005, there could be seen a shift from single Brownfield regeneration efforts to more comprehensive and approaches of sustainable Brownfield regeneration (2007). And from 2007, the initial approaches of a thematic Brownfield regeneration have moved more towards the urban and the spatial planning dimension, Brownfield land management and Brownfield manager training. In 2009, integrated Brownfield redevelopment was emphasized and in 2011 the holistic approach to Brownfield reuse was expanded even further, towards urbanised land recycling principles and towards sustainable urbanised land use management.

At all these stages, transnational and also national projects have produced various training and learning materials, focused on different beneficiaries: from specialist remediation engineers to Brownfield owners, Brownfield managers and finally to local and regional governance actors and their stakeholders. The initial materials were prepared mostly in English and some of them were not really suitable for use in the NMS. Since 2004, when these states started to participate more actively in Brownfield and urbanised land use orientated projects, training and learning materials also appeared in local languages. In some cases, the NMS partners were able to steer the training materials development to a standard, which was accessible to and usable by their national audiences.

The transnational knowhow transfer from the CABERNET network partners proved instrumental to the development of Central & Eastern Europe Brownfield projects in period from 2004-2008. Since then, various other initiatives have sprung up (for example the impact of the Central Europe or URBACT programs) which had altered the partnership focus more on Central European neighbouring countries. There are apparent benefits - these countries systems, history and mentality are relatively similar, but there are also disadvantages – the spatial determination of such programmes limits knowhow transfer from the top performing EU regions located between London and Milan to the NMS.

The large impact of the LEPOB project, especially in the Czech Republic, was caused mainly by a right mix of Czech partners and also by the fact that the dissemination partner had a very large membership. This membership was also well motivated to improve its Brownfield knowhow, by the work remediation opportunities arising from the ERDF funding priorities. Such a project impact was not as yet achieved again by any other projects, which are mentioned here. But there may be opportunities in the CircUse project knowhow, directly influencing the revision of Czech National Spatial Policy and there also appears to be a chance of formulating the regional approach to sustainable urbanised land use management.
